Scope of the Potravinarstvo Slovak Journal of Food Sciences

Potravinarstvo Slovak Journal of Food Sciences is a scientific journal intended for the food industry and scientists working in this field. Articles published in the journal are peer reviewed by two reviewers and available free of charge online on the journal website. Journal covers areas including: food hygiene, food safety and quality, food microbiology, food laws and regulations, ingredients and ingredient functionality, nutraceuticals, product formulation, sensory science and sensory statistical analysis, process control and its contribution to food processing operations, food chemistry, food toxicology, food engineering, food technology and biotechnology, nourishment, public health, primary production of food, food adulteration, food economics and marketing, environmental effect on food and food machinery.

Open Access

We are providing free online access to all published articles in our journal. You are free to:

- Share — copy and redistribute the material in any medium or format.
- Adapt — remix, transform, and build upon the material for any purpose, even commercially.
- The licensor cannot revoke these freedoms as long as you follow the license terms.

If you decide to use articles published in our journal you have to:

- Make statement (citation), that article was published first time in our journal according to the example presented below in the copyright.

VARIATION OF FRUITS MORPHOMETRIC PARAMETERS AND BIOACTIVE COMPOUNDS OF *ASIMINA TRILOBA* (L.) DUNAL GERMPLASM COLLECTION

Ján Brindza, Olga Grygorieva, Svitlana Klymenko, Olena Vergun, Ján Mareček, Eva Ivanišová

ABSTRACT

The objective of this study was to evaluate the morphological parameters and bioactive compounds (antioxidant activity, total polyphenol, flavonoid, and phenolic acid content) of 6 genotypes of dry *Asimina triloba* (L.) fruit from Slovak University of Agriculture in Nitra (Slovakia). Genotypes were obtained from the seeds that were sown in the year 2000. Their morphometric parameters were following: fruit weight from 59.00 to 241.19 g, fruit length from 50.14 to 140.11 mm, fruit diameter from 37.55 to 64.67 mm, number of fruits per cluster from 2 to 8, seed weight from 0.06 to 1.80 g, seed length from 16.33 to 29.11 mm, seed width from 9.56 to 18.33 mm, seed thickness from 4.98 to 9.75 mm, number of seeds in fruit from 4 to 16. The shape indexes of fruits were found ranging from 1.53 to 2.16. The variability of important is the average seeds weight from 7.40 to 35.61%, fruit weight from 14.84 to 32.95%, number of fruits per cluster from 18.21 to 32.54% and a number of seeds in fruit from 13.49 to 27.72%. The other characteristics are more or less stable. Total polyphenol content ranged from 22.13 to 37.36 mg GAE per g, total flavonoid content from 15.10 to 32.03 mg QE per g and phenolic acids content from 0.23 to 0.76 mg CAE per g. All tested samples exhibited DPPH radical scavenging activities with values from 2.84 to 7.04 mg TEAC per g. Antioxidant activity by molybdenum reducing antioxidant power method ranged from 97.25 to 275.41 mg TEAC per g of dry matter. Differences between the genotypes were significant in all observed parameters. This species is potential for propagation and practice used in the Slovak Republic.

Keywords: *Asimina triloba*; Dunal; fruits; seeds; variability; bioactive compounds

INTRODUCTION

The searching of new plant species, which are the valuable source of biologically active compounds, is an actual branch of modern biological science in the last time. The introduction and selection of these plants, cultivation technology and extraction ways of biologically active compounds complex and creation on its basis the new generation of nutritional supplements one of the most important scientific directions **(Brindza et al., 2007; Grygorieva et al., 2014; Monka et al., 2014; Ivanišová et al., 2017; Vinogradova et al., 2017; Horčinová Sedláčková et al., 2018)**. *Asimina triloba* (L.) Dunal. relates to plants that are a source of polysaccharides, free amino acids, mineral compounds, flavonoids, etc.

Species of the genus *Asimina* Adans. belong to the family *Annonaceae* Juss. *Asimina triloba* (pawpaw, paw paw, paw-paw, common pawpaw) is deciduous tree native to eastern North America and Canada **(Layne, 1996)**.

Asimina triloba fruits are rich in nutritive components such as vitamins and minerals **(Templeton et al., 2003; Pomper and Layne 2005)**, a good source of potassium (3000 – 3800 $mg.kg^{-1}$) and several essential amino acids (mean value: 40 $mg.kg^{-1}$ of protein), and they contain significant amounts of riboflavin (0.06 – 0.15 $mg.kg^{-1}$), niacin (10 – 12 $mg.kg^{-1}$), calcium (500 – 800 $mg.kg^{-1}$), phosphorus (400 – 500 $mg.kg^{-1}$) and zinc (10 – 12 $mg.kg^{-1}$) **(Galli et al., 2007)**, to have a high polyphenolic content **(Harris and Brannan, 2009; Brannan et al., 2014; Brannan, 2016)**.

Pawpaws can be used as an alternative to bananas fruits in most recipes **(Jones and Layne, 1995)**. Fruits of pawpaw are very fragrant and resemble a combination of aromas of banana and mango, and may be used commercially in cosmetics and skin products **(Layne, 1996; Brannan and Holben, 2012)**.

Biologically active compounds are not only in fruits but in different parts of the plant: roots, bark, twigs, leaves, flowers, and seeds **(Hui et al., 1989; Zhao et al., 1992, 1993, 1994; Alali et al., 1999; Goodrich et al., 2006; Cuendet et al., 2008; Farag, 2009; Pande and Akoh, 2010)**. The roots, twigs, flowers, and seeds of pawpaw contain acetogenins, which are strong inhibitors of cancer cells **(Ratnayake et al., 1992; McLaughlin and Hui, 1993; Woo et al., 1995; Ko et al., 2011; Sica et al., 2016)**. Pawpaw leaf essential oil has strong activity against cancer cell lines **(Alali et al., 1999; Farag, 2009)**.

Asimina triloba fruit, leaf, bark, and twig extract may be an effective insect feeding deterrent **(Rupprecht et al., 1986; Ratnayake et al., 1992; Zhao et al., 1994; Gu et al., 1999; Sedlacek et al., 2010)**.

Scientific hypothesis

Evaluating of fruit quality formation by their qualitative parameters in the adaptation process of *Asimina triloba* at the agroecological conditions of the experimental base in Nitra.

MATERIAL AND METHODOLOGY

Biological material

The observations of the collection genotypes of *Asimina triloba* in the period 2017 were performed during mass fruiting. We have described 6 genotypes (referred as AzT-01 to AzT-06) of *Asimina triloba*.

Morphometric characteristics

The ripened fruits were picked from trees in maturity stage. Pomological characteristics were conducted with four replications on a total of 30 fruits per genotypes. In the study only one plant was used per genotype. The following measurements were taken: fruit weight, in g, fruit length, in mm, fruit diameter, in mm, and seed weight, in g, seed length, in mm, seed diameter, in mm, number of fruits per cluster, and a number of seeds in fruit.

Chemicals

All the chemicals used were of analytical grade and were purchased from Sigma-Aldrich (St. Louis, MO, USA) and CentralChem (Slovakia).

Preparation of sample extracts

The dry *Asimina triloba* pulp was used for detection of total phenolic content and total flavonoid content. An amount of 0.25 g of each sample was extracted with 20 mL of 80% ethanol for 24 h. Then, the sample in 80% ethanol was centrifuged at 4000 rpm (Rotofix 32 A, Hettich, Germany) for 10 min and the supernatant was used for measurement with the DPPH and molybdenum reducing antioxidant power methods.

Determination of antioxidant activity

Free radical scavenging activity

Free radical scavenging activity of samples was measured using the 2,2-diphenyl-1-picrylhydrazyl (DPPH) **(Sanches-Moreno et al., 1998)**. An amount of 0.4mL of the sample was mixed with 3.6 mL of DPPH solution (0.025 g DPPH in 100 mL methanol). The absorbance of the reaction mixture was determined with the spectrophotometer Jenway (6405 UV/Vis, England) at 515 nm. Trolox (6-hydroxy-2,5,7,8-tetramethylchroman-2-carboxylic acid) (10 – 100 $mg.L^{-1}$; $R^2 = 0.989$) was used as the standard and the results were expressed in $mg.g^{-1}$ Trolox equivalents.

Molybdenum reducing antioxidant power

Molybdenum reducing antioxidant power of samples was determined by the method of **Prieto et al. (1999)** with slight modifications. The mixture of the sample (1 mL), monopotassium phosphate (2.8 mL, 0.1 M), sulfuric acid (6 mL, 1 M), ammonium heptamolybdate (0.4 mL, 0.1 M) and distilled water (0.8 mL) was incubated at 90°C for 120 min, then rapidly cooled. The absorbance at 700 nm was detected with the spectrophotometer Jenway (6405 UV/Vis, England). Trolox (10 – 1000 $mg.L^{-1}$; $R^2 = 0.998$) was used as the standard and the results were expressed in $mg.g^{-1}$ Trolox equivalents.

Determination of total polyphenol content

The total polyphenol content was measured by the method of **Singleton and Rossi (1965)** using the Folin-Ciocalteu reagent. A quantity of 0.1 mL of each sample was mixed with 0.1 mL of the Folin-Ciocalteu reagent, 1 mL of 20% (w/v) sodium carbonate and 8.8 mL of distilled water. After 30 min in darkness, the absorbance at 700 nm was measured with the spectrophotometer Jenway (6405 UV/Vis, England). Gallic acid (25 – 300 $mg.L^{-1}$; $R^2 = 0.998$) was used as the standard. The results were expressed in $mg.g^{-1}$ gallic acid equivalents.

Determination of total flavonoid content

The total flavonoid content was determined by the modified method described by **Shafii et al. (2017)**. An aliquot of 0.5 mL of the sample was mixed with 0.1 mL of 10% (w/v) ethanolic solution of aluminum chloride, 0.1 mL of 1 M potassium acetate and 4.3 mL of distilled water. After 30 min in darkness, the absorbance at 415 nm was measured using the spectrophotometer Jenway (6405 UV/Vis, England). Quercetin (1 – 400 $mg.L^{-1}$; $R^2 = 0.9977$) was used as the standard. The results were expressed in $mg.g^{-1}$ quercetin equivalents.

Determination of phenolic acids

Total phenolic acids content was determined using the method of Farmakopea Polska (1999). A 0.5 mL of sample extract was mixed with 0.5 mL of 0.5 M hydrochloric acid, 0.5 mL Arnova reagent (10% $NaNO_2$ + 10% Na_2MoO_4), 0.5 mL of 1 M sodium hydroxide (w/v) and 0.5 mL of water. Absorbance at 490 nm was measured using the spectrophotometer Jenway (6405 UV/Vis, England). Caffeic acid (1 – 200 $mg.L^{-1}$, $R^2 = 0.999$) was used as a standard and the results were expressed in $mg.g^{-1}$ caffeic acid equivalents.

Statistic analysis

Basic statistical analyses were performed using PAST 2.17. Data were analysed with ANOVA test and differences between means compared through the Tukey-Kramer test ($\alpha = 0.05$). Variability of all these parameters was evaluated using descriptive statistics. Level of variability determined by **Stehlíková (1998)**.

RESULTS AND DISCUSSION

Morphometric measurements of fruits and seeds of selected plants are very important studying parameters because of some reasons such as origin and conditions of growth. It is also necessary indicators at the new conditions of introduction in a new area.

Note: n – the number of measurements; min, max – minimal and maximal measured values; mean – the arithmetic mean; V – coefficient of variation (%).

Morphological parameters of *Asimina triloba* fruits and seeds

In our study, the weight of *Asimina triloba* fruits (Figure 1) was in the range from 92.17 (AzT-02) to 149.31 g (AzT-03) (Table 1). **Crabtree (2004)** determined the fruit weight from 88.10 to 141.80 g**, Donno et al. (2014)** determined the fruit weight from 39.40 to 238.70 g. Investigations of **Klymenko et al. (2017)** established the range of fruits weight of variety from 39.40 to 238.70 g. In our experiments, the fruit length and diameter were determined in the range from 78.16 (AzT-06) to 108.83 mm (AzT-04) and from 44.80 (AzT-02) to 55.06 mm (AzT-03), respectively. The length and diameter of fruits was determined in the range from 61.98 - 91.16 mm and from 41.27 – 49.65 mm, respectively, by **Donno et al. (2014)**, from 14.0 to 46.0 mm and from 7.0 to 20.0 mm by **Szilagyi et al. (2016)**, from 49.25 to 135.00 mm and from 37.55 to 63.80 mm, respectively, by **Klymenko et al. (2017).** A number of fruits per cluster were identified in the range from 2 (AzT-03) to 8 (AzT-06).

Crabtree (2004) determined the average number of fruits from 1.8 to 3.0, **Klymenko et al. (2017)** determined the number of fruits per cluster from 2 to 7.

Morphological parameters of ranged seeds weight from 0.81 (AzT-01) to 1.35 g (AzT-03), seed length from 20.43 (AzT-05) to 26.03 mm (AzT-03), seed width from 10.88 (AzT-06) to 14.86 mm (AzT-03), seed thickness from 6.26 (AzT-06) to 7.71 mm (AzT-05).

Investigations of **Klymenko et al. (2017)** established the range of seeds weight, length, width and thickness of genotypes from 0.60 to 1.80 g, from 17.10 to 28.80 mm, from 10.86 to 16.46 mm, from 5.54 to 9.15 mm, respectively. **Szilagyi et al. (2016)** determined the weight, length, and width of the seeds in the range from 1.30 to 1.65 g, from 2.51 to 2.69 mm, from 1.30 to 1.36 mm, respectively. A number of seeds in fruit were identified in the range from 4 (Az-05) to 16 (Az-04). The number of seeds in the fruit was determined in the range from 5 to 12 by **Klymenko et al. (2017)**.

The analysis of coefficient of variation showed the difference of variability of morphological signs between *Asimina triloba* samples. Data showed that the most variable important selection signs are the seeds weight from 7.40 to 35.71%, fruit weight from 14.84 to 32.95%, a number of fruits per cluster from 18.21 to 32.54% and a number of seeds in fruit 13.49 to 27.72%.

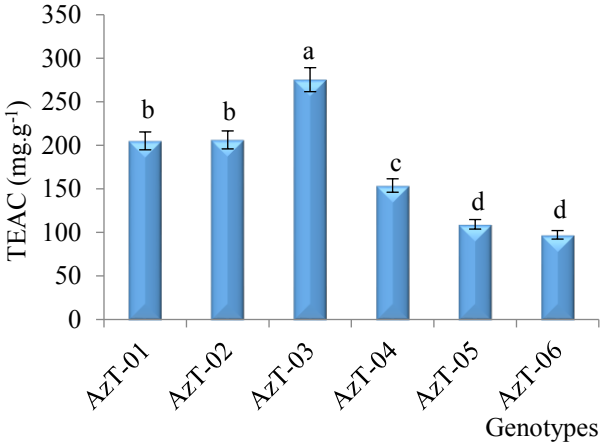

Figure 3 Antioxidant activity of *Asimina triloba* (L.) Dunal genotypes evaluated by the molybdenum reducing antioxidant power (different superscripts in each column indicates the significant differences in the mean at p <0.05).

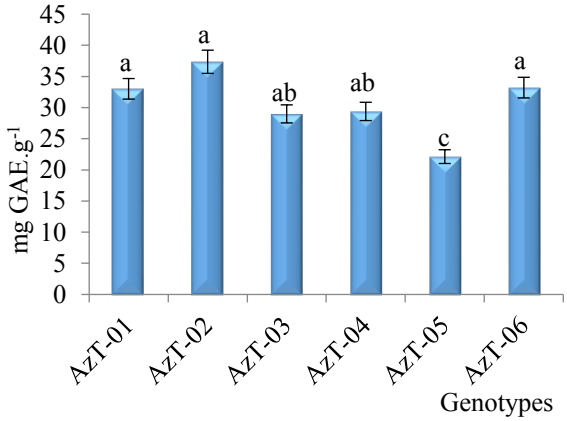

Figure 4 Total polyphenol content in *Asimina triloba* (L.) Dunal genotypes (different superscripts in each column indicate the significant differences in the mean at p <0.05).

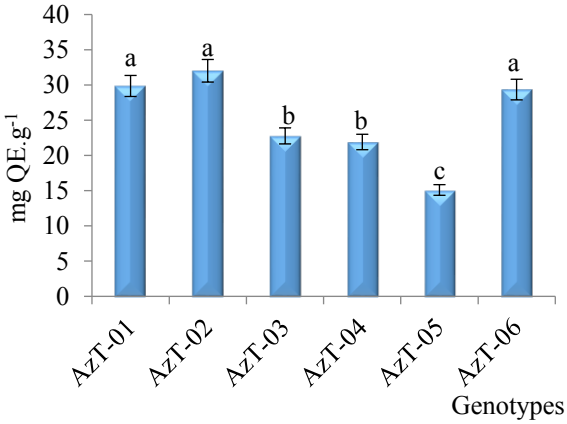

Figure 5 Total flavonoid content in *Asimina triloba* (L.) Dunal genotypes (different superscripts in each column indicate the significant differences in the mean at p <0.05).

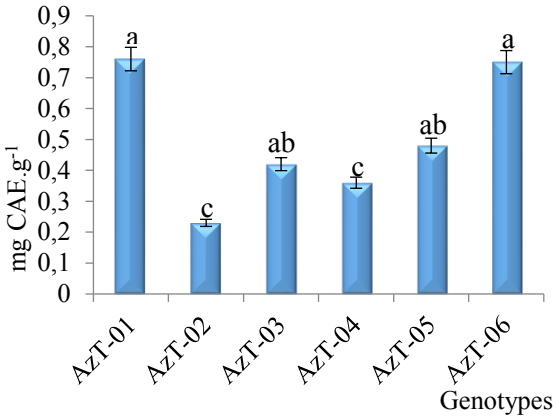

Figure 6 Total phenolic acid content in *Asimina triloba* (L.) Dunal genotypes (different superscripts in each column indicate the significant differences in the mean at $p < 0.05$).

Table 2 The correlation coefficients of a linear relationship between the biological activities of tested *Asimina triloba* (L.) Dunal genotypes.

Parameter	Polyphenols	Phenolic acids	Flavonoids	DPPH method
Phenolic acids	-0.013*			
Flavonoids	0.976*	0.184*		
DPPH method	-0.394	-0.326	-0.518	
MRP method	0.286*	-0.329	0.240*	-0.359

Note: Significant according to the *t*-test ($p < 0.05$).

These results indicate the promise of breeding in this way of investigations. The stable signs are seed width from 7.06 to 9.81%.

Antioxidant activity of *Asimina triloba* measured with the DPPH and molybdenum reducing antioxidant power methods

The antioxidant activity of *Asimina triloba* genotypes evaluated by the DPPH method (Figure 2) ranged from 2.84 (AzT-01) to 7.04 mg TEAC.g^{-1} (AzT-04). The degree of mean variability of parameters was confirmed by the variation coefficient (31.77%) in all the genotypes tested.

The antioxidant activity evaluated by the molybdenum reducing antioxidant power (Figure 3) varied from 97.25 (AzT-06) to 275.41 mg TEAC.g^{-1} (AzT-03). The degree of mean variability of parameters was confirmed by the variation coefficient (35.07%) in tested genotypes.

Nam et al. (2017) from methanolic extracts fruits obtained with DPPH method found the antioxidant activity to be 4.18 mg.mL^{-1}. **Donno et al. (2014)** found the total antioxidant activity from 889.6 to 1519.6 mg.kg^{-1}. **Kobayashi et al. (2008)** in ripe fruits from 15.57 to 17.04 mmol TE.g^{-1} FW. Antioxidant activity of *Asimina triloba* fruits could be influenced by the degree of maturity and cultivars **(Kobayashi et al., 2008; Donno et al., 2014)**. Since there are differences in genotypes of *Asimina triloba* cultivars grown under different geographic and agroecological conditions, our results are difficult to compare with the previously reported.

Total polyphenol, flavonoid, and phenolic acid content

The total polyphenol content (Figure 4) in *Asimina triloba* genotypes ranged from 22.13 (AzT-05) to 37.36 mg GAE.g^{-1} (AzT-02). The variation coefficient (16.87%) confirms the high variability of the parameter.

In our mind, the differences between the present and previously conducted studies may be attributable to the plant geographical origin as well as the different methods of extraction.

The total flavonoid content (Figure 5) varied from 15.10 (AzT-05) to 32.02 mg.g^{-1} QE (AzT-02). The variation coefficient (25.39%) supported the observations on high variability of this parameter.

The total phenolic acid content was found to vary significantly among the various *Asimina triloba* genotypes (Figure 6), which may be due to their different botanical and regional origins. The mean total phenolic acid of the studied fruits genotypes was 25.16 mg.g^{-1} CAE, with the highest phenolic acid recorded by genotypes AzT-02 at 32.02 mg.g^{-1} CAE, indicating its superior antioxidant potential. The variation coefficient (25.39%) supported the observations on high variability of this parameter. **Kobayashi et al. (2008)** found in ripe fruits the total phenolic content from 64.11 to 98.42 mg.g^{-1} GAE.

Correlation analysis

Correlation analysis was used to explore the relationships between the individual polyphenols, phenolics, flavonoids compounds and antioxidant capacities (DPPH and MRP methods) measured for all fruit extracts from six *Asimina triloba* genotypes (Table 2). It was observed a strong linear correlation between the polyphenol and flavonoid contents ($r = 0.976$).

CONCLUSION

Asimina triloba is a new introductive species in the European conditions. Originally it was used for decorative purposes. Nowadays it uses more widespread in many European countries as promising fruit plant. Fruits have specific taste, aroma, energy, therapeutic and pharmaceutics properties and uses. Presented results of this study showed

that *Asimina triloba* was well adapted in the conditions of Nitra in the Slovak Republic. All genotypes produce fruits comparable with foreign cultivars by morphological parameters and also by the content of biologically active compounds. Thus, this species is potential for propagation and practice used in the Slovak Republic.

CONSUMERS´ AWARENESS OF FOOD SAFETY

Ľudmila Nagyová, Alexandra Andocsová, Andrej Géci, Peter Zajác, Jozef Palkovič, Ingrida Košičiarová, Jozef Golian

ABSTRACT
Eating food is one of the most important needs of every person, so their safety and quality should be crucial for everyone. People expect, that food they eat is hygienically and health safe. Unfortunately, people usually start to focus on food safety only when various food scandals are exposed and it is too late. Mass consumption of food is the cause of a high risk to human health, but only in the case of harmful food. Food-borne diseases are a common and widespread phenomenon in all parts of the world, regardless of the economic development of the country. Protection of human, animal and plant health is one of the main economic priorities of each country. The political objective of the European Union is therefore to ensure that European Union citizens have access to safe and nutritious foods, so it must meet strict safety standards. In ensuring food safety, it is necessary to take into account all aspects of the food production chain as a whole, because each subject can have a potential impact on food safety. This paper deals with the issues of food safety and food quality. The main objective was to find out how consumers perceive higher quality food and whether they read information included on the food packaging. Primary data were obtained from a survey that was conducted on the sample of 478 respondents living in Slovakia. For a deeper analysis, several assumptions, which were verified by Friedman Test, Chi-Square Test of Independence, Wilcoxon Signed-Rank Test, were formulated. The survey has found out that 84% of respondents buy higher quality food and 60% purchase them because of health-related reasons. More than half of respondents search for the information about food safety on the Internet and the same percentage considere government as the most reliable source of information about food safety. Unfortunately, just more than one quarter of them read the information on food label and for 34% is this information unsufficient.

Keywords: Food; Product Packaging; Food Safety; Consumer; National Mark

INTRODUCTION
Food safety is undoubtedly one of the major global concerns that human beings have to confront and are continuously fighting for **(Lv et al., 2018)**. The world will need to feed around 9 billion people by the year 2050 and to do so through safe sustainable food chains **(Godfrai et al., 2010)**. Nowadays billions of people in the world are at risk of unsafe food. Many millions become sick while hundreds of thousands die every year because they consume unsafe food. Therefore, safe food saves lives and it also enhances individual and population health **(Fung et al., 2018)**.

Originally, the term "food safety" was used to describe whether a country had access to enough food to meet dietary energy requirements **(Pinstrup-Andersen, 2009)**. Now food safety is defined as the degree of confidence that food will not cause harm or sickness to the consumer when it is prepared, served and eaten according to its intended use **(WHO, 2003)**. Causes of food contamination, that can cause adverse effects in humans if consumed, could be classified into one of the three following groups – biological hazards (e.g. bacteria, viruses), chemical hazards (e.g. veterinary drug residues, disinfectants), or physical hazards (e.g. plastic, metal, bone) **(FSA, 2009)**. Certain groups of people are susceptible to foodborne disease more than others. Especially vulnerable groups are children or people who suffer chronic illnesses **(Socas-Rodríguez et al., 2017)**. Most of the population will surely get over soon, but these groups can have a long-term effect which can be serious in some cases and lead to a final death of the consumer, especially with certain bacteria infections (**U.S. Department of Health & Human Services, 2018**). The most foodborne disease outbreaks occur at home, restaurants, and/or at social functions, so food safety awareness and education should be emphasized and encouraged among citizens **(Stratev et al., 2017)**. The global food sector operates in an environment where policies, standards, regulations, guidelines, education and advice relating to food, including those related to the safety of food, are continuously being either developed or updated **(King et al., 2017)**. Scientific risk assessment is the basis for legislative development. Based on the Regulation no.178/2002 of the European Parliament and of

the European Council, the European Food Safety Authority (EFSA) was established **(Bírošová and Kačenová, 2010)**. EFSA is an independent agency of the European Union. It´s main role as stated in its founding regulations is to provide independent scientific advice and perform risk assessment and communication on food and feed safety topics to support risk managers at EU level, including EC, European Parliament, and EU Member States **(Regulation (EC) No 178/2002)**. Governments in many countries are fighting for safe food too. They have established new institutions, standards, and methods for regulating food safety and have increased their investments in hazard control systems (e.g. good agricultural practices (GAP), good manufacturing practices (GMP), good hygiene practice (GHP), hazard analysis and critical control point (HACCP) facilities **(Liu et al., 2015; Kecskes-Nagy et al., 2016; Korzenszky et al., 2013)**. Animal welfare is an important condition for obtaining high-quality and safe food in many states too **(Adámková et al., 2017)**.

Food safety is the responsibility of every person involved in the food supply chain from farm to the end users in assuring the safety and quality of the food **(New et al., 2017)**. Detection of food contaminants has been attracting remarkable attention in last decade, which ensures the governments and customers to recognize whether the food is safe **(Cocolin et al., 2011)**. As a result, regulators, producers, and retailers alike are trying to regain consumers' confidence by redesigning legislation and quality-assurance programs. These efforts can only succeed in restoring consumers' confidence if new standards of process and product attributes are successfully communicated. Product labeling is one way to accomplish such communication **(Roosen, 2003).** In Slovak Republic, Značka kvality SK is the guarantee of the highest quality of agricultural and food products. It informs consumers that every product labelled with the logo of the Značka kvality SK, has fulfilled the requirements placed on the granting thereof, complied declared technological process and higher quality parameters. Therefore, these products are clearly different from competing products **(MP SR, 2009)**. When it comes to food, nonfood, specific products or services, they can carry prestigious logo Slovak Gold, which in a simple visual form informs that the quality of the product has been professionally verified and confirmed by independent, non-state authority, thereby it protects consumers from problematic production of all sorts of origins.

Scientific hypothesis

Hypothesis No. 1: We assume that most respondents do not buy high quality food.

Hypothesis No. 2: We expect that most consumers search for the information about the food safety on the Internet.

Hypothesis No. 3: We assume that more women than men know the national label for quality agricultural products "Značka kvality SK".

Hypothesis no. 4: We assume that fewer men than women know the product certification system "Slovak gold".

MATERIAL AND METHODOLOGY

The main aim of the present paper is to examine consumers´ awareness of food safety and the relationship between consumers and food quality. In order to meet the stated objective, a questionnaire survey was conducted in the territory of the Slovak Republic in the months of January – March 2018, involving 478 respondents of different age categories. Secondary informations were obtained from the information available to the public as well as from scientific and professional publications of domestic and foreign authors dealing with the given issues. Questions in the questionnaire were divided into two groups - nine classification questions and 16 questions related to the food quality. Potential respondents have received the questionnaire in a paper form. After completing, all correctly filled questionnaires were transformed into the Google Forms internet application.

Statisic analysis

Primarily, the information obtained through the questionnaire survey was processed out by the statistical methods of Friedman´s test, which is a non-parametric alternative to the repeated measures ANOVA where the assumption of normality is not acceptable. Usually it is used in case of ordinal dependent variable. This occurs especially in case of questioner survey, when each respondent assesses more than two products using the same scale. In case of Friedman´s test applications should be met following conditions: One group that is measured on three or more different occasions - group is a random sample from the population, dependent variable should be measured at the ordinal or continuous level and samples do not need to be normally distributed. The non-parametric post-hoc test called Nemenyi test which is based on the Kruskal-Wallis method of ranking in a one-way classification and Chi-Square test of Independence to investigate relationship between categorical variables.

The established hypotheses were verified by appropriate mathematical-statistical methods that enabled the hypothesis to be confirmed or rejected.

The probability level is determined on the base of alpha ($\alpha = 0.05$), which is compared with the significance level (p-value). Based on alpha (α), we can evaluate the hypothesis with the p-value comparison. If p-value is lower than alpha (α), H_0 will be rejected. If p-value is higher than alpha (α), H_0 will be accepted.

RESULTS AND DISCUSSION

The majority of totaly 478 respondents was represented by women (58%). Most of the respondents (46%) were aged from 21 to 30 years, followed by the interval from 41 to 50 years (17%) and further from 31 to 40 years (16%).

Group with completed higher education represented 46.8%, secondary education 41.8%, apprenticeship 8.1% and basic education only 3.3% of respondents.In terms of their permanent residence, respondents came from all 8 regions of the Slovak Republic, namely 47.2% from the rural areas and 52.8% from the urban areas. The monthly family income of questioned respondents ranged from the category "up to" 330 € to the category "more than 831 €" (Figure 1). The obtained results were anticipated because

Table 1: Characteristics of Respondents.

Gender	**%**
Female	59
Male	41
Place of Residence	**%**
Village	53
City	47
Age Structure	**%**
Less than 20 years old	6
21 – 30 years old	46
31 – 4 0 years old	16
41 – 50 years old	17
51 – 60 years old	10
61 years old and more	5
Net Family Income	**%**
Up to 330 €	8
331 – 500 €	9
501 – 660 €	21
661 – 830 €	22
831 € and more	40

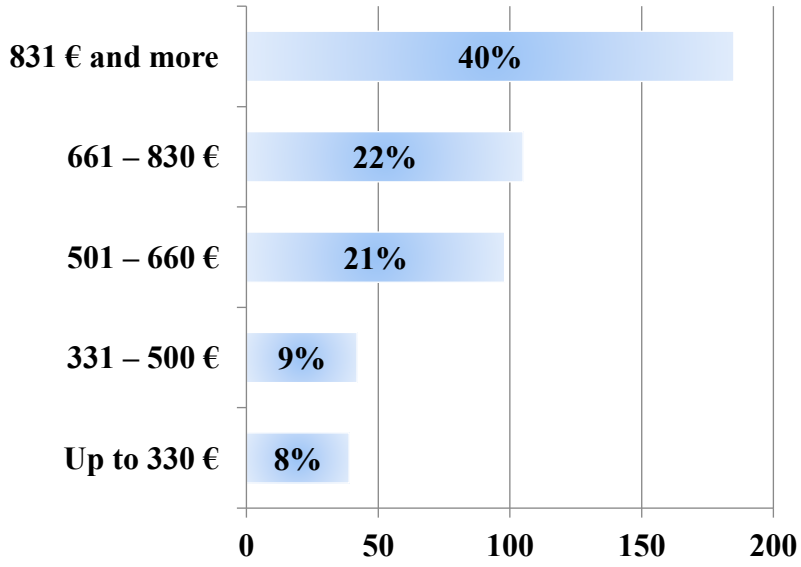

Figure 1 Monthly family income.

the survey was aimed at the general public and all age groups. As it could be seen from the Figure 1, the most respondents reported a monthly family income 831 € and more. Second most-ranked group was represented by an income from 661 € to 830 € (22%). The smallest income ranges (up to 330 €) was marked only by 8% of the respondents.

The first factual question asked in the questionnaire survey was whether the respondent purchases higher quality food. Up to 84% of respondents have claimed that they buy higher quality food on regular basis. This percentage could be so high because of the fact that more than 80% of respondents earn more than 500 € per month. On the other hand, 16% answered this question negatively. Figure 2 reports that 85% of women and 81% of men responded positively. These results were expected, because women are more interested in healthy lifestyle **(Fiala and Brázdová, 2000)** and they are also more likely to have higher quality diet than men **(Hiza et. al, 2013)**.

In relation to this question we formulated the following hypothesis:

H_0: Most consumers do not buy high quality food.

H_1: Most consumers buy high quality food.

To verify the hypothesis, the Wilcoxon signed rank test and significance level were used:

$$p = 0.0742 > \alpha = 0.05$$

Based on the results, we accept the zero hypotheses. Within 5% level of significance, we can claim that consumers do not buy high quality foods.

Most respondents (62%) claimed that they purchase higher-quality food because of health reasons – they believe that these foods can prevent illnesses or in some cases even cure them. The second reason was that these foods are controlled better, so they must fulfil higher requirements (18%), the third was that some people see quality food as pleasure or possibility of trying something unusual and 14% of the sample do so, since they earn enough money to afford them. Healthy foods have many advantages and a lot of customers buy them for various reasons, therefore retailers should focus on creating healthy corners where quality, fresh and especially health beneficial foods are sold. Priority should be to suppress sales of unhealthy products like tobacco, alcohol and various frozen semi-finished products. Based on the **Minkler et al. (2018)** research, in such stores customers buy up to 35% less unhealthy and harmful food.

The following question was dedicated to the factors which could lead to higher frequency of purchasing high quality food even when they are more expensive. Most respondents (60%) said they would be willing to buy more of these food if they had higher living standard. Similar survey was done by **Asif et al. (2018)** who found out that 55% of respondents would be more likely to buy higher quality foods if their economic situation changed to better. This fact can be caused by todays consumption time when people want to earn more money to buy more products. Over 20% of our respondents would purchase them only in the case of their illness and 24% of them would do so if they had more information about them. Consumers´ awareness about food quality and food safety is the key, because if customers do not know about these products, they simply can not search for them in stores and the probability of purchasing them is low. 4% of our respondents would welcome more propagation in electronic media.

On the other hand, 59.2% of respondents do not buy food of higher quality because they believe that more expensive does not always mean better. Another reason was according to 41% their price and 3.6% thought that they simply do not need quality food.

The main objective of the next question was to find out whether and how often respondents perceive information on the food packaging (Figure 3).

The above mentioned figure shows that 164 respondents (34.5%) usually seek for the information on the product packaging when purchasing food. Other 29.8% of respondents do so sometimes and 27.1% read product labels every time they shop. For 41 respondents, these informations are totally irrelevant and not important. According to several studies, packaging plays a very important role in the process of selling food **(Ahmed et al., 2005)**. Nowadays, packaging has become an integrated marketing tool and acts as the most important promotional tool **(Jerzyk, 2016)**. Another study has confirmed that consumers emphasize the freshness of the food, which is mostly stated on the wrapper **(Heide and Olsen, 2017).** There is a strong link between food packaging and consumer behavior, as shopping becomes a habit in which consumers choose individual foods based on their packaging **(Srey et al., 2013)**.

For two-thirds of respondents (66%) the information on food packaging is usually sufficient. Surprisingly, 23% of respondents reported mostly insufficient information and 2.9% always insufficient. Therefore, food producers should be more responsible and maybe consider adding more information than it is required by legislation.

Information on the packaging of products corresponds to the reality according to experience of 82.5% our respondents. Negative experience with discrepancy had only 17.5% of them. Because of many food scandals some customers are sceptic and do not trust companies even if the producers are periodically controled. Legislation states that packaging of packaged foods must include the mandatory data which can also be supplemented by voluntary data. Regulations of the European Parliament and the Council of the EU states that mandatory information must be easily accessible, indelible and big enough to be read. The only exception is represented only by the cathegory of non-packaged food. Mandatory data can not be masked, overlaid, or interrupted by other text or images. Pictograms or symbols can only supplement these data **(Regulation (EU) No 1169/2011)**.

In relation to the previous question we were interested also in the fact, whether information on the packaging of products is understandable. For 294 respondents (61.5%) these informations are clear. However, 21.5% of respondents staited that informations are incomprehensible mostly and for 4.2% always (Figure 4). These results may be caused mostly by the fact, that the above mentioned legislation is in many cases by companies not fulfilled.

Product labels also include information about the country of origin (where every single food comes from, or where it was produced). The following question was therefore addressed to the given issue. In particular, we focused on whether consumers consider it necessary or unnecessary to indicate the country of origin and the manufacturer of the food item. Most respondents, namely 333 (69.8%), consider placing the name of producer and the country of origin directly on the food packaging to be decisive and for one quarter it isimportant. The rest of the respondents (7.5%) consider this information to be unimportant. Even nowadays some consumers do not care where the food they are purchasing and subsequently eating was produced and factors like price, brand or taste and aroma are more important **(Golian et al., 2018)**.

Another pair of questions was focused on knowing how quality food are labeled in Slovakia. The first one was dedicated to the lable "Slovak Gold". Out of 478, 273 respondents said that they are familiar with the mentioned label. Other 42% answered this question negatively. The main reason for the lack of recognition can be the nowadays absence of promotion of this label in television, printed media and on the Internet.

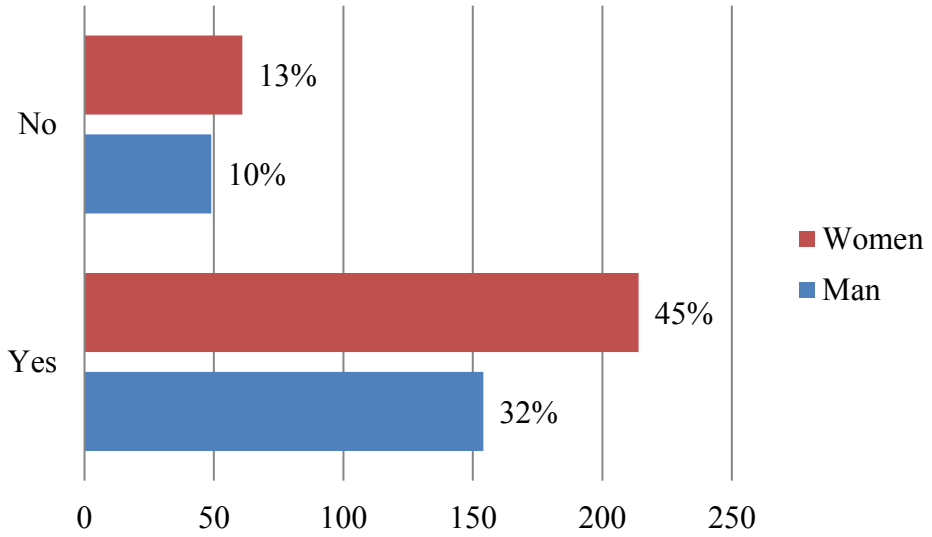

Figure 2 Dependence of buying higher quality food on respondent's gender.

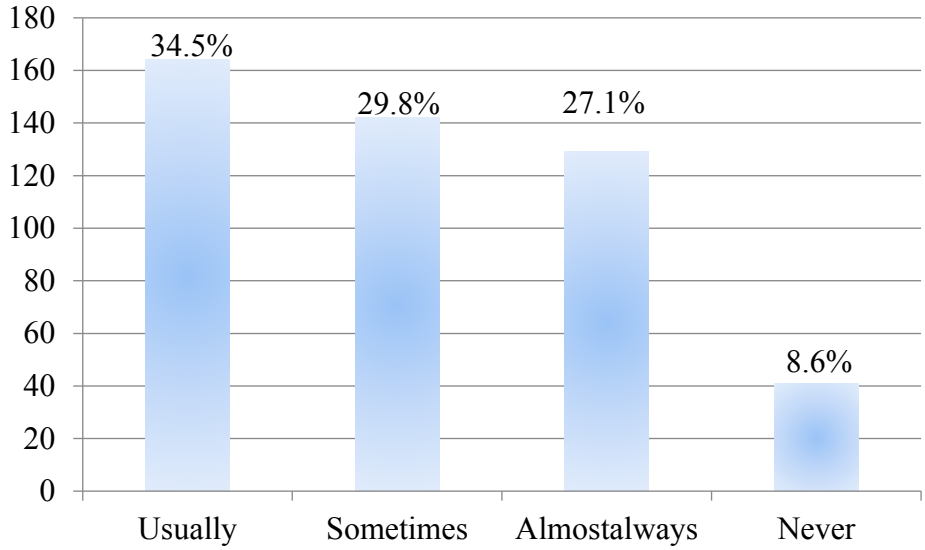

Figure 3 Frequency of reading information on food packaging.

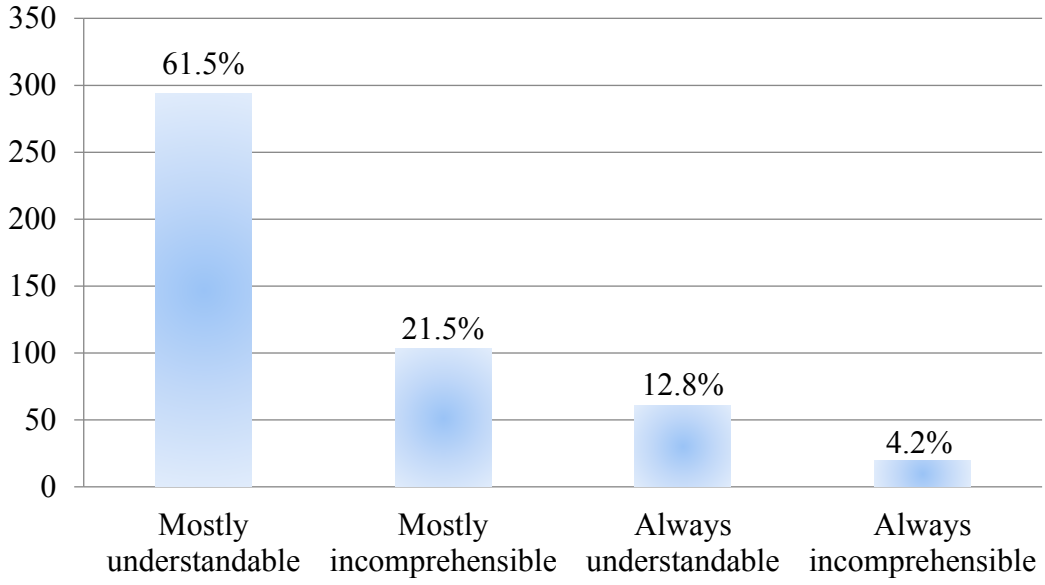

Figure 4 Clarity of information on food packaging.

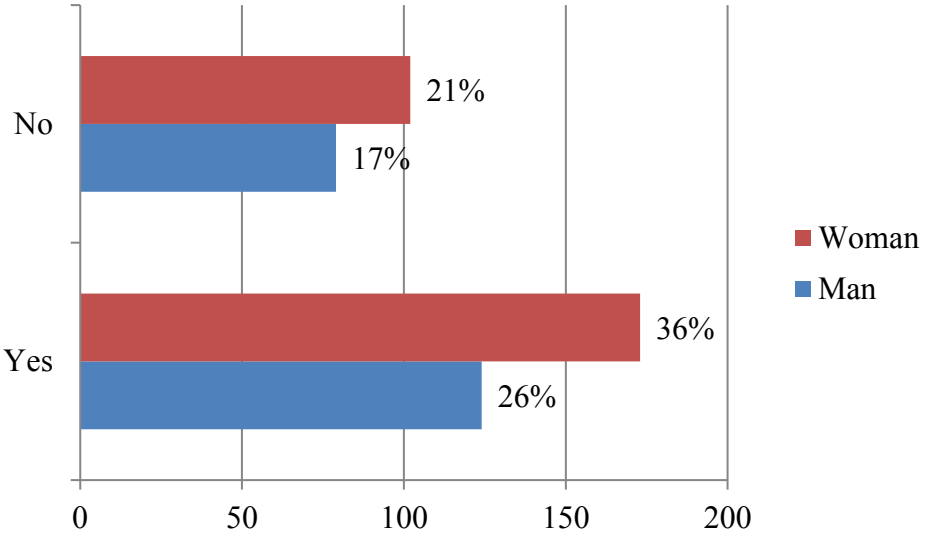

Figure 5 Dependence of knowing "Značkakvality SK" on respondent's gender.

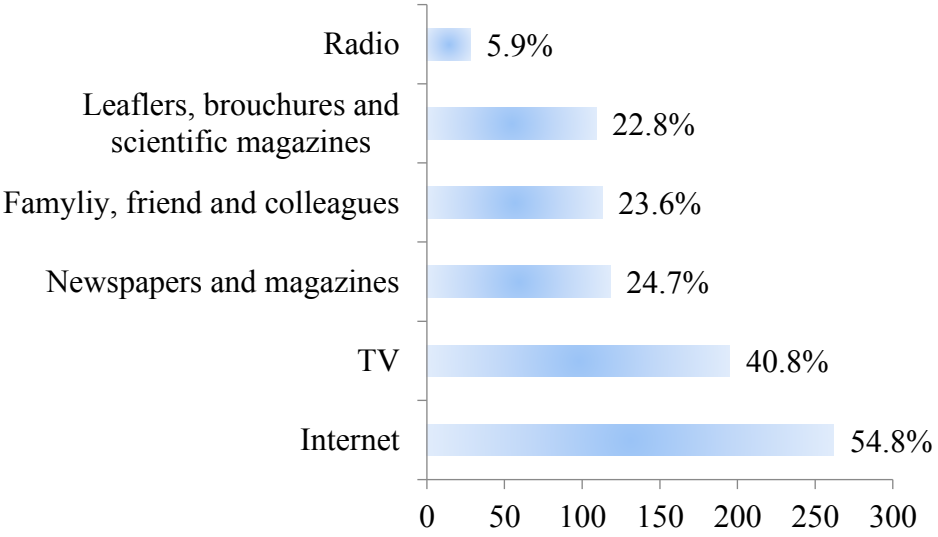

Figure 6 Source of information about food safety.

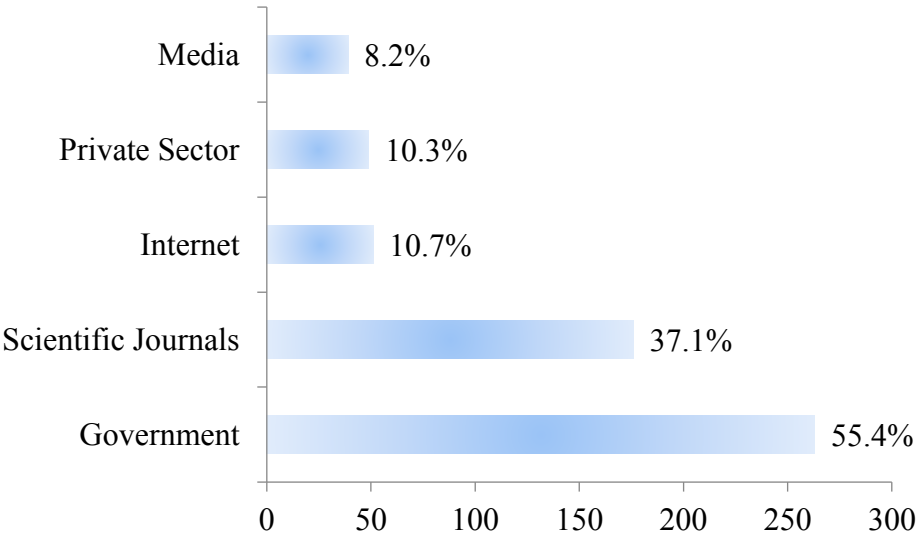

Figure 7 The most reliable sources of information about food safety.

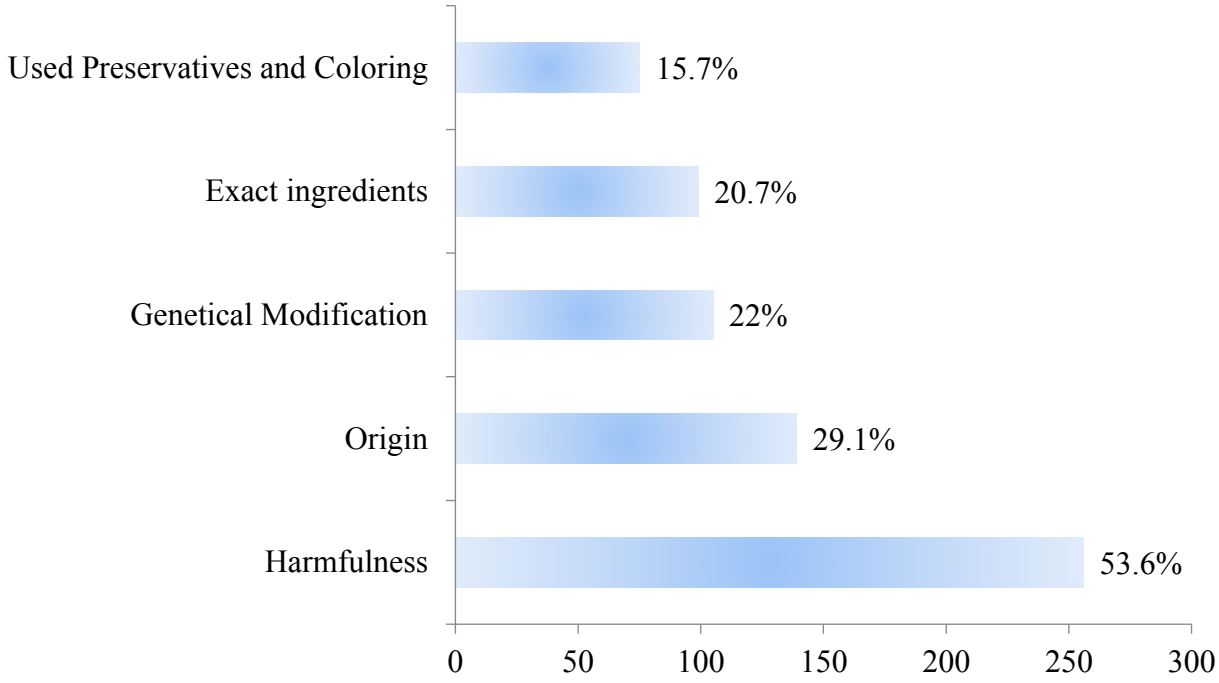

Figure 8 Types of information that are missed by consumers.

H_0: Fewer men than women do not know the lable "Slovak Gold".
H_1: Fewer men than women know the lable "Slovak Gold".
To verify hypothesis no. 4, the Chi-square test of independence and the level of significance were used:

$$p = 0.0001 < \alpha = 0.05$$

To test the hypotheses, calculated *p*-value was compared to the estimation risk alpha. The null hypothesis was rejected and therefore the alternative hypothesis H_1 was accepted. So, with 95% of probability, it is possible to claim that fewer men than women do not know the lable "Slovak Gold".

The second question (Figure 5) was focused on the national brand of high-quality agricultural products „Značka kvality SK“. The brand itself was created in the year 2004 and its main objective was to inform Slovak consumers about the quality of domestic food, which should support the consumption of domestic food products **(MP SR, 2009)**.

The graph shows that more than 50% of respondents know the logo of Značka kvality SK. Very similar results were achieved by **Nadányiová (2015)**, resp. **Košičiarová et al. (2016)**. More women (36%) than men. The larger unknown national brand of high-quality raw materials is visible in women's eyes, and up to 21%. For men it is 17%. This result, the greater lack of recognition of national brands of quality raw materials for women, surprised us. Research is supposed to confirm that women go shopping more often. This fact was also confirmed in the survey above **(Bhaskar et al., 2018)**. Of course, they often go shopping for the unborn, even to observe the information given on the clouds, and therefore do not have to label individual brands.

H_0: More women than men do not know the national label for quality of agricultural products “Značka kvality SK”.
H_1: More women than men know the national label for quality of agricultural products “Značka kvality SK”.

Statistical testing was performed by using the Wilcoxon signed rank test and significance levels:

$$p = 0.0125 < \alpha = 0.05$$

After comparing the *p*-value and the alpha value, we reject the null hypothesis. After accepting the alternative hypothesis, we can conclude that more women than men know the national label for quality of agricultural products “Značka kvality SK”.

The last five questions were devoted to consumers´ awareness of food safety. The largest number of respondents (40.5%) has rather enough information and 14% of them has definitely enough information about the food safety. But it is striking that 45.5% of our respondents were lacking this type of information. Based on the mentioned results, government and producers should teach consumers how to choose safe food in stores, store them at home and prepare them so they can eat nutritious health beneficial food. Even **Zan´s (2017)** survey has found out that food safety education has a positive impact on customers, because up to 37.4% of respondents have showed improved behavior when it comes to food.

In the next question, respondents were asked to identify 3 of the 6 sources they obtain information about the food safety (Figure 6).

Most respondents search for these information on the Internet (54.8%), second mostly used source was TV (40.8%) and third were newspapers and magazines (24.7%).

H_0: Most consumers search for least information about the food safety on the Internet.
H_1: Most consumers search for the most information about the food safety on the Internet.

To test the hypothesis No. 2, the Friedman´s test and the level of significance were used:

$$p = 0.0021 < \alpha = 0.05$$

The last null hypothesis was rejected because the level of significance alpha had a lower value than *p*-value. Qualitative statistics confirmed that most consumers search for the most information about the food safety on the Internet.

Furthermore, the questionnaire survey examined which source of information about the food safety is according to consumers the most trustworthy (Figure 7). When answering this question, respondents could choose more than one answer. The most trustworthy source is according to the survey the government (55.4%). Almost 40% of respondents thought that reliable information can be found in scientific journals dedicated to this issue. Nearly the same percentage marked options the Internet (10.7%) and the private sector (10.3%). Just 8.2% of respondents absolutely rely on information obtained from media. People should choose source they draw information from more carefully, because information coming from media or the Internet can be sometimes distorted. The most reliable are official documents of Ministry of Agriculture and Rural Development of the Slovak Republic (it is the highest organ responsible for safety of food in Slovak Republic) and European Union (its main function is to ensure safe and nutritious food and feed, high level of animal health, animal welfare, plant protection and clear and understandable information about the origin, content and use of food) **(EU, 2014)**.

The last question looked closer to the issue of type of the information which is missed by respondents. Respondents were asked to fill in up to 3 answers (Figure 8). Figure 8 shows that 53.6% of respondents were lacking the information about potential harmfulness of food. Second biggest group (29,1%) want to know the country of origin of the bought food. They are not satisfied with the lable „made in EU "they want the exact country to be identified. 22% of respondents had filled in the option „genetical modifications "and 20,7% the option „exact ingredients ". Customers are interested in ingredients, but moreover they want to know whether they are natural or artificially created in the laboratory.

CONCLUSION

Based on the results of this research we can conclude that 39% of respondents had insufficient information about the safety of purchased foods. One reason for being uninformed may be that they simply do not care about food quality. When it comes to source of information about the food safety, consumers usually search for them on the Internet (54.8%), in TV (40.8%) or in newspapers and magazines (24,7%). Paradoxically, for the most trustworthy source providing food safety information respondents (55.4%) marked the government and just 10,7% trust information found online.

The survey also found out that up to 84% of respondents buy higher quality food on daily basis. Most of them (62%) claimed that they do so for health reasons and to maintain healthy lifestyle. 48% of questioned said they do not recognize the lable "Slovak Gold". This may be due to the consumer's failure to read basic information on the food packaging or to insufficient advertising. Therefore, the Ministry of Agriculture and Rural Development should create informational campaign to support selling domestic food.

For 66% of respondents the information on the food packaging is sufficient. Interestingly, 23% of respondents reported a lack of information, especially about potential harmfullness of food, the state where the food was produced and the origin of used ingredients.

CONSUMER BEHAVIOUR OF YOUNG GENERATION IN SLOVAKIA TOWARDS COCOA-ENRICHED HONEY

Peter Šedík, Elena Horská, Eva Ivanišová, Miroslava Kačániová, Andrzej Krasnodębski

ABSTRACT
The new trend of healthy lifestyle increases consumers´ attention towards superfoods or functional food. Due to this fact, honey enriched with various healthy foods such as cocoa, cinnamon, ginger or dried fruits has started to appear on the European market. The aim of this research paper was to investigate consumer´s perception and preferences for cocoa-enriched honey. Consumer research was based on questionnaire survey extended by product testing. This survey was conducted in 2018 (February and March) and in total 257 young Slovak consumers between 18 - 30 years participated. Each respondent tested and evaluated sensory attributes of the product (taste, aroma, colour and texture) using a 5-point scale. Statistical analyses included Friedman test, Mann-Whitney U test, Fisher's Exact Test, Pearson Chi-square test and Cramer'V coefficient. Results showed that the cocoa-enriched honey was evaluated as tasty, aromatic, gently, delicious, special, with ideal sweetness and amount of cocoa. All sensory attributes were evaluated positively (2 - good). Females were more interested in the purchase of this product. Moreover, the product would be purchased mostly by respondents who consider it a healthier alternative to commercial chocolate spreads or by those who consider their eating habits healthy. Laboratory tests revealed that the antioxidant activity of the product was higher in comparison to normal honey. In conclusion, the obtained information could be used in product positioning, promotion and designing appropriate marketing strategy.

Keywords: honey; cocoa; product testing; questionnaire survey; Slovakia

INTRODUCTION
Honey is considered to be a complex food due to its rich nutritional value and biological variability. In general, honey is perceived as a natural sweetener and widely accepted by consumers as a healthy alternative to sugar. Moreover, it contains a wide spectrum of vitamins, minerals, enzymes, amino acids as well as antioxidant compounds such as phenolics acids and flavonoids **(Pyrzynska and Biesaga, 2009; Weston, 2000; Kačániová et al., 2015)**. Besides nutritional value, honey has many antimicrobial and healing properties. In medicine, honey is used for curing various diseases including skin wounds, colds or diseases of gastrointestinal character. Nowadays, honey is frequently used in apitherapy which is an important part of the complementary and alternative medicine. Honey and other bee products are commonly used in pharmacy as diet supplements, prophylactic agents or drug components **(Gašic et al., 2014; Lusby et al., 2005; Al-Mamary et al., 2002)**.

Cocoa powder is a plant-based product, which is obtained by milling roasted cocoa nibs and contains more than 300 constituents including minerals, polyphenol acids and flavonoids. Many studies have proven its antioxidant, anti-inflammatory and cardio-protective properties. Approximately 30% of polyphenol content is made by flavonoids (procyanidin, catechin and epicatechin) therefore this product has a significantly higher antioxidant activity than for example pomegranate, blueberries or cranberries. There is no doubt that cocoa powder has potential health benefits and is perceived by many consumers as a functional food **(Todorovic et al., 2017; Araujo et al., 2013; Lapčík et al., 2017; Godočíková et al., 2016; Kozelová et al., 2014).**

Due to the increasing attention of consumers towards healthy products and functional food, new honey-based products appeared on the European market. Usually, these products are a combination of honey and other healthy foods such as nuts, dried fruits including cherries, prunes, apricots or even various spices (cinnamon, ginger, chilli or cocoa powder). Sometimes, honey is mixed with other bee products such as propolis, pollen, royal jelly or bee bread. The final product (enriched honey) usually has higher antioxidant properties as well as nutritional value **(Kowalski and Makarewicz, 2017; Ćetković et al., 2014; Tumbas et al., 2012; Vulić et al., 2015; Wilczyńska et al., 2017).**

Scientific hypothesis
The aim of this research paper is to study the perception of young Slovak consumers and their preferences towards cocoa-enriched honey.

Several hypothesis were formulated:
Hypothesis 1: - There exist differences in evaluation of sensory attributes (taste, aroma, colour, texture).
Hypothesis 2: - There exist differences in evaluation of semantic differential between genders.
Hypothesis 3: - There exists dependence between purchase intentions and gender.
Hypothesis 4: - There exists dependence between purchase intentions and one´s perception of healthy eating habits.
Hypothesis 5: - There exists dependence between purchase intentions and product perception as a healthier alternative to commercial spreads.
Hypothesis 6: - The antioxidant activity of cocoa-enriched honey will be higher in comparison to normal honey.

MATERIAL AND METHODOLOGY

Consumer research

The primary data were based on questionnaire survey and product testing both conducted in the spring 2018 (February - March). The tested product was rapeseed honey in creamed consistency enriched with cocoa powder (see Table 1). Respondents evaluated both sensory and abstract attributes using a 5-point scale. Afterwards each respondent answered the questions regarding consumer and purchasing behaviour. Target group were 257 young consumers between 18 – 30 years. According to socio-demographic characteristics, the research sample comprises women (56.03%) with secondary education (73.15%) and living in the city (52.53%). The majority of respondents were students (54.09%) or employed (45.91%) with a monthly income up to 600 € (67.32%).

Figure 1 Cocoa-enriched honey.

Statisic analysis

Statistical analyses were conducted in SPSS version 25 (IBM) and following non-parametric tests were applied:

- Friedman test
- Mann-Whitney U test
- Fisher's Exact Test,
- Pearson Chi-square test
- Cramer'V coefficient

Laboratory testing

Sample preparation

An amount of 0.25 g of sample was extracted with 20 mL of 80% ethanol for 2 hours. After centrifugation at 4000 g (Rotofix 32 A, Hettich, Germany) for 10 min, the supernatant was used for measurement (antioxidant activity, polyphenols, flavonoids, phenolic acids). Extraction was carried out in triplicate and the results reported are the results of those replicate determinations with standard deviations

Determination of antioxidant activity

The radical scavenging activity of extracts was measured using 2,2-diphenyl-1-picrylhydrazyl (DPPH) **(Sánchéz-Moreno et al., 1998)**. The sample (0.4 mL) was mixed with 3.6 mL of DPPH solution (0.025 g DPPH in 100 mL methanol). The absorbance of the reaction mixture was determined using the spectrophotometer Jenway (6405 UV/Vis, England) at 515 nm. Trolox (6-hydroxy-2,5,7,8-tetramethylchroman-2-carboxylic acid) (10 - 100 $mg.L^{-1}$; $R^2 = 0.989$) was used as the standard and the results were expressed in $mg.g^{-1}$ Trolox equivalents. All chemicals were analytical grade and were purchased from Reachem (Slovakia) and Sigma Aldrich (USA).

Determination of polyphenol content

Total polyphenol content extracts was measured by the method of **Singleton and Rossi (1965)**, using Folin-Ciocalteu reagent. 0.1 mL of each sample was mixed with 0.1 mL of the Folin-Ciocalteu reagent, 1 mL of 20% (w/v) sodium carbonate, and 8.8 mL of distilled water. After 30 min in darkness the absorbance at 700 nm was measured using the spectrophotometer Jenway (6405 UV/Vis, England). Gallic acid (25 – 300 $mg.L^{-1}$; $R^2 = 0.998$) was used as the standard and the results were expressed in $mg.g^{-1}$ gallic acid equivalents.

Determination of flavonoid content

Total flavonoids were determined using the modified method of **Willett (2002)**. 0.5 mL of sample was mixed with 0.1 mL of 10% (w/v) ethanolic solution of aluminium chloride, 0.1 mL of 1 M potassium acetate and 4.3 mL of distilled water. After 30 min in darkness the absorbance at 415 nm was measured using the spectrophotometer Jenway (6405 UV/Vis, England). Quercetin (0.5 – 20 $mg.L^{-1}$; $R^2 = 0.989$) was used as the standard and the results were expressed in $mg.g^{-1}$ quercetin equivalents.

Determination of phenolic acid content

Total phenolic acid content was determined using method of **Farmakopea Polska (1999)**. A 0.5 mL of sample extract was mixed with 0.5 mL of 0.5 M hydrochloric acid, 0.5 mL Arnova reagent (10% $NaNO_2$ + 10% Na_2MoO_4), 0.5 mL of 1 M sodium hydroxide (w/v) and 0.5 mL of water. The absorbance at 490 nm was measured using the spectrophotometer Jenway (6405 UV/Vis, England). Caffeic acid (1 – 200 $mg.L^{-1}$, $R^2 = 0.999$) was used as a standard and the results were expressed in $mg.g^{-1}$ caffeic acid equivalents.

RESULTS AND DISCUSSION

Respondents firstly evaluated product´s taste, aroma, colour and texture using a 5-point scale (1 – very good and 5 – very bad). By applying the Friedman test, the differences between these sensory attributes were tested. Based on the results, the first hypothesis was confirmed (p-value = 0.014). In average, all attributtes were evalueted as good. The best evaluation obtained texture (2.29) followedby taste (2.32), colour (2.33) and aroma (2.46). Moreover, Figure 2 illustrates sensory evaluations according to gender. Based on the Mann-Whitney U test, there do not exist significant differences in evaluations between males and females. However, it could be stated that females evaluated slightly better. Similar sensory evaluation was conducted by **Šedík et al. (2018a)**.

Next, respondents evaluated selected characteristics of the product displayed by a 5-point scale using modified semantic differential. In general, results showed that respondents perceived product positively. On average, product was evaluated as tasty (2.3), with ideal sweetness (1.6), aromatic (2.3), gentle (2.6) delicious (2.3) special (2.4) with adequate amount of cocoa (2.4). The product was perceived neither irresistible nor average (3.2), and as for the question whether it has more honey or cocoa taste, respondents felt slightly more the taste of honey (2.7). Furthermore, Figure 2 illustrates evaluations of semantic differential by gender. It could be observed that females evaluated all selected characteristics more positively. Nevertheless, the only statistically significant differences were proven and hypothesis 2 was confirmed (see Table 1) in terms of tasty/disgusting (p-value = 0.044), delicious/tasteless (p-value = 0.039), special/ordinary (p-value = 0.037) adequate/too much amount of cocoa (p-value = 0.030) and honey taste/cocoa taste (p-value = 0.003). Females felt the taste of honey more intensively than males. The third hypothesis assumed differences between males and females in purchase intention of the product. Application of Fisher's Exact Test proved that there exist statistically significant differences. Females are more interested in product purchase than males (Figure 4). The main motives of purchase were taste, followed by health aspect while the frequent reasons of not purchasing the product were too intensive sweet and honey taste, or simply preference of normal honey. Besides purchase motives and barriers, the study investigated the impact of healthy eating habits on purchase intentions. By applying Pearson Chi-square test, hypothesis 4 was confirmed and there exists statistically significant dependency (p-value = 0.000). Based on the results, it could be concluded that the majority of respondents who do not consider their eating habits healthy at all, would not purchase cocoa-enriched honey (Figure 5).

Hypothesis 5 assumed dependency between product perception as a healthier alternative to commercial spreads and purchase intention. Based on the result of Pearson Chi-square test, this hypothesis was confirmed. The majority of respondents who perceive this product as a healthier alternative would purchase it (Figure 6).

In addition, respondents representing the young generation consume honey mostly occasionally. This situation could be improved by health promotion campaigns even in the framework of school catering programs **(Bittsánszky et al., 2015)**. According to **Guziy et al. (2017)**, honey consumers in Slovakia mostly consider the country of origin, type and price before purchasing a product. The size and design of packaging play the least important role, which was proven by applying an eye-tracking experiment as well **(Hazuchová et al., 2018).**

Table 1 Gender differences in product evaluation.

Product characteristic	Sig.
taste	.246
aroma	.059
colour	.341
texture	.302
tasty/disgusting	.044**
ideal/insufficient sweetness	.309
aromatic/without aroma	.051
gentle/strong	.115
delicious/tasteless	.039**
special/ordinary	.037**
irresistible/average	.201
adequate/too much amount of cocoa	.030**
honey taste/cocoa taste	.003**

Note: **Statistically significant for p <0.05 Mann-Whitney U test.

In order to study if enrichment of honey by cocoa powder would increase antioxidant activity and prove the hypothesis, the product was analysed in laboratory conditions.

Antioxidant activity

The antioxidant activity of rapeseed honey enriched with cocoa powder determined with the DPPH method was 6.73 mg TEAC.g^{-1} (Table 3). Pure rapeseed honey is rich in compounds with antioxidant activity, especially flavonoids and phenolic acids. Honey enriched with herbs, spices, bee products, fruits as well as coffee and cocoa beans is very popular nowadays. Some studies reported that phenolic compounds found in cocoa beans may present different properties such as antioxidant, anticarcinogenic, and antiradical activities. Polyphenols are the main antioxidant-active constituents of cocoa. Flavanols and procyanidins have previously been identified as the active antioxidant agents of cocoa **(Bauer et al., 2016)**. Cocoa beans as well as cocoa powder are very attractive for consumer also for organoleptic properties. Bitter and chocolate taste of cocoa powder is very good with the combination of sweet honey taste. Adding cocoa powder to honey can also increase antioxidant activity. **Jaafar et al. (2017)** tested the antioxidant activity of monofloral honey (regarding rapeseed honey) and determined values from 0.08 to 0.51 AEAC.g^{-1} (ascorbic acid equivalent antioxidant capacity). In our study the activity was several times higher probably due to the cocoa powder addition.

Total polyphenol, flavonoid and phenol acid content

The results of total polyphenol, flavonoid and phenolic acid content are summarized in Table 3. Pure rapeseed honey is rich in phenolic substances. **Wen et al. (2017)** determined in this honey presence of gallic, protocatechuic, p-hydroxybenzoic, caffeic, ferulic, p-coumaric and benzoic acid.

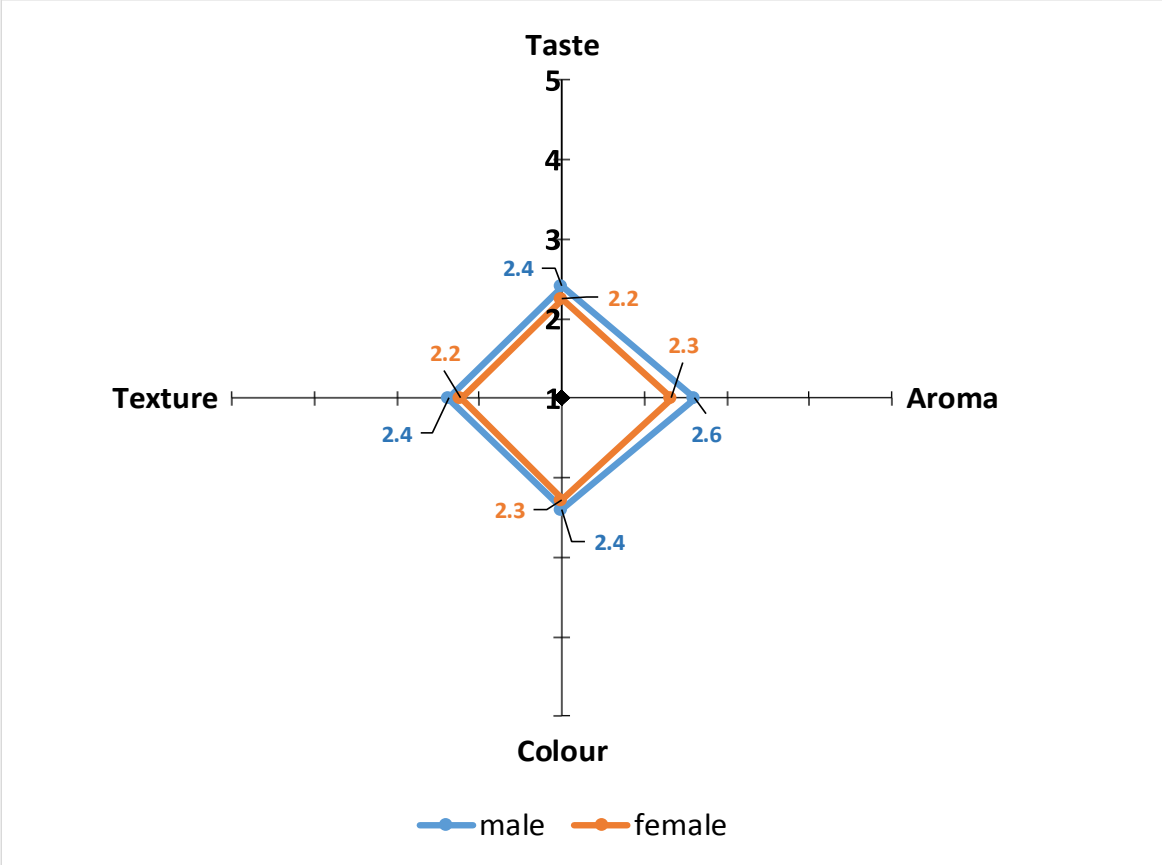

Figure 2 Sensory evaluation of cocoa-enriched honey by gender.

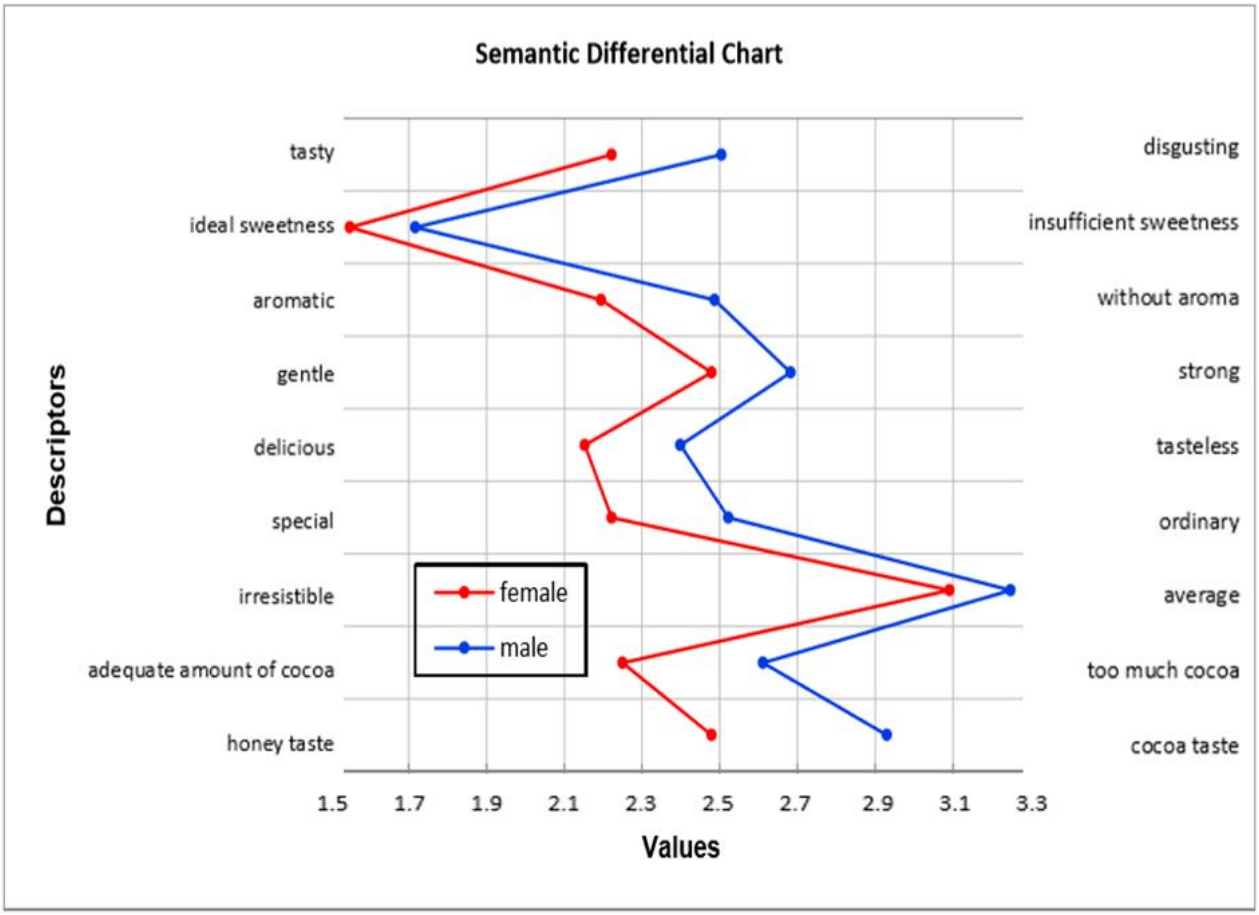

Figure 3 Semantic differential: product evaluation of selected characteristics.

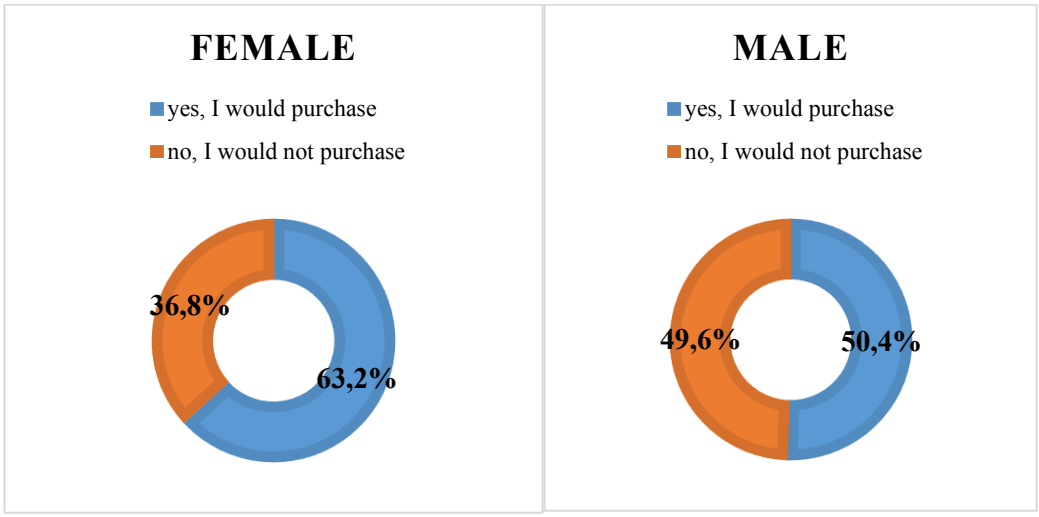

Figure 4 Purchase intentions of cocoa-enriched honey by gender.

Table 2 Impact of selected factors on purchase intentions.

	Sig.	Cramer´s V coefficient
Purchase intentions and gender	.043**	.128
Purchase intentions and healthy eating habits	.000**	.313
Purchase intentions and product perception	.000**	.526

Note: **Statistically significant for p <0.05 Pearson Chi-square test and Fisher´s Exact Test.

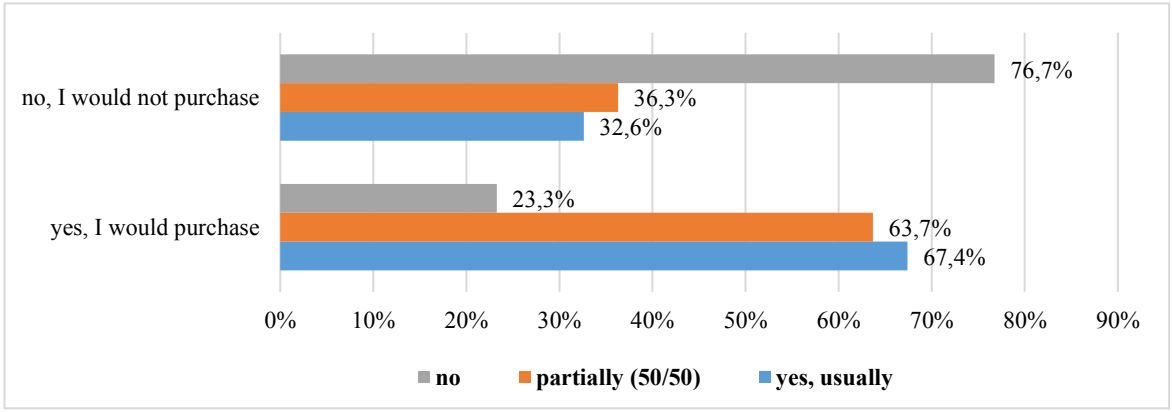

Figure 5 Respondents' purchase intentions and perception of their healthy eating habits.

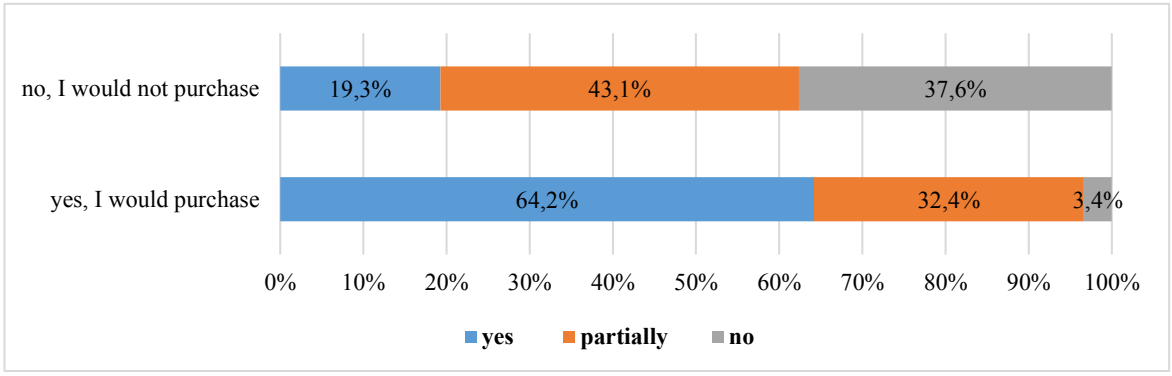

Figure 6 Respondents' purchase intentions and product perception as healthier alternative to commercial chocolate spreads.

While gallic, ferulic and protocatechuic acids were determined only in small amount, benzoic acid (18.11 mg.kg^{-1}) and p-hydroxybenzoic (1.22 mg.kg^{-1}) were dominant, detected in higher amount. **Özkök et al. (2010)** determined total phenolic acid content in Turkish monofloral honey and their results ranged from 0.035 to 0.36 mg GAE.g^{-1} (gallic acid equivalent). Total phenolic acid content in our sample of monofloral honey is higher due to the cocoa powder addition. **Ali et al. (2015)** determined in cocoa powder gallic acid, protocatechuic and chlorogenic. Protocatechuic acid was dominant with amount 18.8 mg.g^{-1}. **Wen et al. (2017)** also determined the flavonoid composition in rapeseed honey and found the presence of rutin, myricetin, morin, quercetin, kaempferol,

galangin, apigenin and chrysin. Morin (11.12 mg.kg^{-1}) and quercetin (5.18 mg.kg^{-1}) were dominant in this type of honey. According to **Ayoub et al. (2009)** the flavonoid concentration in honey is approximately 0.02 mg.g^{-1}. In our sample enriched with cocoa powder the amount of flavonoids was higher. Cocoa powder is a very good source of phenolic compounds especially flavonoids. Flavonoids present in cocoa include flavanols, anthocyanins, flavonols, and flavones. Flavanols, the most abundant flavonoids in cocoa, comprise the monomeric flavanols (+)-catechin and (-)-epicatechin, and their oligomeric and polymeric forms (procyanidins). (-)-Epicatechin has been reported as the major monomeric flavanol in cocoa, representing ca. 35% of the total phenolic content **(Andres-Lacueva et al., 2008)**. Apart from polyphenol content, cocoa is also rich in methylxanthine, namely caffeine and theobromine. These substances have stimulating effect on the human body, so we can recognize that consumption of honey enriched with cocoa powder can have not only antioxidant but also stimulating effect on the organism.

For testing the last hypothesis, the results of antioxidant activity, total polyphenol, flavonoid and phenolic acid content (Table 3) were comapred with similar laboratory tests of normal honey, where resutls were as follows: DPPH [mg TEAC.g^{-1}] 0.313 ±0.018, TPC [mg GAE.g^{-1}] 1.212 ±0.011, TFC [mg QE.g^{-1}] 0.033 ±0.013 and TPAC [mg CAE.g^{-1}] 0.084 ±0.022 **(Šedík et al., 2018b)**. It could be concluded that the antioxidant activity of cocoa-enriched honey was few times higher.

Table 3 Antioxidant activity, total polyphenol, flavonoid and phenolic acid content in analyzed sample.

Parameter	Cocoa-enriched honey
DPPH [mg TEAC.g^{-1}]	6.73±0.98
TPC [mg GAE.g^{-1}]	4.84±0.67
TFC [mg QE.g^{-1}]	0.25±0.03
TPAC[mg CAE.g^{-1}]	2.71±0.16

Note: DPPH - radical scavenging activity; TEAC - trolox equivalent antioxidant capacity; GAE - gallic acid equivalent; QE - quercetin equivalent; CAE - caffeic acid equivalent; mean (n = 3) ± standard deviation.

CONCLUSION

Consumer research showed that cocoa-enriched honey obtained positive evaluations among young consumers in Slovakia. Taste, aroma, colour and texture was evaluated as good. Furthermore, the product was described as tasty, aromatic, gentle, delicious, special, with ideal sweetness and adequate amount of cocoa. The product scored as neither irresistible nor average and the dominant taste of the product was neither honey nor cocoa. However, females felt the honey taste more than males. In some characteristics, females evaluated this product more positively.

In general, the majority of respondents would purchase the product. However, female consumers were more interested in product purchase than male consumers. Moreover, respondents who considered their eating habits healthy and those who perceived this product as a healthier alternative to commercial chocolate spreads had higher willingness to purchase it.

Regarding the antioxidant activity, the tested products obtained a few times higher results than normal honey, therefore, it is assumed that this combination of two ingredients increases the overall benefits for health of final products. In fact, this observation could be used in tailoring a suitable marketing strategy and product positioning as a functional food. The target group should be female consumers who are interested in healthy lifestyle.

ECOTOXICOLOGICAL STUDIES OF AKMOLA REGION LAKES

Lyailya Akbayeva, Erdaulet Tulegenov, Ainur Omarbayeva, Nazira Kobetaeva, Zina Nurgalieva, Yerlan Nurkeyev, Patrícia Martišová, Vladimir Vietoris, Assylbek Zhanabayev

ABSTRACT
The research object is water, bottom sediments in Akmola region lakes located in the intensive agriculture area. The territory of Akmola region is subjected to intensive human impacts, including the inevitable pollution with agricultural pesticides, which are ecotoxicants. The work has carried out hydrochemical studies in technogenic polluted lakes: general hydrochemical indicators, persistent organic pollutant content. The POPs in the samples were determined on the gas chromatograph Clarus 580 (PerkinElmer) with a mass spectrometer detector Clarus-SQ 8. According to the analysis results, the general hydrochemical pollution is classified as an average. The MPC excess indicators in the Akmola region lakes are observed for salt ammonium (up to 0.002 MPC), magnesium (up to 1.15 MPC), nitrites (up to 1.12 MPC), petroleum products (up to 1.98 MPC), iron (up to 2.0 MPC), SSAS (up to 3.8 MPC). High concentration indicators for the sulphate (3.5 MPC), copper (4.3 MPC), magnesium (1.125 MPC). Mainly the lakes are dominated by sulfates, ion chloride. But in general among 21 investigated POPs 8 substances are accumulated in bottom sediments of the investigated Zhalauly, Tastykol lakes, Unnamed Lake to the south of Akkol village, Itemgen lake, Zhalanash lake near Malinovka village (near Astana city), Kokay, Yesey, Bolshoe Chebachie.

Keywords: ecotoxicants; persistent organic pollutants; monitoring; accumulation; lake

INTRODUCTION
In Kazakhstan there is still no universal systematic monitoring of persistent organic pollutants **(Kholubek et al., 2012)**. Upon that, a number of pilot projects of initial assistance to the Republic of Kazakhstan on obligations under the Stockholm Convention on Persistent Organic Pollutants has given reasoned conclusion that the problem is urgent in the republic **(Kholubek et al., 2012; Zhanadilov et al., 2015.; Shabanova et al., 2010)**. This primarily relates to areas exposed to intense pollution by agricultural pesticides.

Ecological problems of Akmola region is largely determined by agro-industrial specialization of the region. The main branch of the region specialization is the production and processing of agricultural products (76%), including grain production – 56.8%. Akmola region has the highest percentage of rural population – 54.8% **(Investment opportunities of the region, 2017; Sydykov et al., 2004; Seitkasymova, 2015)**.

The industry of this region is represented by the gold ore, uranium extraction, pharmaceutical and chemical industry, machine building and production of building materials **(Sydykov et al., 2004; Press service of the Prime Minister of the Republic of Kazakhstan, 2018)**.

The area is rich in land resources. The total area of agricultural land is 13,791.7 thousand ha, areas of natural pastures are wide and occupy 6592.5 thousand hectares, the arable land is about 7,100 thousand ha. Almost all arable lands use some insecticides, fungicides - substances that are long-persistent in the environment, accumulated in the soil, in bottom sediments of stagnant water **(Ljunggren et al., 2014; Jepson and Law, 2016)**.

In addition, the territory of the region under study still keep in some places some pesticides in abandoned warehouses without recycling, that were applied since the middle of last century. Names, respectively, contents of some pesticides are no longer possible to determine without analytical tests.

Thus, the territory of Akmola region is subjected to intensive human impacts, including the inevitable pollution with agricultural pesticides, which are ecotoxicants.

Detecting most POPs directly in water is not recommended **(Kholubek et al., 2012; Ministry of Health of the USSR, 1987)** because many of them are insoluble in water, and soluble POPs can be eliminated through bioaccumulation in living organism tissues. Thus, in our opinion, monitoring surface water for the POP content should begin with bottom sediments. In this case,

hydrochemical indicators should be analyzed as the accompanying background or synergistic factor increasing violations in biocenosis and pathomorphology of aquatic organisms **(Yemelyanova and Lobchenko, 2002.; WHO, 2011; Kukeyeva et al., 2015; Grancová-Bielková and Sokol, 2010; Akbayeva et al., 2014)**.

The research aim: Study the content of ecotoxicants in the Akmola region lakes.

Scientific hypothesis

In Kazakhstan, by virtue of years of the uncontrolled POPs use and production of industrial toxins, violations of their operation and storage rules, a unique dangerous xenobiotic profile could emerge, which practically has not been studied **(Akbayeva et al., 2016)**.

In the Republic of Kazakhstan, an average of up to 0.57 kg of pesticides was applied per 1 ha of arable land **(Shabanova et al., 2010)**. Considering that pesticides were used from the 50s, about 475 tons of pesticides were used on the territory of the Akmola region with an area of 14,621.9 hectares until 2008, including POPs pesticides. In this regard, pesticides from contaminated soil should ultimately accumulate at the bottom of water bodies. Thus, lakes are the ultimate storage of POPs.

The research results should be informative and methodological rationale for more extensive researches in this area.

MATERIAL AND METHODOLOGY

In 2016 some of the chemical components was studied in the water and bottom sediments of the Akmola region lakes: Zhalauly and Tastykol lakes, the unnamed lake to the south of the district center of Akkol village and unnamed lake 40 km south from Astrakhanka village, Itemgen lake at Buland village, Zhalanash lake at Malinovka village (near Astana city). These lakes are located on the territory of the agricultural pesticides intensive use or places of POP substances storage. Lakes of the Korgalzhyn lake system: Kokay, Yesey, Sultankeldy are located in the south of the Akmola region territory in the lower part of the Nura River valley, which runs a large farmland. There have also been studied lakes of Shchuchinsk - Borov resort zone Borovoye and Bolshoe Chebachie that are under intensive anthropogenic impact.

In the lakes, hydrochemical samples of water and bottom sediment were selected in the summer months of July - August 2016.

These analyzes have determined the Hydrochemical water pollution index (WPI) **(Sibagatullina and Mazurkin, 2009)**.

Determining POPs in bottom sediments

It has been carried out in accordance with the methodological guidelines for determining HCH and DDT in silt sulfide medical muds with gas-liquid chromatography **(Ministry of Health of the USSR, 1987)**. The samples were selected with a bottom sampler from 10 – 70 cm depth from the surface. Samples were taken at five points by the "envelope" principle. Selected from all the mud was thoroughly mixed, and an average sample was selected in a glass jar of 500 mL. For further analysis, grounds were air dried.

The POPs in the samples were determined on the gas chromatograph Clarus 580 (PerkinElmer) with a mass spectrometer detector Clarus-SQ 8.

Chromatographic conditions: capillary column RestekRxi®-1 ms 0.25 mm x 30m x 0.25 mm, sample volume: 1.0 mcL, the carrier gas, the carrier gas velocity: 1 $ml.min^{-1}$, flow division of 1:25, t columns: 40 °C, the rise of 2 °C.min^{-1} to 280 °C, t evaporator – 280 °C, mass spectrometric detector: t – 240 °C, EI +=70 eB, the scanning time – 4 to 120 minutes, the ion scan mode – 39 – 500 $m.z^{-1}$.

Statisic analysis

All data were expressed as mean. The percentage components content was automatically calculated based on the peak areas of total ion chromatograms. The components were identified by mass spectra and retention times, using a NIST library.

RESULTS AND DISCUSSION

Indicators of the MPC excess in the Akmola region lakes for salt ammonium (up to 0.002 MPC), magnesium (up to 1.15 MPC), nitrites (up to 1.12 MPC), petroleum products (up to 1.98 MPC), iron (up to 2.0 MPC), SSAS (up to 3.8 MPC). High concentration indicators for the sulphate (3.5 MPC), copper (4.3 MPC), magnesium (1.125 MPC). Mainly the lakes are dominated by sulfates, ion chloride (Table 1).

Lakes the most salty and with a hard water are Zhalauly and Zhalanash lakes - the water hardness of 7.5 $mg.dm^{-3}$ and 8.37 $mg.dm^{-3}$, respectively.

According to the water pollution index (WPI) the first class (relatively clean) may only include Sultankeldy, Yesey, Kokay waters; the second class (slightly dirty) - Zhalauly, Itemgen, Unnamed Lake (Akkol village) Zhalanash, Borovoe, Bolshoe Chebachie; the third class (polluted) - Tastykol, Unnamed Lake (Astrakhanka village) **(Sibagatullina and Mazurkin, 2009)**.

Water is not recommended as a key matrix for lipophilic and non-Arctic initial twelve POPs, so the analysis of surface water is not recommended: for aldrin, chlordane, DDT, dieldrin, endrin, HCB, heptachlor, mirex, PCB, PCDP/PCDF, toxaphene. Water-soluble POPs: chlordecone, α-HCH, β-HCH, γ-HCH, PFOS (perfluorooctanesulfonate). Besides, the POP concentration in water may vary seasonally due to the seasonal activity of phytoplankton and certain organic substances, and other impacting factors, such as rainfall, flow volume, etc. Based on this, we have not detected POPs in the lake waters, and immediately began to define in the bottom sediments, where they can sediment as lipophilic compounds on the adsorbent composed of dead biota, benthic microorganisms.

Almost in all the studied lakes (Table 2), certain POPs have been found, except for the Unnamed Lake (at Astrakhanka village), Borovoye and Sultankeldy. Among the pesticides investigated by us, no sample has such compounds detected as: alpha-hexachlorocyclohexane, beta-hexachlorocyclohexane, chlordecone, hexabromobiphenyl, hexabromodiphenyl ether, lindane, hexachloran, mirex, pentachlorobenzene (in quintozene), perfluorooctane sulfonate and its salts, endosulfan and

isomers, tiodan, paraquat. Thus, among 21 tested substances, 12 substances are not accumulated in the bottom sediments of lakes studied.

Lake, where studied chlorinated pesticides are found, are located in areas of the most intensive agriculture, in particular, Zhalauly lake – where 5 pesticides are found (endrin, heptachlor, hexachlorobenzene, DDT, polychlorinated biphenyl), in 3 lakes 3 pesticides are found: Tastykol (aldrin, hexachlorobenzene, DDT), Itemgen (heptachlor, DDT, polychlorinated biphenyl) and Zhalanash (dieldrin, hexachlorobenzene, DDT). One pesticide – (hexa hexachlorobenzene), Bolshoe Chebachie (Aldrin) and Yesey (Aldrin). 2 pesticides were found in Kokay lake (chlordane, hexachlorobenzene).

The quantitative pesticides distribution in lakes is shown in Table 3: aldrin has been found in 3 samples of Tastykol lake (0.06 x 10^{-6} mg.kg^{-1}), Yesey (0.3 x 10^{-6} mg.kg^{-1}), Bolshoe Chebachie (1.8 x 10^{-6} mg.kg^{-1}), chlordane - in 1 Kokay lake (1.3 x 10^{-6} mg.kg^{-1}), dieldrin in 1 Zhalanash lake (0.04 x 10^{-6} mg.kg^{-1}), endrin - in 1 Zhalauly lake (0.6 x 10^{-6} mg.kg^{-1}), heptachlor - in 2 Zhalauly lakes (0.22 x 10^{-6} mg.kg^{-1}) and Itemgen (0.04 x 10^{-6} mg.kg^{-1}), hexachlorobenzene was found in 5 Zhalauly lakes (0.07 x 10^{-6} mg.kg^{-1}), Tastykol (0.47 x 10^{-6} mg.kg^{-1}),

Table 2a POPs content in the bottom sediments of the Akmola region lakes.

Lake name	Aldrin (mg.kg^{-1})	Alpha hexachlorocyclohexane (mg.kg^{-1})	Beta hexachlorocyclohexane (mg.kg^{-1})	Chlordane (mg.kg^{-1})	Chlordecone (mg.kg^{-1})	Dieldrin (mg.kg^{-1})	Endrin (mg.kg^{-1})	Heptachlor (mg.kg^{-1})	Hexabromobiphenyl (mg.kg^{-1})	Hexabromodiphenyl ether (mg.kg^{-1})
Zhalauly	-	-	-	-	-	-	$0.6\cdot10^{-6}$	$0.22\cdot10^{-6}$	-	-
Tastykol	$0.06\cdot10^{-6}$	-	-	-	-	-	-	-	-	-
Itemgen	-	-	-	-	-	-	-	$0.04\cdot10^{-6}$	-	-
Unnamed Lake in Akkol village	-	-	-	-	-	-	-	-	-	-
Unnamed Lake in Astrakhanka village	-	-	-	-	-	-	-	-	-	-
Zhalanash	-	-	-	-	-	$0.04\cdot10^{-6}$	-	-	-	-
Borovoe	-	-	-	-	-	-	-	-	-	-
Bolshoe Chebachie	$1.8\cdot10^{-6}$	-	-	-	-	-	-	-	-	-
Kokay	-	-	-	$1.3\cdot10^{-6}$	-	-	-	-	-	-
Yesey	$0.3\cdot10^{-6}$	-	-	-	-	-	-	-	-	-
Sultankeldy	-	-	-	-	-	-	-	-	-	-
Total amount of POPs accumulated in the bottom sediments of lakes	$2.16\cdot10^{-6}$			$1.3\cdot10^{-6}$		$0.04\cdot10^{-6}$	$0.6\cdot10^{-6}$	$0.26\cdot10^{-6}$		

unnamed lake in Akkol village (0.066 x 10^{-6} mg.kg^{-1}), Zhalanash (0.5 x 10^{-6} mg.kg^{-1}), Kokay (0.24 x 10^{-6} mg.kg^{-1}), DDT - in 4 Zhalauly lakes (2.3 x 10^{-6} mg.kg^{-1}), Tastykol (1.57 x 10^{-6} mg.kg^{-1}), Itemgen (3.05 x 10^{-6} mg.kg^{-1}), Zhalanash (2.34 x 10^{-6} mg.kg^{-1}), polychlorinated biphenyl - in 2 Zhalauly lakes (0.31 x 10^{-6} mg.kg^{-1}), Itemgen (1.87 x 10^{-6} mg.kg^{-1}).

For all studied Akmola region lakes, the POPs content was summed and their specific content identified in the bottom sediments in the region. It is possible to draw up the next POPs decreasing row: 54% (DDT) >12.71% (polychlorinated biphenyl) >12.59% (aldrin) >7.85% (hexachlorobenzene) >7.58% (chlordane) >3.49% (endrin) >1.51% (heptachlor) >0.23% (dieldrin).

The proposed POPs row in the Akmola region may be represented as a diagram (Fig.1).

Thus, the studied waters cannot be classified as toxic as the POPs content in the bottom sediments is of background character, even without exceeding the maximum allowable concentrations of these substances in the water. However, the presence of these substances in the water may indicate the threat growing as environmentally long persistent toxicants will continue to be accumulated by different migration routes, as they are in the water **(Gopal et al., 2016)**. As a result, this can be a serious obstacle to the production of organic products **(Kádeková et al., 2017)**.

Table 2b POPs content in the bottom sediments of the Akmola region lakes.

Lake name	Hexachlorobenzene (mg.kg^{-1})	Lindane, Hexachlorane (mg.kg^{-1})	Mirex (mg.kg^{-1})	Pentachlorobenzene (in quintozene (mg.kg^{-1})	Toxaphene (mg.kg^{-1})	DDT (1,1,1-trichlor-2,2-di (*n* -chlorophenyl) ethane (mg.kg^{-1})	Perfluorooctane sulfonate and its salts (mg.kg^{-1})	Endosulfan and isomers, tiodan (mg/kg)	Paraquat (mg/kg)	Polychlorinated biphenyl (mg/kg)

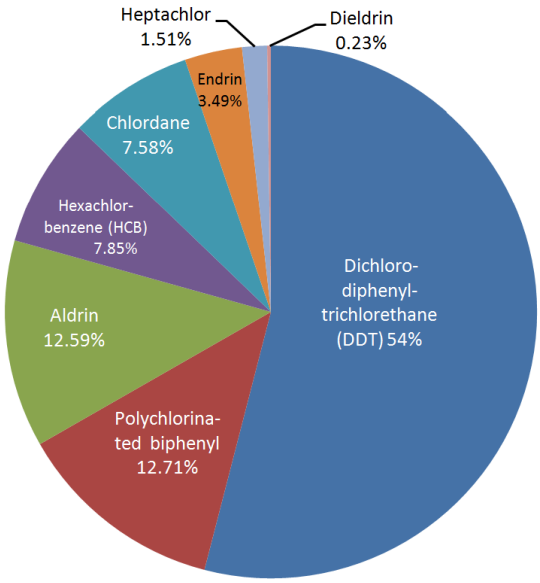

Figure 1 Generalized POPs share in bottom sediments of the Akmola region.

CONCLUSION

The obtained results of the work performed for 2016 allow for the following conclusions:

1. The MPC excess indicators in the Akmola region lakes are observed for salt ammonium (up to 0.002 MPC), magnesium (up to 1.15 MPC), nitrites (up to 1.12 MPC), petroleum products (up to 1.98 MPC), iron (up to 2.0 MPC), SSAS (up to 3.8 MPC). High concentration indicators for the sulphate (3.5 MPC), copper (4.3 MPC), magnesium (1.125 MPC). Mainly the lakes are dominated by sulfates, ion chloride. Lakes the most salty and with a hard water are Zhalauly and Zhalanash lakes - the water hardness of 7.5 $mg.dm^{-3}$ and 8.37 $mg.dm^{-3}$, respectively. For the studied water pollution index, the I class (relatively clean) can include Sultankeldy, Esey, Kokay waters; the II class (slightly dirty) - Zhalauly, Borovoye, Bolshoe Chebachie.

2. Thus, accordance with sanitary requirements, the studied waters cannot be classified as toxic as the POPs content in the bottom sediments is of background character, even without exceeding the maximum allowable concentrations of these substances in the water. However, the presence of these substances in the water may indicate the threat growing as environmentally long persistent toxicants will continue to be accumulated by different migration routes, as they are in the water.

3. But in general among 21 investigated POPs 8 substances are accumulated in bottom sediments of the investigated Zhalauly, Tastykol lakes, Unnamed Lake to the south of Akkol village, Itemgen lake, Zhalanash lake near Malinovka village (near Astana city), Kokay, Yesey, Bolshoe Chebachie.

THE COMPOSITION AND CONTENT OF PHENOLIC COMPOUNDS IN TEA, GROWN IN HUMID SUBTROPICS OF RUSSIA

Nataliia Platonova, Anton Astanin, Sergey Sedykh, Lidiia Samarina, Oksana Belous

ABSTRACT
The article presents the results of studies on the dynamics, qualitative and quantitative composition of phenolic compounds of tea raw materials and tea of new forms of selection of the Institute. The regularity in their synthesis by months is determined, which affects the quality indicators of the end product and necessitates blending to the repaired tea. The accumulation of tannins in tea raw materials depends on hydrothermal conditions, in particular, the amount of precipitation. The content of tannin increases from May to June, then there is some decline in their content, due to hydrothermal stress, slowing the synthesis of tannins in the tea leaf. The content of the water-soluble fraction gradually increases from May to July, and then there is a slight decline. It is shown that the accumulation of phenolic compounds in tea raw materials varies during the collection season. The contents of theaflavins increased from the beginning of the collecting sheet to its completion. The content of thearubigins showed peaks: the lowest rate in June, the highest in August. It was revealed that a sharp drop in the synthesis of thearubigins in June is associated with the onset of the summer dormancy of growth and synthetic processes. The synthesis of both indicators depends on meteorological conditions. The comparative analysis of the samples of tea raw materials collected from experimental plants is carried out. It is shown that the content of tannin and extractive substances in the raw materials of the studied varieties and mutant forms is high. In terms of the ratio of theaflavins and thearubigins, tea made from experienced raw materials meets international requirements. Determination of the qualitative composition of the catechin group of green tea, produced from raw materials of new forms, showed a high level of accumulation of the main groups of catechins.

Keywords: *Camellia sinensis*; cultivar; black tea; green tea; hydrothermal condition; tannin; extractive compounds; flavonoid; catechin

INTRODUCTION
Tea plant (*Camellia sinensis* (L.) O. Kuntze) is the most ancient crop. As a cultivated plant, tea has been cultivated in China since ancient times, since the XVIII century – in India and Sri Lanka, since the XVII century – in Russia, and since the XIX century – on vast areas in various parts of the globe. But now the only European tea producer is Russia, and the only place in Russia where tea is grown on an industrial scale is the humid subtropics of the Krasnodar region **(Ryndin et al., 2017; Belous and Platonova, 2018)**.

The mass distribution of tea is due not only to the fact that it is a pleasant, thirst-quenching drink, but to a large extent, and its effect on the human body. Active substances of tea are polyphenols, flavonoids, aromatic substances, vitamins, plant pigments, amino acids, mineral salts, etc. **(Willson, 1975; Gramza et al., 2005; Khan and Mukhtar, 2007; Belous, 2013)**. The tea contains more than 600 chemicals involved not only in the creation of specific properties of tea-aroma, taste and color of the infusion, but also the healing properties of the product **(Vorontsov, 1946; Mgaloblishvili and Tsutsunava, 1979; Salah et al., 1995; Khvedelidze and Gvinianidze, 2004)**. In the last decade, the interest in tea has increased, due to the content of polyphenolic compounds with antioxidant effect **(Salah et al., 1995; Wright, 2005; Platonova, Belous and Ostadalova, 2017; Platonova and Belous, 2018)**.

Industrial plantations of Krasnodar region are a mixture of different morphological groups, as laid seed populations of Georgian and Chinese origin. In this regard, plants differ in yield, growth ability, and most importantly, biochemical parameters that determine the quality of the finished product. Improving the varietal composition of tea plantations is one of the urgent tasks of tea growing. On the basis of the all-Russian research Institute of floriculture and subtropical crops for a long period of work on the culture of tea created varieties characterized by high yield and product quality (cv. Sochi, Karatum, Matsestinsky, Vano, etc.) **(Prokopenko and Tuov, 1994)**. But work in this direction continues. The presence at the Institute of

highly productive varieties, as well as promising clones and hybrids, are a reliable basis for the creation of modern tea plantations. This article is devoted to the study of the features of the composition and changes of the catechin complex of new forms of tea, selected by scientists of the Institute. We have determined the composition of the catechin complex in green tea, made from raw materials grown on the plantation of the Institute.

Scientific hypothesis

All over the world works on studying of a green tea leaf and transformations which proceed in it at technological processing are conducted, biochemical researches of raw materials and a finished product are carried out. The study of the content, accumulation and transformation of substances during growth, development of green leaf, it's processing, is necessary to improve the quality of raw materials and finished tea. The main purposes in tea biochemistry are the transformation and accumulation of phenolic compounds, as they provide the most valuable properties of tea. The compositions of phenolic compounds of tea are change and depending from season and the technology of tea processing.

MATERIAL AND METHODOLOGY

Objects of study were samples of green tea made from 2 – 3 leaf sprouts following promising forms: form No. 3823, No. 582, No. 855, No. 2264, grown for an experienced collector-uterine site, founded in 1984 – 1985 in the village of Uch-Dere (Sochi, Lazarevsky region). Control – cultivar Colchida.

Colchida is a clone of large-leaved Chinese tea, high-crop productivity, in 1995 entered in the State register of selection achievements. Form No. 3823 – source population Kimini, high gustatory qualities and yield. Form No 582 – the initial population of Colchida, the variety productivity is high, has a specific flavor infusion. Form No. 855 – the original Georgian population of the No. 8, the average crop productivity, specific aroma with a light rose fragrance. Form No. 2264 – the original Georgian population of the No. 15, crop productivity and quality indicators are above average **(Gvasaliya, 2018; Prokopenko and Tuov, 1994)**.

Green tea was produced in the laboratory of biotechnology, physiology and biochemistry of plants (BPhBP) of the Russian research Institute of floriculture and subtropical crops.

The study was performed on the chromatograph MiLiChrom A-02 (Institute of Chromatography "EcoNova", Novosibirsk, Russia), 2 × 75 mm column with a sorbent ProntoSIL 120-5-C18 AQ (Bischoff Analysentechnik und Geräte, Germany). Chromatograms were processed using a computer program AlphaChrom (Institute of Chromatography "EcoNova", Novosibirsk, Russia). Aqueous 0.2 M LiClO4 in 0.005 M HClO4 was used as eluent A, and acetonitrile (NPK Cryochrome, St. Petersburg, Russia) was used as eluent B. The following catechins were used as standards: catechin, epicatechin, gallocatechin, gallocatechin gallate, epigallocatechin, epicatechin gallate, epigallocatechin gallate, gallic acid, caffeine. All reagents were chemically pure or analytical grade and contained more than 98% of the main substance. Extraction method was based on well-known method **(ISO 14502-2:2005)** with some modifications. The dried tea leaf was homogenized in a mortar, sieved through a 0.5 mm sieve; a portion of 20 mg was placed in a 1.5 mL tube and extracted with 1 mL of ethanol 70% for 30 minutes at 70 °C. After extraction, the sample was filtered through a 0.45 μm filter and used for HPLC analysis.

The conditions of chromatographic analysis are: column temperature 40 °C, flow 200 $\mu L.min^{-1}$, detection 210, 220, 230, 240, 250, 260, 280, 300 nm. Elution was made in gradient mode from 0% to 40% B for 2800 μL. All measurements were performed in triplicate.

Flavonoids were determined on a PE – 5400 wi spectrophotometer at a wavelength of 665 nm (theaflavins) and 825.5 nm (thearubigins) **(AOAC International, 2009)**.

The tannin content was determined by the method of Levental with a conversion factor of 5.82 according to **Dzhemuhadze (1946)**, extractive substances – by the gravimetric method according to **Vorontsov (1946)**.

Statisic analysis

Statistical processing of the experimental data was carried out using the ANOVA package in STATGRAPHICS Centurion XV (version 15.1.02, StatPoint Technologies) and MS Excel 2007. Statistical analysis included univariate analysis of variance (method of comparing averages using variance analysis, *t*-test) and variance analysis (ANOVA). The significance of difference between the means of the least significant difference (LSD) results with $p < 0.05$ was considered statistically significant. All experiments were performed in triplicate and the values were expressed as mean ±SD. The differences between the samples were assessed using unpaired *t*-test. Correlation analysis with calculation of pair correlation coefficient, for establish the dependence of parameters on abiotic factors was used.

RESULTS AND DISCUSSION

One of the main places among the substances that make up the tea leaves is a complex of tannins. All the basic properties of the finished product – its color, taste and aroma – are to varying degrees related to their transformations in the tea leaf. Tannins are the most mobile and active compounds, so they are primarily subject to certain changes under different growing conditions or processing of tea.

Studying the content of tannins in tea raw materials in the dynamics, we identified the main patterns in their synthesis by months, which significantly affects the quality indicators of the finished product and necessitates the blending of finished tea (technological method of mixing the semi-finished product to obtain a quality brand). We noted that the total content of tannins in the three-leaf flush varies during the tea leaf collection season (Figure 1).

As can be seen from Figure 1, the quantitative content of tannin in Russia's humid subtropics (unlike other tea-producing countries) increases from May to June, then there is some decline in their content, which is connected, in our opinion, with temperature and arid stress slowing down the synthesis of tannins in the tea leaf.

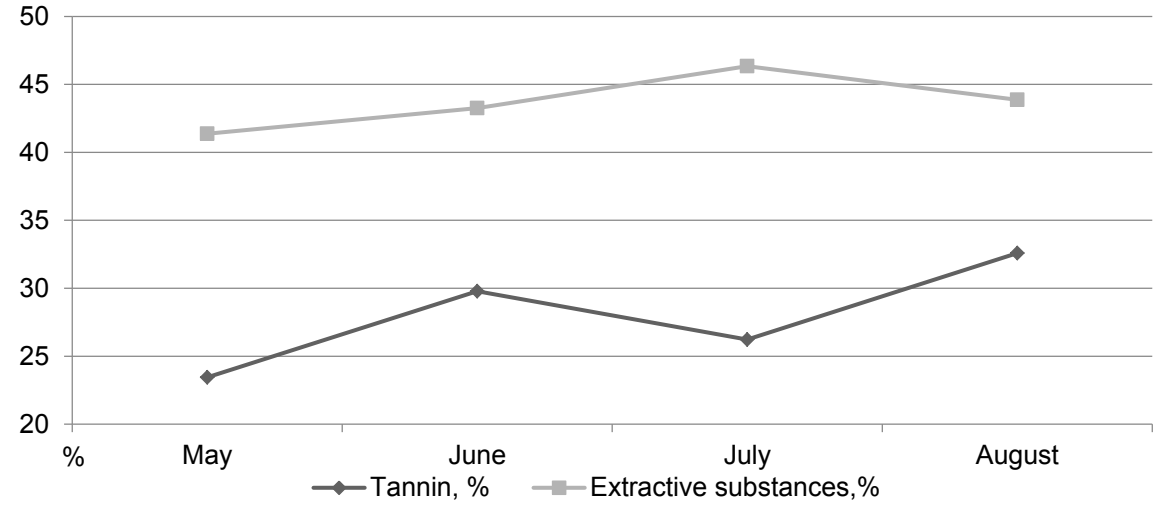

Figure 1 Seasonal changes in the content of tannins and extractive substances in tea raw materials, average over 11 years.

Table 1 Pair correlation coefficients between quality indicators of tea raw materials and hydrothermal factors, average over 11 years.

Parameter	Precipitation, mm	T, °C
Tannin, %	-0.88	-0.45
Extractive substances, %	-0.74	-0.35
Caffeine, %	-0.86	-0.54

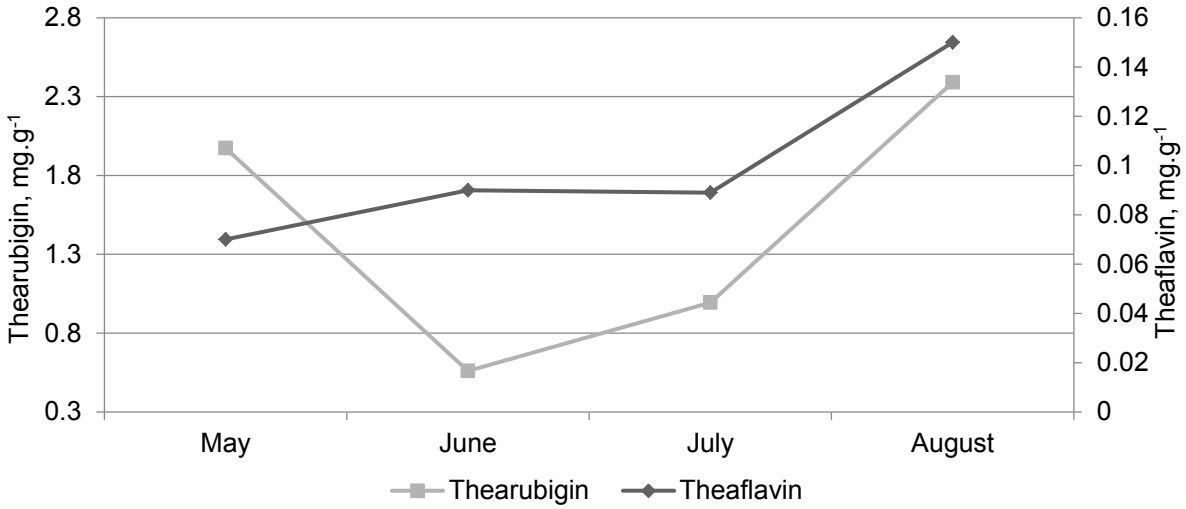

Figure 2 The content of flavonoids in the samples of finished tea made from plants of the variety Colhida, average over 2 years.

Table 2 Pair correlation coefficients between hydrothermal factors and flavonoid content ($p \leq 0.05$).

Parameters	**Theaflavins, mg.g^{-1}**	**Thearubigins, mg.g^{-1}**
Thearubigins, mg.g^{-1}	0.928	-
Temperature, ºC	0.860	0.184
Precipitation, mm	-0.776	-0.562

As the hydrothermal conditions reach their optimum, the tannin content is rapidly increasing, reaching an average of 30.29 – 32.58% in August.

Other dynamics were noted in the accumulation of extractive substances in the tea leaf (Figure 1). From May to July there is a gradual increase in the content of the water-soluble fraction, followed by a slight gradual decline.

Statistical processing showed that the accumulation of tannins in tea raw materials directly depends on hydrothermal conditions, and to a greater extent, not on temperature conditions of vegetation, but on the amount of precipitation (Table 1). Moreover, the relationship between quality indicators and climatic factors is opposite, as the strength of the factor increases, the content of tannins decreases significantly ($p \leq 0.05$).

Also, we were able to trace the dynamics of the formation of thearubigins and theaflavins in finished tea by months and their dependence on hydrothermal factors. It was established that the content of theaflavins increased from the beginning of the collection of the leaf (in May 0.07 $mg.g^{-1}$) to its completion (in August 0.15 $mg.g^{-1}$). Peaks were observed in the content of thearubigins: the lowest value in June was 0.56 $mg.g^{-1}$, the highest – in August, 2.39 $mg.g^{-1}$ (Figure 2).

The sharp decline in the synthesis of thearubigins in June may be due to the onset of a period of summer dormancy of growth and synthetic processes, especially since during the same period the accumulation of theaflavins reached a plateau - from June to July there were no changes in their content (Figure 2).

To establish the influence of hydrothermal factors on the accumulation of flavonoids, the relationship between these indicators was calculated (Table 2).

As can be seen from the given data presented in Table 2, the synthesis of both indicators is quite closely related, which is a well-known fact: it is precisely during oxidation that theaflavins quickly turn into thearubigins. At the same time, the accumulation of these flavonoids by the tea plant directly depends on meteorological conditions: as the air temperature rises and the amount of precipitation decreases, the content of both flavonoid groups increases. This may be due to a high concentration of cell sap and, as a consequence, activation of the antioxidant system of plants. Dispersion analysis indicates that it is theaflavins that closely correlate with hydrothermal factors, while thearubigins, being secondary metabolites relative to theaflavins, react poorly to the temperature factor. Rainfall are affecting the functional state of the plant itself **(Belous, 2008)**, it was provided an optimal water balance of cells and the synthesis of flavonoids. Flavonoids in the manufacture of tea, during oxidative processes, can indirectly affect the synthesis of thearubigins.

In addition to identifying dependencies and establishing the dynamics in the accumulation of tannins, we conducted a comparative analysis of samples of tea raw materials collected from experimental plants (Table 3). As can be seen from Table 3, the content of tannin and extractive substances in the raw materials of the studied varieties and mutant forms are high.

Tea produced from plants of mutant forms No. 582 and No. 2264 in terms of the content of theaflavins showed the highest values, while the highest content of thearubigins was observed in tea obtained from raw materials of the Colkhida variety and form No. 2264 (Table 3). Since theaflavins are unstable compounds and easily oxidize to thearubigins during oxidation, at present there is no single standard for their content in the finished product. But, according to international rules, any blend of tea should have a ratio of theaflavins and thearubigins not lower than 1:16, and in super tea 1:10. According to this indicator, all the tea produced in the laboratory of the institute`s laboratory from raw materials harvested from experimental plants complies with international requirements.

Determination of the qualitative composition of the catechin group in green tea, using the example of the most promising form No. 582 (Figure 3), showed that the largest amount of epigallocatechin gallate, which is characterized by the highest antioxidant activity of the main catechins (epicatechin, epigallocatechin, epicatechin gallate, epigallocatechin gallate), the prevalence of this group in selected forms of teas reflects their high value.

A comparison of tea in terms of the quantitative content of the catechol complex showed that tea of new forms of selection of the institute is characterized by a high level of accumulation of various groups of catechins (Table 4).

The variety Colchida, being a large leaf tea, is characterized by a higher content of EGKG, which is also confirmed by literature data. **(Haslam, 1989; Gzhidzhiechvili et al., 1984)**. At the same time, all selected forms contain a lower caffeine value. Despite the fact that the chemical connection between caffeine tea and tannins neutralizes its effect on the human body (compared to pure caffeine coffee), the lower content of theine in new forms of tea makes them more attractive against the background of a rich caffeine variety Colchida.

Table 3 Phenolic compounds of black tea and tea leaves (raw materials), average over 5 years.

Varieties, variety forms	Tannin, %	Extractive substances, %	Theaflavins $mg.g^{-1}$ *	Thearubigins, $mg.g^{-1}$ *

The closest to the control variety is green tea, produced from raw materials of mold No. 582. The low content of catechin group substances is characteristic of forms No. 3823, 855 and 2264.

CONCLUSION

Thus, we have studied the dynamics, composition and content of phenolic compounds in tea raw materials and tea of new forms of plant selection. It is shown that the total content of tannins in the three-leaf flush varies during the harvest season and the accumulation of phenolic compounds in tea raw materials directly depends on the hydrothermal conditions, in particular, on the amount of precipitation during the growing season. The dynamics of the formation of thearubigins and theaflavins in finished tea by months is traced; it has been established that the accumulation of flavonoids directly depends on meteorological conditions: as the air temperature rises and the amount of precipitation decreases, their content increases. A comparative analysis of black tea samples was carried out, which showed that, based on the ratio of theaflavins and thearubigins, tea collected from experimental plants complies with international

requirements. Determination of the qualitative composition of the catechin group in green tea showed that the greatest amount falls on epigallocatechin gallate and tea of new forms of selection of the institute characterized by a high level of accumulation of identified groups of catechins.

NEUROMARKETING AND THE DECISION-MAKING PROCESS OF THE GENERATION Y WINE CONSUMERS IN THE SLOVAK REPUBLIC

Jana Němcová, Jakub Berčík

ABSTRACT

In recent years, interest in scholarly research on buying behaviour of Generation Y has grown. However, studies are mainly realized abroad and many of them deal with this issue in general. The purpose of this paper is to identify the factors influencing the decision-making process of the Generation Y customers in the selection of wine in the Slovak Republic. A total of 21 respondents participated in the survey. Eye-tracking and a questionnaire were selected for research. For processing and evaluating the eye-tracking research, the Gazepoint Analysis UX Edition software and Microsoft Excel were used. For statistical data analysis, the Kruskal-Wallis test and Spearman's non-parametric test were performed. Based on the results of the questionnaire and the testing, a label was the most important factor. Differences were noted at the moment of examining the information on a label. The most important factor determined by the questionnaire survey was variety, or vintage year, but by using measurement, the most important factor was label design. With regard to bottle shape, the most preferred was the Bordeaux type of bottle. Testing was carried out in laboratory conditions that only simulated the real selection of wine. This could have caused the difference between conscious decision-making and unconscious visual attention. Therefore, in the future, it is recommended to carry out similar research using a mobile eye camera to realize the test with real wine bottles. It is also assumed to involve other methods to obtain information about real attention of the tested probands. The presented research provides information for winegrowers and merchants who can improve their products and communicate effectively with customers. Findings are particularly beneficial because this research is among the first carried out in this area and it was not based only on conscious participation of respondents, but also on unconscious perception, because a deeper understanding of unconscious influences, that shape consumer's decision, helps to better understand consumer's behaviour.

Keywords: consumer behaviour; decision-making process; Generation Y; wine factor; Slovak Republic

INTRODUCTION

Many marketing specialists have been dealing with consumer behaviour for a long time to get the best possible placement of their products on the market. **Schiffman and Wisenblit (2015)** describe consumer behaviour as a set of consumer activities while searching for, purchasing, using, evaluating, and disposing of products or services that are expected to meet their needs. Businesses need to know the answers to questions such as how and why consumers buy and consume in order to develop their products and effectively communicate with customers **(Szmigin and Piacentini, 2015)**. The key point of marketing is the focus on the customer and his decision-making. Understanding the processes relating to these decisions is crucial to establishing a policy **(Sethna and Blythe, 2016)**. The consumer decision-making process consists of many theoretical constructs and is often complicated, as stated by **Roe and Bruwer (2017)**. According to **Tomek and Vávrová (2011)**, no company on the market knows in advance when and whether buyers will demand its products at all. In order to be successful sellers on the market, they must ensure that their activities meet the wishes and needs of target customers. Based on this, they must understand the mechanisms and determinants that influence the purchasing decisions of customers. Understanding the forecast of consumers' and purchasing behaviour is one of the main goals of marketing specialists.

Today's market has changed significantly. Sale is more difficult, in part due to more sophisticated buyers who have more information, more intense competition, a longer sales cycle, and increased resistance to traditional techniques. However, a modern approach using neuromarketing helps to create effective marketing strategies, thereby increasing motivation to purchase, the number of concluded contracts and the multiplication of

revenue **(Berčík et al., 2016)**. Neuromarketing is a newly emerging discipline discovered in 2002 that connects consumer behaviour with neuroscience. It provides modern methods for direct mind detection without the need for demanding cognitive or conscious participation **(Morin, 2011)**. Currently, neuromarketing is used for the commercial exploitation of neuroscience knowledge and tools which help companies to better understand consumer reactions to the various communication efforts connected with brands, products or services **(Ramsøy, 2015)**.

There is a large amount of wine products for retail and it is very difficult for the consumer to decide what to buy. However, there is no united approach or theory of wine consumer decision-making that describes consumer characteristics, product involvement, etc. **Lockshin and Corsi (2012)** add that a large number of published articles show growing popularity of wine and interest in consumer behaviour research, and provide a detailed analysis of articles divided by theme in their publication. According to **Babin and Harris (2016)**, consumers make decisions for the purpose of getting something of value and quality to improve their lives. Companies then try to offer consumers products and services, including experience, that will bring them such value.

Anchor and Lacinová (2015) mention that, for the consumer behaviour research on the wine market, it is important to know the motives for wine drinking. Identifying the importance of wine in the consumers' lifestyle and recognizing the situations in which the consume of wines by customers facilitate the understanding of the issue of consumer purchasing decisions. According to **Marinelli et al. (2014)**, understanding the approach of purchasing wine is an important factor for the winemaking industry. Understanding these attitudes, particularly among the younger generation, can be useful for solving the long-standing traditions of the wine region. At present, many marketers deal precisely with the needs of young people aged between 18 and 34, called Generation Y or Millennials **(Schiffman and Wisenblit, 2015)**. In recent years, this generation has also been intensively studied in relation to the wine market **(Mueller et al., 2011)**. In general, Generation Y is defined as the age cohort born in the 1980s and 1990s. Some authors define this segment as people who were born slightly later in time, for example **Sethna and Blythe (2016)** describe this generation as a generation of people born between 1981 – 2001 (aged between 17 – 37 in 2018). This generation cohort has an increasing interest in wine, it is willing to pay for wine and its consumption is different from previous generations **(Hall et al., 2004; Thach and Olsen, 2006)**. It is a very promising wine consuming segment, which will become more and more important in the future as wine consumers **(de Magistris et al., 2011; Charters et al., 2011)**. **Chrysochou et al. (2012)** are inclined to think that young Generation Y is quickly adopting wine as its preferred drink and is therefore a consumer segment with the potential to increase the growth of wine consumption in the near future. Taking into account the differences among age groups will bring new opportunities for winegrowers and wine merchants. Also **Fountain and Lamb (2011)** highlight the need to promote an interest in wine among the younger generation. This results from the fact that the Baby Boomer generation, for a long time perceived as the leading wine consumers, is ageing and, therefore, it is now necessary to pay more attention to young consumers in the wine industry. Generation Y is currently considered one of the largest demographic groups. However, there are also differences within generations, especially among these young people who behave very differently and therefore cannot even generalize this cohort **(Bergh and Behrer, 2016)**. Therefore, only a narrower part of this generation has been selected for consumer behaviour research on the wine market in Slovakia, namely young people aged between 18 – 25.

There are many foreign studies in which authors deal with the purchasing behaviour of Generation Y in relation to wine. As far as the importance of attributes is concerned, this issue was most often explored by **de Magistris et al. (2011); Elliot and Barth (2012); Dlačić and Kadić-Maglajlić (2013); Stanciu and Neagu (2014); Hristov and Kuhar (2015)** and **Lategan et al. (2017)**. In the Czech Republic, the area of consumer behaviour and Generation Y is solved by **Veselá and Zich (2015)** who describe the effect connected to the country of origin and its influence on the consumer behaviour of the Czech and Slovak young consumers, and **Velčovská (2018)** who examines perception of product origin and its labelling in the context of food quality and safety among Czech, Slovak and Polish Generation Y. However, there is a lack of research applied to Generation Y and wine market. Scientific literature on wine Generation Y is very rare also in Slovakia. This study should therefore contribute to the expansion of literature on this issue.

Wine is one of the most consumed beverages and has been known in human civilization for many millennia. Besides its economic importance, it can also positively influence human health. In some European countries, a glass of wine is intrinsically linked to good food **(Tariba, 2011; Brunner and Siegrist, 2011)**. There are many studies that confirm the usefulness of wine when consumed in low quantities. The moderate consumption of this traditional drink may have positive effects, for example, in cardiovascular diseases, diabetes, osteoporosis or neurological diseases **(Artero et al., 2015; Šamánek and Urbanová, 2013)**.

The wine market has made significant progress over the last two decades. Both the legislation and the level of technical equipment for wine production have improved. According to The International Organisation of Vine and Wine **(OIV, 2017)**, world wine consumption has a relatively stable character over the long term. Although there was a slight decline in wine consumption in France last year, other traditionally wine consuming countries such as Spain and Portugal notified a stable consumption. On the contrary, there was a significant increase in wine consumption in Italy. The USA also showed a growing domestic consumption and once again confirmed its excellent position on the global wine market.

The Slovak Republic is not part of the world's significant producers or consumers of wine. However, the wine-growing tradition of this country has deep roots and vine growing on the territory of today's Slovakia is connected with an interesting history. **Regulation No 313/2009** divides the Slovak wine-growing region into 6 areas, namely Malokarpatská, Južnoslovenská, Stredoslovenská,

Nitrianska, Východoslovenská and the Tokaj wine-growing area. The total area of vineyards currently stands at 10,800 ha, of which the cultivated area of vineyards represents 8,872 ha. In 2015, the total wine consumption was 80,210 hL, which was 14.8 hl per capita. In 2016, there was a slight decrease and the consumption of wine per capita fell to 13.9 hL. The production of wine reached 310,000 hL for the period 2016/17, but in the following year the production of wine is expected to increase to 340,000 hL. The countries with the largest import of grapes and wine to Slovakia include Hungary, Italy and Germany. On the other hand, Slovakia most often exports grapes and wines to the Czech Republic and Hungary **(Meravá, 2017)**.

Scientific hypothesis

As mentioned above, many authors are concerned with consumer behaviour on the wine market. However, these surveys are aimed at all age groups, and thus there are few publications describing behaviour of the young generation. Therefore, this article is concentrated on the still often marginalized Generation Y and its decision-making process in the selection of wine in the Slovak Republic. The main objective of the article is to reveal the factors that have a crucial influence on decision-making of the Generation Y customer when choosing wine in Slovakia. The purpose of research is to identify the wine attributes by which young customers choose wines, and thus to understand their purchasing decision-making process. In relation to the hypothesis, the *p*-value $p = 0.05$ was used, where we tested whether there is difference in tracking wines based on location in the image stimulus (whether it is located on the right, left or centre). Using the *p*-value $p = 0.05$, we verified the dependence between first tracking and time spent.

MATERIAL AND METHODOLOGY

For this research, a neuromarketing method called eye-tracking was chosen, which explores unconscious visual attention of the respondents. Specifically, the Gazepoint GP3 eye-tracker (Gazepoint Canada) with data collection frequency of 60 Hz was selected – the respondent was sitting in front of the computer screen and was watching the images presented. Eye-tracking testing was then completed by a questionnaire that was conducted electronically using a cloud storage service called Google Drive. For the purposes of this research, which ran from April to May 2017, the Laboratory of Consumer Studies at the Faculty of Economics and Management of Slovak University of Agriculture in Nitra was used.

Testing was attended by a total of 21 respondents who subsequently completed a questionnaire containing questions that resulted from eye-tracking testing. The aim of the questionnaire was to find information about wine preferences given consciously by the respondents. Subsequently, it was examined whether there are differences between conscious (questionnaire) and unconscious (eye-tracking) perceptions of marketing stimuli.

This research was based on the theoretical background and consultation offered by the specialist staff of the wine shop in Zlín in the Czech Republic. Before the research itself, different combinations of wine bottles had to be created, which were then professionally photographed and adjusted. Each photo contained 3 wine bottles. Variants were drawn up in combinations by brand, variety and discount, then by brand, variety and quality class, by bottle shape and by bottle that was awarded medal. Measurement included 5 photos with white wine. Prepared photos were then uploaded into the software program and were projected to the respondents in the eye-tracking testing. The factors influencing customers' decision-making in the wine selection included: colour of wine, label design, the information on a label (brand/producer, variety, vintage year, quality class of wine, wine-growing region, residual sugar content, actual alcoholic strength and nominal volume), bottle shape, bottle colour, medals, price and discounts.

Three research questions were defined:

RQ1: What are the key factors that influence conscious decision-making of Generation Y on the wine market?

RQ2: What are the key factors that influence unconscious decision-making of Generation Y on the wine market?

RQ3: Is there a difference between conscious and unconscious perceptions of marketing aspects when choosing wine among Generation Y?

The Sample of the Respondents

Eye-tracking was attended by 21 respondents who filled out a questionnaire immediately after the testing. The purpose of the questioning was to find the conscious answers to the questions. These were the respondents aged 18 – 25 who had drunk or at least bought wine for the last 12 months. According to **Noble et al. (2009)**, precisely this age category is an important segment in the lucrative college market. Eye-tracking was conducted using a stationary eye camera, and following filing of a questionnaire was carried out electronically using a cloud storage service called Google Drive.

As shown in Table 1 below, 11 women (52%) and

Table 1 Sample characteristics.

Sample characteristics		Number	%
Gender	Female	11	52
	Male	10	48
Age	19 years	1	5
	20 years	5	24
	21 years	11	52
	23 years	1	5
	25 years	3	14
Social status	Student	21	81
	Employee – part time job	5	19
	Employee – full time job	0	0
	Self-employed	0	0
	Unemployee	0	0
Region	Bratislavský	0	0
	Trnavský	2	10
	Nitriansky	14	67
	Trenčiansky	2	9
	Žilinský	2	9
	Banskobystrický	1	5
	Prešovský	0	0
	Košický	0	0

10 men (48%) were among the total sample of the respondents. Regarding the age of the participants, 5% were 19 years old, 24% were 20 years old, 52% were at the age of 21. 5% at the age of 23, and 14% were 25 years old. Most of the participants were students (81%) and then 19% (5 respondents) employed in part-time. The majority of the respondents (67%) came from the Nitriansky region, then Trnavský (10%), Trenčiansky (9%) and the Žilinský region (9%) and only 1 respondent (5%) lived in the Banskobystrický region.

Statistic analysis

For processing and evaluating eye-tracking research, the Gazepoint Analysis UX Edition software – version 3.1.0 (Gazepoint Canada) and Microsoft Excel were used. Timing for switching individual slides was set to 15 seconds. For the statistical data analysis, inductive statistics was selected, namely the Kruskal-Wallis test and Spearman's non-parametric test. The statistical processing was carried out in R version 3.5.1 (R Core Team (2017)). R: A language and environment for statistical computing. R Foundation for Statistical Computing, Vienna, Austria **(R Foundation, 2017)**.

RESULTS AND DISCUSSION

As the testing was conducted in laboratory conditions through graphic visuals on which 3 wines were displayed at the same time, the detection of the actual perception of individual attributes was preceded by a test, which verified whether it depends where the product (wine) is located in the picture (right, centre, left) in order to find out the influence of the respondents. Based on the data derived from an eye camera (Time to first view in (ms)), the Kruskal-Wallis test, which is a non-parametric one-way anova, it was discovered that there is no difference ($p = 0.44$) in tracking wines based on location in the image stimulus (whether it is located on the right, left or centre).

The correlation between all dates of individual wines viewing time, measured using the Spearman's non-parametric coefficient, represents a value (-0.77), which is a strong negative dependence, which means that the more people watch the wines on the left, the more time raises the other two wines (centre and right), respectively, when they look at the first wine on the left, other wines have a longer viewed time (Viewed Time in (s)).

In the questionnaire, a Likert's five-point scale, ranging from 'completely agree' (1) to 'completely disagree' (5) with influence of factor, was used for the identification of the key factors influencing conscious decision-making of Generation Y on the wine market. Based on the answers of the Generation Y respondents recorded in the questionnaire and the relative calculated score, label and data associated with it (e.g. brand, variety, quality class etc.) appear to be the most important factor influencing the wine selection. According to the answers and the score achieved, bottle shape (16) and bottle colour (-8) are the least important factors, as can be seen in Figure 1.

The finding that the label is the most important factor when choosing white wine is also confirmed by the measuring through an eye camera. Based on the eye-tracking curves (fixation points), it is possible to see in Figure 2 that the primary views led precisely to the label. This fact is also confirmed by the areas of interest in Table 2, where the lowest value (1.69 ms) is based on elapsed time to the first fixation (view) and the calculated median.

Similarly, in the case of the length of time spent (Table 3), it can be stated that the longest visual attention based on the measured median values happened in the case of a label (3.19 s). Contrary to the answers of the questionnaire, the fact is that the probands were more interested in bottle shape/colour compared to 'price', or 'discount'. The median of elapsed time when they were tracking bottle shape/colour is 1.94 ms, while for prices it is up to 5.36 ms. In terms of time spent, bottle shape/colour even represented the longest viewed attribute (3.63 s), as can be seen in Table 3.

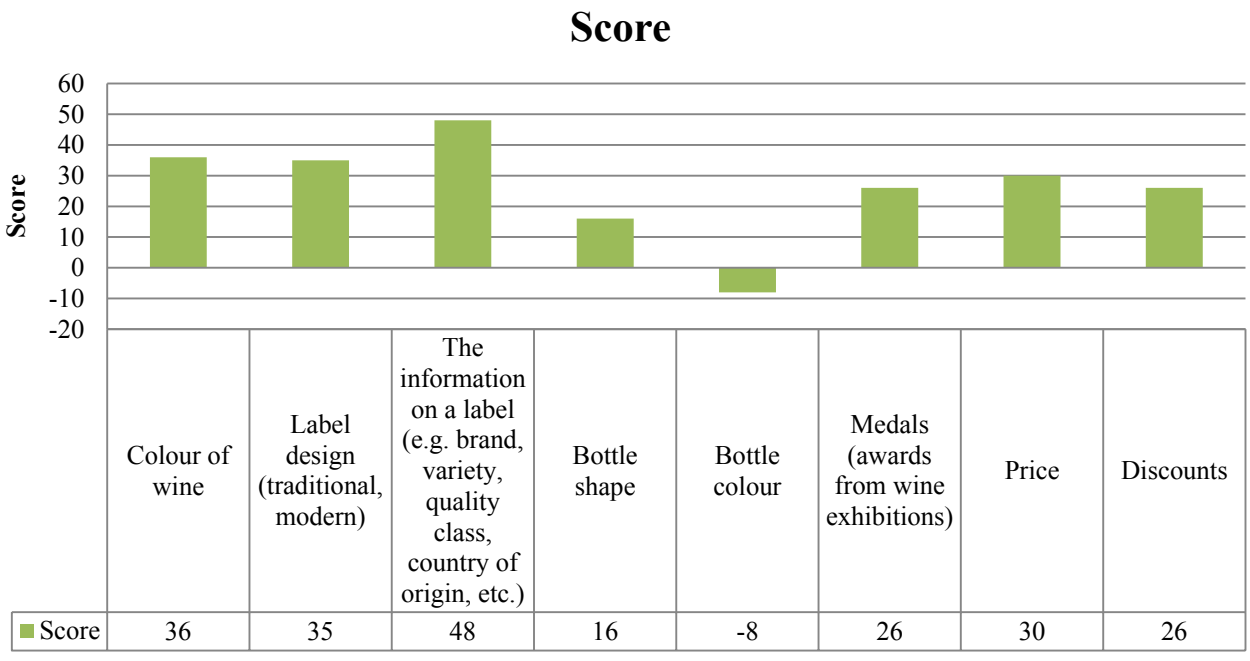

Figure 1 Factors Influencing the Bottled Wine Selection of Generation Y.

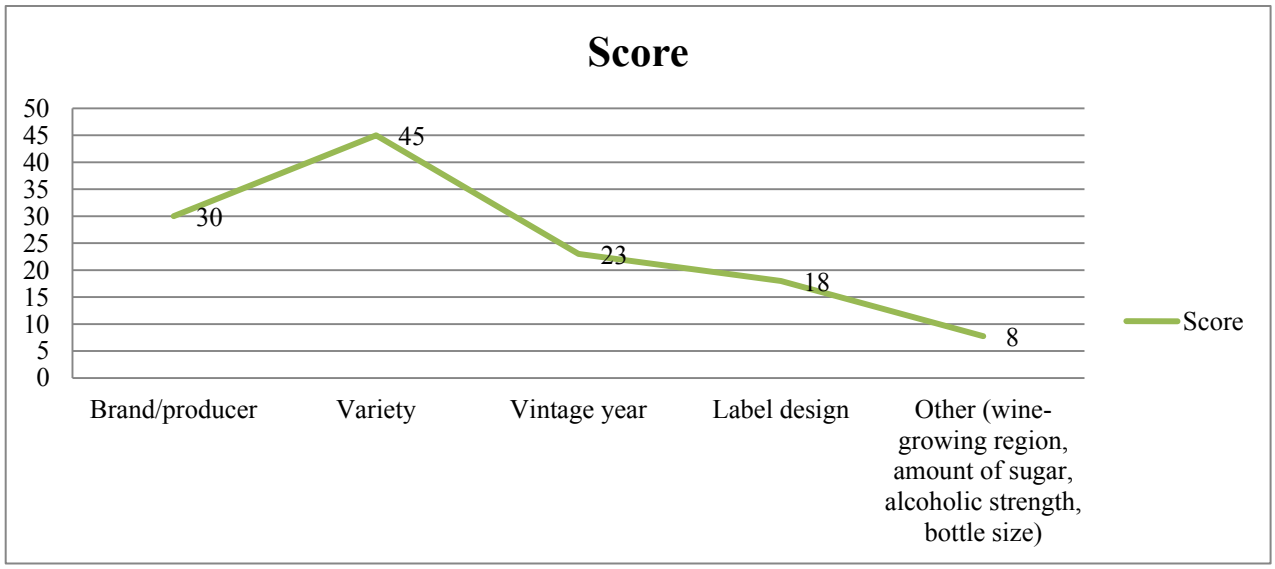

Figure 3 Importance of the Information on a Label Based on the Questionnaire Survey.

Based on conscious feedback (Figure 3) and the calculated score (45), indication of variety (e.g. Grüner Veltliner) is the most important information on a wine label. On the other hand, according to the respondents' answers, data such as a wine-growing region, the amount of sugar, alcohol, and bottle size (the 'other' option) are the least important.

However, in terms of visual attention and overall time spent, they were interested in the whole label design, in which they spent up to 3.585 s based on the measured median values. In this context, up to 76% of the respondents say that they prefer the traditional look of the label (motives of grapes, the grapevine or other wine theme) compared to the modern ones (geometric patterns, spirals, and non-traditional colours). Variety and vintage year interested the respondents only 1.140 s based on the median, which is 0.435 s less than brand. Based on the time spent, it can be said that consumer was most interested in total label design, brand and then variety or vintage year (Table 4). This fact and the difference over conscious feedback (variety was the most important) could also be caused by the fact that it was not a real choice and consumers saw the stimuli only in visual form.

Regarding bottle shape, the Generation Y respondents reported the most Bordeaux type of a bottle (62%) in the questionnaire (see Figure 4), which is often used primarily for red wine. A minor part of the respondents (5%) preferred Burgunder type (a bottle which is smaller and a little dumpy with dent), which is used all over the world for white and red wine. Based on the measurement of

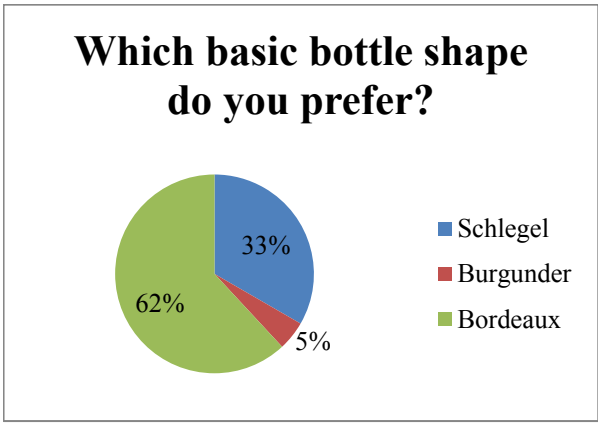

Figure 4 Wine Bottle Preference Based on the Questionnaire Survey.

Table 4 Comparison of Perception of the Information on a Label through Areas of Interest (AOI) – Viewed Time (s).

Product/ attribute	Šlechtitelská stanice vinařská Velké Pavlovice	Vinařství Gréger	Vinařství Ampelos (green bottle, classic)	Vinařství Ampelos (white bottle, classic)	Vinařství Ampelos (gray-green bottle, modern)	Vinařství Popela	Vinex	Median
Variety and vintage year	1.21	0.99	0.53	1.07	1.22	1.91	1.49	**1.140**
Brand	1.68	1.33	1.25	1.47	2.21	1.94	2.66	**1.575**
Price	0.63	0.23	0.29	0.39	0.38	0.40	0.25	**0.385**
Label design	3.33	3.59	1.97	4.32	3.60	4.25	5.60	**3.595**
Bottle cap	0.27	0.57	0.28	0.49	0.35	0.40	0.26	**0.375**

visual attention through an eye camera, it is possible to say that wines from brands such as Vinařství Ampelos (Time to first fixation 0.53 ms), Šlechtitelská stanice vinařská Velké Pavlovice (Time to first fixation 0.63 ms), Vinařství Gréger (Time to first fixation 0.99 ms), which are filled in Bordeaux type of bottles, attracted the majority of attendants' attention.

CONCLUSION

The submitted paper is focused on the examination of the factors influencing the selection of white wines, by means of a questionnaire survey and biometric method – eye-tracking. The most important factor influencing decision-making of Generation Y can be considered a wine label based on the results of the performed test. In the real selection, it is possible to assume that the most important factor would be price, or discount, that was greatly ignored in this case, because it was not a real scenario. In the case of a detailed examination of the information on a label, differences between the respondents' answers and real visual attention were noted. While the participants considered variety, or vintage year as the most important factors, on the other hand, on the basis of the answers of the questionnaire, they were most concentrated on label design and subsequently on the brand of the wine on the basis of visual attention. In the case of bottle preferences in which wine is stored, the respondents' answers also coincided with their real attention in terms of primary attracting. Despite some weaknesses, this test shows that the use of an eye camera when examining the factors influencing consumer choice has a great potential because it can provide a new view of the decision-making process based on real data.

In the future, it is planned to carry out similar research using a mobile eye camera to realize the test with real wine bottles. It is also assumed that engaging of other methods will be possible (e.g. biometric methods of recognizing micro-emotions based on facial expressions – Facereading) in order to obtain information about real attention of the tested probands due to the individual attributes that influence their selection. Based on the statistical tests, it was found out that wine to which the respondents look at first has the least viewed time compared to the other two wines, and so it would be good to use a balancing block, such as Latin squares, to prevent this effect, which should be a subject for further experiments. Latin squares are one of the CRBD systems (Complete Randomized Block Design). The first evaluator gets the ABC order, the second BCA, the third CAB (Williams Latin square).

RHEOLOGICAL AND FUNCTIONAL PROPERTIES OF ROSELLE (*HIBISCUS SABDARIFFA*) LEAVES PUREE

Jaga Mohan Meher, Amit Keshav, Bidyut Mazumdar

ABSTRACT
Pureed form of leaves (*Hibiscus sabdariffa* L. (Roselle)) was taken for physicochemical and rheological analysis at temperatures and TSS range of 278 K – 318 K and 3 – 5 °Brix respectively. The steady-state rheological analysis was performed with a shear rate of 1 – 100 $s^{-1.}$ Different rheological models are tried; Power-law was best fitted with the experimental data (R^2 ≥0.98). Temperature dependence of viscosity was found out using an Arrhenius-type relationship at a shear rate of 10, 50, 100 s^{-1} IR analysis was done to know the influence of functional groups on rheological properties of purees. Consistency index (K) of puree increases with increase in TSS content but at a fixed TSS, there is a decrease in K with an increase in temperatures but the opposite was observed for flow behavior index (n). Puree showed a shear thinning behavior with an increment in temperature level and puree having 5 °Brix (8.37) has higher activation energy ($kJ.mol^{-1}$) than 3 °Brix (6.32).

Keywords: Roselle leaves; puree; TSS; temperature

INTRODUCTION
Roselle (*Hibiscus sabdariffa*) locally known as gongura, belongs to the *Malvaceae* family and are cultivated in large quantities in the tropical regions of Asia, Africa and Central and South America. It is an annual or perennial herb with leaves is 8 – 15 cm long and profoundly 3 to 5 lobed and arranged alternately on the stem (Figure 1). These leaves are most commonly used by the people as curries, potherbs and mixed green salad **(Adegunloye et al., 1996)**. Roselle consumed throughout the southern part of India, is one of the unique dishes in many eateries, hotels, restaurants and food joints, and often called as the king of all Andhra food. The leaves are used for making pickles and chutney and are often named as gongura pickle, ambadi, and chutney. It is a very good source of folic acid and iron **(Sutton, 2004)**. The high iron content imparts the leave sourness and bitterness. It is a rich source of minerals, organic acids, vitamins, and antioxidants, which have distinctive medical benefits such as antiscorbutic, diuretic impacts, emollient, narcotic and many more uses **(Ramakrishna et al., 2008)**.

Fresh Roselle leaves are perishable in nature and the quality of the leaves deteriorates due to microbial and physiological activities during the period of storage and transportation and hence requires immediate processing and preservation **(Singh et al., 2014)**. Minimally processed state in form of puree has been very attractive in processing, handling, storing and selling. These are easily consumable and hence, there is a need for methods to preserve and maintain the quality of purees within fresh form until consumed by the customer. As puree is a mixture of soft particles in serum or viscous gel and finds uses in as topping, seasoning and as recipes for the fast-food industry **(Colin-Henrion et al., 2007)**.

Flow properties of purees product are of extensive interest for the development of new product items for manufacturing, quality control, and engineering applications **(Bayod, 2008; Alvarado and Romero, 1989; Rao et al., 1981)**. Also, there is a need to characterize the effect of rheological properties during food handling operations and storage period. With increasing demand, and its commercial importance of puree in our day to day activity, the present research was conducted: a) to assess the physicochemical properties of the puree, b) to assess the change in the rheological behavior of the purees and try to decide a best rheological model to the concerned flow curves obtained during rheological analysis, c) study the effect of various parameters such as TSS (3 – 5 °Brix), pH (1.3 – 5.3), and temperature (278 K – 318 K) on the rheological behavior of puree concentrate.

Scientific hypothesis
Temperatures, TSS and pH are the important parameters, which affect the rheological properties of Roselle leaves puree.

MATERIAL AND METHODOLOGY

Preparation of blanched puree

Roselle leaves were purchased from the local market of Raipur (Chhattisgarh, India), washed thoroughly with running water, and then destemmed. Leaves were blanched at 363 K for 5 min. Efficacy and duration of blanching were determined by peroxidase inactivity test. Chilled leaves after removing excess amount of water were grounded using a mixer grounder (Bajaj, India) at 298 K for 15 min with the addition of distilled water. The grounded puree was filtered through filter paper (Whatman, 125 mm). Uniform consistency of the puree was maintained by passing through a 12-mesh screen. The lab size rotary evaporator (Cole-Parmer, India) prepared the puree concentrates of different TSS at 323 K and 160 mm Hg pressure. Samples of the desired range of TSS (3, 4.35, 5 °Brix) were obtained by diluting with appropriate amounts of distilled water.

Physico-chemical analysis

Moisture content was determined as per **Garcia-Segovia et al. (2010)** at 333 K on a wet basis. Ash content was calculated as per the standard method of **AOAC (1984)**. Chlorophyll content was analyzed using the method described by **Arnon (1949)**. The ascorbic acid content of the puree was found out by titration method **(Ranganna, 1986)**. Titratable acidity was calculated in terms of citric acid equivalent as per the process proposed by **Wang et al. (1995)**. TSS (°Brix) and pH was measured using digital refractometer (Atago, Japan) and pH meter (Handy) respectively. The acidic pH (1.3 – 5.3) of purees was maintained by using a buffer for physicochemical and rheological analysis.

FTIR analysis of Roselle puree

The spectra of puree are used for analysis by FTIR instrument (Bruker, Germany) in the frequency ranging from 500 cm^{-1} to 4000 cm^{-1}. The functional groups present in the puree are identified using the spectral data obtained with the reference.

Rheological measurement

The rheological test was conducted in a modular compact Rheometer MCR 102 (Anton Paar, Germany), mounted with ST22-4V-40 (four-bladed vane geometry). The temperature of the cup was varied from 278 K – 318 K, for various experimental runs. The experiment was performed within shear rate (1 – 100 s^{-1}). The rheological estimations were investigated utilizing the Rheoplus software package of Anton Paar.

Rheological models

Numerous factors influence the selection of a rheological model to describe the flow behavior of a particular fluid. In this work, the experimental values of shear rate and shear stress were fitted to the various non-Newtonian models as listed in Eq. (1 – 6).

Power Law: $$\tau = K(\gamma)^n \quad (1)$$

Herschel-Buckley: $$\tau^{0.5} = \tau_0 + K(\gamma)^n \quad (2)$$

Casson : $$\tau^{1/2} = \tau_0^{1/2} + K\gamma^{1/2} \quad (3)$$

Heinz-Casson: $$\tau^n = \tau_0 + K\gamma^n \quad (4)$$

Vocadlo: $$\tau^{1/n} = \tau_0^{1/n} + K\gamma \quad (5)$$

Mizrahi- Berk: $$\tau^{1/2} = \tau_0^{1/2} + K\gamma^n \quad (6)$$

where, τ , γ , K, n, τ_0 is shear Stress (Pa), shear rate (s^{-1}), consistency index ($Pa.s^{-1}$), behavior index (dimensionless), yield stress (Pa), respectively.

Statisic analysis

The selection of most suitable model among these, for prediction of the flow behavior of puree, was investigated taking account of the statistical parameters, root means square error (RMSE) (Eq. (7)) and coefficient of determination (R^2) (Eq. (8)). The fitted data, which showed the lowest values for RMSE and highest values for the R^2, was considered as the best-fit model. ANOVA and t-test were used to determine the mean differences. The significant difference was defined at p <0.05 with 95%

Figure 1 Photo of Hibiscus Sabdariffa leaves attached with stem part.

level of confidence.

The average value of all the experimental data was analyzed using statistical parameters including Root mean square error (RMSE) and coefficient of determination (R^2) were determined and were defined as,

$$RMSE = \sqrt{\frac{\sum_{i=1}^{N}(EV - MV)^2}{N}} \quad (7)$$

$$R^2 = 1 - \frac{\sum_{i=1}^{N}(MV - EV)^2}{\sum_{i=1}^{N}(EV - EV_{avg})^2} \quad (8)$$

Where EV is the experimental value, MV is the modeled value EV_{avg} is the average of the experimental value and N is the number of observations.

Effect of temperature on apparent viscosity

Temperature dependency on its viscosity was determined using Arrhenius model (Eq. (9)) **(Sengül et al. 2005)**.

$$\eta = \eta_0 \cdot \exp\left(\frac{E_a}{RT}\right) \quad (9)$$

Where, η_0 is the proportionality constant, E_a the activation energy (kJ.mol^{-1}), R the universal law gas constant (J.mol^{-1} K^{-1}), and T the absolute temperature (K).

Effect of TSS on activation energy

Two models, namely, the power law Eq. (10) and exponential model Eq. (11) were used to describe the variation of the activation energy with the TSS, as given below.

$$E_a = a(C)^b \quad (10)$$

$$E_a = a \exp(bC) \quad (11)$$

Where, a (Empirical constant (kJ.mol^{-1})), C (TSS (°Brix)) and b (Constant).

The combined effect of temperature and TSS content on apparent viscosity

The combined effect of temperature and TSS on apparent viscosity was evaluated by Power law type Eq. (12), first-order exponential model Eq. (13) and second-order exponential model Eq. (14) **(Juszczak and Fortuna 2004; Manjunatha et al. 2012)**. The estimates and fits of the different parameters were found at 5% significant level (p <0.05). The suitability of the model was choose based on RMSE values and correlation coefficient (r).

$$\eta = a(C)^C Exp(\frac{E_a}{RT}) \quad (12)$$

$$\eta = aExp(\frac{E_a}{RT} + cC) \quad (13)$$

$$\eta = aExp(\frac{E_a}{RT} + cC + dC^2) \quad (14)$$

Where, η, E_a, R, C, T is apparent viscosity (Pa.s^{-1}) at shear rates (10, 50 and 100 s^{-1}), flow activation energy (kJ.mol^{-1}), gas constant, TSS (°Brix), absolute temperature (K), respectively, a is pre-exponential constant (mPa.s^{-1}), b=Ea/R, c is constant (°Brix^1) and d is constant (°Brix^2).

Effect of temperature on K and n

The effect of temperature on flow behavior index (n) and consistency coefficient (K) was evaluated using a modified Turian approach through a regression analysis **(Turian, 1964)** (Eqs. (15) and (16)):

$$\log k = \log k_0 - A_1 T \quad (15)$$

$$n = n_0 + A_2 T \quad (16)$$

Where A_1 and A_2 are the slopes for Turian models. Higher A_1 and A_2 represent more dependency of n and k to the temperature.

Effect of pH on viscosity of puree

Changes in viscosities of puree with TSS (3 °Brix) having different pH value were assessed. The pH range was varied from 1.3 to 5.3 (increment of 2 was adjusted using 0.2 M Na_2HPO_4 and 0.1 M citric acid) at shear rates (10, 50 and 100 s^{-1}) and fixed temperature of 303 K.

RESULTS AND DISCUSSION

Physico-chemical measurements

The physicochemical characteristics of purees are shown in Table 1. The purees having 3 °Brix shows the high moisture content, due to the presence of higher concentration of water. Purees having higher TSS showed the highest value of acidity, compared to that of lower TSS value, probably due to the presence of the highest amount of total organic acid (like ascorbic acid) in the leaf (57.2 mg.100g^{-1}).

The amounts of ascorbic acid reported in the present

Table 1 Physicochemical composition of Roselle leaves puree concentrates used for experiments.

Parameter		Quantity		
		3 °Brix	4.35 °Brix	5 °Brix
Moisture (%)		84.25 ±1.81	81.19 ±1.11	77.55 ±0.81
pH		1.4 ±0.011	2.3 ±0.014	5.8 ±0.023
Density		1.052 ±0.04	1.066 ±0.05	1.069 ±0.082
Ash content (%)		4.52 ±0.11	4.64 ±0.19	4.72 ±0.17
Dry matter content (%)		38.29 ±0.032	39.5 ±0.092	40.1 ±0.019

Titrable acidity (%)		0.62 ±0.012	0.65 ±0.022	0.69 ±0.015

Note: The results were expressed as mean values ±SD (n = 2).

work were found higher than the ones previously reported in the literature **(Nnam and Onyeke, 2003)**.

The differences observed might be due to different varieties, harvest conditions, genetics, environment, and ecology. The different TSS of purees showed different values of chlorophyll content due to the difference in the soluble solid present in the puree of all TSS. Ash content and density of puree increase slightly with an increase in TSS value, as TSS value represent its solid content.

The FTIR spectra confirmed the presence of –OH stretching (have a similarity to 3672 – 29,345 cm^{-1}), –CH stretching (have a similarity to 2856 cm^{-1}), bending aromatic compounds overtone (have a close similarity to 1792 and 1734.8), C=N stretching imine/oxime or C=O stretching (have a similarity to 1659.1 cm^{-1}), conjugated ketone or alkenes (have a similarity to 1635.1 cm^{-1}), and OH bending phenol (have a similarity to 1368 cm^{-1}).The frequency of absorbance at 2856 cm^{-1} confirmed the presence of –CH stretching due to the formation of H-bond. At 1659.1, broad-shaped bands with medium intensities were observed which indicates the C=O stretching of COOH and Acetyl groups in the sample **(Femenia et al. 2003)**. It was noted that with the increase in TSS, the intensity of the peaks also increased, this might be due to the reason that during the concentration process there is a conversion in functional groups. The presence of the biologically active compound is indicated by the presence of acetyl group, which helps to develop cross-molecular barrier in the cell **(Chang et al. 2011)**. In the case of Aloe Vera powder, **Kim et al. (2009)** reported similar band formation. The previous studies of strong bands on Aloe Vera depict the presence of monosaccharide units in the branched regions such as glucan and galactose in the range of 1156 – 1230 cm^{-1} **(Gentilini et al.2014; Ray and Aswatha, 2013)**.

Rheological analysis of Roselle puree

Figure (1-3) exhibits the effect of temperature on steady shear properties of the purees with a TSS of 3, 4.35 and 5 °Brix.

The obtained data were fitted to six non-Newtonian models (Eqs. (1-6)). The best numerical models for characterizing the flow characteristics of purees was chosen based on the coefficient of determination (R^2), RMSEs, the presence of yield stress and overall bias factors acquired during the fitting (Table 3 – 8). Although all models fitted well with the test data, at 5 °Brix esteem, Herschel-Buckley, Heinz-Casson, Vocadlo, and Mizrahi-Berk fitted model demonstrated negative values, which are having no physical importance. Hence RMSE values were not calculated for the rest of these unfitted models. Power law and Casson model fit satisfactorily at all temperature ranges examined and the R^2 value was found to be greater than 0.97 and hence were more appropriate to describe the rheological flow behavior of the puree.

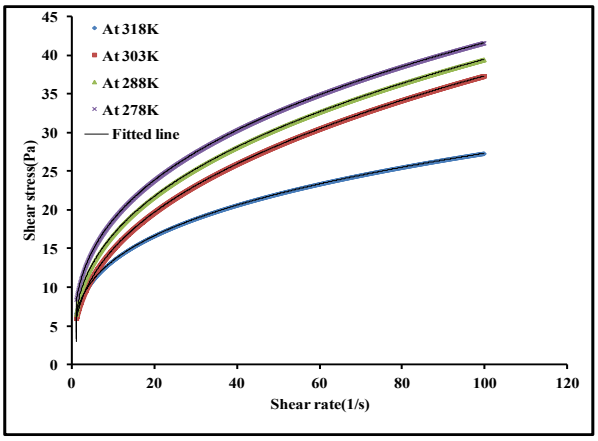

Figure 1 Shear rate vs. shear stress for the 3 °Brix of Roselle leaves puree at various temperatures (T=278 K – 318 K).

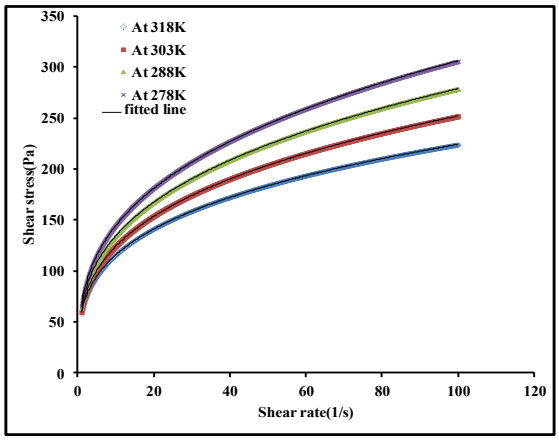

Figure 2 Shear rate vs. shear stress for the 4.35 °Brix of Roselle leaves puree at various temperatures (T = 278 K – 318 K).

Effect of K and n on the temperature at different TSS

The variation of K value with temperature (278 – 318 K) of puree is given in Table 3 for power law fitted model. K varied from 6.01 to 350.28 $Pa.s^{-1}$ in puree with different TSS range. The lower values for K were observed at a higher temperature (318 K). The variation was more noticeable on puree having lower TSS value (3 °Brix). Higher TSS purees were found to have higher K value in magnitude. The increments in K were found with an increase in TSS value at a fixed temperature probably due to increment in the particle-to-particle contact **(Chin et al., 2009)**. A similar result was obtained for another vegetable **(Ahmed et al., 2013; Karababa and Develi Isikli, 2005)**. The impact of factors was discovered significant (p <0.05) for all TSS (Table 3). The dependence of K on the temperature variation was also performed using Turian model (Eq. (15)) for Puree. Highest flow behavior dependency was found for 5 °Brix at varying temperatures

(Table 9). Increments in the temperature from 278 K to 318 K significantly affect the consistency index.

The *n* value of the puree ranged from 0.068 to 0.396 (Table 3) for various TSS studied, signifying gently non-Newtonian pseudoplastic shear thinning behavior of puree **(Muller 1974, Steffe, 1996)**. Turian models (Eq. (16)) were used to monitor the dependence of *n* on its temperature change and the model parameters are shown in Table 9. The variation of *n* value with temperature was lower (0.307 – 0.396) in lower TSS value as compared with the higher TSS value (0.068 – 0.193) in all temperature range. This may be because of the increase in soluble solid content. The decrement in n value of puree showed the steady loss of pseudo-elasticity **(Sikora et al., 2007)**. The sample having different temperature demonstrated different flow behavior values for different TSS sample. When the temperature varied from 278 K to 318 K, the n values decrease with increment in temperature. Comparative patterns for the n were accounted by **Rao et al. (1981)** for tomato juice concentrate. Besides TSS, the impact of every single other variable was found significant (p <0.05) (Table 3).

Effect of temperature on viscosity at a different shear rate

Effect of temperature on viscosity is important in determining the rates of heat exchange, energy utilization, and flow rates so it is feasible to assure persistent product flow **(Nindo, 2005)**. **Karwoski (2013)** reported that TSS and temperature influence physical properties, such as viscosity, specific heat, refractive index, density and boiling point, of the fruit product. The plot of the log of viscosity against 1/T (K^{-1}) at various shear rates shown in Figure 5 and the constants of Eq. (9) were determined. It was observed that viscosity of puree concentrates diminish with increment in temperature over the range of shear rates. Figure 6 shows that viscosity decreases with a shear rate, which may be because of increased versatility of macromolecules, because of temperature rise, causing less resistance to flow. The change of the magnitude of viscosity was more at shear (10 s^{-1}) contrasted with the little distinction in a shear rate of 50 and 100 s^{-1}. Interaction impact of temperature and shear rate was additionally assessed and was significant for puree at all Brix value (p <0.05).

Activation energy is minimum energy required for particles to get away from the impact of its neighboring particles during the characterizing the viscous flow. The extent of the vitality of initiation for flow increased with increment in the TSS of the puree, it demonstrates that more energy was required to defeat potential vitality hindrance at higher TSS. Both the power law (Eq. (10)) and exponential model (Eq. (11)) were tried to determine the effect of flow activation energy on TSS of Puree. A nonlinear trend of increment in activation energy ($p \leq 0.05$) of puree with the increase in solids content was observed. The exponential model (r >0.75) was more effective in explaining the impact of the TSS on the flow activation energy of the puree than the power law model (r <0.75) as shown in Table (10). A similar type of results was recorded in the case of pomegranate **(Kaya and Sözer, 2005)**. The activation energy ranged between 3.544 – 8.610 $kJ.mol^{-1}$ for puree having different TSS range (3 – 5 °Brix) (Table 11). Higher values of activation energy may be associated with the higher temperature and TSS of the puree **(Ahmed et al., 2007)**. In pseudoplastic vegetable product, the activation energy was proportional to the n i.e., the more pseudoplastic the product, the less the impact of temperature on its apparent viscosity **(Sharoba et al., 2005)**. In this study, it was found that the activation energy was discovered lower for the puree having lower TSS value at a fixed shear rate (Table 11). Similar types of trends were observed by **Hernandez et al. (1995)** and **Vitali and Rao (1984)**. However, it was also observed that for all TSS Value, the activation energy of puree concentrates increase with an increase in shear rate. Higher activation energy values show a more impact of temperature on its viscosity, i.e. faster change in viscosity with temperature **(Sanchez et al., 2009)**. The outcomes demonstrated that temperature and TSS had significantly affected the thickness of puree concentrates. The viscosity value increases altogether with increment insoluble solid substance. Similar results were obtained by **Alpaslan and Hayta (2002); Akbulut et al. (2012); Arslan et al. (2005)**.

Combined Effect of Temperature and TSS on apparent viscosity

From the food process designing perspective, it is necessary to get a single equation, which represents the effect of both temperature and TSS dependency on the viscosity of puree. Few authors have utilized different types of equation to depict the joined impact of temperature and TSS on viscosity of the liquids **(Juszczak et al., 2010; Kaya and Sozer, 2005; Ibarz et al., 2009; Nindo et al., 2005; Nindo et al., 2007; Altan and Maskan, 2005; Juszczak and Fortuna, 2004)**.

Table 12 demonstrates the parameters for the various models for depicting the combined impact of temperature and TSS on the viscosity of puree. The correlation coefficients values of 0.992, 0.998 and 0.999 and % RMSE values of 10.259, 10.324 and 6.887 were obtained for the first order, exponential first order, and exponential second-order models, respectively. The second order exponential condition was ideal, because of high correlation coefficient and low percent RMSE values. The Estimated parameter values of Eqs. (12), (13) and (14) are given in Table 12 and model equation may be represented as (Eqs 17 – 19).

$$\ln \eta = -8.13685 + \left(\frac{602.275}{T}\right) + 6.045833 \quad (17)$$

$$\ln \eta = -6.1791975 + \left(\frac{602.275}{T}\right) + 1.56987034C) \quad (18)$$

$$\ln \eta = -4.900 + \left(\frac{602.275}{T}\right) + 0.89C + 0.085C^2) \quad (19)$$

The viscosity of puree was significantly (p <0.05) influenced by temperature and TSS of puree. The surface plot for the joined impact of temperature and TSS on the consistency of puree at various shear rates is shown in Figure 7 (a – c).

At lower temperatures the magnitude of viscosity increases quickly with a fixed TSS of Puree and increases insignificantly at higher temperatures, this was because of increment in thermal energy of the particles, which increase its intermolecular spacing. A comparable sort of results was accounted for other liquid food **(Nindo et al., 2005; Ibarz et al., 1989)**. Size, shape, nature of solute and its condition of hydration and the type of solute and solvent influences the viscosity determination, thus might account for deviation in various cases. In the case of Roselle leaves, the solids present in the puree may be mainly fiber, diverse sugars (sucrose, fructose), vitamins, minerals, amino acids, proteins, hormones etc. The condition of hydration was distinctive for various TSS, the magnitude of viscosity relies on upon the sort of solids parts present in the puree **(Nindo et al., 2005; Telis et al., 2007)**.

Effect of pH on apparent viscosity

The influence of pH on the apparent viscosity of puree is shown in Figure 8. As the initial puree prepared from leaves is having pH of 1.3 ±0.26, so the puree is an anionic polysaccharide containing a great number of negative charge-bearing groups such as carboxyl groups, which may undergo different degrees of ionization with changing pH value, leading to changes in viscosity and rheological properties **(Lapasin and Pricl, 1995)**. At shear rates less than 50 s^{-1}, the highest viscosity was obtained over the pH range of 1.3 – 5.3.

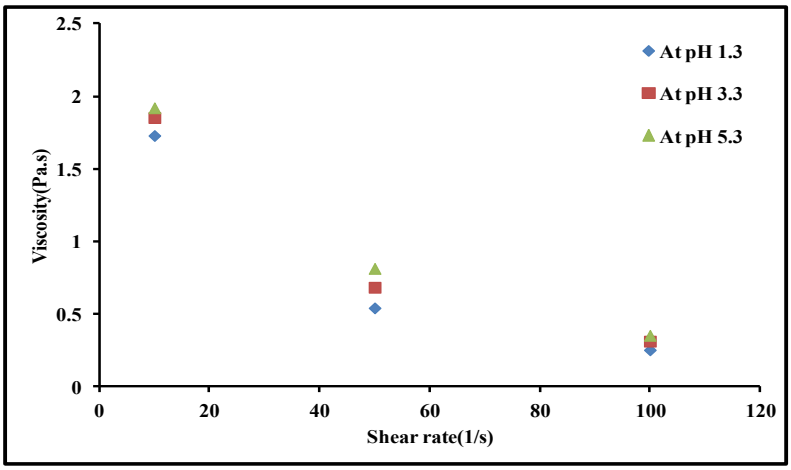

Figure 8 Rheogram of viscosity vs. shear rate for the 3 °Brix of Roselle leaves puree with varying pH (1.3 – 5.3).

There is an increment in viscosity is due to the ionization of carboxyl groups. As per **Feng et al. (2007)**, the viscosity will be at a most extreme when its atomic chains present in puree are entangling with each other. Past research work by the researcher on the impact of pH on viscosity of sweet potato puree and quince puree demonstrated that the consistency of puree increase with pH value **(Ice et al., 1980)**. On the other hand, in the more basic region, the solution consistency dropped at a fixed TSS. As the pH is raised, the functional group present induces electrostatic repulsion that tends to keep the atoms in a developed shape, in this manner producing an exceedingly thick solution **(Onweluzo et al., 1994; Launay et al., 1986)**. Results likewise demonstrated that at higher shear rates (more than 50 s^{-1}); changes in pH had no extensive impact on the viscosity.

In addition, the pH-dependence of viscosity may be due to change in puree confirmation. At low pH, polysaccharide chains tend to appear in coil state with acid groups in free acid form. With increasing pH, acid groups of coils are gradually ionized and the coils are expanded due to increase in electrostatic repulsion between functional groups, leading to more intermolecular interactions among the coils and consequent higher viscosity of the puree **(Feng et al., 2007)**.

The maximum viscosity was obtained around the pH 5.3 for Puree, where the shape of chains may be close to rod conformational state **(Achi and Okolo, 2004)**. This condition usually appears at where acid groups are ionized and electrostatic repulsion reaches a maximum and consequently, tends to keep the molecules in an extended form, leading to a high viscous solution and higher K values **(Medina-Torres, 2000; Coupland, 2013)**. The decrease of viscosity from pH 1.3 to 5.3 may be explained by the neutralization effect of added alkali on the negative charges of the puree, which reduces the hydrodynamic volume of the puree and consequent viscosity **(Chen et al., 2001; Porto et al., 2015)** and puree depolymerization under alkali condition, proposed by **Achi and Okolo, (2004)**.

CONCLUSION

Physicochemical properties of the Roselle leaf puree was found to increase with an increase in TSS value. FTIR spectra confirmed the presence of free alcohol, alkanes, alkene, intermolecular bonded alcohol, aromatic compounds, ketone, amine, phenol, imine, and oxime stretching in the puree. The observation of bands in the IR region made it evident resulting in the chlorophyll molecule masking the other molecules. The rheological analysis also plays a vital role to know the effect of the presence of different compounds on its flow behavior. In the present study, there was a 4 to 5% variation in chlorophyll contents with an increase in TSS contents of puree.

Rheological models were tried to fit with the experimental data of Puree and *best model was selected*. The power-law model display well-fitted data and was considered as a favored model for depicting the rheological properties of puree as impacts of temperatures, TSS and pHs. Puree samples exhibited pseudoplastic behavior (n <1) with the flow behavior index (n) between 0.28 and 0.82. The values of K were found to increase with TSS at a fixed temperature. The Arrhenius model describes satisfactorily, the temperature dependence of viscosity of puree. The activation energy of puree concentrates increase with an increase in TSS and shear rate. The model equation was developed and evaluated by the combined effect of TSS and temperature on the viscosity of puree.

THE FIELD AND LABORATORY STUDY OF THE COLLECTION SAMPLES OF ONION BREED *ALLIUM CEPA* L.

Viktor Nemtinov, Yulia Kostanchuk, Svetlana Motyleva, Lidiya Timasheva, Olga Pekhova, Ivan Kulikov, Sergei Medvedev, Alexander Bokhan

ABSTRACT

Thirteen collection samples of *Allium cepa* L. of different ecology-geographical origin grown in the Crimea conditions are given. Morphometric characteristics of the bulbs – the form index, the diameter, the height, the weight, the thickness and the quantity of rich skins are analyzed. The greatest output of standart production (90 – 95.6%) was observed for all breeds. The biochemical values of the *Allium* cepa L. samples under study were examined by the traditional methods. It is marked that the dry substances, the sugars sum, the mono- and disaccharides in the majority of the samples exceed the standart (Yaltinsky rubin) on 14 – 39%, 11 – 48% and 36 – 150% correspondently. The samples with the high concentration of essential oil are singled out: Yaltinsky rubin (Crimea), Tavrichesky (Crimea), Blood red flat (Netherlands) and Brown Beauty (USA) – 4.5, 6.2, 5.6 and 4.4% correspondently. The microsculpture of *Allium cepa* L. leaf was studied by the method of raster electron mi-croscopy and the essential breed differences of the stomata quantity and their arrangement towards the leaf level were distinguished. The results of electron-microscopic research indicate the different level of *Allium cepa* L. samples adaptability. *Allium cepa* L. samples under study of the southern subspecies are recommended for the development of the new breeds with the advanced nutritional qualities.

Keywords: sample; *Allium cepa* L.; bulb onion; morphological and biometric characteristics; essential oils; the parameters of the stomata of the leaves

INTRODUCTION

The peculiarities of the bulb onion breed *Allium cepa* L. growth in Russia are the increase of the cultivated areas in the Southern regions, the yield and the gross collection rise (**Litvinov et al., 2015**). The bulb onion consumption increases not only for the fresh usage, but also for the industrial processing (**Pivovarov, et al., 2001**). For 2006 – 2009 the world gross collection of the bulb onion grew almost on 12% from 66 mln. t to 74 mln. t **(BUSINESSTAT, 2011).** On the world market of *Allium cepa* L. production China is on the first place – 30% of onion in the total production structure; 19% are produced in India; 4.9% in the USA and 2.2% in the Russian Federation. The main production of *Allium cepa* L. in the Russian Federation is placed in three districts: Privolzhsky, Southern and Central. The new breeds and hybrids of *Allium cepa* L. should possess early ripening, yield, stability to diseases and blasts, good storability, small variability of morphological characteristics, the concentration of dry substances in the bulbs 7 – 10% for the salad breeds and 12 – 18% for pungent ones (**Nemtinov et al., 2006**).

The adaptability of the ontogenesis stages, cytological peculiarities of the leaf's epidermis surface, the stomata quantity on 1 mm^2 of intercellular structure of the leaf surface allow to judge about the economical valuable characteristics of the breed **(Yudaeva et al., 2017).** The adaptability of the plants to new conditions depends on the genetic variability in the selection process (**Grinberg et al., 2007; Kalbarczyk, 2008; Bystrická et al., 2014**).

Allium cepa L. is a useful vegetable plant and the source of some biologically active substances. The vitamins and phenol compositions, especially quercetin, possess antioxidant and antibacterial activity **(Ulyanova, 1998; Platonova, 2000; Parr et al., 2000; Romanova et al., 2008; Kavalcová et al., 2015; Silva, et al., 2007; Tawaha, et al., 2007**). The aminoacids – arginine, lysine, leucine, isoleucine, threonine, phenylalanine, alanine, glycine, histidine, serine as well as glutamic and asparlic acids are found in the bulbs. The prolonged consumption of food rich in plant polyphenols guarantees the organism protection from cancer, heart diseases, diabetes, osteoporosis and neurodegenerative diseases (**Pandey et al., 2009**). *Allium cepa* L. antioxidant activity of the bulbs

of different colour is not the same. **Prakash et al. (2007)** and **Cheng et al. (2013)**, experimentally determined the value of the antioxidant activity: 50.6% in the red bulb onion and 13.6% in the white one. **Nuutila et al. (2003)** discovered that the antioxidant activity of yellow and red-coloured breeds is in the range from 32.9% till 44.5%.

Scientific hypothesis

Comparative morphological and biochemical assessment of *Allium cepa* L. varieties of different ecological and geographical origin has not been studied sufficiently. We tested the influence of the *Allium cepa* L. genotype on the economically valuable and morphological features when grown in conditions of Crimea.

MATERIAL AND METHODOLOGY

Objects of research

Investigated of the samples of the bulb onion from 9 countries of Federal Reach Center "All-Russian Institute of Plants Genetic Resources named after N. I. Vavilov" collection was used. The samples differed by origin: 4 samples from Russia (the Crimea: Yaltinsky rubin, Yaltinsky model №3, Tavrichesky and Krasnodarsky Kray: Mestniy); 2 ones from the USA (Southport red, Brown Beauty); as well as from Australia (B12132B0, Azerbaijan (Mestniy), Algeria (Rouge pale), Bulgaria (Trimontzium), Bolivia (Red Wethers field), Netherlands (Blood red flat) and Portugal (Valensiya). Breed Yaltinsky rubin was accepted as the standart.

The researches place and methods

The field researches were held in 2016 – 2017. The onion plants were grown in the collection nursery of Federal State Budget Scientific Institute "Scientific-Research Institute of Agriculture of the Crimea" (FSBSI SRIA of the Crimea). The grounds are presented by the southern calcareous black soil. The agrochemical characteristics of 20 sm ground layer: the humus concentration by Tyurin – 4.5 – 5.4%; pH reaction – 7.85; mineral nitrogen N – NO_3 – 6.3 mg.100g^{-1} of the soil; labile phosphorus concentration P_2O_5 (by Machigin) – 18.4 mg.100g^{-1} of the soil; exchangeable potassium concentration K_2O (by Machigin) – 73.0 mg.100g^{-1} of the soil. The plants were grown in 4 replications on the registration plots with the squares from 0.5 m^2 till 1 m^2.

Environmental assessment of output

The ecological evaluation of the output yield was fulfilled, the photometric peculi-arities of the leaves and bulbs were described – the form index, diameter, height, weight, thickness of rich skins, quantity (rich skins rudiments) **(Vavilova, 2005)**.

Chemicals

All chemical substances chosen forthe analysis were of analytical sortand were bought from Sigma Aldrich (USA) and Merck KgaA (Germany).

Sample preparation

300 g of the average sample was homogenized with the help of high-speed homogenizer (10 000 rpm, 1 min, UltraTurrax T25 Basic, IKA). The extractionaswell as the measurements were held in three-time repetition.

Basic chemical analyses

The following biochemical characteristics of the bulbs quality were determined: dry substance – using the thermographic method **(GOST 2173-2013, 2014)**, ascorbic acid – using the titrimetric method by Murri **(R 4.1.1672-03, 2003)**, the sugars and the reductive sugars sum in accordance with **GOST 8756.13-87 (2010)**, the essential oil concentration – using the distillation chromatographic method **(Timasheva et al., 2018)**.

Electron microscopic examination

The morphologic characteristics of *Allium cepa* L. samples leaves were studied in the Laboratory of Physiology and Biochemistry of Federal State Budgetary Scientific Institution "All-Russian Horticultural Institute for Breeding, Agrotechnology and Nursery" by the method of raster electronic microscopy (REM). For the researches the leaves cuttings from the central part of the rosette (in the second decade of June) with the dimensions 5 × 5 mm were placed on a special gluing tape set on the object table of REM JEOL JSM 6010-LA. The epidermis was studied from the leaf abaxial side in accordance with REM operating rules.

Statisic analysis

Results were statistically evaluated by the Analysis of Variance. All the assays were carried out in triplicates and results are expressed as mean ±SD. All calculations were made with the help of Microsoft Office 2013 software package (Microsoft, USA).

RESULTS AND DISCUSSION

Allium cepa L. prolonged vegetation period in the southern regions of Russia and the duration of the bulbs storage period determined the traditionally vested rules: the bulbs onions should be mid-ripening, half-pungent and sweet (salad). The bulb form was an important grading factor and influenced on the consumer's demand for the salad onion of the southern subspecies. The form index 0.5 – 0.7 corresponded to six samples – two from the Crimea (Yaltinsky rubin – standart and Yaltinsky model №3), Mestniy (Krasnodar, Russia), Rouge pale (Algeria), Mestniy (Azerbaijan), Red Wethers field (Bolivia). The rest samples had the index 0.8 – 0.9. The sample B12132B (Australia) had index 1.1. The greatest bulbs diameter (7.4 – 9.0) is characteristic of the samples Mestniy (Azerbaijan), Valensiya (Portugal), Brown Beauty (USA), Yaltinsky rubin (Crimea) – standart and Yaltinsky model №3 (Crimea). The maximal bulbs height is 7.8 sm is typical for the sample B12132B (Australia). Seven samples annually exceeded the standart by the bulbs height. Sample 5 (Tav-richesky) had the bulb diameter of small size 3 – 5 sm, middle size was at 9 samples (1, 2, 3, 4, 6, 7, 8, 10 and 11) and large 8 – 9 sm – at standart and sample 12. Within 2 years the value of the bulbs diameter was less than the standart except the sample Yaltinsky. During the evaluation of the bulbs morphological factors are the thickness, the rich skins and rudiments quantity. The greatest thick-ness of the bulb rich skins (from 5.2 till

7.6 mm) is marked for the samples Brown Beauty (USA), Rouge pale (Algeria), Yaltinsky rubin (Crimea) – standart and Yaltinsky model №3 (Crimea) (Table 1).

The rudiments quantity in the bulb influences the bulb onion reproduction coefficient. The samples Mestniy (Krasnodar, Russia), B12132B (Australia), Tavrichesky (Crimea), Blood red flat (Netherlands), Brown Beauty (USA) and Yaltinsky model №3 (Crimea) showed the rudimentariness less than 2pcs., the rest ones corresponded to the standart level (2 – 2.5 pcs.).The bulbs weight relates to the economical characteristics of the breed. The biggest bulbs weight is marked at the samples Brown Beauty (USA), Southport red (USA), Yaltinsky rubin (Crimea) – standart and Yaltinsky model №3 (Crimea) – 152, 166, 170 and 211 g correspondently. The samples yield at average for 2 years varied in the range 2.2 – 4.5 kg.m^{-2}, the highest one is at the standart 45 kg.m^{-2}. The sample Mestniy (Azerbaijan) was less than the standart on 2.0%. The largest output of the standart products 93.2 – 95.6% was marked at the samples Mestniy (Azerbaijan), Yaltinsky model №3 (Crimea), Brown Beauty (USA), Valensiya (Portugal) and Valensiya (Portugal) (Table 2). It is known the the bulbs colour indicates the presence of the antioxidants – polyphenols: flavonoids (quercetin, rutin) and anthocyans in the products **(Nuutila et al., 2003; Kong et al., 2003; Lu et al., 2011; Cheng et al., 2013)**. As a result it can be supposed that yellow, white and light-pink bulbs contain flavoids (quercetin and rutin), and brown-purple, dark-purple and purple bulbs Yaltinsky rubin (Crimea) – standart, Yaltinsky model №3 (Crimea) and Trimontzium (Bulgaria) – anthocyans. Such breeds are very popular on the onion market (Figure 1).

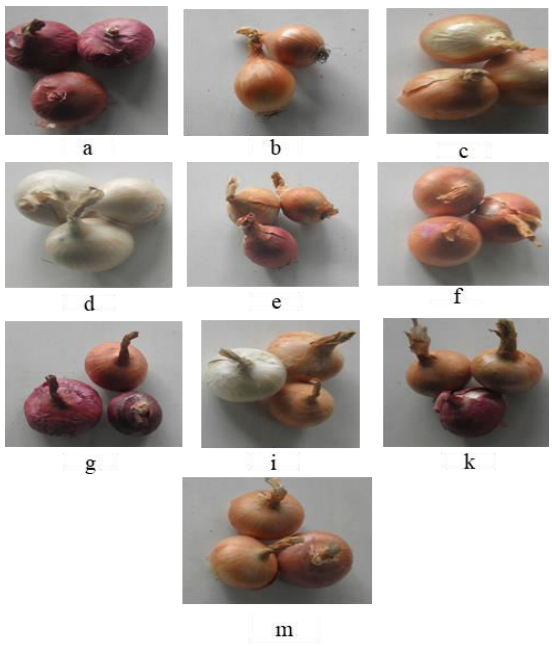

Figure 1 *Allium cepa* L. samples of different bulb colour a: Yaltinsky rubin (Crimea) – purple, b: Mestniy (Krasnodar, Russia) – yellow, c: Southport red (USA) – yellow, d: Trimontzium (Bulgaria) – white, e: Tavrichesky (Crimea) – light pink, f: Rouge pale (Algeria) – yellow, g: Red Wethers field (Bolivia) – dark-purple, i: Blood red flat (Netherlands) – yellow, k: Valensiya -(Portugal) – yellow, m: Brown Beauty (USA) – yellow.

The biochemical composition analysis of the collection samples at the dry substance concen-tration, the sugars sum including mono - and disaccharides showed that the majority of them enlarge the standart on 13 – 46%, 11 – 48% and on 36 – 150%, except the samples B12132B (Australia) and Yaltinsky model №3 (Crimea), in which the concentration of the dry substance on 12 – 19% and the sugars sum on 2% lower than the standart sample, and the fraction of disaccharides is on 22% lower than sample 12 (Table 3). The highest concentration of the sugars sum and disaccharides is marked at samples Red Wethers field (Bolivia), Valensiya (Portugal) and Brown Beauty (USA). In the bulbs of sample Yaltinsky model №3 (Crimea) the increase of monosaccharides and ascorbic acid relatively on 10 and 47% higher than the standart was marked.

The maximal concentration of ascorbic acid in the bulbs contains at samples Red Wethers field (Bolivia) – 21.1 $mg.100g^{-1}$ and Yaltinsky model №3 (Crimea) – 27.3 $mg.100g^{-1}$, this is on 5 – 14% higher in comparison with the standart (18.6 $mg.100g^{-1}$). At *Allium cepa* L. samples under study for the years of the researches the weight fraction of the essential oil in the range from 0.9 till

6.2% that is typical for the salad breeds. The samples singled out according to the studied factors are used in the selection process. The results of electronic-microscopic researches of the tudied *Allium cepa* L. samples leaves allowed to distinguish the peculiarities of cuticle surface micromorphology (the presence of girders and folds, the wax layer), the peculiarities of the stomata position, as well as their length and the quantity on 1 mm^2 of *Allium cepa* L. leaf surface (Table 4).

The highest stomata quantity on the adaxial leaf side of *Allium cepa* L. leaf is observed on samples B12132B (Australia), Valensiya (Portugal), Tavrichesky (Crimea) and Trimontzium (Bulgaria) – 49.9 x 10^2, 47.4 x 10^2, 38.9 x 10^2 and 37.6 x 10^2 $pcs.mm^{-2}$ correspondently. At the majority of the samples the stomata length varies slightly from 8.71 µm (B12132B (Australia)) till 22.49 (Blood red flat (Netherlands)). The largest stomata – 34.32 µm is at sample Yaltinskiy rubin (Crimea), however, the stomata quantity on 1 mm^2 of the leaf surface is not essential – 37.6 x 10^2 pcs.

The stomata sculptural peculiarities of three main contrasting collection samples: Trimontzium (Bulgaria); Mestniy (Azerbaijan) and Yaltinsky rubin (Crimea) are presented on Figure 2.

It is determined that the leaf surface microstructure of each *Allium cepa* L. studied samples is specific. The cuticle wax which is mostly developed at Trimontzium (Bulgaria) is clearly seen. The analysis of leaves epidermis low surface ultrastructure showed that the stomata at *Allium cepa* L. studied samples are basically prolonged (the length is bigger than the width) with clearly seen auxiliary epidermal cells covered with wax layer. In relation to the cuticle surface level the stomata are placed differently, for example: at sample Trimontzium (Bulgaria) the stomata are strongly deepened in the cuticle, placed lower than the surface. At the sample Mestniy (Azerbaijan) the stomata are raised above the cuticle surface and have well developed girders that possibly provide the better stomatal pore opening and closing. At the sample Yaltinsky rubin (Crimea) the stomata are placed at the cuticle level and have well-developed stomatal rollers.

It is determined that the stomata length was larger and was 21.15 – 34.32 µm at more productive samples with thick rich skins and their quantities at the level of 5.4 – 5.8 pcs.

Table 4 Morphological factors of *Allium cepa* L. breeds vegetable part**.**

CONCLUSION

The complex evaluation of morphometric factors and biochemical composition of 13 *Allium cepa* L. collection samples of different ecology-geographic origin is given.

It is determined that *Allium cepa* L. samples are characterized by different bulbs colour that indicates about *Allium cepa* L. samples leaves add their morphologic characteristic that indicate the variental differences of the leaf epidermal structures and the various level of adaptability.

The studied collection of the southern subspecies *Allium cepa* L. samples is the base for the acquisition of the best samples according to the factors: the concentration of dry substance, sugars, ascorbic acid and essential oil and is used in the selection work for the improvement of flavouring and curing characteristics of the existing salad onion breeds.

BIOINFORMATICS ANALYSIS OF AFLATOXINS PRODUCED BY *ASPREGILLUS* SP. IN BASIC CONSUMER GRAIN (CORN AND RICE) IN SAUDI ARABIA

Latifa Al Husnan, Muneera Al Kahtani, Randa Mohamed Farag

ABSTRACT
The food contaminants by aflatoxins are inevitable even when all precautions and good agricultural practices are applied. Samples of white rice and corn (yellow, red) grains were collected from different local markets and houses. Three *Aspergillus flavus* strain isolated were identified using molecular characterization of *AFLR* (*aflR*) toxin gene. DNA genome of the three *A. flavus* isolates (namely *A. flavus* _ YC; *A. flavus* _ RC; *A. flavus* _ Rice) which corresponds to isolates from, yellow corn, red corn and white rice respectively were used as a template for PCR to amplify *Aspergillus flavus AFLR* (*aflR*) toxin gene. Partially sequenced was amplified using a specific primer set to confirm its identity, phylogenetic relationships between the three isolates as well as determination of the corresponding antigenic determinants. The epitope prediction analysis demonstrated that there were 1, 2, 3 and 4 epitopes whose score were equal 1 in *A. flavus* _ YC; *A. flavus* _ RC; *A. flavus* _ Rice, respectively. Interestingly, there were great dissimilarity in the epitope sequences among the three isolates except in RLQEGGDDAAGIPA, SPPPPVETQGLGGD, RPSESLPSARSEQG and PAHNTYSTPHAHTQ were found to be similar between all isolates. This work articulates that the molecular identification and characterization of three *A. flavus* using *Aspergillus flavus AFLR (aflR)* toxin gene and the unique antigenic determinants that could be used for design of a broad-spectrum antibody for rapid detection of *A. flavus* in foods and support quality system of food safety.

Keywords: PCR; sequences; phylogenetic tree; protein toxic gene; antigenic determinants

INTRODUCTION
Fungi caused major crops diseases during harvest and storage under higher temperature and humidity conditions **(Bhat et al., 2010; Pasquali et al., 2016)**. While more than 25 different fungi species known to invade stored grains and legumes **(Duan et al., 2007)** some species such as *Aspergillus, Fusarium, Penicillium* are responsible for most spoilage and germ damage during storage **(Boutigny et al., 2012; Aamot et al., 2015; Kachapulula et al., 2017)**. Crop transfers through international trade have made aflatoxins contaminated food a worldwide problem **(Passone et al., 2010)**. Mycotoxins are secondary metabolites produced by fungi, which cause health hazards to animals and human beings; the majority of mycotoxins of greatest concern to human and animal health are produced by the genera *Aspergillus, Penicillium,* and *Fusarium,* the so-called field fungi that frequently infect various food commodities **(Reddy et al., 2010)**. Toxicity of a mycotoxin will be manifested by its effect on the human and animal health and productivity of crops **(Abdel-Wahhab et al., 2006)**. The main routes of mycotoxins exposure are ingestion, inhalation or through skin contact. The toxicity of a mycotoxin is determined by metabolism involving the, transformation, administration, distribution, absorption, excretion and molecular interactions of the toxin and its metabolites. Nowadays the main mycotoxins of interest are aflatoxins (AFs), ochratoxins, **(Frisvad et al., 2019)**, trichothecenes, zearalenone, fumonisins, ergot alkaloids and deoxynivalenol **(Reddy et al., 2010; Cendoya et al., 2014; Covarelli et al., 2015; Singh and Cotty, 2019)**. Mycotoxin producing fungi which are associated with groundnuts, peanuts, cereals such as maize, rice, sorghum, wheat, barley and oats and spices such as black pepper, ginger, nutmeg, chilly, etc. are considered to be of greater significance for all over world **(Kumar et al., 2008; Brožková et al., 2015)**. Several studies have revealed mycotoxin contamination in rice worldwide: for example, aflatoxins in the United Arab Emirates **(Osman et al., 1999)** fumonisins in Iran, Argentina **(Alizadeh et al., 2012; Cendoya et al., 2014)** OTA in Morocco **(Juan et al., 2008)**, ZEA in Nigeria **(Makun et al., 2007)**, DON in Italy **(Lorè et al., 2011)** nivalenol in Korea **(Lee et al., 2011)** and citrinin in Egypt **(Abd Allah and Ezzat, 2005)**. As most of the corn and rice is grown during the wet season; it is

susceptible to mycotoxin contamination. Rice is shown to be a good substrate for toxigenic fungi like *A. flavus, A. ochraceus, Penicillium citrinum,* and *F. proliferatum* **(Aamot et al., 2015; Arino et al., 2007; Sánchez-Hervás et al., 2008)**. Humidity, temperature, storage conditions, and transportation period are the factors that influence mycotoxin production in rice **(Ariño et al., 2007)**. Regarding legumes in Saudi Arabia, very little information exists with respect to its natural contamination with toxigenic fungi and mycotoxins. Aflatoxins were detected in some *Aspergillus* isolates while fumonisin was detected in some *Fusarium* isolates **(Ibrahim et al., 1998; Abdel-Fatah et al., 2017)**. Among food contaminants, mycotoxins may cause substantial economic loss due to lower availability of commodities with acceptable levels of mycotoxins present and possibly greater cost of mycotoxin-safe and acceptable foods **(Mwanza et al., 2013; Samina, 2015)**. Mycotoxins continue to pose various health risks to consumers depending on specific mycotoxin consumed and level of exposure, and health status of individuals in the population **(Voss et al., 2014; Pasquali et al., 2016)**. Many human diseases, especially carcinogenic, teratogenic, hepatic, and gastrointestinal ones, have been found linked with the ingestion of mycotoxin-contaminated products **(Fung and Clark, 2004; Shephard, 2008; Samina, 2015)**. Outbreaks of mycotoxicoses in humans and animals, caused by ingestion of products containing mycotoxins, **(Peraica and Rašić, 2012)**. Risk assessments relating to food safety are frequently hampered by the lack of quantitative data **(Schmidt-Heydt et al., 2007)**. The sequencing fungal genomes and the studies of the molecular basis of fungal pathogenicity provide the study of risk factors associated with continuous exposer of mycotoxins **(Bilodeau, 2011; Taha et al., 2012)**. This paper was shown concentrated on aflatoxins produced by *Aspregillus* sp. and possibility for used the similarity between amino acid toxin gene of *Aspregillus* isolates strain for produced antibodies. Where the database of *Aspregillus* genomes provides a comprehensive resource of genomics data information's an important plant and human pathogenic fungal genus *Aspregillus*. It's given useful for discovery of genes encoding industrial enzymes, and antibiotics which may control in aflatoxin food contaminations **(Spröte et al., 2009; Taha et al., 2012)**. AFs are a group of polyketide-derived furanocoumarins, with at least 16 structurally related toxins that have been characterized. These toxins are produced by a number of different *Aspergillus* species are primarily produced by *Aspergillus flavus* and *Aspergillus parasiticus* **(Geiser et al., 2007; Ito et al., 2001)**. There are four major AFs (AFB1, AFB2, AFG1, AFG2) all of which occur naturally **(Abbas et al., 2010)**. AFB1 is the most commonly occurring of the mold producing compounds **(Abdulkadar et al., 2004)**. AFB1 has been included in category 1A of active carcinogenic compound **(Abou-zeid et al., 1997; Abdel-Wahhab et al., 2006)**. Factors influencing the presence of mycotoxins in foods or feeds include environmental conditions related to storage that can be controlled **(Park et al., 2005)**. So, in this study, we have hypothesized that mycotoxins effects in human populations year to year because other factors as the fungal strain specificity, strain variation, and instability of toxigenic properties are more difficult to control **(El-Manzalawy et al., 2008a; El-Manzalawy et al., 2008b)**. However, by the articulate the molecular identification and characterization of mycotoxins, can be control in mycotoxins effects. In this study our aim advocate to using molecular detection and bioinformatics characterization for study the properties of protein toxin gene of aflatoxins in main consumer grains as rice and corn. Many human diseases occurring in Japan and other Asian countries were attributed to mycotoxins after consumption of mold-damaged rice **(Taligoola et al., 2011)**. Unfortunately, enactment of stringent rules for mycotoxin control in food is not always the best solution **(Samina, 2015)**. The impact of mycotoxin standards is more drastic for the population of developing countries **(Pasquali et al., 2016; Yassin et al., 2010)**.

Scientific hypothesis

Therefore, the aim of this study was to determine the *Aspergillus* species by the molecular identification of toxigenic mycotoxin profiles of those species that are naturally occurring in contaminating corn and rice seeds (as the main crops imported in Saudi Arabia) and protein structural analysis depicted from the gene(s) responsible for toxin biosynthesis. Which can be used as screening test for cost-effective control of mycotoxin and their products. We have hypothesized that by study the molecular characterizations and bioinformatics properties of Aflatoxins could in future be able to produce vaccine for species of *Aspergillus* genera which have higher prevalence rate in development countries **(Bhatnagar et al. 2003; Pasquali et al. 2016)**.

MATERIAL AND METHODOLOGY

Grains samples and isolation of mycotoxigenic *Aspergillus* species

One hundred fifty grains corn (yellow and red grains) and rice were collected from different area of Saudi Arabia (Riyadh, Hail, Qasim, Asir,Tabuk, Jizan, Jouf, Jeddah and Dammam), where collected from storage markets and houses. The collected grains were randomly and its weight between 0.5 – 1 kg of each grain in cleans and dries packaging. Agar plate and blotter tests were used to isolate *Aspergillus* sp. as described by **Neergaard (1977)**. Grains were divided into two groups, the first group was disinfected with sodium hypochlorite 1% for 2 min and the second group was non-disinfected. All grains were washed several times by sterilized water, and then dried between sterilized filter papers. The half of each group was plated on potato dextrose agar (PDA) (Sigma-Aldrich, USA). All dishes were incubated for 5 – 7 days at 25 °C. All isolation process under sterilized conditions to prevent any contamination of grain.

Purification and identification of *Aspergillus* species

Aspregillus species were initially identified to species based on the morphological characteristics **(Leslie, Summerell and Bullock, 2006)** of the macroconidia, microconidia and general mycelium presentation from a single spore isolate grown for 7 – 10 days on SNA with an Olympus BH-2 (Olympus America, New York) light microscope. Potato Dextrose Agar (PDA) was used to identify colony pigment characteristics of aerial mycelium on the agar **(Leslie, Summerell and Bullock, 2006)**.

Carnation Leaf Agar (CLA) (bio-WORLD, USA) was used to identify macroconidia, chlamydospores and the presentation of aerial mycelium single colony was transferred and purified by hypha tip technique onto PDA medium in the presence of streptomycin (50 $mg.ml^{-1}$). The developing fungi were prepared for molecular identification using primers specific for the *Aspergillus flavus AFLR (aflR)* toxin gene. All conditions of isolation and purification of mycotoxins were performed under sterilization for prevent any external agent of seeds pollutions.

Molecular identification of *Aspergillus flavus AFLR (aflR)* toxin gene

Isolation of DNA genome

The mycelium mass of *Aspergillus* species isolates grown on PDA broth medium was harvested by centrifugation at 6000 rpm for 10 min. The pellets were washed twice by PBS buffer and stored at 200 °C. Total DNA of the three isolates was isolated using lysozyme – dodecyl sulfate lysis method as described by **Leach et. al. (1990)**.

Amplification and purification of Aspergillus flavus AFLR (aflR) gene

Specific PCR reactions were conducted to assess the presence of *AFLR (aflR)* gene. The primers used as described by **Cary et al. (2000)** were: Omtl-F (*aflR*) (5′-GCCTTGCAAACACACTTTCA-3′); Omtl-R 5′-AGTTGTTGAACGCCCCAGT3′) and optimal annealing (Tm = 55 °C). The PCR amplification conditions included initial denaturation at 94 °C for 5 min then 35 cycles at 94 °C for 30 s, 55 °C for 60 s followed by extension step at 72 °C for 90 s. and a final extension at 72 °C for 7 min. The amplification reaction was performed by thermal cycler (Applied Biosystems, USA). Purification of PCR product was detected by electrophoresis (PNU, Faculty of science, Research center) using agarose 1.5% in 1x TAE buffer and staining with ethidium bromide (Qiagen, Berlin, Germany) **(Sambrook et al., 1989)**. The resultant fragment of *Aspergillus flavus AFLR (aflR)* toxin gene was excised from the gel and purified using a QIA quick gel extraction kit (Qiagen, Berlin, Germany).

DNA sequencing

The purified PCR products were prepared for Sanger sequencing technology using DNA sequencer technique (Sigma, central lab, PNU, KSA). DNA sequences of *Aspergillus flavus* isolates were aligned using Bio Edit software version 7 (www. Mbio-NCUs. Edu/bio. Edit) and were compared of the often accessions of *Aspergillys* sp. available in the NCBI data base using BIASI- algorithm to identify closely related sequences (http/WWW.NCbI.Nih.Gov). Dendrograms were constructed by using unweighted pair Group method with Arithmetic (UPGMA) on Gen bank.

Epitope prediction and antigenicity

The primary amino acids sequence of the *Aspergillus flavus AFLR (aflR)* toxin gene protein was evaluated from the corresponding nucleotide sequence using MEGA 6.0 software. The linear B-cell epitopes in the primary amino acid sequence of the coat protein was performed using BCPREDS server with default parameters (http://ailab.cs.iastate.edu/bcpreds/) which implements a support vector machine (SVM) and the subsequence kernel method **(El-Manzalawy et al., 2008a)**. Flexible length linear B-cell epitopes were predicted using FBCP red **(El-Manzalawy et al., 2008b)** method with a specificity cut-off; 75%. The antigenicity of each amino acid residue in the primary protein sequence was determined using a semi-empirical method **(Kolaskar and Tongaonkar, 1990)** which makes use of physicochemical properties of each amino acid and their frequencies of occurrence in experimentally known segmental epitopes.

RESULTS AND DISCUSSION

Three *Aspergillus* isolates from tested grains by PDA method was purified by single spore and hypha tip on PDA slant medium. The *Aspergillus* isolates were selected for molecular identification using *Aspergillus flavus AFLR (aflR)* toxin gene sequencing. Three *Aspergillus* isolates represented grains from yellow corn, red corn and white rice and designated as A. *flavus* _ YC; *A. flavus* _ RC; *A. flavus* _ Rice respectively.

Molecular characters of toxin gene

Total DNA was extracted from *A. flavus* _ YC; *A. flavus* _ RC; *A. flavus* _ Rice isolates infected grains. *Aspergillus flavus AFLR (aflR)* toxin gene was amplified from isolated DNA of mycelium using PCR reaction mixture and specific primer sets. PCR amplicons were allowed for sequencing reaction through cycle sequencing method. The DNA amplicons returned as electropherogram files. Electropherogram showed distinct peaks for each base cell as well as high *Q* values for each cell. Sequences obtained for each primer for each isolate had sufficient overlap between them and used to form one continuous sequence (Coting). The nucleotide partial sequence of *Aspergillus flavus AFLR (aflR)* toxin gene in the three isolates was compared with published isolates on Gen Bank. The sequence homology revealed that the gene of interest *Aspergillus flavus AFLR (aflR)* toxin gene and the test fungal isolates was *Aspergillus flavus* isolates. A multiple sequence alignment was constructed using ClustalW software (GNU Lesser GPL) between the three studied isolates. The alignment showed many conserved regions in all sequences as well as distinguished the heterogeneity positions among the aligned sequences (Figure 1a, 1b, 1c). Phylogenetic analysis was performed by construction of phylogenetic tree using a neighbor joining method to unravel the relationships among all *Aspergillus flavus* isolates (Figure 2). The phylogenetic tree resulted in two clades in which *A. flavus* _ Rice (white rice isolate) and *A. flavus* _ RC (red corn isolate) were in the same cluster whilst *A. flavus* _ YC (yellow corn isolate) was separate in a different cluster (Figure 2). Thus, the molecular identification based on sequence homology of the *Aspergillus flavus AFLR (aflR)* toxin gene confirmed the identity and phylogeny of the studied three *Aspergillus flavus* isolates.

The epitope prediction analysis demonstrated that there were 1, 2, 3 and 4 epitopes whose score were equal 1 in *A. flavus* _ YC (yellow corn), B: *A. flavus* _ RC (red corn) and C: *A. flavus* _ Rice (white rice). Also, there were great

variations in the epitope sequences among the three isolates except in RLQEGGDDAAGIPA, SPPPPVETQGLGGD, RPSESLPSARSEQG and PAHNTYSTPHAHTQ were found to be common between all isolates. These residues with high frequencies of occurrences in antigenic determinants were highlighted (yellow) in the antigenicity profile (Figure 3). Figure (3) also show the variability in the positions and types of amino acid residues with high antigenic frequency.

Mycotoxin detection is a major problem in developing countries where contaminated food commodities may readily reach food stores and homes **(Bilodeau, 2011; Boutigny et al., 2012; Taha et al., 2017)**. The risk of contamination by mycotoxins is an important food safety concern for grains and other field crops **(Abdulkadar et. al., 2004; Mwanza et al., 2013)**. Humans are exposed to mycotoxins throughout their life time due to consumption of fungus-contaminated food products and many human diseases, especially carcinogenic, teratogenic, hepatic, and gastrointestinal ones, have been found linked with the ingestion of mycotoxin-contaminated products **(Fung and Clark, 2004; Shephard, 2008; Mwanza et al., 2013)**. Sufficient quantities of mycotoxins in food and feedstuff can adversely affect human and animal health **(Qiu and Shi, 2014)**. Environmental factors and host species have a strong impact on the occurrence of a specific chemotype and the incidence of *Aspergillus* species **(Bhatnagar et al., 2003)**. The distribution of *Aspergillus* species in maize is influenced by optimal climatic conditions, pathogenicity and competition between other fungi **(Bhatnagar et al., 2006)**. The type of environmental factor identified in the incidence of *Aspergillus* species as demonstrated in recent EU maize surveys **(Creepy, 2002)**. In those studies, the prevalence of species varied year-to-year and was believed to be associated with the differences in climatic conditions between years **(Caldas et al., 2002; Scauflaire et al., 2011)**. As was reported by **Covarelli et al. (2015)** the emergence of toxigenic fungi on small grains has a negative impact on the safety and quality of feed and food. in this study We isolate mycotoxins strains of *Aspergillus* sp from contaminated corn and rice grains by a genomic library through amplication mycotoxins structure genes *(aflR)* by polymerase chain reaction (PCR) and sequencing of amplicans this result was agree with **(Chen et al., 2002)**. Data clearly reveal that the PCR technique is efficient in distinguishing mycotoxins **(Bilodeau, 2011; de Souza et al., 2005; Taha et al., 2012; Allam et al., 2015)** from commonly inhabiting stored grains. We isolate *Aspergillus* sp. from both zellow and red corn which used in food and feed in human and animal; also isolated from long and short rice **(Niessen, 2007; Fox and Howlett, 2008)**. *Aspergillus* species being able to grow at moderate to high temperature **(Ehrlich et al., 2003)** and its responsible for spoilage of food commodities during transport and storage. In addition, reduction in nutritive value, insipidness and discoloration are other problems resulted from contamination of grains by *Aspergillus* **(Dean et al., 2012)**. Rapid and accurate identification of *Aspergillus* and/or their metabolites are mandatory for the implementation of preventive measures in the whole food production system as was reported by **Bok and Keller, (2004); Bhatnagar et al. (2003)** and **Dean et al. (2012)**. The molecular characterization of three *Aspergillus* sp. isolated from small grains (yellow corn, white rice and red corn) using the mycotoxins gene, aflatoxin *AFLR (aflR)* allowed for coupled identification and mycotoxins screening in the three *Aspergillus* isolates **(Bhatnagar et al., 2006)**. Mycotoxins-producing fungi were isolated from sorghum grains from Saudia Arabia before **(Mahmoud et al., 2013; Yassin et al., 2010)**. Following the molecular identification of *Aspergillus* sp. B-cell epitopes in the aflatoxin *AFLR (aflR)* gene were predicted. The characterization of B-cell epitopes using computational tools is highly advantageous for the synthesis of specific antibodies for rapid detection of microbial pathogens in their environments. The epitopes prediction saves labor and time for validation experiments. The identification of epitopes plays a crucial role in the vaccine design, immunodiagnostic testing and antibody production **(Sette and Fikes, 2003)**. In this study, BCPREDS server was used to predict epitopes found in the primary amino acids sequence of aflatoxin *AFLR (aflR)* protein. BCPREDS proved high efficiency to predict linear B-cell epitopes in SARS-CoV S protein **(El-Manzalawy et al., 2008a; El-Manzalawy et al., 2008b)**. There was variability in the sequence and numbers of epitopes among the three toxin proteins analyzed. Here, a fixed length of epitopes (14 residues) was observed. The epitope prediction analysis demonstrated that there were 1, 2, 3 and 4 epitopes whose score were equal 1 in *A. flavus* _ YC; *A. flavus* _ RC; *A. flavus* _ Rice respectively. In this study, there were great dissimilarity in the epitope sequences among the three isolates. But we found that there some epitope sequences were common between all isolates in RLQEGGDDAAGIPA, SPPPPVETQGLGGD, RPSESLPSARSEQG and PAHNTYSTPHAHTQ. This result suggesting its exploitation for design of a specific antibody to be used for rapid detection of different *Aspergillus* species in small grains **(Ehrlich et al., 2003; Degola et al., 2007)**. The highly frequent residues with high antigenicity profiles such as valine, leucine, isoleucine, aspartic acid, glutamine and glutamic acid are mostly hydrophobic **(Duan et al., 2007)**. The occurrence of hydrophobic residues in epitopes is frequent and do have a hierarchy signature **(Zhang, 2002; Aftabuddin and Kundu, 2007; Suga and Galel, 2007; Scauflaire et al., 2011)**. Epitope prediction has many implications in pathogen detection and differentiation applications. The consideration of occurrence of *Aspergillus* sp. on small grains is important in risk assessment of mycotoxins and setting up preventive measures proactively. The main problems concentrated in high risk outbreaks of aflatoxicosis have been reported in different countries all over the world; that because the widespread of aflatoxin contamination especially in developing countries **(Pitt 2000a; Pitt 2000b; Kovacs, 2004)**. No doubt, that the safety control in food and feed processing should be by prevention of mycotoxin contamination in agriculture by used as simple and rapid screening tests for cost-effective control of food diseases by production of vaccines **(Sette and Fikes, 2003; Probst et al., 2014; Mwanza et al., 2013; Allam et al., 2015)**.

CONCLUSION

A best strategy to control mycotoxins is only by prevention, because most mycotoxins are chemically stable, so they remain unaffected during storage and processing. For this reason, we believed that by using a highly sensitivity and selectivity methods as molecular identification and bioinformatics characterizations of protein toxic gene for mycotoxins gives chance for production of antibody against its toxicity. This paper was show that molecular identification in *Aspergillus flavus* in three isolates in small grains (rice and corn) with the epitope prediction analysis demonstrated that there were great differentiations in the epitope sequences among the three isolates except in four position (as described above) were found to be common between all isolates. This work articulates that the molecular identification and characterization of three *A. flavus* using *Aspergillus flavus AFLR (aflR)* toxin gene and the unique antigenic determinants that could be used for design of a broad-spectrum antibody for rapid detection of *A. flavus* in foods and feeds that conducive to control in aflatoxin levels and cover prevention of mycotoxins.

SENSORY PROFILE OF PARENICA CHEESE VARIETIES MADE FROM PASTEURIZED COW'S MILK

Boris Semjon, Jana Maľová, Tatiana Vataščinová, Pavel Maľa

ABSTRACT
Parenica is a steamed, lightly smoked or unsmoked cheese wounded into a roll made from pasteurized cow's milk, with characteristic pronounced fibrous structure of curd. The aim of this work was to set up the sensory profile of smoked and unsmoked parenica cheese varieties made from pasteurized cow's milk and changes in sensory descriptors during 14 days of storage period at the temperature of 4 ±2 °C. Descriptive analysis was carried out by 18 trained assessors, who used a vocabulary of 26 terms to quantitatively describe appearance, aroma, consistency and taste of the experimental samples and also these overall sensory parameters with acceptability. Assessors evaluated the intensity of each descriptor by assigning the score on a 10 points linear scale. Analysis of variance found significant differences between cheese varieties (p <0.05) and the effect of storage period (p <0.05) on sensory quality of experimental parenica cheese varieties. The analysis showed that each sample group in observed representative sensory attributes was significantly different (p <0.05). Multiple factorial analysis showed in parenica cheese samples three selected components that explain more than 69% of the total variation in the dataset at the level of statistical significance p <0.05.

Keywords: cheese; sensory profile; parenica; storage; statistics

INTRODUCTION
The pasta filata cheese is a diverse group of cheeses, which originated mainly in the northern Mediterranean, in countries such as Italy, Greece, the Balkans, Turkey and Eastern Europe **(Zimanová et al., 2016)**.

Parenica is a steamed, lightly smoked or unsmoked cheese wounded into a roll made from pasteurized cow's milk. It is known for the characteristic pronounced fibrous structure of curd. The roll is ussualy bounded with cheese string.

In the last years, there has been a growing attention towards food quality and food safety, as well as an increasing demand for "natural" products, especially those enjoying a 'recognition of quality' status and recognition of 'geographical indications and traditional specialties' (PDO, PGI and TSG) conferred by the European Community to promote and protect the names of quality agricultural products and foodstuffs **(Todaro et al., 2017)**.

Steamed cheese production has a long tradition in Slovakia, although originally made from sheep's milk **(Čuboň et al., 2015)**. However, similar dairy product "Slovenská parenica" cheese obtained the "Protected Geographic Indication" designation (PGI) in 2008, but according the "Methods of Production" described in application for registration of "Slovenské parenica", it could be made from fresh raw, unprocessed sheep's milk or a mixture with fresh raw, unprocessed cow's milk, containing at least 50% sheep's milk **(Council Regulation (EC) No. 510/2006)**.

In comparison to Cheddar and Dutch-type cheeses, pasta-filata cheeses represent a special case, in terms of proteolytic pattern **(Salek et al., 2017)**. The pasta filata cheeses varied in sensory quality, which depends on the quality of milk and processing technology (including the process of pasteurisaztion). These cheeses could be made according the following methods: 1. traditional process of making steamed cheese, 2. a method of making steamed cheese using direct acidification of the milk and continuous processing **(Zimanová et al., 2016)**.

Recent studies aimed to the traditional pasta filata, stretched or steamed cheese making technology have been published **(Di Grigoli et al., 2015; Scatassa et al., 2015; Sulejmani and Hayaloglu, 2016; Cuffia et al., 2017; Paz et al., 2017; Salek et al., 2017; Todaro et al., 2017)**. However, many of them deal with the physicochemical and microbial quality of the pasta filata cheeses.

Cheese is an irreplaceable dairy product in human nutrition and it could be consumed fresh or ripened **(Ozcan et al., 2011)**. Parenica cheese could be lightly smoked during the processing of curd. Smoking is technique of food preservation, but it is also used to enhance sensory properties, taste, color and texture **(Esposito et al., 2015)**. The special taste and textural parameters of traditional

cheese specialties could make them popular **(Farahani, Ezzatpanah and Abbasi, 2014)**.

Generally, smoking of high protein foods enrich the food with aromatic components that provide organoleptic properties as color and flavour to meals and have bacteriostatic and antioxidant effect **(Amran and Abbas, 2011)**. Because of that it is very important to study the qualitative sensory parameters that define the product in order to determine its acceptability to consumers **(Semjon et al., 2018)**. The sensory quality of a product like parenica cheese can be also evaluated using quantitative descriptive analysis.

The aim of this study was to describe sensory profile of smoked and unsmoked parenica cheese manufactured according to the traditional method of production during storage period.

Scientific hypothesis

Hypothesis 1: There exist differences in evaluation of sensory overall attributes (appearance, aroma, consistency, taste and acceptability) in parenica cheese varieties before and after storage of 14 days at 4 ±2 °C.

Hypothesis 2: Sensory profile of parenica cheese varieties changes during storage for 14 days at 4 ±2 °C.

Hypothesis 3: Statistically significant correlations exists between individual sensory descriptors and overall sensory parameters in parenica cheese varieties.

Hypothesis 4: A dissimilarity in sensory parameters exist between each sample groups (smoked/unsmoked parenica cheese samples and samples before/after storage).

MATERIAL AND METHODOLOGY

Processing of experimental cheese

Raw milk was standardised to fat content that final parenica cheese has a minimum fat in dry matter content 30%. Subsequently, raw milk was pasteurised before curdling at a temperature of 72 °C for 20 seconds. The milk was heated to the temperature 30 ±2 °C and inoculated with a fermenting agent composed of mesophilic lactic acid bacteria (*Lactococcus lactis* ssp. *lactis, Lactococcus lactis* ssp. *cremoris*). After adding the rennet was milk curdled at a temperature 29 – 32 °C. Curdled cheese mass was mixed using a cheese harp to produce 1 cm pieces. The cheese mass was left to settle down before being moulded into a lump. The lump was then lifted out of the whey with a cheese cloth and left to drain. After 8 hours of draining and solidifing was the lump placed on a rustproof shelf to ferment. Fermentation continued approximately 24 hours at a temperature 20 ±2 °C to achieve a pH level for the cheese about 5.2. Then the lump cheese was cut into smaller pieces and placed in a water bath (temperature of 60 – 70 °C). When the cheese curd become more plastic, it was removed from the bath and excess water was squeezed out. Subsequently it was streched and folded over several times and a cheese strips were formed by hand, so that they had a length of 1 – 2 m, a width of about 3 cm and a thickness 2 – 3 mm. The cheese strips were placed in a prepared cold saturated salt solution to cool down and after that they were squeezed out. Cheese strips were rolled up and bounded with a cheese strings made separately in water bath from the lump cheese. Then they were dried and a half of them were smoked in a smoking chamber. From a dairy plant to laboratory were the samples packed and transported at the temperature of 4 ±2 °C in plastic bags.

Sampling

To study the sensory profile and quality of parenica cheese were evaluated following sample groups (Figure 1):

- PU (unsmoked parenica cheese made from pasteurized cow's milk),
- PS (lightly smoked parenica cheese made from pasteurized cow's milk).

A total of 72 experimental parenica cheese samples were evaluated in this study. On the initial day of manufacture were from each group (PU, PS) randomly selected samples and divided into the following groups:

Figure 1 Experimentally made smoked and unsmoked parenica cheese varieties.

• the first group consisted of initial samples (n = 18) which were analyzed before storage period (BS),
• the second group contained samples (n = 18) that were placed in plastic bags to prevent desiccation but exposed to normal atmosphere conditions and stored for 14 days at the temperature of 4 ±2 °C (samples after storage – AS).

Plastic bags used in AS sample groups were made from polyethylene with thickness of 70 μm (G-PACK, LLC. Slovak Republic).

All experimental parenica cheese samples were produced in compliance with the traditional methods of production in a dairy plant according to the traditional processing procedures for parenica cheese according **Zimanová et al. (2016)** and modified method of production of "Slovenská parenica" PGI cheese **(Council Regulation (EC) No. 510/2006)**.

Sensory analysis

Samples were received from the dairy plant in plastic bucket containers and stored at 4 ±2 °C until use. The cheeses were portioned into 25 × 25 × 25 mm cubes with approximate weight of 25 g using a wire slicer, served in white plastic dishes and coded with three-digit random numbers. Samples were served at temperature of consumption 20 ±2 °C. Mineral water was provided for mouth rinsing.

Descriptive Analysis

The descriptive sensory evaluation was carried out in a standardized sensory laboratory **(ISO 8589, 2007)** built in the Institute of Postgraduate Education of Veterinary Medicine in Košice according to **Lawless and Heymann (2010)**. The sensory evaluation was performed by a panel from the staff of the University of Veterinary Medicine and Pharmacy in Košice. The group contained 18 panelists aged between 28 and 65. All the assessors were trained in the sensory analysis. Sensory profile was conducted according the General guidance for establishing a sensory profile **(ISO 13299, 2016)**.

Steps in establishing a sensory profile included following steps: establishing a sensory facility (design of test rooms), selection of products by trained experts, selection and traing assessors for the study purpose (selected assessors and recognition of odours), selection of descriptors suitable for the application (vocabulary, flavour profiles, identification of descriptors and texture profile), determination of the perception order of the attributes in the profile (evaluation using scales and magniture estmation), training the assessors to use the selected descriptors and scale (selected assessors and expert assessors), conduction the test (general guidance and flavour profiles) and reporting the results.

Subsequently, the panel evaluated experimental parenica samples before and after the 14th day by the same panel. Assessors evaluated the intensity of each descriptor by assigning the score on a 10 points linear scale (0 – absence of sensation and 10 – extremely intense). Each assessor evaluated also the overall sensory parameters (appearance, smell, consistency and taste) of the served samples.

Statisic analysis

Data analysis was carried out with R-statistics software **(R Core Team, 2017)**. The differences between experimental parenica cheese varieties and the effect of storage were set as the main factors. A two-way analysis of variance (ANOVA) and multiple factor analysis with "FactomineR" **(Sebastien, Josse and Husson, 2008)** and "factoextra" package **(Kassambara and Mundt, 2007)** were conducted and a confidence interval was set at 95%.

RESULTS AND DISCUSSION

Description terminology for the sensory attributes of both varieties of parenica cheese (PU and PS) was introduced during the training sessions of panellist. Descriptors for appearance (white, polished, fibrous, smoked), aroma (lactit, buthyric, yoghurt, nutty), consistency (firm, elastic, cohesive, gummy, juicy, sticky, formable, fibrous, supple greasy) and taste (sour, bitter, sweet, salty, lactic, creamy, spicy, smoked), were selected.

The results of overall sensory characteristics in PU experimental cheese samples during storage period are shown in Figure 2. We observed decreased trend in overall sensory characteristics after storage in PU samples at a statistical significance level $p < 0.05$ (Figure 2). Descriptive sensory analysis performed on unsmoked experimental parenica cheese samples demonstrated statistically significant influence of storage on the intensities of sensory descriptors of white appearance; descriptors of aroma: buthyric, yoghurt, nutty; descriptors of consistency: firm, cohesive, juicy, sticky, formable, fibrous, greasy; descriptors of taste: sweet, lactic, spicy and smoked ($p < 0.001$). In comparison to Cheddar and Dutch-type cheeses, pasta-filata cheeses represent a special case (in terms of proteolytic pattern). Particularly, the casein molecules ("fibres" or "strings") are arranged distinctly after the stretching process **(Costabel, Pauletti and Hynes, 2007)**.The cheese stretching temperature can dramatically influence the behavior of aroma compounds, colour and texture attributes **(Sulejmani and Hayaloglu, 2016).** The immersion of the cheese-curd in the hot liquid is a specific process enhancing its plasticization and stretching properties **(Salek et al., 2017)**.

At the initial stage of storage were found statistically significant differences between experimental cheese varieties in each sensory descriptor except fibrous appearance, nutty aroma, firm, elastic, cohesive, gummy, sticky, fibrous consistency, and sour and spicy taste.

Figure 3 shown that overall sensory paramters in PS samples significantly changed after storage period only in consistency, taste and acceptability ($p < 0.05$).

Descriptive sensory analysis performed on smoked experimental parenica cheese samples demonstrated statistically significant influence of storage on the intensities of sensory descriptors of white and smoked appearance; descriptors of aroma: buthyric and nutty; descriptors of consistency: elastic, cohesive, gummy, juicy, sticky, formable and greasy; descriptors of taste: sweet, lactic and smoked ($p < 0.001$). Consistency is an important viscoelastic property of the product **(Amiri et al., 2018)**. **Cais-Sokolińska, Pikul and Lasik (2012),** found that changes in texture parameters of cheeses as a result of smoking depended on their storage time. We agree with the autors that smoked cheese not subjected to storage was harder than unsmoked cheese. It could be caused by increased dry matter of smoked cheese, or by loss of water content, respectively.

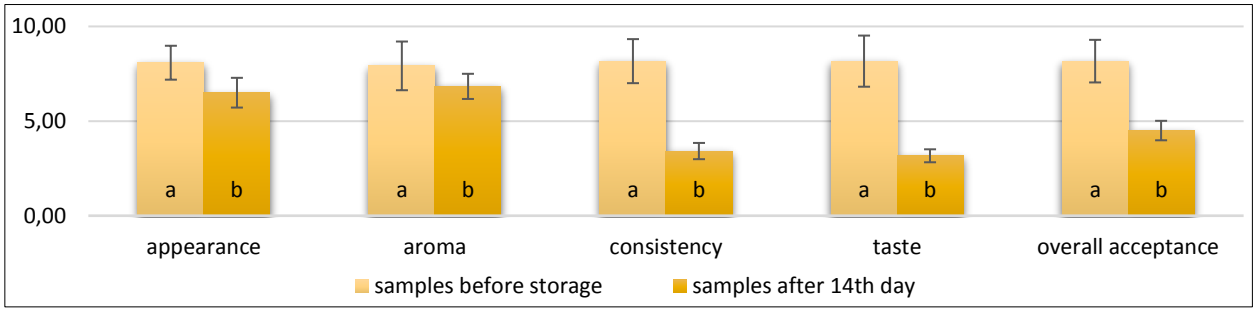

Figure 2 Overall sensory parameters of experimental unsmoked parenica cheese (PU) during storage period.

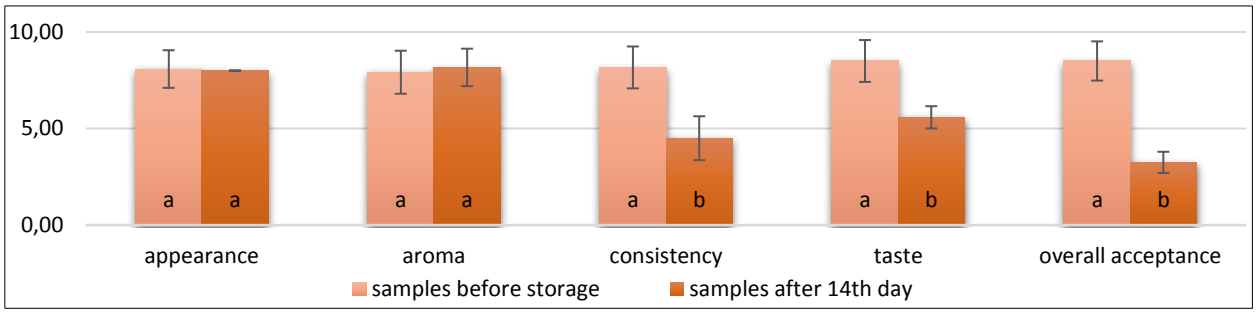

Figure 3 Overall sensory parameters of experimental smoked parenica cheese (PS) during storage period.

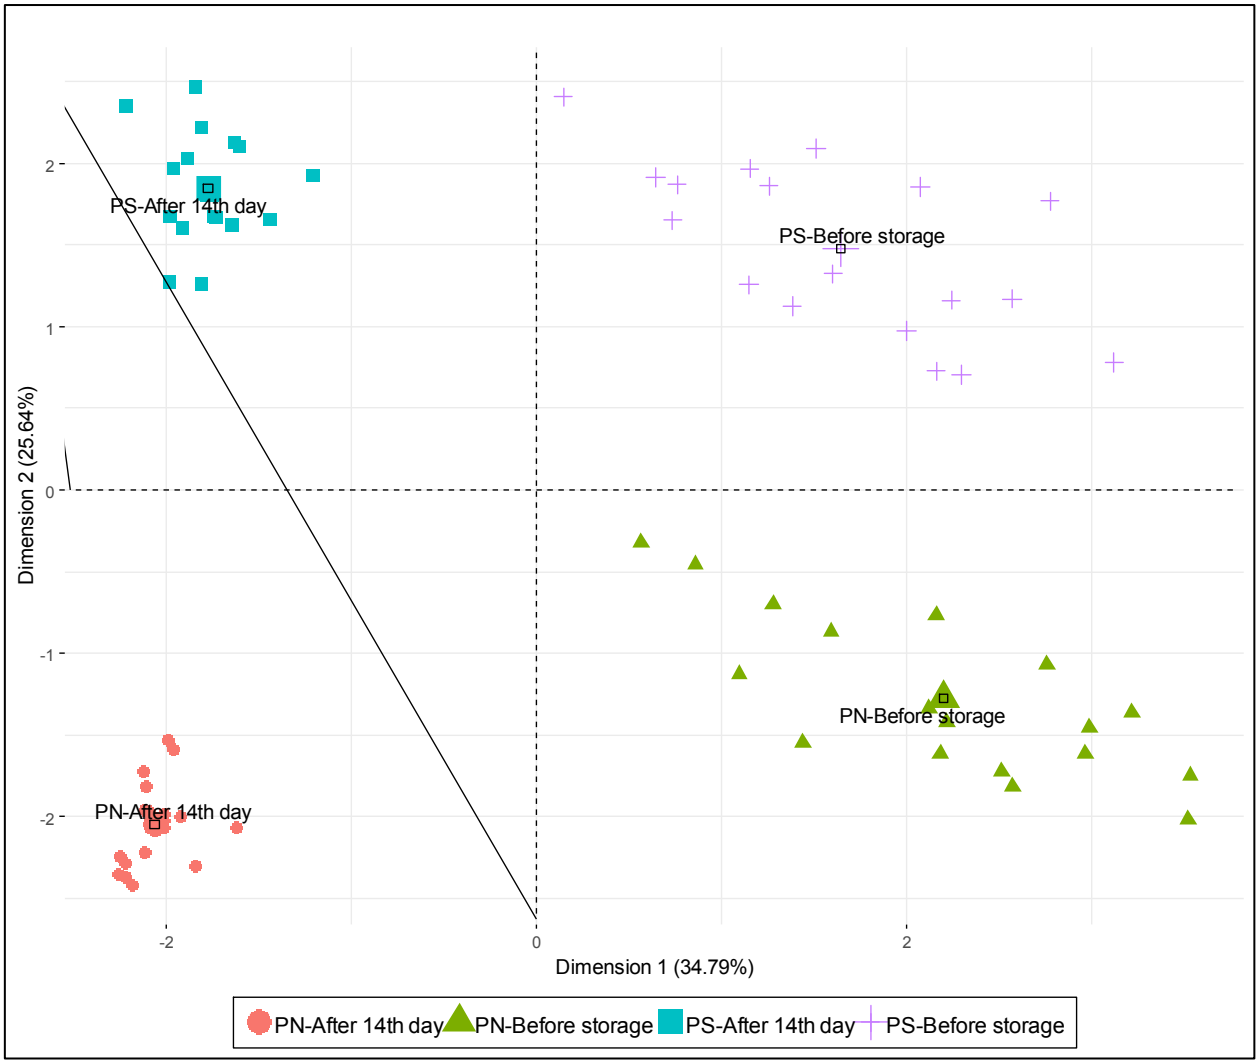

Figure 4 Multiple Factor Analysis plot of parenica cheese varieties individuals during storage.

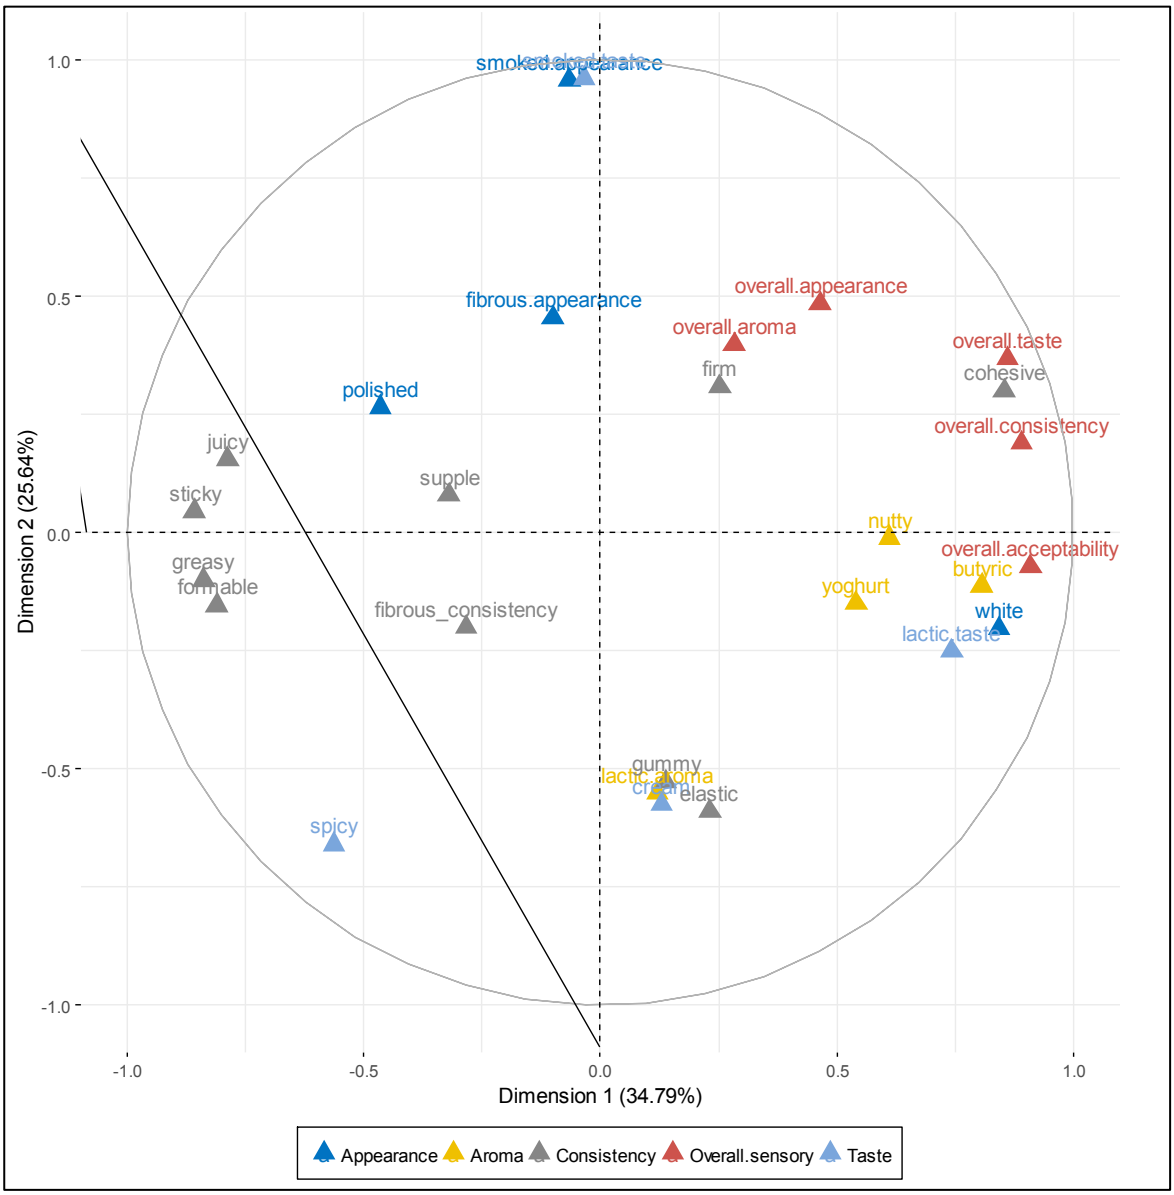

Figure 5 Quantitative variables of Multiple Factor Analysis used for evaluation of parenica cheese varieties during storage.

We observed statistical significant efect of storage on salty taste only in PU samples. Assessors evaluated salty taste in PU samples after storage with higher intensity. On the other hand, intensity of salty taste in PS samples was at the same level before and after storage period of 14 days. We agree with the authors **Todaro et al. (2017)** and **Gaucheron et al. (1999)** who found a slightly increase of salt during 14 days of storage of stretched cheese, and moreover, these authors established a migration of sodium, potassium and chloride ions from the outer layer versus the core of cheese which ended after 5 days.

In our study, multiple factorial analysis (MFA) method was applied to the sensory data, whereas were analysed results of overall sensory characteristics and sensory profile of two varieties of parenica cheese samples during storage period of 14 days. The analysis extracted the most significant variables with a minimum loss of information. Kaiser's criterion (eigenvalue >1) was applied to determine the number of final factors from the initial ones **(Chapman, Lawless and Boor, 2001)**.

The results of MFA showed in parenica cheese samples three selected components that explain more than 69% of the total variation in the dataset. The first dimension (Dim1) explains 34.79% of variation, second dimension (Dim2) 25.64% and third dimension (Dim3) 8.39%.

The highest contribution of the analysed data in Dim1 was related to the effect of storage period (21.93%, r = 0.95) and overall sensory parameters (18.19%, r = 0.89). The highest contribution in Dim 1 included following overall sensory parameters: acceptability (r = 0.91), consistency (r = 0.89), taste (r = 0.86), appearance (r = 0.46) and aroma (r = 0.28), which correlated at statistically significant level (p <0.05).

The first two dimensions explained a total of 60.43% of variance (Figure 4). The highest effect of variety on parenica cheese characteristics was in Dim2 (30.33%, r = 0.84), followed by the descriptors of taste (30.48%, r = 0.52) and descriptors of appearance (21.59%, r = 0.89). In Dim 2 were significantly correlated following descriptors of taste smoked (r = 0.96), lactic (r = -0.25), creamy (r = -0.59) ans spicy (r = -0.66) and following descriptors of appearance: smoked (r = 0.96), fibrous (r = 0.45) and

polished (r = 0.26), at statistically significant level (p <0.05) (Figure 5).

Descriptors of consistency contribute mainly to Dim3 with 25.07% (r = 0.67), followed by the descriptor of aroma 24.64% (r = 0.57). In Dim3 were correlated following descriptors of consistency: supple (r = 0.65), firm (r = 0.54), greasy (r = 0.34), formable (r = 0.32), fibrous (r = 0.28) and juicy (r = 0.24).

MFA analysis showed that each sample group was different in observed sensory characteristics, according to measured attributes data (p <0.05). Figure 4 shown that experimental cheese samples groups were not plotted closely to each other. We agree with the authors **Smit et al. (2005)** that flavor of cheese improved with storage days because during ripening the metabolic processes are responsible for the basic flavor and texture changes. However, further study of individual sensory dexriptors, particularly their intensities, could provide methods such as measurement of intensity in time **(Pavelková, Flimelová and Vietoris, 2012)**.

CONCLUSION

In this experiment we set up the sensory profile of smoked and unsmoked parenica cheese varieties made from pasteurized cow's milk. Panelist evaluate each sensory descriptor of two parenica cheese varieties before and after 14 days of storage period. Sensory profile of parenica cheese varieties changed during storage (p <0.05). We observed decreased trend in overall sensory characteristics after storage in unsmoked parenica cheese samples, but in smoked variety only in consistency taste and overall acceptability (p <0.05).

HEALTHY EATING INDEX AND DIFFERENT FRUIT DIETARY HABITS IN SLOVAK ADULT FEMALE

Katarína Fatrcová-Šramková, Marianna Schwarzová, Tűnde Juríková

ABSTRACT

The healthy index is a tool for evaluation of nutrition recommendation aimed at prevention of chronic diseases. A lot of studies have been devoted to HEI of different aged groups of people but dates about Slovak population have been still missed. The goal of the study was to evaluate the Healthy Eating Index (HEI) in nutrition of adult female, determine their components in relation of parameters of anthropometry and body composition. Secondly, the research work was also aimed at the comparison of partial score HEI among groups of female with different fruit intake. Daily nutrition was evaluated by 24 hours dietary recalls. In set of female (average age 31.1 ±9.1 years) the average HEI index reached up 53.0 ±8.8 points in accord with medium degree of diet, it means dietary improvement has been highly recommended. In respect of all assayed components of index the best results achieved the variety of diet (8.8 ±1.3 points) and the worst the natrium intake (0.7 ±2.0 points). The average score for the individual components pointed to neccesary of increase in the grain intake and vegetable, on the other hand the intake of cholesterol, saturated fats and especially natrium should be decreased. The differences between groups with various intake of fruit (with recommended intake and insufficient intake) in the rest 9 components have not been proved as significant. The occurrence of risk values of body index, body fats determined by bioelectric impedance and android risk based on circumference of hips can not be considered between groups as significant. Average HEI has been in significance correlation with age ($r = 0.240$; $p < 0.05$), circumference of hips ($r = 0.2312$; $p < 0.05$) and body weight $r = 0.1748$; $p < 0.05$). Future studies have been needed to evaluate diet according to the HEI in different groups of population in Slovakia.

Keywords: diet quality; Healthy Eating Index; fruit intake; anthropometric parameters; Slovak female

INTRODUCTION

Nutritional factors and factors of life style have been significantly contributed to prevalence of chronic diseases. Composition of diet has been influenced by different socially-economic aspects and preferences of consumers **(MH SR, 2001)**.

Healthy Eating Index (HEI) has been implemented as measure of food quality of USDA (United States Department of Agriculture). USDA has been aimed at improvement of health with the diet recommendations for American population **(Guo et al., 2004)**. It has been introduced as a key tool to evaluate the extent to which Americans are following the dietary recommendations for safety and healthy food **(Willett and Skerrett, 2005)**. HEI represents the first and very simple model for generalization and monitoring of changes in dietary habits. Index expresses and measures how well a set of foods aligns with nutrition recommendations, dietary patterns and Food Guide Pyramid **(Variyam et al., 1998; Edelstein, 2011)**. HEI give general image about type and quantity of diet of individuals and their compliance with the specific nutrition recommendations for nutrients and food groups **(Gibson, 2005)**.

The HEI was originally developed in 1995 (HEI-1995) utilized dates from 1989 up to 1990 **(USDA, 1995)**. Dietary intakes of individuals were collected on 2 nonconsecutive days and using the 24-hour dietary recall method including 7500 respondents aged 2 years and older. In this approach it was necessary to separate probands into 3 energetic groups **(Dixon, 2008)**. Subsequently, the index has been periodically evaluated **(Bowman et al., 1998; Basiotis et al., 2002)**. Serving definitions based on Food Guide Pyramid **(USDA, 1997)** for different levels of energetic intake were reflected consistency with the serving definitions among people with different Recommended Energy Allowances as we can see at Table 2. The upper limits for intake of total fats, saturated fats, cholesterol and natrium were determined on the base of consultations with diet and nutrition experts and research of distribution intake of components

(Basiotis et al., 2002). Diet recommendations for American population, Food Guide Pyramid and National Research Council emphasized the importance of diet variety **(National Research Council, 1989a; USDA, 1996; Dietary Guidelines Advisory Committee, 2000)**. Unfortunatelly, nowdays there has not been accepted pattern how to quantify the measure of diet variety. HEI was utilized for evaluation of food quality within NHANES III with dates of reports 1999 – 2001. The results showed that only 10% nutrition of american population could be considered as good, 16% bad and the rest of american nutrition required to be improved. Subgroups of american population also displayed the lower quality of nutrition, especially men 15 – 18 years old, groups with lower incomes, non-hispanic Americans of African origin, persons with lower education. For 1999 – 2000 has been established the average HEI score for american population 63.8 **(Basiotis et al., 2002)**. In the same way **Dubois et al. (2000)** applicated HEI for evaluation of nutrition quality based on Canadian Nutrition Report, Quebec, 1990. HEI has been improved taken into account the Canadian Nutrition Recommendations from 1990 **(Health Canada, 1990)**. It has been also adapted in some countries, considering the local dietary habits **(Fernandes et al., 2015)**. HEI has been evaluated also in relation to plasmatic biomarkers. **Hann et al. (2001)** pointed to the fact that nutrition with high score of HEI has been in positive correlation with plasmatic concentration of carotenoids and ascorbic acid. It has been indicated that choice of food based on food pyramid leaded into healthy nutrition. On the other hand, the increased level of biomarkers has not been uniquely indicated decrease incidence of diseases.

There has been lack of evidence between food intake, biomarkers and diseases. It has been confirmed only a weak correlation between HEI and risk of chronic diseases (cardiovascular and oncological) **(McCullough et al., 2000a; McCullough et al., 2000b)**. Development of new nutrition recommendations for american population in 2005 was motivation for revision HEI (HEI-2005). Standards for food groups have been based on new recommendation of food pyramid („My Pyramid“) **(Britten et al., 2006)**. HEI-2005 has been standardized and can be used in nutrition monitoring, intervention and research as well. It consists of 12 components **(Guenther et al., 2006)**. **Guenther et al. (2008)** found out that score in 9 – 12 components was lower in group of smokers in comparison with non-smokers.

The study of HEI is requisite and necessary for the Slovak population as well **(Fatrcová-Šramková, 2010; Fatrcová-Šramková, 2013)**. The aim of study was to evaluate the Healthy Eating Index (HEI) in nutrition of adult female, to determine their components in relation of parameters of anthropometry and body composition. The research work was also aimed at the comparison of partial score HEI among groups of female with different fruit intake.

Scientific hypothesis

The average HEI of the set of female has been minimally in the medium level according to descriptors (it has not been in accord with the worst level “bad nutrition”).

Group of female with the recommended consumption of fruit achieved the better evaluation in HEI, anthropometric parameters and body composition than female with insufficient intake of fruit.

MATERIAL AND METHODOLOGY

Characteristic of the research sample

The set of analyses was performed using dates from the group of adult female (n = 165). The average age reached up 31.1 ±9.1 (range 21.0 – 49.4 years, median 38.9). The age characteristics and distribution of research sample is presented at Table 1.

Evaluation of the Healthy Eating Index (HEI)

It has been used 24 hour dietary recalls and 3 day – day food intake records. 24 hours dietary recalls were processed by nutrition software Alimenta version 4.3e originated from Food Research Institute, utilised The Slovak Food Composition Data Bank.

Daily consumption of food has been evaluated by 10 components of index HEI (Healthy Eating Index) (Table 1). All components from HEI-1995 have been taken into account. Ten components represented the different aspects of healthy nutrition. Healthy Eating Index from 1995 consists of 10 components (Table 2). The components 1 – 5 (the first partial index) deal with adequency of food composition of individuals reflected recommendations of Food Guide Pyramid from 1992. They measured the compliance of nutrition of individuals with recommendation for 5 basic food groups of Food Guide Pyramid as: cereals (bread, grain, rice and pasta), fruit, vegetable, milk (milk, youghurt and cheese), meat and its substitutions (poultry, fish, legumes, eggs and nuts). The second partial index (components 6 – 10) devotes the part of food that should be intaken minimally: total fats, saturated fats, cholesterol and natrium. The final component examines variety in person´s diet. The each component of index can reach maximum score 10 and minimum 0 **(Kennedy et al., 1995; Basiotis et al., 2002; Guenther et al., 2008; Guenther et al, 2013)**. Food Guide Pyramid expresses the diet recommendations for Americans (Dietary Guidelines for Americaners) **(Dietary Guidelines Advisory Committee, 2000)**.

The recommended servings of food lead to healthy diet. The recommended servings in pyramid have been in accord with energy intake for individuals **(National Research Council, 1989b)**. Table 2 showed recommended servings for different groups of people in relation to age, gender and for energy level 1600 kcal, 2200 kcal and 2800 kcal, i.e. 6700 kJ, 9200 kJ and 11700 kJ **(USDA, 1997)**. According to Food Guide Pyramide is the recommended servings per day (Table 2) for female aged 11 – 24 years and as well 25 – 50 years (energy intake 2200 kcal, i.e. 9200 kJ) for grains 9 servings, vegetable 4 servings, fruit 3 servings, milk 2 servings, meat 2.4 servings **(USDA, 1996)**.

Each component within HEI (Table 1 and Table 2) was scored by minimal point 0 (in case of insufficient nutrition) up to 10 points (in case of sufficient nutrition). High component score indicates intake close to recommended range or amount, low component score indicates less compliance with recommended range or amount. The maximum overall score for the 10 combined

Table 1 Distribution of female in relation to age (%).

Age	Consumption of fruit			
	Recommended Group A	**Insufficient** Group B	**Together** Group A +B	***p*-value**
25 – 30 years	32.2	33.3	32.7	**0.998**
31 – 35 years	6.9	15.4	10.9	**0.384**
36 – 40 years	12.6	12.8	12.7	**0.999**
41 – 45 years	12.6	9.0	10.9	**0.903**
46 – 50 years	35.6	29.5	32.7	**0.871**

Note: group A – recommended consumption of fruit (higher than score 10 point); group B – insufficient consumption of fruit (lower than score 10 point); $p \geq 0.05$.

Table 2 HEI (Healthy Eating Index) **(Basiotis et al., 2002)**.

Parameters	**Score ranges**[a] (points)	Criteria for Maximum Score of 10 points	Criteria for Minimum Score of 0 points
Consumption of different group of food			
1. grain	0 – 10	6 – 11 servings[b]	0 servings
2. vegetable	0 – 10	3 – 5 servings[b]	0 servings
3. fruit	0 – 10	2 – 4 servings[b]	0 servings
4.milk	0 – 10	2 – 3 servings[b]	0 servings
5. meat	0 – 10	2 – 3 servings[b]	0 servings
Nutrition recommendations			
6. total fat intake	0 – 10	30% or less energy from fat	45% or more energy from fat
7. saturated fat intake	0 – 10	Less than 10% energy from	15% or more energy from
8. cholesterol	0 – 10	saturated fat	saturated fat
9. natrium	0 – 10	300 mg or less	450 mg or more
10. food variety	0 – 10	2400 mg or less	4800 mg or more
		8 or more different items in a day	3 or fewer different items in a day

Note: [a] People with consumption or intakes between the maximum and minimum ranges or amounts were assigned scores proportionately. [b] Number of servings depends on Recommended Energy Allowance; see Table 3. All amounts are on a per day basis.

Table 3 The recommended food servings per day according to Food Guide Pyramid **(USDA, 1996; USDA, 1997)**.

Energy (kcal)	**Grain**	**Vegetable**	**Fruit**	**Milk**	**Meat**
1600	6	3	2	2	2
2200	9	4	3	2	2.4
2800	11	5	4	2	2.8

components is 100. Scores were calculated using the population ratio method. The calculation of HEI index was provided in accord with recommendations of **Kennedy et al. (1995); Dietary Guidelines Advisory Committee (2000); Basiotis et al. (2002); Guenther et al. (2008); Guenther et al. (2013)**.

For HEI evaluation the descriptors on the base of USDA recommendation were used **(Gibson, 2005)**. An HEI score over 80 implies a „good" diet, an HEI score between 51 and 80 implies a diet that „needs improvement", and an HEI score less than 51 implies a „poor" diet. Except for HEI score for all components we also aimed at partial score (for selected components). For partial score (evaluation of 5 parameters from 10) the adequate proportion of points (50% evaluation) was used. The following descriptors were utilised for evaluation of the partial score: „good diet" over 40 points, „need improvement" 25.5 – 40 points, „poor diet" less than 25.5 points.

In aspect of for evaluation of partial HEI adult female were separated according to quantitative intake of fruit. It has been established 2 groups of female. Group A („recommended fruit consumption) can be characterised by daily minimally consumption of fruit 3 servings. Group B („insufficient consumption of fruit") mean the low intake of fruit in amount less than 3 servings.

Evaluation of the body composition, anthropometry

It has been characterised and evaluated the anthropometric parameters, parameters of body composition: body weight (kg), height (cm), waist circumference (cm), hip circumference (cm), body fat (absolut in kg, relative in %), body mass index – BMI ($kg.m^{-2}$) as relation weight to height, and waist to hip ratio – WHR (index of centrality). BMI was evaluated according to criteria of **WHO (2018)**, index centrality according to **Kleinwächterová and Brázdová (2001)**. For determination of body composition the bioelectrical impedance analysis (BIA) by Bodystat Quadscan 4000 (Bodystat Ltd, Doubles, Isle of Man, UK) has been used.

Statisic analysis

Statistical evaluation was provided by Statistica.cz (verzia 10, StatSoft, Inc., Česká republika). The differences among groups were tested by one-way t-test and chi-squared test ($\chi 2$–test). Statistical significant

differences were stated as *p*-values ($p = 0.05$). Correlations were expressed by correlation coefficient r.

There has not been confirmed the significant differences in age distribution of female between group A and group B (Table 1).

RESULTS AND DISCUSSION

According to assayed scores the evaluation of components of HEI index has declined tendency in the following order: diet variety > total fat > fruit > milk > meat > grains > vegetable > cholesterol > saturated fats > natrium (Table 4). The highest score reached up the variety of diet (8.8 ±1.3 points). On the other hand, the lowest score had natrium (0.7 ±2.0 points) in exceeded daily intake. The biggest problem in nutrition of female was the daily recommended intake of natrium.

In respect of intaken food, nutrients and quantification of diet variety there has been proved statistically significant differences between real and recommended intake in case of all 10 components of HEI ($p < 0.001$, $p = 0$). Of the first 5 components of the HEI, the most favourable group was represented by fruit and fruit products (7.2 ±3.7 points). On the contrary, the most insufficient was the daily consumption of vegetable. Of the rest nutrition recommendations (components 6 – 9) the highest score achieved diet variety, the mostly insufficient was natrium intake.

Tangney et al. (2001) studied HEI index of elder people and found out that the lowest proportions of perfect scores occurred for grains, vegetables, milk and meat. The highest proportions with perfect scores occurred for total and saturated fat (as a percentage of energy), cholesterol and sodium intakes.

In the base of fruit component the set of female was divided into 2 groups (with recommended intake of fruit – group A and insufficient intake of fruit – group B). For more detailed comparative evaluation the set was dividing according to food group with the best score – fruit. There has been confirmed differences between group A of female meet recommended serving of fruit (minimally 3 servings) *versus* group B of female with insufficient fruit in the rest of 9 components of HEI as well (Table 4 and 5). In group A except for fruit consumption the best evaluation (from maximum 10 points) reached up variety of diet (8.9 ±1.2 points) and total fats (7.9 ±2.8 points) (Table 4). The same order was estimated also in group B: variety of diet 8.8 ±1.4 points and total fats 7.9 ±2.2 points. Similarly, the worst score in group A and B displayed natrium (1.0 ±2.3 points; 0.5 ±1.5 points). The daily natrium intake significantly exceeded the recommendation (group A 9071.1 ±4089.8 mg and group B 8897.2 ± 3999.0 mg). The daily recommended natrium intake represented 2400 mg and less (Table 5).

The insufficient intake of fruit regularly 5 times a day has been evaluated in research work of **Juríková et al. (2016)**. The majority of college students consumed fruit and vegetable only once a day. The vegetable as a source of natural antibiotics has been intaken only once a week as well **(Juríková et al., 2017)**.

It was also interesting observed not only intake of recommended dose of fruit but also vegetable as an important source of bioactive compounds (Table 6).

The results showed that 40% of respondents did not meet criteria for the recommended daily intake of fruit and vegetable, non respondents from group A and majority from group B (0% *versus* 84.6%). Only one of recommendations – fruit was covered by 47.3% of female in group A. There has been proved statistically significant differences between evaluated groups (75.9% *versus* 15.4%, $p = 0.000$). Generally, the recommendations for fruit and vegetable were taken into account in 12.7% female, minimally 1 recommendation (fruit/vegetable) had 60% of probands (all respondents of group A and 15.4% respondents of group B).

In case of fruit the maximum score (10 points) achieved 52.7% female (Table 7). The order of components in accord to maximum score was following: fruit > meat > milk > total fat > variety of diet > cholesterol > vegetable > grains > natrium > saturated fats. Generally, female did not meet the guidelines in parameters of nutrition in consumption of grains (96.4%), natrium intake (98.2%) and saturated fat (all respondents). Our results are in accord with the study of **Ervin (2008)** (56% of older female met the recommendation for diet variety). Similarly, **Shah et al. (2010)** reported that participants according to HEI 2005 consumed more than recommended amounts of sodium, saturated fats, and discretionary calories.

The assayed female groups were significantly differed in component fruit, the rest differences in components has not been proved as significant. The recommended daily intake of milk had more probands of group B (47.4%) *versus* group A (34.5%). On the contrary, the higher consumption of vegetable and total fats was higher in group A (24.1%; 42.5%) *versus* group B (15.4%; 37.2%).

Particularly it was determined the distribution of female in components of HEI at least 50% (score 5 points or more for the individual components) (Table 8). The groups were represented by female has not been covered recommendation of fruit intake (on 50% with score less than 5 points) (B group) and female has been covered at least 50% of recommendations with 5 points and more) (A group). The most significant differences between groups have been determined in consumption of fruit (in group A higher value by 52.6%) and milk (higher value by 14.3% in group B). Differences in consumption of vegetable represented only 5.8%, cholesterol 5.5% and total fats 4.6%. The results pointed to the fact that group B with lower consumption of fruit has achieved weeker results also in another components (in 6 components was determined score under 5 points). Group A displayed also better results in consumption of milk (by 14.3%), total fats (by 4.6%), cereals intake (by 2.8%) and meat (1%). On the other hand, in group B were more female with insufficient diet and score under 5 points in consumption of fruit (by 52.6%), vegetable (by 5.8%), cholesterol (by 5.5%), natrium (by 4.1%), saturated fat (by 0.6%) and diet variety (by 0.6%).

It was monitored the occurence of worst score with 0 points in case of cereals (0.6%), vegetable (16.4%), fruit (13.3%), milk (2.4%) and meat (12.1%) (Table 9). Extremely high proportion of fats (more than 45% of daily energy intake) had only 3.6% probands. The proportion of fats in energy intake must cover 30% (saturated fat acids 10%, monounsaturated fatty acids 10 – 12% and

Table 4 Score for components HEI (mean ±SD).

Components HEI (points)	**Consumption of fruit**		
	Recommended Group A	**Insufficient** Group B	**Together** Group A +B

Note: p <0.001.

polyunsaturated fatty acids 8 – 10%) **(Kajaba et al., 1999; MH SR, 1997; PHA SR, 2015)**. Limit maximally 30% of daily energy intake has been overlapped by majority of Europeans **(MH SR, 2001)**. The recommended energy value from saturated fats (max. 10%) was highly overlapped by 25% of probands (with values higher than 15% of saturated fat from energy intake).

In USA and Europe saturated fat acids represent 12 – 15% from total energy intake. On every 1% of energy intake in the form of saturated fatty acids has been increased level of LDL cholesterol in comparison with oleic acid by 2 $mg.dL^{-1}$ (0.025 $mmol.L^{-1}$) **(Grundy, 2003)**. The content of n-6 fatty acids should not be 4 – 10 higher in comparison with n-3 fatty acids. Oil originated from sea fish represents a very valuable source of eicosapentaenoic (EPA and docosahexaenoic acid (DHA) decreased the probalibility of trombosis in veins. Nutritionally fats and oils can be considered as healthy if the proportion of fatty acids has been approximate to mentioned relation **(MH SR, 2001)**.

In the set of assayed female was noticed overlapped intake of cholesterol (450 mg and more) among 60% of female with negative impact on incidence of cardiovascular diseases. The better results in cholesterol intake achieved **Ervin (2008)**, 72% of older adults met the guidelines for cholesterol. Human body is able to synthetize essential amount of cholesterol, its excessed intake increase the risk of cardiovascular diseases. It is a reason for recommendation of nutrition experts not consumed more than 300 mg cholesterol **(MH SR, 2001)**. On every 200 mg of intaken cholesterol it has been increased the concentration of serum LDL-cholesterol (LDL – low density lipoproteins) on average by 6 $mg.dL^{-1}$ (0.155 $mmol.L^{-1}$) **(Grundy, 2003)**. Saturated fatty acids increase, polyunsaturated fatty acids decrease the level of cholesterol **(MH SR, 2001)**.

The daily intake of natrium significantly overlapped the recommended dose reached up 4800 mg in case of (83.6%) probands. Female had minimally 0.5 serving from all food groups so diet variety represented the smallest problem in

Table 7 Distribution of female in the evaluated groups based on scores for componenents of HEI.

Components HEI (score)	Consumption of fruit			*p*-value
	Recommended Group A	Insufficient Group B	Together Group A +B

Note: * criteria for maximum score (10 points); $p \geq 0.05$.

nutrition. On the other hand, the biggest problem of female was overlapped sodium intake.

Average HEI score achieved the mean value 53.0 ±8.8 points (58.2 in the first and 51.4 in the second group, Table 10). This result is in accord with medium level of nutrition according to **Gibson (2005)** with necessary improvement of diet. This value represented also lower value in comparison with **Basiotis et al. (2002)** (HEI 63.8%) monitoring American population in 1999 – 2000. In the same way in the project Chicago Health and Aging was studied adult population 65 year and more (4932 participants) and the average HEI index was calculated 70.7 it means very close to healthy diet **(Tangney et al., 2001)**. According to research study of **Ervin (2008)** only 17% of older adults consumed a "good" quality diet. HEI-2015 for the american population for the years 2013 – 2015 was calculated as following: 59 for 2013 – 2014, 60 for years 2011 – 2012, 59 for 2009 – 2010, 57 for 2007 – 2008, 56 for 2005 – 2006 (from top score 100). HEI-2015 demonstrated that the nutrition of Americans are in medium level and did not align with the nutrition guidelines "2015 – 2020 Dietary Guidelines for Americans" **(USDA, 2015; USDA, 2018)**. Partial score for parameters 1 – 5 was compared with partial score for parameters 6 – 10 (Table 10). The better results were achieved in first partial score for parameters 1 – 5 (30.5 versus 22.5) within set of female and group of A and B with different intake of fruit. Evaluation of partial score 1 – 5 was in accord with medium level of nutrition with needs for improvement of diet, score 6 – 10 is in agreement with bad level of nutrition.

For HEI index, also partial HEI (1 – 5) and HEI (6 – 10) has been confirmed significant differences in comparison real and recommended score ($p < 0.001$; $p = 0$).

In set there have been evaluated anthropometric parameters as well (Table 11). On the basis of BMI classification **(WHO, 2018)** the proportion of female with normal weight took 60%, pre-obesity in 27.3% and overweight in 12.7% (Table 12). Obesity class III or underweight were not be noticed. Cumulative evaluation pointed to high prevalence of pre-obesity and obesity (BMI 25 $kg.m^{-2}$ and more) in 40%. Between groups A and B with different fruit intake there has not been proved statistically significant differences in BMI ($p \geq 0.05$). Normal weight had 54.0% and 66.7% probands in groups A and B, pre-obesity 32.2% a 21.8%, obesity class I – III 13.7% a 11.5%. Only third of respondents in group B displayed risk BMI. Pre-obesity or obesity was identified more often in group A with higher intake of fruit (45.9% *versus* 33.3%). According to index of centrality there has been higher occurence of android body type in group A than in group B (WHR ≥0.85, 16.1% *versus* 0%,

Diet variety (0 items)	0.0	0.0	0.0	-

Note: * criteria for minimum score (0 points) according to HEI **(Basiotis et al., 2002)**, ($p \geq 0.05$).

$p \geq 0.05$). By measurement of body fat was also observed the higher occurence of health hazard in group A. In the same way **Kant and Graubard (2005)** reported that the HEI score was associated with obesity and biomarkers of cardiovascular diseases and *diabetes mellitus*. The occurence of the risk values of anthropometry and body composition of female with recommended intake of fruit can be caused by total structure of intaken diet and also with presence of nutrition risk factors as well as with

Table 10 Scores for total HEI, partial HEI (1 – 5) and partial HEI (6 – 10) (mean ±SD).

Risk	>25	34.5	19.2	27.3	**0.185**

Note: $p \geq 0.05$.

lifestyle (the level of moving activity). Overlapped intake of fruit has been in relation with increased intake of sugar over dairy recommendations. Separately it has been evaluated relation between HEI score and anthropometric parameters. HEI index was in significant correlation with age ($r = 0.2402$; $p < 0.05$), body weight ($r = 1748$, $p < 0.05$) and hip circumference ($r = 0.2312$; $p < 0.01$). The mentioned anthropometric parameters were correlated to partial HEI (1 – 5) for group of food and HEI 6 – 10 for diet recommendations. The statistically significant relations have been confirmed between partial HEI (6 – 10) and anthropometric parameters: body weight, body height, waist circumference, hip circumference, BMI ($p < 0.001$) and body fat (% BF, $p < 0.001$; kg BF, $p < 0.05$). There have been proved significant correlation between HEI (1 – 5) and body weight ($p < 0.01$), age, height, waist circumference, body fat (% BF), BMI, WHR ($p < 0.05$).

Higher HEI 2005 scores have been associated with favorable lipid profile **(Shah et al., 2010)** and lower risk of obesity **(Gao et al., 2008)**. We can also conclude that components 6 – 10 significantly contributed to occurence of obesity and chronic diseases (especially increased proportion of total fat, saturated fatty acids, cholesterol or natrium). A version of the HEI calculated from food frequency questionnaires was associated with a lower risk of cardiovascular disease in men in the research study of **McCullough et al. (2000a; 2000b)**. The risk values of anthropometric parameters have been more often occured

Table 13 Correlation between HEI score and anthropometric parameters.

Parameter	HEI (1 – 5)	HEI (6 – 10)	HEI
Age (years)	$r = 0.1740$	$r = 0.1133$	$r = 0.2402$
	$p = 0.025$	$p = 0.147$	$p = 0.002$
Height (cm)	$r = 0.1747$	$r = 0.3715$	$r = 0.1425$
	$p = 0.025$	$p = 0.000$	$p = 0.068$

Note: HEI – healthy eating index, BMI – body mass index, WHR – waist to hip ratio.

in the group of female with recommended intake of fruit and their products. It can pointed to lower quantity level of nutrition despite the incorporation of nutritionally valued food from group of fruit. It has been confirmed also in assessment of the rest HEI components as well.

There has been surprisingly little dietary information and HEI data for Slovak population in literature. Many adults, and in particular, adults with insufficiet fruit intake, may have diets inadequate according to dietary recommendations.

There has not been existed food with ideal nutrition composition so food groups must be selected in the way that daily intake of diet include all sufficient nutrients in ideal proportion **(MH SR, 2001)**. Nutrition education programs and innovative interventions may help meet food and nutrients recommendations and daily nutrition requirements. Keeping of nutrition recommendations are essential for good healthy status of individuals.

CONCLUSION

This is the first study using the complete HEI to assess the quality of foods and nutrients in the diet of Slovak selected adult population. Results of the study indicate the necessity of diet improvements in adults.

The mean score for the individual components showed the needs to increase the proportion of consumed food especially grains and vegetable. On the other hand, it has been seen to be reasonable decrease the intake amount of cholesterol, saturated fats and especially natrium. The assayed results (total HEI 53.0 from 100.0; partial HEI (1 – 5) 30.5 from 50.0; partial HEI (6 – 10) 22.5 from 50.0 points) indicated the needs for distinct improvement of quality of intaken food as well as provide the necessary daily intake of food in accordance with nutrition recommendations. Average HEI has been corresponded with the medium evaluation level. It has been also confirmed correlation between HEI and partial HEI index and body weight. The group of female with insufficient fruit intake reached up the worse evaluation in comparison with group with recommended intake in all 10 HEI components. There has not been established statistically significant differences between groups in occurrence of risk values of the anthropometric parameters.

Future studies have been needed to evaluate diet according to the HEI in different population groups in Slovakia. Studies have been necessary to examine associations between HEI and components with individuals characteristics and additional factors.

BIOACTIVE COMPOUNDS EVALUATION IN DIFFERENT TYPES OF CZECH AND SLOVAK HONEYS

Soňa Škrovánková, Lukáš Snopek, Jiří Mlček, Eva Volaříková

ABSTRACT

Honey contains important bioactive compounds (enzymes, phenolic compounds, vitamins, and minerals) with several positive health effects for humans. In the study six types of honey (acacia, rape, floral, multi flower, forest, and honeydew honeys), of Czech and Slovak origin, were evaluated for bioactive compounds by means of color, polyphenols and antioxidant capacity analyses. The brightest color of honeys, the lowest values measured spectometrically, had acacia and rape honeys, followed by floral, and darker multi flower and forest honeys, and honeydew honeys. Polyphenols (PP) amount, determined by spectrophotometric method with Folin-Ciocalteu reagent, was highest for the darkest honeydew honeys, followed by multi flower and forest honey, brighter floral honeys, and rape and acacia honey. Honeys polyphenols were in the range from 54.0 to 254.2 mg GAE.100g^{-1}. The total antioxidant capacity (TAC) was analyzed by spectrometric methods with ABTS and DPPH reagents. Antioxidant capacity values are in agreement with the PP contents order. They were highest also for honeydew honeys (59.2 – 89.6 and 73.1 – 118.7 mg TE.100g^{-1}), followed by multi flower (66.0 and 56.7 mg TE.100g^{-1}) and forest honey (56.0 and 49.1 mg TE.100g^{-1}), then floral honeys (33.0 – 49.2 and 27.8 – 38.7 mg TE.100g^{-1}) and the lowest values for rape (19.0 and 28.1 mg TE.100g^{-1}) and acacia (15.5 and 11.3 mg TE.100g^{-1}) honey. A positive correlation between color, PP amount and TAC was evaluated for analyzed honeys. Darker honey samples showed higher values of phenolic compounds and antioxidant potential, therefore they belong to the honey types with higher amount of bioactive compounds such as antioxidants.

Keywords: honey; color; polyphenol content; antioxidant capacity; DPPH; ABTS

INTRODUCTION

Honey could be generally defined as foodstuff containing mainly sugars, monosaccharides fructose and glucose that form about 70% of sugar content, and about 10% of oligosaccharides (disaccharides and trisaccharides; sucrose, maltose, turanose, isomaltose, maltulose, trehalose, nigerose, kojibiose and trisaccharides maltotriose and melezitose). It is quite energetic food due to sugar content. Further there are enzymes, with important biological activity, such as catalase and glucoseoxidase; amino acids and proteins; organic acids; vitamins (such as ascorbic acid, vitamin E), carotenoid derivatives (β-carotene), minerals, and polyphenols **(Miguel et al., 2017; Bertoncelj et al., 2007; Gheldof et al., 2002)**.

As **Miguel et al. (2017)** mentioned honey is an effective nutraceutical foodstuff and its biological activity is mainly dependent on honey's floral or geographic origin. Composition of honey depends on several parameters such as honey type (blossom nectar or honeydew honey), geographical origin (locality of the collection), flora, soil, weather and season, and also post-harvest conditions and honey storage **(Bogdanov et al., 2008)**.

Honey could be defined as product of honey bees (*Apis mellifera*) as a nectar of flowers, flowering plants, they are floral honeys; unifloral if they are produced from the nectar of one type of flowers; or multifloral. They could be also non-floral, honeydew honeys, which are from honeydew (secretion), a sugar-rich substance secreted by various animals such as secretions of aphids plant sucking insects **(Pita-Calvo and Vázquez, 2017)**. Honeydew honey is chemically different from common blossom nectar honey because nectar is dissimilar from honeydew that is usually darker and has higher mineral content **(Grembecka and Szefer, 2012)**. Its darker color is produced by sugars, minerals and amino acids **(Sanz et al., 2005)**. Even nectar honeys from the same floral origin can vary in their chemical composition.

Honey is quite expensive natural product that was found to be adulterated sometimes **(Bušová and Kouřimská, 2018)**. The situation about the honey quality in the Czech

Republic is specified in the Situational Outlook Report of the Czech Ministry of Agriculture **(MZe, 2017)**. The honey consumption in the Czech Republic is only about 0.7 kg per person per year, in Slovakia is marked higher consummation **(Guziy et al., 2017)**.

Honey is known as a potential therapeutic product with bioactive compounds for the treatment and prevention of various diseases. There were studies of honey and its antioxidant, antibacterial, antiviral, anti-inflammatory, antihypercholesterolemic, vasodilatative, and hypotensive activities **(Viuda-Martos et al., 2008; Hadagali and Chua, 2014)**.

Honey is supposed to be a good natural antioxidant for foods. Honey addition can help to prevent or delay food spoilage due to oxidative reactions, to enhance the oxidative stability of the meat, such as dry honey applied to turkey products **(Antony et al., 2000; Antony et al., 2006)**. Dark honeys have higher content of phenolic compounds and possess better antioxidant activity, so they could be used as a good complement of these products **(Beretta et al., 2005; Bertoncelj et al., 2007)**. Free radical scavenging activity of honeys was found to be related with the water-soluble vitamins **(Chua et al., 2013)**. Also **Gheldof et al. (2002)** found an association between antioxidant activity and water-soluble honey fraction consisted of phenolics, peptides, proteins, organic acids, gluconic acid, ascorbic acid, the enzymes glucose oxidase, catalase and peroxidase.

Due to the study of **Schramm et al. (2003)** consumption of honey (buckwheat honey) increased plasma total phenolic content and also plasma antioxidant and reducing capacities. So phenolic antioxidants from processed honey are bioavailable, and increase antioxidant activity of plasma. It is speculated that phenolic antioxidants may augment defenses against oxidative stress and might be able to protect humans from oxidative stress.

The goal of this study was to evaluate amount of several bioactive compounds of few honey types produced from the Czech Republic and Slovakia by determination of polyphenols and antioxidant capacity.

Scientific hypothesis

The scientific hypothesis of this study was to examine the differences in various types of honeys from Czech and Slovak beekeepers due to their bioactive compounds evaluation measured by polyphenolic content and antioxidant capacity of two methods (DPPH and ABTS tests), and correlations between them.

MATERIAL AND METHODOLOGY

Honey samples

There were evaluated 11 honey samples (nectars and honeydew honeys) of 6 honey types of Czech (produced in Moravian region, CZ) and Slovak origin (SK). There were 1 sample of acacia honey (A1) sample (SK), 1 rape honey (R1; CZ), 3 samples of floral honey (FL1-FL3; all CZ), 1 multi flower honey (MF1) sample (SK), 1 sample of forest honey (FO1; SK), 4 samples of honeydew honeys (HD1-HD4, all CZ), collected from private beekeepers, seasons 2013 and 2014. The samples were stored in glass jars in the dry dark place at room temperature (approximately 20 °C) and after jar opening they were analyzed up to ten days.

Determination of Honey Color

For the determination of honey color a modified spectrometric method of **Beretta et al. (2005)** was used. The honey samples were diluted to 50% (w/v) solution with distilled water. They were sonicated for 5 min and filtered through a paper filter and used for color analyses. Absorbances of samples were measured at two wavelengths, 450 nm and 720 nm against blank on the spectrometer (Libra S6 Biochrom, GB). The difference in absorbances (ΔA) was expressed. Determinations were made in triplicate.

Determination of Polyphenolic Content

The polyphenolic (PP) content in honeys was evaluated by a modified spectrophotometric method with Folin-Ciocalteau reagent **(Socha et al., 2009)**. Samples for PP evaluation were prepared with 10 g honey and 40 mL of distilled water. After sonication (5 min) the solutions were filtered through a paper filter and quantitatively transferred into a 50 mL volumetric flask. Afterwards the samples were made up to 50 mL with distilled water and used for the analyses of PP. To extracts (0.1 mL) with 1 mL of distilled water, Folin-Ciocalteau reagent (1 mL; 10% (w/v); Penta Chemicals, CZ) was added and after agitation it was left for 5 min in the dark at room temperature, then 1 mL of sodium carbonate (10% (w/v); Penta Chemicals, CZ) solution was added and mixed again. After 15 min of standing in the dark at lab temperature absorbance of samples was measured at $\lambda = 750$ nm against blank using a Libra S6 Biochrom spectrometer (GB). Gallic acid was used as a standard and PP values were expressed as gallic acid equivalents (GAE) in $mg.100g^{-1}$ sample. Determinations were made in triplicate.

Determination of Antioxidant Capacity

For the total antioxidant capacity (TAC) determinations modified spectrometric methods using ABTS and DPPH reagents **(Škrovánková et al., 2018; Beretta et al., 2005)** were used.

The procedures for honey samples extraction were same for both determinations. There were mixed 10 g of honey sample and 40 mL of distilled water. After sonication (5 min) the solutions were filtered through a paper filter and quantitatively transferred into a 50 mL volumetric flask. Afterwards the samples were made up to 50 mL with distilled water and used for the analyses.

ABTS method: To 50 μL of honey extract the reactive radical mixture (4 mL), composed of ABTS (2,2′-azino-bis-3-ethylbenzthiazoline-6-sulphonic acid; Sigma Aldrich, CZ) (12 mL; 3.5 mM) with $K_2S_2O_8$ (0.06 M; Lukes, CZ) and acetic buffer (pH 4.3), was added. The reaction mixture was shaken vigorously on a Vortex mixer and for 30 min it was left to react without light exposure at room temperature. Honey samples absorbance (A) and absorbance of control samples (AC) were after time limit measured at $\lambda = 734$ nm against blank by spectrometer Libra S6 Biochrom (GB). Inactivation (I) was calculated from the decrease of absorbance (%) according to relation (1). Results of TAC (ABTS) were calculated from

inactivation using calibration curve with trolox as standard. It was expressed as trolox equivalents (TE) in mg.100g^{-1} sample. Average results were obtained from three parallel determinations.

$$I = \frac{AC-A}{AC} . 100 \quad (1)$$

DPPH method: To prepared honey extract (0.2 mL) a DPPH (1,1-diphenyl-2-picrylhydrazyl) solution in ethanol (1.9 mL; 0.02 mM; Sigma Aldrich, CZ) and acetate buffer solution (1 mL; pH 5.5) were added. The mixture was shaken vigorously on a Vortex mixer in capped glass and left without light exposure for 1 h at room temperature. Absorbance of samples (A) and absorbance of control samples (AC) was measured at λ = 517 nm against blank on the spectrometer (Libra S6 Biochrom, GB). Their inactivations (I) were also calculated from the decrease of absorbance according to relation (1) and the values were expressed as trolox equivalents (TE) in mg.100g^{-1} sample. Average results were obtained from three parallel determinations.

Statistic analysis

All analyses were provided in triplicate, and the data were expressed as mean values ± standard deviation (SD). Statistic evaluation of the results was made by Statistica program, StatSoft version 9.0 (Dell, USA) using parametric test comparing mean values of two independent assortments (Student *t*-test). Differences at a 95% confidence level (p <0.05) were considered statistically significant. Correlations between the parameters evaluated were obtained using Pearson's correlation coefficient (r).

RESULTS AND DISCUSSION

Color of honeys

In terms of our measurements and also due to sensorial examination, honey color ranges from white pale, pale yellow to amber and dark brown with the values ΔA from 0.139 to 0.817, the average 0.478 (Table 1). As expected, as the darkest honeys with the highest values were evaluated honeydew honeys (HD samples). Their values (average 0.779) were nearly five times higher than the brightest ones, acacia and rape honeys (average 0.161); and nearly three times to the values of floral honeys (0.268). Multi flower and forest honeys belong to the group of darker honeys. Several compounds, pigments are responsible for honey color. To the most important honey pigments belong water soluble polyphenols, flavonoids, and lipid soluble carotenoids **(Isla et al., 2011)**.

Also mineral composition is important for honey color. As **González-Miret et al. (2005)** evaluated lightness is significantly related with minerals such as S, Ca, Fe, As, Pb, and for the dark honey types (chestnut, and honeydew honeys) also Cd is considerable. Due to these facts, there are therefore expectations of higher content of polyphenols and probably also higher antioxidant values for darker honeys **(Bertoncelj et al., 2007; Kuś et al., 2014)**.

Content of phenolics

In the determination with Folin-Ciocalteau reagent electron-donating antioxidants such as polyphenols, ascorbic acid, and vitamin E are evaluated. The total polyphenols (PP) contents of the honey samples (Table 1) range from 54 to 254.2 mg GAE.100g^{-1} with the average 150 mg GAE.100g^{-1} honey. There were marked differences between honeys (p <0.05, Student *t*-test). Also **Bertoncelj et al. (2007)** mentioned that total phenolic content differs widely among different honey types. As it was expected due to other scientist researches **(Moniruzzaman et al., 2014; Alvarez-Suarez et al., 2010)** brighter, pale honeys had lower polyphenol values. PP results for honeys were in agreement with literature sources; lowest for acacia honey, where also **Beretta et al. (2005)** evaluated the lowest content (5.5 mg GAE.100g^{-1}). It was followed by rape honey and floral ones, forest and multi flower honey, whereas the highest PP content had the darkest honeydew honeys with the nearly five times higher values in comparison to the lowest ones. These findings are in agreement with the values previously reported for other European honeys, as **Kuś et al. (2014)** determined in Polish honeys total phenolic content in the range 12.2 – 117.4 mg GAE.100g^{-1}. The composition of honeys is dependent on the botanical origin, floral source, and also seasonal and environmental factors, as well as processing **(Kıvrak and Kıvrak, 2017; Cavazza et al., 2013; Dimitrova et al., 2007)**.

Honey samples exhibited similar order of samples for color and PP values. To characterize the relationships between color and polyphenolic content the correlation (Figure 1) was evaluated. They are strongly related with a correlation factor r = 0.8294. **Sant'ana et al. (2014)** also discovered that the lowest total phenolic content corresponded to light-colored honey and the highest values to dark honeys. Positive correlation between color and PP determined also other scientists **(Alvarez-Suarez et al., 2010; Kuś et al., 2014).**

Honey color thus seems to be a relatively reliable parameter to indicate high PP content in honey.

Antioxidant capacity

The antioxidant potential that means overall hydrogen/electron-donating activity of present antioxidants, was measured by two methods, with ABTS and DPPH test. The total antioxidant capacity (TAC) results for honey samples are demonstrated in Table 1. The TAC values of ABTS method were in the range from 15.5 to 89.6 mg of trolox equivalents per 100 grams of honey sample with the average 54.5 mg TE.100g^{-1}; and from 11.3 to 118.7 mg TE.100g^{-1} for DPPH method with the average 58.4 mg TE.100g^{-1}, respectively. There were marked differences between honeys (p <0.05, Student *t*-test). Also, **Frankel et al. (1998)** showed in their study that great variations exist in the chemical nature of honey from different floral sources as they found in best honey source 20.3 times higher concentration of antioxidants in comparison with that of the lowest one. The least active honeys in our research were, similarly like in PP evaluation, the brightest honeys **(Beretta et al., 2005; Kuś et al., 2014),** pale acacia **(Bertoncelj et al., 2007)** and rape honeys, for both methods.

Higher potency in scavenging of DPPH free radical and also ABTS test showed floral honeys (average 34.8 and 40.2 mg TE.100g^{-1}, respectively), forest and multi flower honey. Honeys with the best antioxidant potency were evaluated honeydew honeys (average 98.1 mg and 80.6 mg TE.100g^{-1}, respectively). The highest results for TAC (DPPH and ABTS test) were nearly eleven and nearly six times higher, respectively, than the lowest TAC value. Also, **Ferreira et al. (2009)** obtained the highest antioxidant values in the dark honeys.

Table 1 Color evaluation (ΔA), polyphenols content (PP) and total antioxidant capacity (TAC) of honey samples.

Honey sample	ΔA ±SD	PP (mg GAE.100g^{-1} ±SD)	TAC (ABTS) (mg TE.100g^{-1} ±SD)	TAC (DPPH) (mg TE.100g^{-1} ±SD)
A1	0.139 ±0.009^{a}	54.0 ±1.7^{a}	15.5 ±2.4^{a}	11.3 ±1.3^{a}
R1	0.183 ±0.016^{b}	56.8 ±1.2^{a}	19.0 ±0.2^{b}	28.1 ±0.9^{b}
FL1	0.238 ±0.013^{c}	126.5 ±0.6^{b}	33.0 ±1.0^{c}	37.9 ±2.0^{c}
FL2	0.273 ±0.010^{d}	111.3 ±0.5^{c}	49.2 ±6.5^{d}	38.7 ±2.8^{c}
FL3	0.293 ±0.016^{e}	146.2 ±0.9^{d}	38.5 ±1.6^{e}	27.8 ±0.8^{b}
MF1	0.467 ±0.019^{f}	155.3 ±0.4^{e}	66.0 ±3.0^{f}	56.7 ±0.3^{d}
FO1	0.552 ±0.024^{g}	150.1 ±0.5^{d,e}	56.0 ±1.1^{g}	49.1 ±0.9^{e}
HD1	0.745 ±0.027^{h}	164.5 ±0.4^{f}	59.2 ±4.3^{g}	73.1 ±1.3^{f}
HD2	0.753 ±0.025^{h,i}	203.0 ±1.5^{g}	84.5 ±2.0^{h}	99.5 ±1.1^{g}
HD3	0.801 ±0.020^{i,j}	224.6 ±1.3^{h}	89.1 ±9.0^{h}	101.2 ±1.8^{g}
HD4	0.817 ±0.031^{j}	254.2 ±1.4^{i}	89.6 ±2.5^{h}	118.7 ±1.3^{h}

Note: Means within a column with at least one identical superscript are not significantly different by Student's *t*-test (p <0.05).

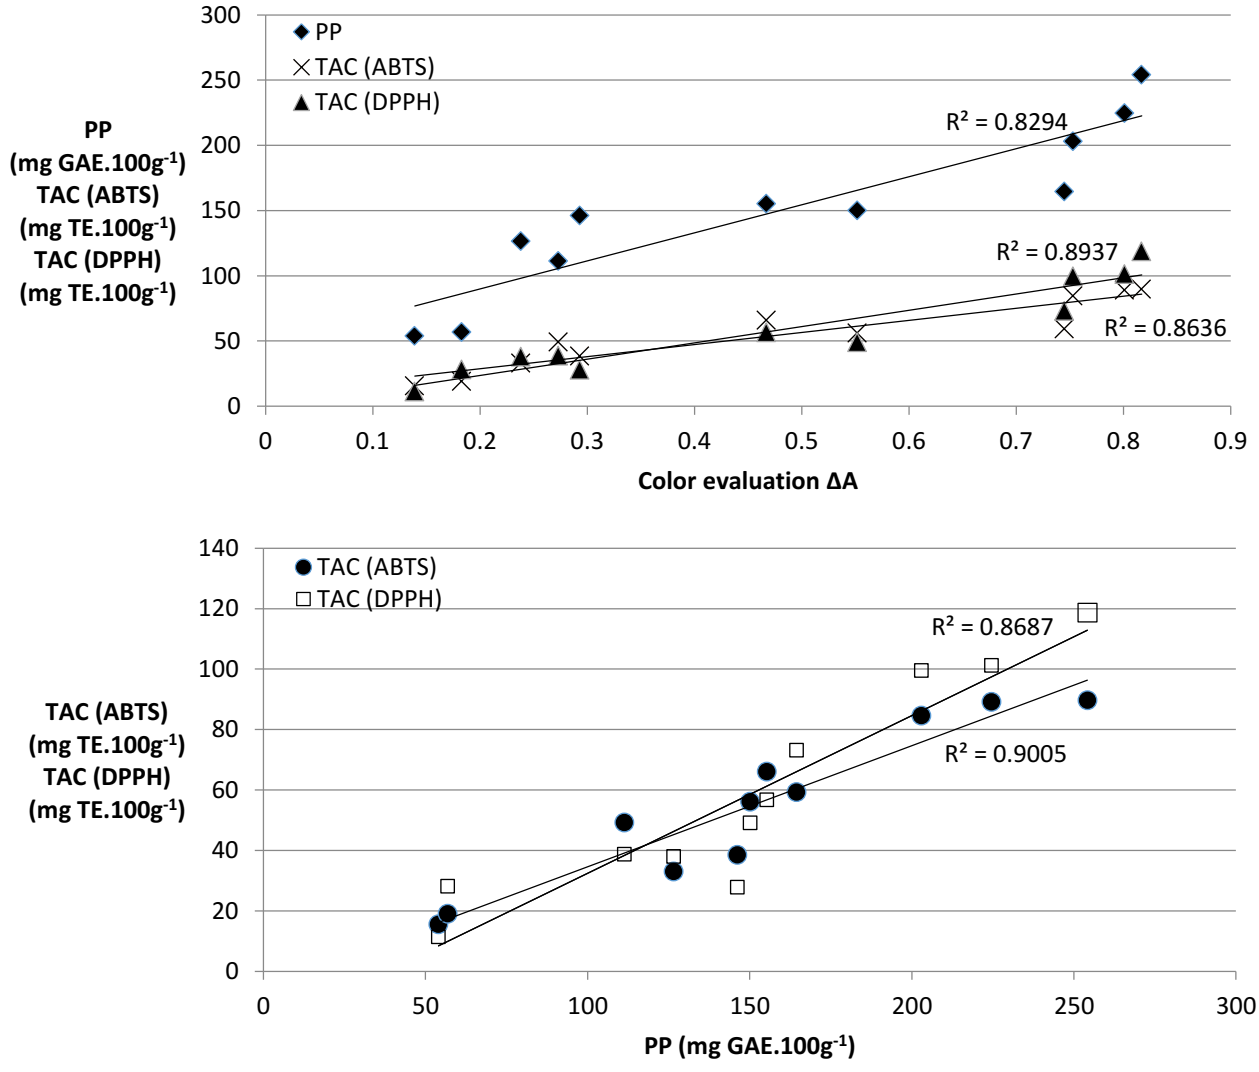

Figure 1 Correlations between color evaluation (ΔA) and PP and TAC values (top), and PP and TAC values (bottom).

Similar descending order of TAC values was observed also for honey color. The correlations to examine the relationships between them (Figure 1) were evaluated. Antioxidant capacity showed a strong relationship comparing both assays and color intensity, for ABTS evaluation $r = 0.8836$, and for DPPH test $r = 0.8937$. High correlation between color and antioxidant capacity was determined also by other researchers **(Sant'ana et al., 2014; Pontis et al., 2014; Beretta et al., 2005; Bertoncelj et al., 2007)**. Honey color thus seems to be a relatively reliable parameter to indicate not only PP content but also antioxidant potential in honey.

Antioxidant capacity determined by both analyses was also strongly positively associated with the polyphenolic content ($r = 0.9005$ for ABTS; $r = 0.8687$ for DPPH), as shown in Figure 1. Therefore high PP contents predicate high TAC values in analyzed honey samples. Also **Wilczyńska (2014), Sant'ana et al. (2014), Pontis et al. (2014), Beretta et al. (2005),** and **Bertoncelj et al. (2007)** found positive correlation between PP and TAC for honey samples. Although **Pontis et al. (2014)** determined high flavonone and dihydroflavonol content in some honeys, no correlations between them and antioxidant potential they observed. Generally, our findings and data in the literature have shown a linear relationship between honey color, phenolic compounds and antioxidant capacity.

CONCLUSION

Honey has several positive health effects for humans. They are related to their bioactive compounds such as enzymes, phenolic compounds, vitamins and some minerals. Honeys with the best polyphenols content and antioxidant capacity values evaluated by both methods are honeydew honeys, the darkest ones. The color of honeys was determined in the progression: pale acacia, then rape honey, floral, multi flower and forest honeys, and dark honeydew honeys. The polyphenol content in honeys was in the range from 54.0 to 254.2 mg GAE.100g^{-1}, in the descending order: honeydew honeys, multi flower and forest honey, followed by floral honeys, then rape and acacia honey. Antioxidant capacity values by two evaluation methods (ABTS, DPPH), are in agreement with polyphenols content order. They were highest also for honeydew honeys (59.2 – 89.6 and 73.1 – 118.7 mg TE.100g^{-1}), followed by multi flower (66.0 and 56.7 mg TE.100g^{-1}) and forest honey (56.0 and 49.1 mg TE.100g^{-1}), then floral honeys (33.0 – 49.2 and 27.8 – 38.7 mg TE.100g^{-1}) and the lowest values for rape (19.0 and 28.1 mg TE.100g^{-1}) and acacia (15.5 and 11.3 mg TE.100g^{-1}) honey. There was established a positive correlation between the color, polyphenolic amount and antioxidant capacity of the evaluated honeys. Darker honey samples showed higher content of phenolic compounds and increased antioxidant capacity.

MOLECULAR CHARACTERIZATION AND GENETIC DIVERSITY IN SOME EGYPTIAN WHEAT (*Triticum aestivum* L.) USING MICROSATELLITE MARKERS

Ayman El-Fiki, Mohamed Adly

ABSTRACT

Wheat (*Triticum aestivum* L.) is the most important and strategic cereal crop in Egypt and has many bread wheat varieties. Seventeen Egyptian bread wheat varieties used in this study with a set of sixteen wheat microsatellite markers to examine their utility in detecting DNA polymorphism, estimating genetic diversity and identifying genotypes. A total of 190 alleles were detected at 16 loci using 16 microsatellite primer pairs. The number of allele per locus ranged from 8 to 20, with an average of 11.875. The polymorphic information content (*PIC*) and marker index (*MI*) average values were 0.8669, 0.8530 respectively. The (GA) n microsatellites were the highest polymorphic (20 alleles). The Jaccard's Coefficient for genetic similarity was ranged from 0.524 to 0.109 with average of 0.375. A dendrogram was prepared based on similarity matrix using UPGMA algorithm, divided the cultivars into two major clusters. The results proved the microsatellite markers utility in detecting polymorphism due to the discrimination of cultivars and estimating genetic diversity.

Keywords: DNA polymorphism; genetic diversity; heterozygosity; PIC; SSR; wheat

INTRODUCTION

Wheat (*Triticum aestivum* L.) is an important and strategic grain crop in the majority of the world. In Egypt, wheat is considered the most important and strategic cereal crop. It represents about 10 percent of the total agricultural production value and about 20 percent of all agricultural imports **(FAOSTAT, 2008)**. Wheat is a self-pollinating polypoid crop that has been bred for a wide array of specific end-use quality traits and various adaptive characteristics, resulting in the development of distinct cultivars tailored to specialized end uses and specific production environments.

Botanists have long used morphological characterization to classify and distinguish genotypes within plant species. The emergence of the Plant Variety Protection (PVP) Act in 1970 had an impact on the protection of plant varieties. Hence, it was necessary to develop the critical tools for classifying and distinguishing genotypes within plant varieties **(Rongwen et al., 1995)**. The polymorphisms of DNA provide a powerful tool for determining and discriminating the levels of genetic variation in plant germplasm. Molecular markers have thus become accurate and reliable tools for identifying and characterizing plant varieties and it has become effective tool for efficient selection of desired agronomic traits since it depends on genotype rather than phenotype. The advances in molecular genetics methodology have led to widespread use of co-dominant molecular markers, especially Simple Sequence Repeats (SSRs), Single Nucleotide Polymorphisms (SNPs) and the amplified fragment length polymorphisms (AFLPs) **(Röder et al., 1998; Bohn et al., 1999; Prasad et al., 1999; Prasad et al., 2000; Roy et al., 1999; Varshney et al., 2000;** for reviews see **Gupta et al., 1999; Gupta and Varshney, 2000; Bered et al., 2005)**.

The first one define microsatellite term was **(Litt and Lutty, 1989)**, as multilocus probes creating complex banding patterns and usually non- species specific occurring ubiquitously. They essentially belong to the repetitive DNA family. Microsatellite are repeated as of only a few bases, like two or three or five, and the whole repetitive region spans less than 150 bp. Therefore, it needs cloning and sequencing for designing the primers **(Weissenbach et al., 1992; Morgante and Olivieri, 1993; Powell et al., 1996)**. Furthermore, these markers have provided high reproducibility and genetic informativeness **(Coombs et al., 2004; Garcia et al., 2007)**.

Microsatellites produced from whole genome sequences, subgenomic sequences, ESTs and gene sequences have also been applied to DNA fingerprinting and the estimation of genetic diversity within a gene pool. Genetic diversity is defining the heritable variation within and between population's organisms **(Ramanatha and Hodgkin, 2002)**. Knowledge of the genetic diversity and population structure within germplasm collections is an

important foundation for crop improvement **(Thomason et al., 2007)**. Progress in plant breeding requires a broad genetic base with a rich and diverse germplasm collection being the backbone of every successful crop improvement program. In this study, we evaluate the potential of 16 microsatellite primer pairs in general and specific SSRs in particular for polymorphism determination, cultivars identification and to evaluate the level of microsatellite based genetic diversity between 17 Egyptian bread wheat cultivars that were potentially useful in wheat breeding programs.

Scientific hypothesis

It is expected that there will be a significant similarity between the wheat varieties used in this experiment due to their genetic resources.

MATERIAL AND METHODOLOGY

Seed Material

In this experiment, some elite Egyptian bread wheat cultivars (17) were selected in different regions in Egypt as shown in Table (1). These cultivars have been obtained from Gene Bank, Egyptian Ministry of Agriculture.

DNA isolation and microsatellite primers

Twenty five seeds of each wheat varieties have been planted in pots in greenhouse. After two weeks of planting, the plants were enough to get fresh leaves and were collected from each sample. The samples were immediately transferred to liquid nitrogen tank to prevent deterioration. Weighed about 1.5 g from plant leaves samples and ground by liquid nitrogen to obtain fine powder. Total genomic DNA was isolated from leaves of each of the seventeen varieties according to the protocol described by **Anderson et al. (1992)**, with a few modifications intended to improve the quality of DNA: two consecutive extractions with phenol: chloroform (1:1) were carried out by an additional wash of 97% (left at -20 °C for one hour) an 70% pre-cooled ethanol, respectively. The yield and quality of DNA were assessed by spectrophotometer and gel electrophoreses.

SSR markers and protocols

Sixteen microsatellite primer pairs (SSR) were selected from **(Röder et al., 1998)**, Table 2. Amplification reactions were carried out in a total volume of 25 µL, which contained 250 nM of each primer (Metabion GmbH, Germany), 0.2 mM of each deoxynucleotide, 1.5 mM $MgCl_2$, 1 unit *Taq* polymerase (Bioline, GmbH, Germany) and 50 – 100 ng of template DNA. All reaction volumes were 25 µL overlaid with a drop of mineral oil. The thermocycling program (MJ Research PTC-100 thermal cycler) used was: one cycle at 94 °C for 3 min, 45 cycles at 94 °C for 1 min at either 50, 55 or 60 °C (depending on the individual microsatellite), 2 min at 72 °C, and the final extension step of 10 min at 72 °C. Electrophoresis was done to visualize the PCR amplified product. It was carried out on 2.0% agarose gel and amplified fragments were visualized by staining wit ethidium bromide. Fragment sizes were determined with PyElph 1.4 software, is the commercial program Quantity One from Bio-Rad **(Pavel and Vasile, 2012)**. The fragment size in "Chinese Spring" was taken as standard **Röder et al., (1998)**.

Statistic analysis

The fragment(s) sizes in 'Chinese Spring' were taken as standard, and the size differences of the fragments in other genotypes were considered to be the result of alterations in the repeat number of the simple sequences at the corresponding site(s). All distinct DNA fragments scored as present (1) or absent (0) were used to compute pair-wise similarity coefficients **(Jaccard, 1908)** for each of the markers for the purpose of assessing genetic diversity leading to cluster analysis. PowerMarker software (v3.0, 2004) is statistical software for genetic marker data analysis **(Liu and Muse, 2005)** was used for estimating of allele number, allele frequencies, genotype, heterozygosity and polymorphic information content (PIC). However, Marker index (MI) was calculated according to **Powell et al. (1996)**, MI = Average polymorphic information content (PIC) x Proportion of polymorphic bands x Average number of loci per assay unit.

Cluster analysis

For phylogenetic analysis, data only from the polymorphic SSR loci were subjected to MVSP software statistical software (Kovach Computing Services, Pentraeth, Wales, U.K). All the 17 wheat varieties were clustered based on the estimated genetic distance. The phylogenetic analysis was carried out with the clustering method of the unweighted Pair Group Method Using Arithmetic Average (UPGMA).

Principal component analysis (PCA)

The original 1 – 0 data matrix was used for calculating a correlation matrix between pairs of markers. The correlation matrix was employed for the calculation of eigenvalues, which were then used for determining the coordinates for each genotype that were used for PCA.

RESULTS AND DISCUSSION

DNA polymorphism and genotype identification

The results of PCR amplification of a number of microsatellite loci in seventeen Egyptian bread wheat cultivars using sixteen microsatellite primer pairs are summarized in (Table 2). Altogether, 190 alleles at 16 loci were obtained with average 11.875 alleles per locus. The maximum number of alleles detected at *Xgwm32-3A* belonging to (GA) n was 20 alleles with size ranged from 163-179 bp. However, the minimum number of alleles detected at *Xgwm156-5A* belonging to (GT) n and *Xgwm157-2D* (CT) n was 8 alleles with size from 270-299 bp and 107-113 bp respectively, Table 2. Allele frequency per locus varied from eight (*Xgwm156-5A* and *Xgwm157-2D*) to twenty *Xgwm32-3A*. It is known that microsatellite primer pairs are locus specific and that is meant to be a single locus marker comparing with other molecular markers as RFLP probes, RAPD, ISSR and SCoT primers which multilocus **(Vivodík et al., 2016)**. In the present study, the 16 loci that were assigned to specific chromosomes were able to distinguish between 17 Egyptian bread wheat and thus useful for detecting polymorphism.

Table 1 List of the elite Egyptian wheat cultivars and region of cultivation.

No.	Wheat cultivars	Cultivation region	No.	Wheat cultivars	Cultivation region
1	Misr 1	North Delta - Central & South Delta - New Land - North & East Coast	11	Sids 13	Central Egypt

Such a discriminatory set should also ensure the uniform distribution of the microsatellite primers of this set across the three genomes of bread wheat since in several studies, including the present study, microsatellites have been shown to be more frequent in the A and B genomes, than in the D genome **(Röder et al., 1998; Stephenson et al., 1998)**.

The SSRs relative with them, more alleles detected at (CA) n and (AC) n one loci each, however, (GA) n loci 4 loci, (CT) n and (GT) n loci5 loci each. **Röder et al. (1995)** reported that (GT) n repeats to be more polymorphic than other simple repeats such as (GA) n in wheat. However, in barley more alleles were detected for (GA) n repeats than for (GT) n repeats **(Struss and Plieske 1998)**. The results were obtained agreement with **(Dreisigacker et al., 2004; Dvojkovic et al., 2010; Spanic et al., 2012)** and opposed with **Kumar et al. (2016)**. The loci of microsatellite are multi-allelic and the alleles co-dominant, proved that the microsatellite marker strict in determined DNA polymorphism and highly informative genetic markers **(Devos et al., 1992; Devos et al., 1993; Xie et al., 1993; Mason, 2015)** than other markers as single nucleotide polymorphisms (SNPs) which are biallelic and dominant. The earlier studies proved that four microsatellite markers set each had the ability to distinguish between 24 genotypes in barley and 16 genotypes in tomato **(Rusell et al., 1997; Bredemeijer et al., 1998)**. Furthermore, the microsatellite set could be used to distinguish each genotype in a set of more than 100 wheat genotypes **(Manifesto et al., 1999)**.

Genetic diversity

Polymorphism Information Content (PIC) was estimated for 16 loci (Table 2). The PIC values ranged from 0.8137 of locus Xgwm157-2D to 0.9342 of locus Xgwm32-3A with an average of 0.8669. As well as, the heterozygosity values were estimated as well, ranging from 0.8235 to 1.00 with average 0.9816. The marker index (MI) value over all 16 microsatellite markers was 0.8530. The heterozygosity was detected in three loci (Xgwm71.2-2A, Xgwm113-4B and Xgwm161-3D) with values 0.9412, 0.9412 and 0.8235 respectively, (Table 3). The genotype number per locus was estimated based on allelic frequency data, where the highest number detected 17 of locus Xgwm32-3A and lowest number founded 10 of locus Xgwm156-5A and Xgwm157-2D with an average 13.6250 (Table 2). The data of microsatellite loci and the corresponding alleles were used to calculate the polymorphic information content (PIC) and heterozygosity (H) to evaluate a marker system for its ability to detect high levels of DNA polymorphism in an analysis of genetic diversity. In earlier studies on bread wheat, the PIC values were ranged from 0.23 to 0.79 **(Röder et al., 1995)** and from 0.29 to 0.79 **(Plaschke et al., 1995)** and 0.21 to 0.90 **(Prasad et al., 2000)**. On the other hand, the PIC values obtained by **(Bohn et al., 1999)** were very low (0.30). However, **(Saeidi et al., 2006; Khalighi et al., 2008; Tahernezhad et al., 2010; Mir et al., 2012; Arora et al., 2014)** studies were the opposite of the previous results and consistent with our results where PIC value > (0.7). The marker index is also used to measure the efficiency of polymorphism **Khodadadi et al., (2011)**.

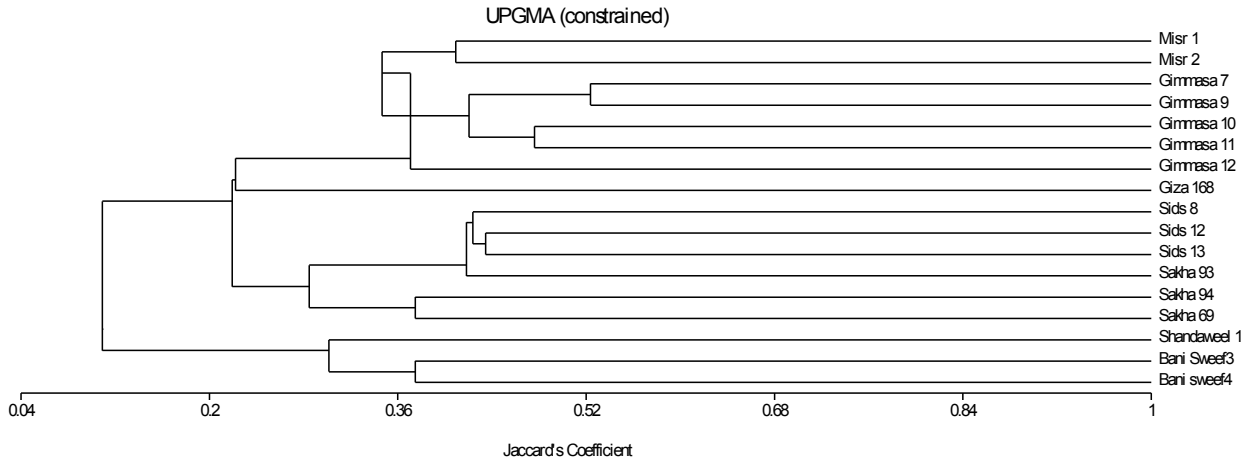

Figure 1 Dendrogram of 17 Egyptian bread wheat based on data on allelic profiles generated using 16 microsatellite primer pairs.

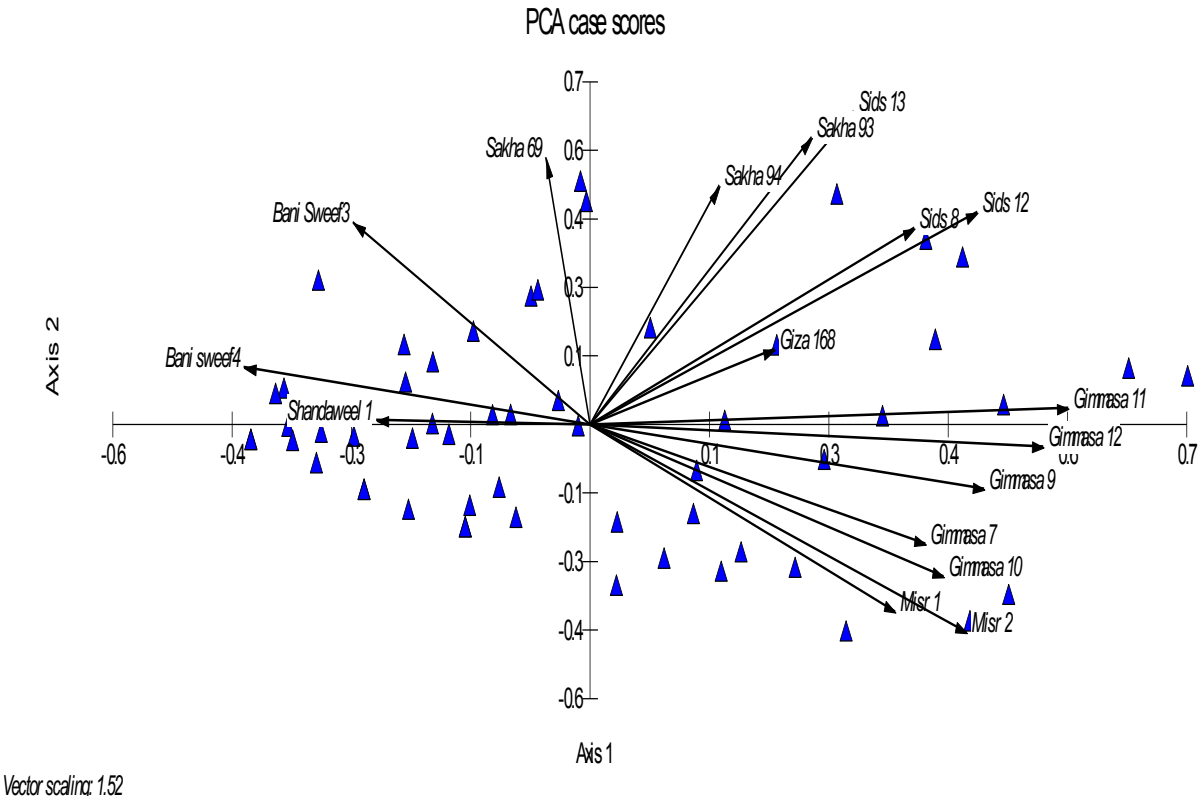

Figure 2 Matrix plot among 17 Egyptian bread wheat cultivars revealed by principle component analysis based on SSR data.

The marker index (MI) value was calculated also for used markers and was close to (0.8530) the MI value (0.70) reported by **(Prasad et al., 2000)**, however those results were higher than the MI value (0.21) obtained by **(Bohn et al., 1999)** on SSRs wheat. When comparing the MI value with other markers found that, SAMPL (9.61) and AFLP (3.41) in bread wheat **(Bohn et al., 1999)**. However, MI value (6.14) that is intermediate between the above two contrasts was also available for AFLPs in soybean **(Powell et al., 1996)**.

Genetic similarity

In order to investigate, genetic relationships between 17 Egyptian wheat genotypes cluster analysis based on Jaccard's similarity coefficients and UPGMA algorithm were calculated for the 43 durum wheat germplasm. A Jaccard's genetic similarity matrix is presented in Table 4a and 4b. The average similarity among 17 Egyptian bread wheat was 0.357. The nearest neighbor cluster analysis obtained from Jaccard's similarity coefficient (Figure 1) illustrated the variability between 17 Egyptian bread wheat. The detected of DNA polymorphism by 16 microsatellite markers allowed of estimates genetic distance and clustering of 17 Egyptian bread wheat cultivars in two major groups. The first group (Group I) included Misr 1, Misr 2, Gimmasa 7, Gimmasa 7, Gimmasa 9, Gimmasa 10, Gimmasa 11, Gimmasa 12 and Giza 168. The second group (Group II) included the other cultivars Sids 8, Sids 12, Sids 13, Sakha 93, Sakha 94, Sakha 69, Shandaweel 1, Bani Sweef 3 and Bani Sweef 4. The similarities between 17 Egyptian bread wheat based on 16 microsatellite markers were ranged from 0.109 in Shandweel 1, Bani Sweef 3 and Bani Sweef 4 cultivars to 0.524 in Gimmaza 7 and Gimmaza 9 with average of 0.357. A Jaccard's genetic similarity matrix was estimated between pairs of Egyptian wheat cultivars using 16 microsatellite markers through cluster analysis. This study used UPGMA cluster analysis based on genetic similarity values for SSR alleles from all the wheat cultivars to construct a dendrogram (Figure 1). The similarity value between 17 Egyptian wheat cultivars was ranged from 0.109 to 0.524 with average value 0.357. This average of genetic similarity value (0.357) can be compared with other studies, whereas SSR-based genetic similarity coefficient values of 0.31 **(Plaschke et al., 1995)** and 0.57 **(Bohn et al., 1999)**. However, STS-based genetic similarity coefficient value of 0.81 **(Chen et al., 1994)** were reported. In these different studies on genetic diversity in bread wheat, undertaken using a variety of molecular markers, the variation in genetic similarity coefficient values may be attributed either to the differences in number of genotypes and the probes/primers used (e.g. 119 RFLP probes were used by **Paull et al. 1998**) or to the relative superiority of microsatellites to detect DNA polymorphism. An unusually low value of RFLP-based genetic similarity (0.18) reported by **Paull et al. (1998)** is certainly due to the larger sample of 124 diverse genotypes and bigger set of 119 RFLP probes used in this study. From the previous study it illustrated the importance and usefulness of the microsatellites (SSR) technique in wheat **(Prasad et al., 1999; Roy et al., 1999)**. Based on the results obtained are considered the

microsatellites technique was sensitive and critical in differentiating between the different varieties of Egyptian wheat under study, as well as in determining the polymorphism, genotype identification, genetic similarity and estimation of genetic diversity.

The principle component analysis was used to visualize the genetic relationships among genotypes shown in Figure 2. Of the total polymorphism, only 40.44% was accounted for by the first two components, implying that the used markers possessed a suitable dispersion of markers in the genome. The 17 Egyptian wheat cultivars were clustered into two groups. The principle component analysis thus is largely compatible to those from cluster analysis obtained from UPGMA.

CONCLUSION

Microsatellites or SSR markers are one of the most common genetic markers and used in many genetic applications. Microsatellites are codominant, highly polymorphic, and Mendelian inherited, all these qualities made it very suitable for such study and the ability to accurately identify differences between wheat varieties in this study. The species specific markers identified would be utilized in future introgression breeding programs.

WHEAT BRAN STABILIZATION AND ITS EFFECT ON COOKIES QUALITY

Michaela Lauková, Jolana Karovičová, Lucia Minarovičová, Zlatica Kohajdová

ABSTRACT

Wheat bran are widely used as a source of dietary fiber with enhanced health benefits. However, its hight application level in bakery products caused lower quality of these products (eg. reduced volume and increased hardness of product). Different mechanical, physical or chemical methods are used for modification of wheat bran physicochemical properties. Wheat bran obtained from two wheat variety was used to evaluate the effect of bran stabilization process on qualitative properties of baked goods. Stabilization was performed using hot air and microwave heating. Threated and unthreated wheat bran were blended with wheat flour at 5, 10 and 15% substitution level. Influence of bran addition on rheological properties was evaluated using Mixolab 2. Stabilized wheat bran increased water absorption up to 11.7% (hot air stabilization) and 11.9% (microwave stabilization), respectively. Hot air stabilization of wheat bran improved heat resistance of dough proteins during mixing and the stability of hot gel during heating. Stabilization process of wheat bran using both methods also increased the volume and spread ratio values of enriched cookies. Cookies incorporated with hot air treated bran were significantly softer than cookies contained raw bran. Sensory evaluation showed that addition of stabilized bran improved the shape and taste of cookies. Additionally, it was concluded that the most acceptable cookies were obtained at 5% addition level of bran stabilized using microwave heating.

Keywords: wheat bran; stabilization; dough rheology; cookie

INTRODUCTION

Wheat (*Triticum aestivum*) is a leading cereal crop which is mainly utilised for human consumption and livestock feed. A wheat kernel comprises three principal fractions – bran, germ and endosperm. The outer layers are all parts of the bran. The bran fraction is a by-product of milling and has food and nonfood applications **(Onipe et al., 2015)**. Bran can be processed from red or white, hard or soft, and durum wheat. Besides the obvious color difference, the bran from white wheat has a milder flavor than the bran from red wheat. The bran to be used in a specific application depends on the flavor, color, and appearance desired. The breakfast cereal industry uses both red and white wheat bran, but the bakery industry primarily uses red wheat bran. White bran has excellent potential for use in flour tortillas and pizza dough **(Lauková et al., 2016)**.

Wheat bran has a rich nutritional profile and shows beneficial physiological effects, making consumption of bran-rich food products more interesting from a health perspective than products based on refined flour. Because consumers become more aware of its benefits, wheat bran is increasingly added to mostly cereal-based food products (bread, cookies, breakfast cereals, pasta, snacks, cakes, and more) **(Hemdane et al., 2016)**.

In refined flours, the main components responsible for the water absorption are the gluten network proteins. Wheat bran particles can interfere with the gluten network, decrease dough resilience and impair the framework of gas cells and, thus, gas retention. These effects can lead to low bread specific volume and inferior baking quality **(Prückler et al., 2014)**. During the storage, rancidification can reduce the nutritional value of food, and cause some quality changes, involving flavor, texture, and appearance. Due to the possibility of rapid rancidity there is a necessity for stabilization **(Ertaş, 2016)**. Pretreating the bran before it is added back into the flour is a key to eliminating its adverse effects on the processing and quality of the flour system. Ultrafine milling, extrusion, heating, and biological methods are useful for bran pretreatment **(Zhang et al., 2018)**. Thermal steps like roasting, steaming, cooking under forced air or microwave radiation usually have little impact on the chemical composition, but some effects on the processing properties could be observed, like for example increased loaf volume of bread when containing autoclaved bran **(Prückler et al., 2014)**.

When heating in a forced air oven at 150 °C, the cellulose content decreases with the processing time in wheat. Thermal processing increased the soluble dietary fraction. In general, the changes in the dietary fiber composition

during thermal processing may be partly attributed to the redistribution of the insoluble and soluble components of dietary fiber, and partly to the formation of resistant starch. An increased temperature breaks week bonds between polysaccharide chains and split glycosidic linkages in the polysaccharides. As consequence, the architecture of the fiber matrix may be modified, and insoluble fiber solubilized **(Căpriţă et al., 2012)**.

Scientific hypothesis

Previous work focused to study the effect of wheat bran products has confirmed the negative influence of wheat bran on the quality parameters of bakery products. In this study, different stabilization methods were tested to remove the deterious effect of wheat bran on wheat dough and qualitative parameters of cookies.

MATERIAL AND METHODOLOGY

Wheat flour (moisture 11.36%, wet gluten 35.47%) and other ingredients (sugar, shortening, sodium bicarbonate, and sodium chloride) were purchased in local market. Wheat bran from wheat variety PS Bertold (BB) and PS 215 (WB) were observed from Research and Breeding Station, Vígľaš Pstruša, Slovakia and Research Institute of Plant Production Piešťany, Slovakia.

Wheat bran stabilization

Wheat bran from different wheat variety were stabilized using hot air and microwave heating acording to method described by **Ertaş (2016)**.

Hot air stabilization

Wheat bran was heated in hot air oven (Mora, Czech Republic) at 150 °C for 20 min and cooled for 30 min. Cooled bran was packed to polypropylene bags.

Microwave stabilization

Wheat bran was heated using microwave (Whirpool MWO602, USA) at 800 W for 2 min and cooled for 30 min. Cooled bran was packed to polypropylene bags.

Thermo-mechanical properties of dough

Effect of wheat bran addition (5, 10 and 15%) on thermo-mechanical properties of wheat dough was evaluated using Mixolab 2 (Chopin Villeneuve-la-Garenne, France) according to method described by **Lauková et al. (2018)**. The settings used in the test were 8 min at 30°C with a temperature increase of 4 °C.min^{-1} until the mixture reached 90 °C. There was a 7 min holding period at 90 °C, followed by a temperature decrease of 4 °C.min^{-1} until the mixture reached 55 °C, and then 6 min of holding at 55 °C. The mixing speed during the entire assay was 80 rpm. Determined parameters were: water absorption (WA), dough development time (DDT), stability (ST), initial maximum consistency (C1), protein weakening (C2), starch gelatinization (C3), stability of the starch gel formed (C4), starch retrogradation (C5).

Cookie preparation

The cookies were prepared using a recipe described by **Lauková et al. (2016)**, which included: 100 g wheat flour, 53 g sugar, 26.5 g shortening, 1.1 g sodium bicarbonate, 0.89 g sodium chloride and 12 cm^3 water. Prepared dough was rolled out (3 mm height) and cut into round shape (50 mm diameter). The cookies were baked for 8 – 9 min in hot air oven (Mora, Czech Republic) at 180 °C. After cooling, the cookies were packed in polyethylene bags. In the bran enriched cookies, the wheat flour was replaced by wheat bran at level 5, 10 and 15%.

Qualitative parameters of cookies

Qualitative parameters of cookies were evaluated 2 h after baking. The volume of cookies was measured by rapeseeds displacement method **(AACC Method 10-05.01)**. Volume index of cookies was measured using method acording to **Lauková et al. (2016)**. Baking loss (%) is determined according to dough weight before baking and product weight, which was detected one hour after baking according to **Minarovičová et al. (2018)**. Spread ratio was evaluated according to method described to **Kuchtová et al. (2016)** as the ratio of the diameter to the thickness of cookies. To determine the diameter, six cookies were placed edge to edge and the total diameter was measured. The cookies were rotated at 90 degree for duplicate reading. The average diameter was calculated. To determine the thickness, six cookies were placed on top of one another. The total thickness was measured. This process was repeated twice, and average thickness was calculated.

Texture analysis

Texture properties of baked cookies was determined using a texture analyser Ta.XT plus (Stable Micro Systems, GB) with 3-Point Bending Rig (HDP/3PB) according to modified method described by **Filipčev et al. (2012)**. A pre-test speed 1.0 mm.s^{-1}, test-speed 1.0 mm.s^{-1} and post-test speed 10 mm.s^{-1} were used. The gap distance was 20 mm. Texture determination was repeated 10 times.

Hardness and fracturability of cookies were recalculated using Exponent software (Stable Micro Systems, GB) version 6.1.4.0.

Sensory evaluation

The sensory evaluation of baked cookies was performed according to **Kohajdová et al. (2011)** by panel of 11 judges (staff and students of the Faculty of Chemical and Food Technology, Slovak University of Technology, Slovakia) using five-point hedonic scale (5 – most liked, 1 – most disliked). Descriptors determined were: shape, colour, taste, flavour, hardness. The overall acceptance of cookies was determined using 100 mm graphical non-structured abscissas with the description of extreme points (0% – minimal intensity, 100% – maximal intensity).

Statisic analysis

All determinations were carried out in triplicate except texture analysis and the average values were calculated. Student`s test at p <0.05 was used to establish the significant differences between mean values. As the statistical analysis software was used Microsoft Excel version 2010.

RESULTS AND DISCUSSION

Thermo-mechanical properties of dough

Knowledge of the influence of fibers on rheological properties is essential for the development of good quality products. The most serious technological drawbacks related to the rheological properties of dough include problems with adhesion to work surfaces and changes in shape, color, density and texture of the baked product. These modifications prove inconvenient in the production process and in sensory aspects of the product, both visual and flavor **(Blanco Canalis et al., 2017)**. One of the latest instruments used to determine the rheological quality of dough is Mixolab. Mixolab allows the characterization of the physicochemical behavior of dough when submitted to dual mixing and temperature constraints. Therefore, it is possible to record the mechanical changes due to mixing and heating simulate the mechanical work as well as the heat conditions that might be expected during the baking process **(Xhabiri et al., 2016)**. Effect of wheat bran addition on thermo-mechanical properties of wheat dough is sumarised in the Table 1.

Water absorption (WA) represents the amount of water that flour can absorb to obtain a pre-set dough consistency to produce a torque (peak C1) of 1.1 Nm ±0.05 at 30 °C **(Blandino et al., 2015)**. It was noticed, that WA significantly increased with addition of raw wheat bran from 55.83% (wheat flour) to 60.25% (15% BB) and 57.75% (15% WB), respectively. The higher WA of wheat bran is explained by the greater number of hydroxyl groups in the fiber structure, which allows more water interaction through hydrogen bonding. These effects can be also related to the presence of arabinoxylans, which tightly bind water in the dough system thereby reducing the availability of water for developing the gluten network **(Prückler et al., 2014)**. Stabilization of wheat bran using different methods significantly increased the WA. The highest values (62.40 and 62.50%) were obtained after addition of 15% WB stabilized by hot air and microwave heating.

Dough stability (DS) is indicator for the kneading properties of doughs and thus for the flour strength, whereas stronger doughs have higher values. The addition of wheat bran in general causes shorter DS values, a fact which is due to the interruption of the gluten network **(Prückler et al., 2014)**. From the results, it was noted that DS significantly decreased with increasing addition level of raw wheat bran. Incorporation of wheat bran stabilized using microwave caused shorter DS compared to addition of raw bran.

The C2 indicates a dough consistency loss during exposure to physical-mechanical and thermal stress **(Wang et al., 2017)**. Higher the C2 torque, lower is the protein weakening (Moza and Gujral, 2018). Control C2 value for wheat flour sample was 0.58 Nm. Generally, addition of wheat bran caused decreasing of C2 values to 0.50 Nm (15% BB) and 0.41 Nm (15% WB). The stabilization of wheat bran using a hot air resulted in a lesser weakening of the protein structure compared to raw bran and stabilization using a microwave.

The torque at C3 indicates the starch gelatinization behavior and viscosity of the dough upon heating and it strongly depends upon type and quality of starch **(Moza and Gujral, 2018)**. Wheat flour contributed to a better starch performance of the samples (higher starch gelatinization, C3) than composite flour with bran. This could be ascribed to the competence for water established between the starch and the bran **(Lauková et al., 2018)**. From the results concluded, that C3 values with addition of raw wheat bran ranged from 1.94 Nm (5% WB) to 1.80 Nm (15% WB) which was significantly lower than C3 value for wheat flour (2.11 Nm). Addition of wheat bran using microwave resulted in lower gelatinization of starch (1.92 – 1.65 Nm) compared to adition of raw bran. On the other hand, with the incorporation of hot air heated bran, C3 values were significantly higher (2.01 – 1.84 Nm).

The further reduction in viscosity (C4 value) is the result of the physical breakdown of the granules due to the mechanical shear stress and the temperature constraint **(Dapčević Hadnađev et al., 2011)**. As can be seen from the Table 1, C4 value (hot gel stability) for wheat flour was 2.11 Nm. Increasing addition level of bran caused significant decreasing of hot gel stability. Xhabiri et al. (2016) reported that wheat bran mostly represents the cover of the grain which contains a high amount of α-amylase, which is the cause of decrease of C4 values. From the results concluded, that adition of bran stabilized by hot air increased the stability of hot gel (2.01 – 1.84 Nm) compared to raw bran (1.94 – 1.80 Nm). Incorporation of bran stabilized by microwave resulted in lower stability of hot gel. The C5 values were related to starch gelatinization, pasting, and retrogradation properties **(Koksel et al., 2009)**. From the results concluded that incorporation of wheat bran to wheat dough significantly decreased the C5 values (wheat flour 2.92 Nm). Moreover, addition of stabilized wheat bran using hot air heating caused higher C5 values compared to raw wheat bran. A higher C5 values means more starch retrogradation, thus the decreased value of C5 portrays longer shelf stability and better texture of the end products **(Ding et al., 2018)**.

Cookies quality and texture

Effects of wheat bran addition on qualitative properties of cookies are sumarised in Table 2.

Generally, addition of raw wheat bran resulted in reduced volume from 8.90 cm3 (control sample) up to 7.14 cm3 (15% WB). Reduced volume may also be caused by gluten dilution and physicochemical reactions among fibre components, water and gluten **(Kurek et al., 2016)**. This effect is in agreement with previous study after incorporation of wheat bran from different wheat variety in cookies **(Lauková et al., 2016)**. Compared to cookies contained raw bran, stabilization of wheat bran led to increase the volume about 10% (hot air treatment) and 15% (microwave treatement).

Dough making and handling, cookie baking and quality of the final product are thus largely influenced by cookie dough components. Cookie spread, i.e. the extent to which the dough piece spreads during baking represents one of the major quality parameter **(Dapčević Hadnađev et al., 2011)**. Cookies with higher spread ratios are considered the most desirable **(Ostermann-Porcel et al., 2017)**. Spread ratio for control sample was 9.68. With increasing adition level of raw bran the spread ratio significantly decreased up to 5.69. Stabilization of wheat bran using

both methods improved this parameter of enriched cookies. This is in agreement with results observed by **Nandeesh et al. (2011)** after incorporation of roasted, steamed and microwave treated bran.

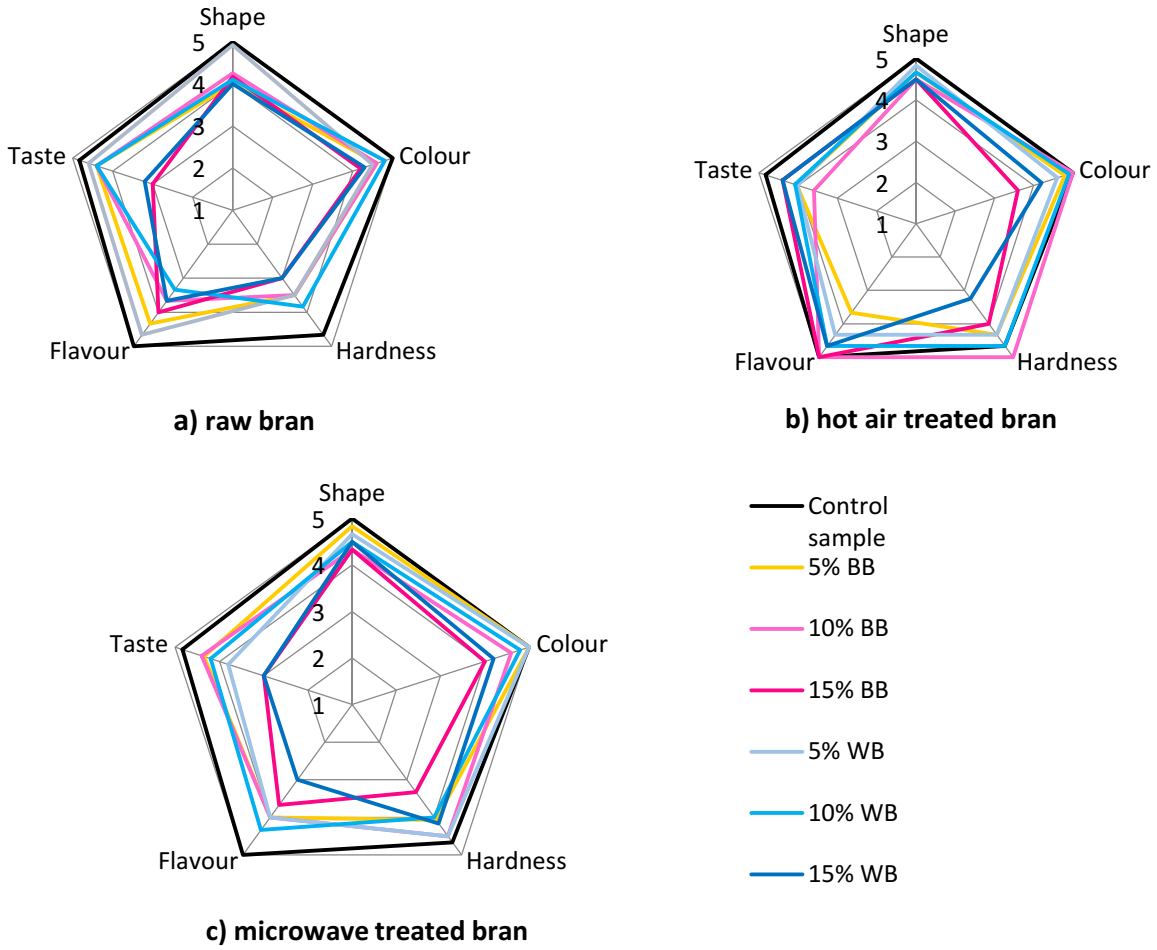

Figure 1 Sensory evaluation of cookies with addition raw wheat bran (a), hot air threated bran (b) and microwave treated bran.

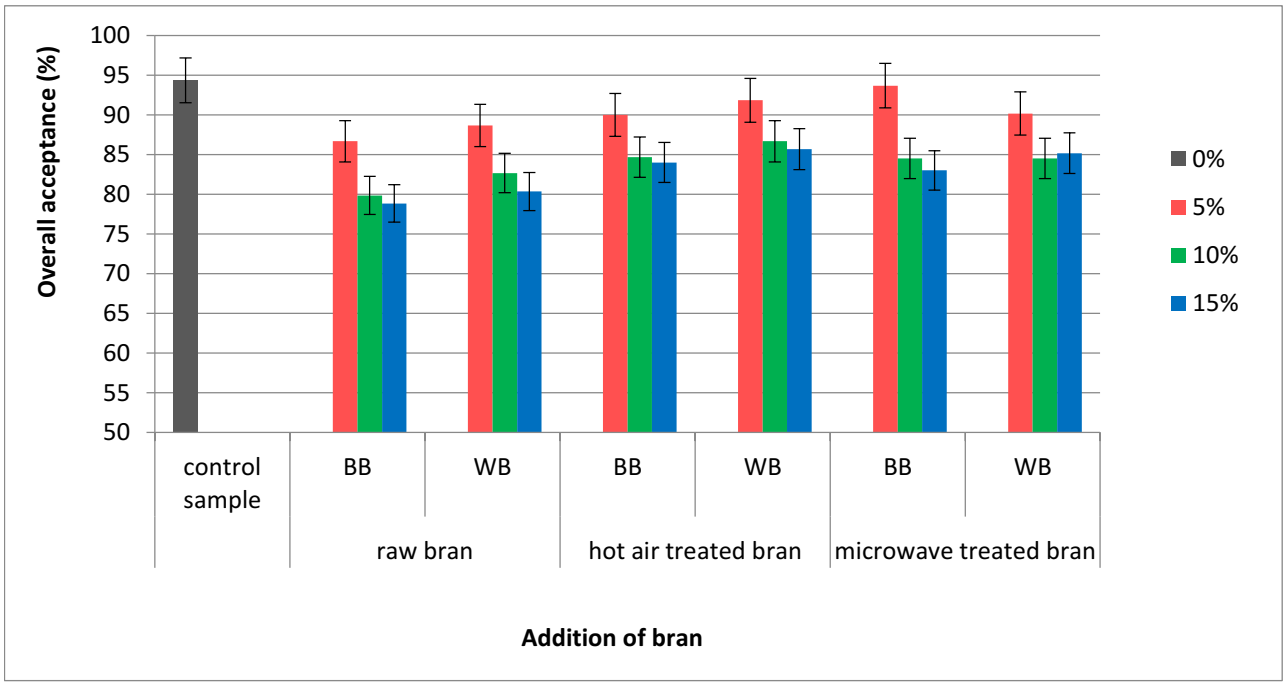

Figure 2 Overal acceptability of wheat bran incorporated cookies. Note: WB – wheat bran from wheat variety PS 215, BB – wheat bran from wheat variety PS Bertold.

Determining the actual baking losses is very important as the finished product after baking must have a defined weight. The loss by baking is influenced mainly by the weight of the product, by shape and moisture content **(Minarovičová et al., 2018)**. Evaluation of baking loss showed that addition of raw wheat bran increased this parameter from 15.09% (control sample) up to 15.98% (5% WB). Higher water evaporation may be due to initially higher water content in the bran-containing biscuit dough as compared to the control because addition of bran to biscuit formulation increases the level of water required **(Filipčev et al., 2017)**. The results also showed that stabilization of bran caused significantly lower values of baking loss (12.57 – 14.80% and 13.85 – 15.86% for cookies enriched with hot air and microwave treated wheat bran, respectively) compared to control sample.

This study shoved that volume index values of cookies enriched with wheat bran were higher compared to control sample of cookies. The highest volume index (2.39 cm) was observed after 15% incorporation of BB.

Texture evaluation of cookies with addition of wheat bran is summarized in Table 2. Maximum peak force recorded from force/distance curve (the maximum force required to break a cookie or maximum resistance of cookie when break) has been reported as hardness **(Dapčević Hadnađev et al., 2013)**. The results showed that supplementation of wheat flour with wheat bran resulted in hight hardness of cookies. This fact is in agreement with study of cookies enriched with roasted, steamed and microwave treated bran by **Nandeesh et al. (2011).** On the other side, cookies incorporated with 15% of bran stabilized using hot air was about 16% softer compared to cookies with addition of raw bran. Stabilization of bran using microwave concluded in about 11.5% decrease of cookies hardness.

Sensory evaluation

Sensory evaluation of cookies incorporated with treated and raw wheat bran is showed in Figure 1 a-c. The surface color of a baked product is, together with texture and taste, a very important element for the initial acceptability of baked goods by consumers **(Ostermann-Porcel et al., 2017)**. From the results concluded that sensorial scores for cookies shape and colour decreased with increasing level of raw wheat bran. Stabilization of wheat bran improved the sensory score of cookies shape. It was also noticed that taste score decreased with increasing addition level of bran. Moreover, the evaluation of taste showed that addition of wheat bran increased the bitter taste of cookies, which is due to content of tannins and phenolic acids **(Heiniö et al., 2016)**. The assessors also describe that incorporation of bran led to dryer cookies. The drying effect of wheat bran might be explained by its water-absorptive properties. Both wheat bran and flour absorb water, but during baking wheat bran may lose water more readily than flour. Biscuits containing wheat bran had less flour; consequently, less water may have remained after baking and the resultant biscuits therefore were perceived as dry by panelists **(Khalil et al., 2015)**. Incorporation of wheat bran in cookies caused lower sensory score of cookies hardness. From the results concluded that stabilization of bran using different methods led to higher hardness acceptance of cookies.

The overall acceptability of cookies with addition of raw and stabilized wheat bran is shown in Figure 2. In general, higher addition levels of bran (10 and 15%) significantly decreased the overall acceptability of cookies. It was noticed that stabilization of bran improved the acceptability of enriched cookies.

CONCLUSION

This study was focused on influence of wheat bran stabilization on qualitative parameters of enriched cookies. Incorporation of wheat bran significantly modified the thermo-mechanical properties of wheat dough. Stabilized bran caused higher protein resistance and stability of hot gel in dough during heating. This study also shoved that pretreatment of wheat bran (using hot air and microwave heating) may improve the qualitative properties of cookies such as volume and hardness. Moreover, the cookies enriched with stabilized bran were more acceptable for assessors.

CHARACTERISTICS OF TEXTURAL AND SENSORY PROPERTIES OF OŠTIEPOK CHEESE

Peter Zajác, Patrícia Martišová, Jozef Čapla, Jozef Čurlej, Jozef Golian

ABSTRACT

Oštiepok is a traditional half-fat semi-hard cheese made in Slovakia. The basic raw material used to produce oštiepok cheese is ewe's milk, a mixture of ewe's and cow's milk or cow's milk. Oštiepok cheese is produced either directly at a small-scale mountainside sheep farm, using the traditional on-farm method of production, or at dairies, using the industrial method. Oštiepok cheese was produced as far back as the beginning of the 18th century. An industrial production of Oštiepok cheese using cow's milk were laid by the Galbavý family in Detva (Slovakia) in 1921. The cheese is originally made by cutting off fresh sweet cheese, which is pressed into a wooden, hand-cut and decorated round shape where it is left to stand. Subsequently, it is removed and immersed in warm salty water, left to stand there until the salt penetrates completely in. Then it is necessary that it pass slightly. In its salty water, the ostrich produces its traditional durability, its surface is slightly peeled, mostly yellowish. This cheese may or may not be steamed and may be smoked or unsmoked. Slovenský oštiepok is a protected trade name under the EU's protected geographical indication. A similar cheese is made in the Polish Tatra Mountains under the name Oscypek. The cheeses differ in ingredients' ratios, cheesemaking process and the characteristics of the final products. In this study we have characterized textural and sensory properties of the Oštiepok cheese produced in Slovakia made from ewe's milk, a mixture of ewe's and cow's milk and cow's milk.

Keywords: Oštiepok cheese; Slovak oštiepok cheese; Slovenský oštiepok; cheese; traditional Slovak cheese

INTRODUCTION

Oštiepok cheese (Slovenský oštiepok – Slovak oštiepok) is characterised by its special shape, that of a large egg, pine cone or ellipsoid with decoration. The colour is golden-yellow to golden-brown on the outside after smoking, white to buttery-yellow on the inside. Consistency is solid, firm, slightly fragile, with minor cracks and cavities appearing when cut. Aroma and flavor is savoury, pleasant distinctive cheese flavour, mildly piquant to sour, moderately salty, with a typical smoky aroma resulting from the smoking process; must not be overly acidic, yeasty, tallowy, soapy, rancid, putrid, sharp, spicy or bitter or have other strange flavours. Composition depends on the raw material used and the method of production, a minimum of 48 % dry matter by weight, a minimum of 38.0 % fat in dry matter by weight.
(Council of the European Union, 2007).

Slovenský oštiepok is presented in the Figure 1. The protection of geographical indications and designations of origin for Slovenský oštiepok was estabilished by the Commission Regulation **No. 943/2008**.

Slovenský oštiepok is produced using ewe's milk obtained from grazing ewes, particularly the *Wallachian*, *Improved Wallachian* and *Tsigai* breeds. These breeds are reared and graze in mountainous areas on mountain slopes within the delimited area. Small producers obtain cow's milk by hand or mechanically and process it immediately after milking. On-farm production of Slovenský oštiepok at a *salaš* (small farm), the stages involved are as follows: curdling, shaping, salting, drying, smoking. In the case of the industrial production, the stages involved are as follows: pasteurisation, addition of cultures, curdling, curd stretching, pressing, acidification, steaming, shaping, salting, drying and smoking **(Council of the European Union, 2007)**.

The cooled cheeses are placed in hygienic food packaging. They are packaged whole to ensure that their characteristic shape and decorations are retained (which would not be the case if they were cut and then packed) and that the quality is preserved, the product is not adulterated and consumers are not deceived. All stages of production take place within the delimited geographical area **(Council of the European Union, 2007)**.

The cheese should be produced only from milk meeting the criteria of the Slovak technical standard **STN 57 05 10** Ewe's milk and **STN 57 05 29** Raw cow milk for dairy treatment and processing. Also, the Commission

Figure 3 Salaš Zbojská. Note: (Salaš is Slovak name for small farm in mountain region).

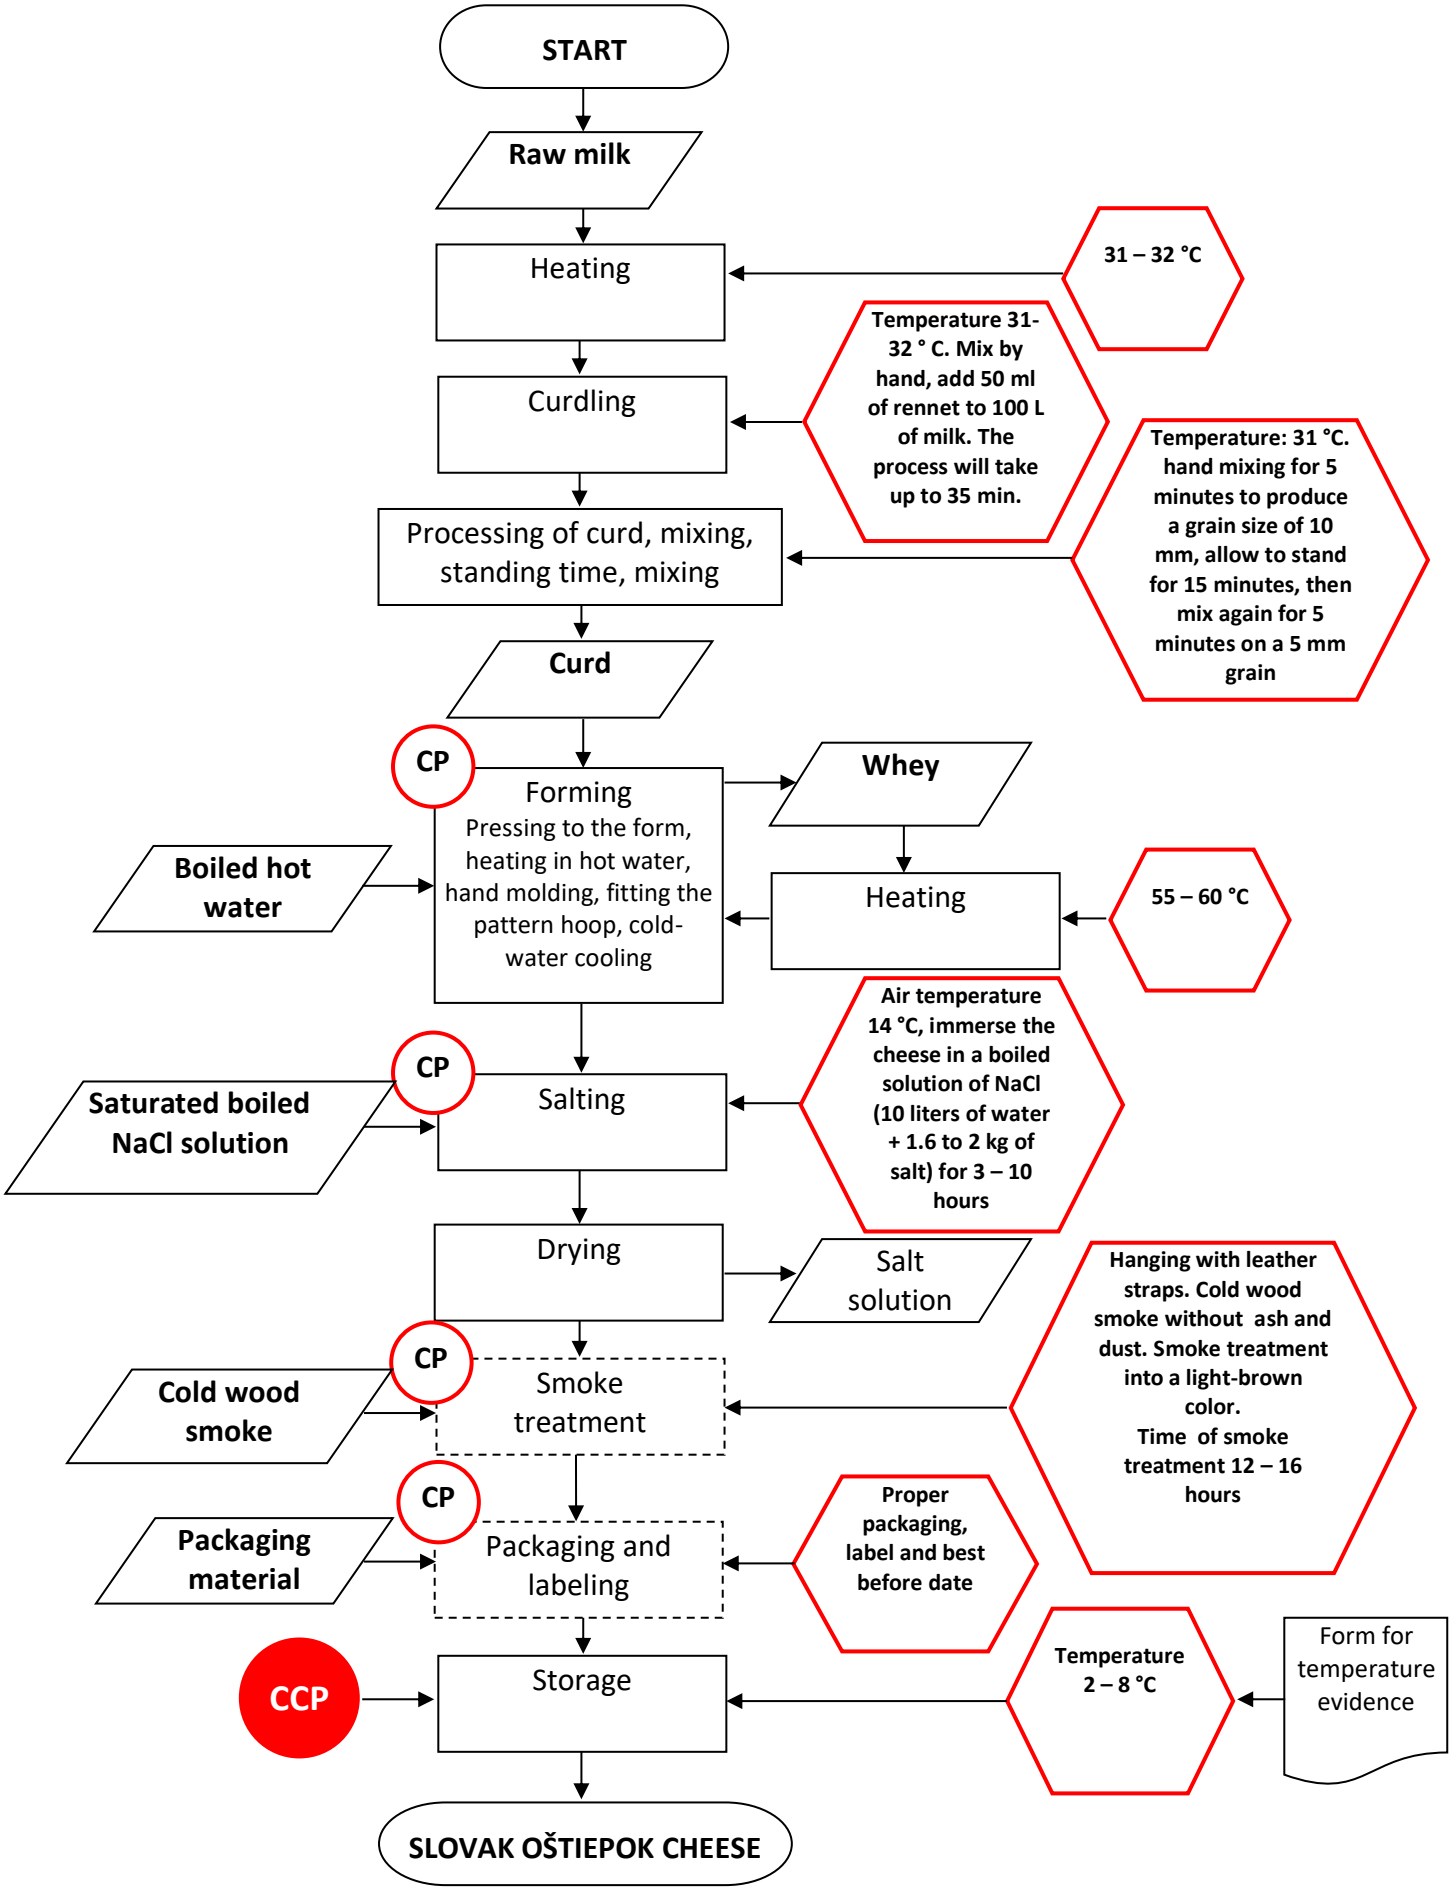

Figure 4 Technological steps of the Slovenský oštiepok (Slovak Oštiepok cheese) production.

Regulation (EC) **No. 1662/2006** and **No. 2073/2005** has to be fulfilled regarding to the hygienic and microbiological criteria.

In this study, we have described in detail the characteristic textural and sensoric properties of Slovenský oštiepok cheese made from ewe's milk, a mixture of ewe's and cow's milk and cow's milk. The hypothesis we have tested was that textural and sensoric characteristics of the Slovenský oštiepok cheese may vary depending on the type of milk used for the production.

Scientific hypothesis

There is a statistically significant difference between Oštiepok cheeses produced in different regions of Slovakia.

MATERIAL AND METHODOLOGY

Cheese samples

Product 1: Ewe's Oštiepok cheese 100% – smoked (Producer: Papúchová D. (Ružomberok, Slovakia), made in: PD Liptovské Revúce), characteristic: dry matter – 48 wt%, fat in dry matter – 50 %, NaCl – max. 2 %, weight – 0.356 kg.

Product 2: Orava ewe's Oštiepok cheese – smoked (Producer: Panči M. (Ružomberok), made in: Šurinák M. (KOLIBA Revišné, Veličná, Slovakia)), characteristic: dry matter min. 45 wt%, fat in dry matter: min. 48 %, NaCl: 4.5 g.100^{-1}g, proteins: 23.1 g.100^{-1}g, carbohydrates: 1.8 g.100^{-1}g, fat: 30 g.100^{-1}g, weight: 0.344 kg.

Product 3: Original ewe's Oštiepok cheese – smoked (Producer: Syrex – Zázrivá, Slovakia), characteristic: fat in dry matter: min. 45 %, salt: 4.5 g.100^{-1}g, proteins: 23.1 g.100^{-1}g, carbohydrates: 1.8 g.100^{-1}g, fat: 30 g.100^{-1}g, weight: 0.218 kg.

Product 4: Ewe's Oštiepok cheese – smoked (Producer: Plachtinská farm – Baránek, Slovakia), characteristic: dry matter: 56 wt%, fat in dry matter: 51 %, salt 1 g.100^{-1}g, proteins: 22.4 g.100^{-1}g, carbohydrates: 1.91 g.100^{-1}g, fat: 29.2 g.100^{-1}g, weight: 0,390 kg.

Product 5: Oštiepok, 100% ewe's cheese – smoked (Producer: Bryndziareň and syráreň – Zvolenská Slatina, Slovakia), characteristic: fat in dry matter: 45 – 60 %, salt: 2.37 g.100^{-1}g, proteins: 22.55 g.100^{-1}g, carbohydrates: 2.61 g.100^{-1}g, fat: 28.65 g.100^{-1}g, weight: 0.542 kg.

Product 6: Ewe's cheese Kolibka Spiš – smoked (Producer: Endel M. – VALACH (Sp. Nová Ves, Slovakia), made in: Kluknavská dairy – OOD Jaklovce, Slovakia), characteristic: fat in dry matter: min. 45 %, salt: max. 2.5 g.100^{-1}g, proteins: 24.5 g.100^{-1}g, carbohydrates: <1 g.100^{-1}g, fat: 26 g.100^{-1}g, weight: 0.328 kg. (Note: Not declared as Oštiepok cheese).

Product 7: Ewe's Oštiepok cheese – smoked (Producer: Badánik – Salaš Krajinka, Slovakia).

Product 8: Oštiepok Ewe's cheese - smoked (Producer: Konečný I. – KONNY (Trenčín, Slovakia), made in: Dairy Krivá, Slovakia), characteristic: dry matter: min. 50 wt%, fat in dry matter: min 40 %, salt: max. 2.5 g.100^{-1}g, fat: 35.26 g.100^{-1}g, weight: 0.242 kg.

Product 9: Ewe's Oštiepok cheese – smoked (Producer: Zúbek M. – OBERT (Ladce, Slovakia)).

Product 10: Ewe's Oštiepok cheese – smoked (Producer: Zvara J. (Detva, Slovakia)).

Product 11: Ewe's Oštiepok cheese – smoked (Producer: Agrosev made in: Plachtinská farm Baránek, Slovakia), characteristic: dry matter: 56 wt%, fat in dry matter: 51 %, salt: 1 g.100^{-1}g, proteins: 22.4 g.100^{-1}g, carbohydrates: 1.91 g.100^{-1}g, fat: 29.2 g.100^{-1}g, weight: 0.284 kg.

Product 12: Oštiepok – Ewe's cheese – smoked (Producer: AgroIna (Banská Bystrica, Slovakia), made in: AgroMagura s.r.o., Slovakia), characteristic: dry matter: min. 40 wt%, fat in dry matter: min. 50 %, salt: 2.5 g.100^{-1}g, weight: 0.458 kg.

Product 13: Original Oštiepok ewe's cheese – smoked (Producer: Chlustová P. (Liptovský Mikuláš, Slovakia), made in: Syrex (Zázrivá, Slovakia)), characteristic: fat in dry matter: min. 45 %, salt: 4.5 g.100^{-1}g, proteins: 23.1 g.100^{-1}g, carbohydrates: 1.8 g.100^{-1}g, fat: 30 g.100^{-1}g, weight: 0.360 kg.

Product 14: Orava ewe's loaf cheese – smoked (Producer: Válek M. (Revišné – Veličná, Slovakia), made in: Šurinák M. – Koliba Revišné (Veličná, Slovakia)), characteristic: dry matter: min. 45 wt%, fat in dry matter: min. 48 %, salt: 4.5 g.100^{-1}g, proteins: 23.1 g.100^{-1}g, carbohydrates: 1.8 g.100^{-1}g, fat: 30 g.100^{-1}g, weight: 0.350 kg. (Note: Not declared as Oštiepok cheese).

Product 15: Ewe's cheese Kolibka Spiš – steamed (Producer: Endel M. Jr. – VALACH (Sp. Nová Ves, Slovakia), made in: Kluknavská dairy – ODD Jaklovce, Slovakia), characteristic: fat in dry matter: min. 45 %, salt: max. 2.5 g.100^{-1}g, proteins: 24.5 g.100^{-1}g, carbohydrates: <1 g.100^{-1}g, fat: 26 g.100^{-1}g, weight: 0.324 kg. (Note: Not declared as Oštiepok cheese).

Product 16: Original ewe's Oštiepok cheese – fresh (Producer: Chlustová P. (Liptovský Mikuláš, Slovakia), made in: Syrex (Zázrivá, Slovakia)), characteristic: fat in dry matter: min. 45 %, salt: 4 g.100^{-1}g, proteins: 19.7 g.100^{-1}g, carbohydrates: 0.8 g.100^{-1}g, fat: 25 g.100^{-1}g, weight: 0.286 kg.

Product 17: Oštiepok Ewe's cheese – fresh (Producer: Dairy Krivá (Krivá, Slovakia)), characteristic: dry matter: min. 50 wt%, fat in dry matter: min. 40 %, salt: max. 2.5 %, weight: 0.270 kg.

Product 18: Orava ewe's Oštiepok cheese – fresh (Producer: Panči M. (Ružomberok, Slovakia), made in: Šurinák M. – Koliba Revišné (Veličná, Slovakia)), characteristic: dry matter: min. 45 wt%, fat in dry matter: min. 48 %, salt: 1.85 g.100^{-1}g, proteins: 26.61 g.100^{-1}g, carbohydrates: 2.15 g.100^{-1}g, fat: 15.18 g.100^{-1}g, weight: 0.374 kg.

Product 19: Original ewe's Oštiepok cheese – fresh (Producer: Syrex (Zázrivá)), characteristic: fat in dry matter: min. 45 %, salt: 4 g.100^{-1}g, proteins: 19.7 g.100^{-1}g, carbohydrates: 0.8 g.100^{-1}g, fat: 25 g.100^{-1}g, weight: 0.296 kg.

Oštiepok cheeses: 1, 2, 3, 4, 5, 7, 8, 9, 10, 11, 12, 13, 16, 17, 18 and 19.

Ewe's cheese not labelled as the Ošiepok cheese, but it meets the requirements for Oštiepok cheese: 14.

Ewe's cheese, but not the Ošiepok cheese: 6 and 15.

INSTRUMENTAL TEXTURAL ANALYSIS

Sample prepraration

We have pilled of the crust of the cheese and the cheese was cut into 30 equal parts of the size 1 x 1cm. Fifteen parts represented the middle of cheese and 15 parts was from edge parts of cheese **(Figure 6)**. Cutted chees blocks were tempered in fridge to 10 °C.

Materials and instruments

We used:

- texturometer TA.XT Plus (Stable Micro Systems),
- computer with a program Exponent (Stable Micro Systems),
- spherical probe (P/1S),
- fridge,
- cheese samples,
- knife.

The analysis of the textural properties of cheese samples was tested using texturometer TA.XT Plus (Stable Micro Systems) at 10 °C. The instrument was setu up according to the manufacturer's recommendations. We focused on following indicators **(Stable Micro Systems, 2016)**:

- firmness of the cheese (g),
- consistency of the cheese (g.s^{-1}).

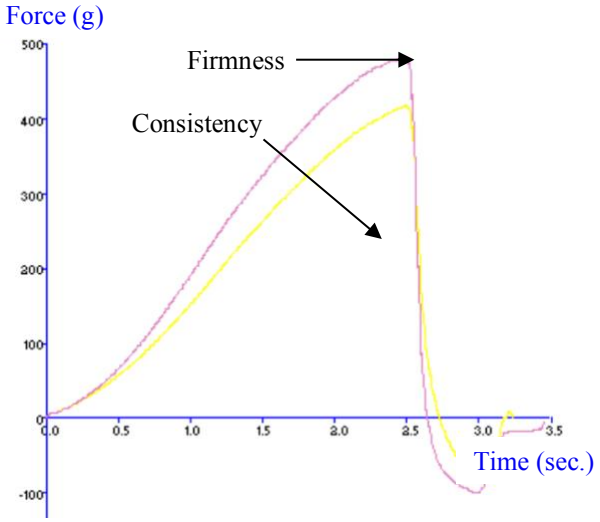

Figure 5 A curve showing the textural properties of cheese in the program Exponent (Stable Micro Systems).

The **Figure 5** shows the textural properties of the measured Oštiešpok cheese. At the highest point of the curve is the firmness of the cheese. The harder the cheese is, the higher is the curve peak (higher the value). The consistency of the cheeses shows the inner area between the curve and the x-axe in the positive area of the figure. The stronger the consistency of the cheese is, the higher is the consistency value this mean the larger is the area in the figure.

SENSORY ANALYSIS

Sample prepraration

We have stripped each Oštiepok cheese and cut into 30 equal parts of the size 1 x 1cm. The sensory analysis was tested using skilled evaluators. The cheese was tempered to 10°C and the temperature in laboratory was 20 °C.

The organoleptic properties of the individual samples were evaluated using a modified profile test. Values for descriptors were: 10 – extremely strong, 9 – very strong, 8 – strong, 7 – moderately strong, 6 – above average, 5 – medium, 4 – weak, 3 – very weak, 2 – treshold, 0 – none.

a) Odor: evaulators focused on two descriptors for odor: cheesy and smoke,

b) Taste: evaulators focused on four descriptors for taste: salty, after smoke, total flavour and other/foreign,

Table 1 Texturometer TA.XT Plus setup

Parameter	Setup
Mode	Measure Force in Compression
Option	Return to Start
Pre-Test Speed:	1.5 mm.s^{-1}
Test Speed:	2.0 mm.s^{-1}
Post-Test Speed:	10.0 mm.s^{-1}
Distance:	5 mm
Trigger Type:	Auto – 2.5 g
Tare Mode:	Auto
Data Acquisition Rate:	400 pps
1“ Spherical Probe (P/1S)	Max. load: 5 kg
	Max. temperature: 200 °C

Note: texturometer setup for measuring firmness and consistency of Oštiepkok cheeses.

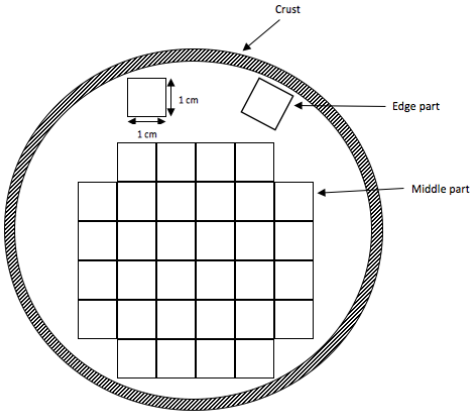

Figure 6 Otiepok cheese **s**ample cutting.

c) Texture: evaulators focused on two descriptors for texture: overall appearance, colour, consistency and scroop.

CHEESE COMPOSITION ANALYSIS

The cheese composition was analysed with standard laboratory methods.

Fat content: ISO 1735:2004 (IDF 5:2004) Cheese and processed cheese products -- Determination of fat content -- Gravimetric method (Reference method).

Protein content: ISO 8968-1:2014 (IDF 20-1:2014) Milk and milk products -- Determination of nitrogen content -- Part 1: Kjeldahl principle and crude protein calculation.

Lactose content: ISO 22662:2007 (IDF 198:2007) Milk and milk products -- Determination of lactose content by high-performance liquid chromatography (Reference method).

Dry matter content: ISO 5534:2004 (IDF 4:2004) Cheese and processed cheese -- Determination of the total solids content (Reference method).

Ash content: Ash content was detected after burning a sample in a muffle furnace at 550 °C for 5 h.

Salt content: ISO 5943:2006 (IDF 88:2006) Cheese and processed cheese products -- Determination of chloride content -- Potentiometric titration method.

STATISTICAL ANALYSIS

Statistical analysis of composition and texture determined by instrument

The results were statistically evaluated using XLSTAT, v. 2018.1 (Addinsoft, USA) statistical program. Firstly, we used the Shapiro-Wilk's test for verifying the normality of data. The significance level (α) was determined at level 0.05 for this test. Consequently, the Kruskal-Wallis one-way ANOVA and Dunn's test were used to test whether there is significant difference between Oštiepok chceeses in composition and texture parameters. We consider the results significantly different at $p < 0.001$. Consequently, we used the principal component analysis (PCA) to show the manin factors of variance between cheeses.

Statistical analysis of data determined by sensory analysis

The results were evaluated using statistical software (XLSTAT, v. 2018.1, Addinsoft, USA). We used a method for a comprehensive assessment of similarity and organoleptic acceptability: Principal component analysis (PCA).

RESULTS AND DISCUSSION

Statistical analysis of composition and texture determined by instrumental analysis

The mean values of composition of Oštiepok cheeses are presented in **Table 2** and were as follows: dry matter 58 wt%, fat ind dry matter 49%, fat 28.42 g.100g^{-1}, carbohydrates 1.81 g.100g^{-1}, protein 22.62 g.100g^{-1}, NaCl 2.85 g.100g^{-1}, other minerals 1.83 g.100g^{-1}.

The results of the normality test showed that the data had a non-normal distribution; the Shapiro-Wilk's test value was <0.05. Subsequently, we performed a Kruskal-Wallis one-way ANOVA and we found that individual products were statistically different ($p < 0.001$) in fat in solid content, solid content, fat, carbohydrates, proteins, NaCl, other minerals and also in textural parameters firmness and consistency. Also, the Dunn's post hoc tests identified, that there are significant diferences ($p < 0.001$) between cheeses in texture parameters determined by texturemeter (consistency and firmness). These results are presented in **Table 3**. The highest values of firmness and consistency parameters were determined for products No. 3 and No. 13 **(Table 3)**. It is because these products has one of the highest values of % of dry metter in comparison of other cheeses analysed in our experiment. The lowest values of firmness and consistency were detected in cheese No. 7 and No. 16 **(Table 3)**.

The mean value of firmness for middle parts of cheeses was 1.332 kg and 1.383 kg for edge parts. The mean value of consistency for middle parts of cheeses was 1.049 kg.s^{-1} and 1.038 kg.s^{-1} for edge parts. There was no significant difference ($p = 0.301$) between middle and edge parts of cheeses in firmness parameter. Also, there was no significant difference ($p = 0.819$) between middle and edge parts of cheese in consistency parameter. The overall mean of firmness of all cheeses was 1.349 ±0.705 kg and Cv 52%. The overall mean of consistency of all cheeses was 1.045 ±0.578 kg.s^{-1} and Cv 55%.

1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19

Figure 8 PCA Analysis of Oštiepok cheeses (sensory parameters: saltines, scroop, consistency, total flavour, odor, smokiness, colour, overall appearance,another foreign taste).

According to **Olešová (2015)**, the average firmness of her own innovated oštiepok chesee ranged from 5.761 kg to 1.843 kg. The highest firmness had oštiepok after 5 weeks of maturing. Oštiepok cheeses after 2 weeks and 3 weeks of maturing did not differ in firmness. The average consistency of her own innovated oštiepok cheeses varied from 3.438 kg. s^{-1} to 1.175 kg. s^{-1}. The highest consistency had the Oštiepok after 5 weeks of maturing. In our study, we have found the highest consistency in product No. 13 (2.259 kg. s^{-1}).

For consumers, texture is a very important factor of quality. It is mainly influenced by the degree of proteolysis, salt, fat and pH **(Pachlová et al., 2012)**.

Cheese texture, especially firmness and sensory properties, changes during the maturing process **(Forde a Fitzgerald, 2000)**. We agree with this, because evin in our work we have confirmed the change in the textural and organoleptic properties of cheeses during maturation.

Cheese texture, consistency and structure depend on the degrre of primary proteolysis. Insufficient proteolysis can cause inadequate cheese consistency, which is described as a gum **(Rodriguez et al., 2011)**.

The firmness of the cheese can also be influenced by the penetration of NaCl **(Pachlová et al., 2012)**.

We have found statistically significant (p <0.001) difference between the product No. 3 with the highest NaCl content (4.44 g.$100g^{-1}$) and the product No. 11 with the lowest NaCl content (1.52 g.$100g^{-1}$) in firmness parameter 2.078 kg vs 0.959 kg. But in our experiment, this could be influenced also by the difference in Dry matter content 62 wt% vs 58 wt% and Fat in dry matter content 49% vs 51%.

The results of sensory analysis

The results of the normality test showed that the data had a non-normal distribution; the Shapiro-Wilk's test value was <0.05. Subsequently, we performed a Kruskal-Wallis one-way ANOVA and we found that individual products were statistically different (p <0.001) in all sensory parameters tested. Also, the Dunn's post hoc test identified, that there are significant (p <0.001) diferences between cheeses, specially between smoked and not smoked cheeses.

The sensory properties of Oštiepok cheeses were different because the technological process can slightly differ between the producers. Some of the most important factors, which can affect this process are: milk pasteurisation temperature, rennet, rennet dose and power, temperature of milk during curdling, different curd processing and mixing time, pressing to the form, salting, drying, smoking, temperature during storrage and maturation. Differences in these technological steps lead to the differences in textural and sensory parameter, which we were identified in this work. The quality of the traditional product can varies from farm to farm and is also different among farmers.

Similar results and differences in quality of traditional products have also been achieved by **Čuboň et al. (2015)**

The temperature during cheese maturation influences the content of microorganisms **(Kunová, et al., 2015; Cwiková, 2015)**.

In the case of microbial cross contamination, or inadequate pasteurisation, the risk of the presence of microorganisms will increase.

Figure 26 Product 18: Orava ewe's Oštiepok cheese – fresh (Producer: Panči M. (Ružomberok), made in: Šurinák M. – Koliba Revišné (Veličná, Slovakia)).

There is a lot of microorganisms, which can affect the quality and safety of the product.

The process of cheese maturation affects the growth of probiotic cultures in cheese **(Poľáková, Dudriková and Gallo, 2010; Lovayová et al. 2010)**.

The occurence of *S. aureus, E.* coli and others microorganisms in ewe's milk can lead to the serious health problems **(Poľáková, Dudriková and Gallo, 2011; Medveďová et al. 2010)**.

It is necessary to follow the rules of good hygiene practice, good manufacturing practice, sanitation, to use raw milk of good quality in the production of cheese and to follow the HACCP system guide **(Medveďová et al. 2010; Zajác, Čapla and Golian, 2017a; Zajác, Čapla and Golian, 2017b),** which was preprared and by the Union of sheep and goats breeders in Slovakia and implemented in all small salaš farms in our country.

In our experiment we have identified one product, No. 9 **(Figure 17)** with evident microbial defect. In the cut of this cheese you can see an activity of sporoform microorganisms (a lot of air cavities in cheese). This defect could occur not only for technological reasons but also as a result of transport or storage at the wrong temperature.

Sensory properties can be influenced by the addition of flavorings **(Pavelková, Flimelová and Vietoris, 2012),** but in our experiment we didn't found any cheese with additional flavorings. All of the producers were used only the raw materials authorized by legislation (milk, rennet, NaCl and some of them also $CaCl_2$).

Majcher et al. (2011) states that in shaping curd into a characteristic shape is the cheese pressed into a two-part wooden mold with a cut out ornament, obtaining a Oštiepok

cheese that will be decorated on the surface with an ornament.

We agree, cheeses analysed in this work had characteristic special shape, taste and odor and ovrall appearance. We found that most of the Oštiepok cheese had these properities **(Figures 9 – 27)**, but two of them, product No. 6 and No. 15 does not comply this traditional shape.

The natural preservation method, such as smoking at the salaš (small farm in the mountain region) delivers to Oštiepok cheese a typical golden brown to brown color and typical taste. **(Majcher a Jelen, 2011)** and these aromatic compounds play a very important role in the quality of food **(Attaie, 2009, Benešová, Golian and Zajác, 2018)**.

It is, because cheese taste is the result of the balance between volatile and non-volatile chemical compounds **(Hayaloglu et al., 2013)** and the smoking of cheese add extra portion of these volatile compounds.

From the consumer point of view, it is important to ensure the quality and safety of the products. Because ewe's milk is more expensive than cow's milk, adulteration of Oštiepok cheese may occur. Oštiepok cheese produces with the addition of cow's milk are issued as products made only from ewe's milk. Various laboratory methods can be used to detect adulteration **(Zeleňáková et al., 2016)**.

As part of our experiment, we have tested three ewe's cheeses, which were not the Oštiepok cheese (Products No. 6, No. 14 and No. 15) but sometimes the consumers may buy them instead of the Oštiepok cheese. These products had a different look, they were shaped like a bowl or the loaf. The composition of these cheese were similar to Oštiepok cheeses. The producer of the product No. 14. didn't use the possibility to mark this product as the Oštiepok cheese despite the fact that this product meets the requirements of the Oštiepok cheese. In the case of the Products No. 6 and 15 the difference was in one extra technological step – steaming the cheese in hot water and in the case of the product No. 15 also the the addition of dairy culture. The labelling of these products was correct. The producers correctly did not mark them as the oštiepok cheese.

The consumers can distinguish traditional products, but some may have a problem. It is therefore appropriate to designate such products with a specific protected geographical indication PGI mark of the European Union. At the time of our experiment, no producer of Oštiepok cheese in Slovakia used the protected geographical indication (PGI) mark "Slovenský oštiepok" in the product labelling or in its immediate vicinity of the product during its sale despite the fact that the Slovak Republic has such possibility given by the European Union and Slovak legislation. It means, the competent government authority Ministry of Agriculture and Rural Development of the Slovak Republic and interested parties like the Dairy association od the Slovak Republic or the Union of sheep and goat breeders of the Slovak Republic should do more to inform the producers of the possibility to mark this Slovak national specialty with PGI mark and help them with a bureaucratic process of this matter. It will then be necessary to carry out an information campaign for consumers to recognize such traditional products from ordinary products in the market.

CONCLUSION

Oštiepok cheese is a traditional half-fat semi-hard cheese made in Slovakia. Oštiepok cheese can be made from raw ewe's milk, a mixture of ewe's and cow's milk or cow's milk. Oštiepok cheese is characterised by its remarkable shape, that of a large egg, pine cone or ellipsoid, and is decorated according to the practices and with the typical designs of the individual area in which it is produced. The surface of this cheese is firm, smooth and shiny. Subsequent smoking gives the product its typical colour, smoked aroma and taste. This special process is originated in and is carried out throughout the entire delimited area of Slovakia mainly in small montains farms called salaš or in dairy companies. We have found significant (p <0.001) differences between Oštiepok cheeses from different regions of the Slovakia. The mean values of composition of Oštiepok cheese was: dry matter 58 wt%, fat in dry matter 49%, fat 28.42 $g.100g^{-1}$, carbohydrates 1.81 $g.100g^{-1}$, protein 22.62 $g.100g^{-1}$, NaCl 2.85 $g.100g^{-1}$, other minerals 1.83 $g.100g^{-1}$. The overall mean of firmness of all cheeses was 1.349 ±0.705 kg and Cv 52%. The overall mean of consistency of all cheeses was 1.045 ±0.578 $kg.s^{-1}$ and Cv 55%.

THE EVALUATION OF SELECTED QUALITATIVE PARAMETERS OF SWEET POTATO (*IPOMOEA BATATAS* L.) IN DEPENDENCE ON ITS CULTIVAR

Miroslav Šlosár, Alžbeta Hegedűsová, Ondrej Hegedűs, Ivana Mezeyová, Ján Farkaš, Marcel Golian

ABSTRACT

The sweet potato (*Ipomoea batatas* L.) is relatively known vegetable species, but it is grown only on small area in the Middle European region. Its cultivars are characterized by different colour of tuber flesh which can be white, beige, yellow, orange and purple. The aim of this study was to determine and compare selected qualitative parameters of tubers (total carotenoids, vitamin C and total soluble solids) among orange, white and purple sweet potato cultivars. The field experiments were established at Slovak University of Agriculture in Nitra in 2016 and 2017. Sweet potatoes were grown by hillock system with using of black non-woven textile for soil mulching. The tuber harvest was realised on the 6th October 2016 and 13rd September 2017. The highest content of total carotenoids was found in orange sweet potato cultivars (78.47 – 122.89 mg.kg^{-1} fresh weight) and its values were multiple-fold higher in comparison with purple (4.22 mg.kg^{-1} f. w.) and white (10.71 mg.kg^{-1} f. w.) cultivars. Orange cultivars were also richer source of vitamin C (246.31 – 325.99 mg.kg^{-1} f. w.) compared to white (179.66 mg.kg^{-1} f. w.) and purple (187.75 mg.kg^{-1} f. w.) cultivars of sweet potatoes. The total soluble solids, expressing mainly sugar content, was higher in purple (10.13 °BRIX) cultivar of sweet potatoes, followed by cultivars with orange (8.52 – 9.72 °BRIX) and white (5.57 °BRIX) tuber flesh. Obtained results showed the significant effect of cultivar, characterized by different tuber flesh colour, on the composition and contribution of sweet potatoes for human health.

Keywords: sweet potato; quality; carotenoids; vitamin C; total soluble solids

INTRODUCTION

Sweet potato (*Ipomoea batatas* L.) belongs to the family *Convolvulaceae* and genus *Ipomoea* **(Firon et al., 2009)**. **Loebenstein (2009)** indicate, that sweet potatoes (syn. batatas) were domesticated before more than 5000 years in tropical America. According to the database **FAOSTAT (2019)**, world sweet potato production within period 2007 – 2016 was ranged from 101,3 to 105,4 mil. tonnes. **Musilová et al. (2017)** state that sweet potatoes are grown in Slovak republic only by small growers.

Sweet potatoes are universal and delicious vegetable species with high nutritional value because of many medicinally valuable compounds with anticarcinogenic, antidiabetic and anti-inflammatory activity **(Mohanraj and Sivasankar, 2014)**. According to the database **USDA (2019)**, sweet potato tubers are characterized by higher energetic value in comparison with classical potatoes (*Solanum tuberosum* L.). Sweet potatoes have higher ratio amylose to the amylopectin compared to the potatoes. The amylose increases the sugar level in blood more slowly compared to the simple saccharides and it is recommended as healthier food component, including for people suffering by diabetes **(Mohanraj and Sivasankar, 2014)**.

The flesh of sweet potato tubers can be white, beige, yellow, orange and purple **(UPOV, 2010)**. **Allen et al. (2012)**, sweet potato cultivars with orange flesh colour contain are rich sources of carotenoids, known as provitamins A. The dominant carotenoid substance in sweet potatoes is β-carotene **(USDA, 2019)**. **Kammona et al. (2015)** found that β-carotene ratio from total carotenoid content in sweet potatoes was varied from 79.0 (white flesh) to 97.9% (purple flesh). The biochemical change of β-carotene in human body is formed vitamin A; however, it is not possible to state that β-carotene should have the same importance as vitamin A **(Hegedűsová et al., 2016)**. The β-carotene is very effective scavenger of free oxygen radicals which could be responsible for skin damage, eye retina degeneration, cataract formation or various types of cancer. From this reason, β-carotene is ranged to the group of important antioxidant substances **(Pisoschi and Pop, 2015)**.

The vitamin C (syn. ascorbic acid) belongs to the most important vitamins and it is characterized by significant antioxidant properties. The most of plants and animals synthesize vitamin C from glucose; however, the human organism is not able to form vitamin C and is dependent on

its intake from food **(Schlueter and Johnston, 2011)**. The vitamin C is the less stable and most sensible vitamin and it is used as the indicator of change level in relation to the plant product processing **(Giannakourou and Taoukis, 2003)**. **Schlueter and Johnston (2011)** state that vitamin C protects human body against infection of respiratory system and reduces the risk formation of cardiovascular diseases and several cancer types. **Mei and Tu (2018)** indicate that intake of sufficient amount of vitamin C acts against *Helicobacter pylori* which is marked as an important risk factor for stomach cancer formation. According to the study of **Harrison (2012)**, vitamin C plays important protective role against Alzheimer's disease, characterized by decrease of cognitive abilities. The vitamin C is also important for sperm protection against oxidative damage and higher sperm quality of smokers **(Colagar and Marzony, 2009)**.

Scientific hypothesis

The sweet potato is relatively known but a few grown vegetable species in the Middle European region. There is expected a variable content of tested qualitative parameters among sweet potato cultivars with different-coloured flesh tuber.

MATERIAL AND METHODOLOGY

The field experiments with sweet potato were realized on the land of the Slovak University of Agriculture in Nitra in 2016 and 2017. The climate of experimental area is characterized by warm and dry summer and slightly warm, dry or very dry winter. According to the climatic normal 1951 – 2000 for Nitra, annual mean temperature is 9.9 °C and mean rainfall total is 548 mm **(Šlosár et al, 2016)**. Within vegetation period (May – September), the average air temperature was 18.7 °C in 2016 and 19.3 °C in 2017. The rainfall total, during vegetation period, was 312 (2016) and 216 mm (2017).

Plant material

Sweet potato seedlings were purchased from Croatian producer. In Europe, situation with cultivar assortment of sweet potato is often unclear and confusing. A lot of seedlings are produced according to the mother's tuber availability on the market. Thus, the origin of sweet potato seedlings on market is often un-known. Within this study, four cultivars with different tuber flesh colour were tested (Figure 1). The sweet potato cultivar 'Beauregard' was only one certified cultivar and it is very known cultivar with orange flesh colour. Other three cultivars were marked according to the market place from which tubers for seedling production was purchased and used. These cultivars were named as 'Dubaian' (orange cultivar from United Arab Emirates), 'Višnjica white' and 'Višnjica purple' (white and purple cultivar from Croatia). The basic characteristics of all cultivars, evaluated according to the descriptor **UPOV (2010)**, is described in the Table 1.

Experiment organization

The sweet potato is warm-requiring crop which needs warm season lasting at least four months with an average temperature more than 20 °C and without freeze **(Antonio et al., 2011)**. From this reason, out planting of sweet potato seedlings was realised on the 25th May 2016 and 1st June 2017 when the risk of later spring freeze is significantly reduced.

Within soil preparation for sweet potato growing, nitrogen was only applied on the soil supply level of 60 kg.ha^{-1} according to results of agrochemical soil analyses (Table 2). Sweet potato plants were grown by hillock system, similar to the carrot growing (height of 0.30 m). The distance between hillock rows was 1.20 m. In each row, 18 sweet potato seedlings were planted in distance of 0.30 m. Rows for all tested cultivars were divided to three replications with 6 sweet potato plants. The black non-woven textile was used for soil mulching before planting of sweet potato seedlings because of better microclimate around plants.

The harvest of sweet potato tubers was realised on the 6th October 2016 and 13rd September 2017. Harvested tubers of sweet potato were classified according to average weight of tubers in two size classes: >150 g – marketable yield of tubers and <150 g – non-marketable yield of tubers. Qualitative parameters of sweet potatoes were evaluated in marketable tubers. The average sample of each sweet potato cultivar for analyses was prepared from 6 tubers. All tubers were quartered, and opposite quarters were used for qualitative analyses.

Determination of qualitative parameters

Total carotenoid content estimation

The estimation of total carotenoid content was realised in the laboratory of Department of Vegetable Production, Slovak University of Agriculture in Nitra. The total carotenoid content was estimated by spectrophotometric measurement of substances absorbance in petroleum ether extract on spectrophotometer PHARO 200 at 445 nm wavelengths. As an extraction reagent, acetone was used acetone **(Hegedüsová et al., 2018)**.

Vitamin C content estimation

The estimation of vitamin C content was realised in the laboratory of Department of Chemistry, Janos Selye University in Komárno. HPLC method of vitamin C content estimation **(Hegedüsová et al., 2018)** was used by the help of liquid chromatograph with UV detector, for separation was used RP C18 column, mobile phase was methanol:water (5:95, v/v), UV detection was adjusted to 258 nm (HPLC Waters 2489 UV/VIS Detector).

Total soluble solids estimation

The juice from the homogenized sample of sweet potatoes was squeezed on the dry block of the digital hand-held refractometer (Kern ORD 45BM, Balingen, Germany). The value of soluble solids was directly read. Measurement was performed at room temperature according to **Hegedűsová et al. (2018)**.

Statistic analysis

The statistical analysis of obtained results was performed by using of the Statgraphic Centurion XVII (StatPoint, USA). Results were evaluated by analysis of variance (ANOVA) and average values were tested by LSD test performed at the significance level of 95% (p <0.05).

Table 1 Evaluated morphological characteristics of sweet potato tubers.

Parameter	Beauregard	Dubaian	Višnjica white	Višnjica purple
Shape	ovate	ovate	ovate	ovate/irregular/oblong
Main skin color	light-purple	red-purple	beige	red-purple
Secondary skin color	orange	-	pink	-
Main flesh color	orange	orange	white	purple
Secondary flesh color	beige	-	-	beige

Table 2 Agrochemical soil characteristics before trial experiments in 2016 and 2017.

Year	pH_{KCl}	Humus (%)	Nutrient content (mg.kg^{-1} of soil)					
			$N_{min.}$	P	K	Ca	Mg	S
2016	7.14 N	4.17 H	13.0 M	198.8 VH	487.5 VH	6100 H	816 VH	26.3 M
2017	7.18 N	3.75 G	10.1 M	147.5 H	477.5 VH	5850 H	762.6 VH	91.3 H

Note: N_{min} – N mineral (N inorganic); N – neutral; G – good; M – medium; H – high; VH – very high.

Table 3 Average content of total carotenoids, vitamin C and total soluble solids in sweet potatoes.

Cultivar	Total carotenoids (mg.kg^{-1} ±SD)	Vitamin C (mg.kg^{-1} ±SD)	Total soluble solids (°BRIX ±SD)
Beauregard	78.47 ±7.74^{c}	246.31 ±86.36^{b}	8.52 ±1.61^{b}
Dubaian	122.89 ±9.57^{d}	325.99 ±127.12^{c}	9.72 ±1.63^{c}
Višnjica white	10.71 ±1.51^{b}	179.66 ±41.52^{a}	5.57 ±0.90^{a}
Višnjica purple	4.22 ±0.81^{a}	187.75 ±71.76^{a}	10.13 ±1.63^{d}

Note: SD – standard deviation.

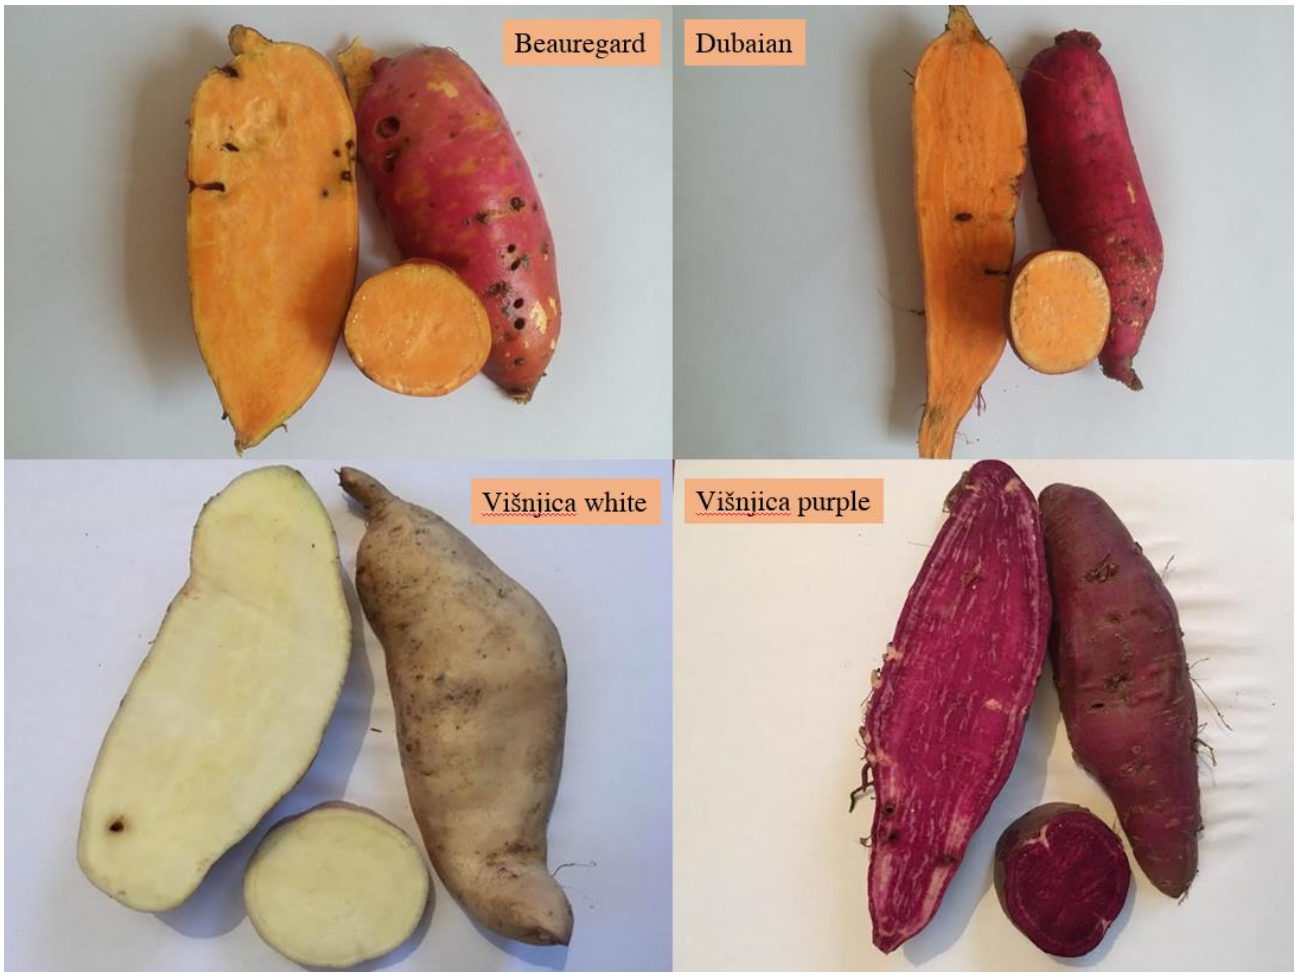

Figure 1 Tested sweet potato cultivars.

Total carotenoid content (TCC)

The statistical analysis of obtained results showed statistically significant (p <0.05) differences of TCC among tested sweet potato cultivars (Table 3). The average values of TCC were ranged from 4.22 ('Višnjica purple') to 122.89 mg.kg^{-1} fresh weight ('Dubaian'). Significant differences of TCC were found among orange and purple/white cultivars; it confirmed similar findings presented by **Allen et al. (2012)** or **Sebuliba, Nsubuga and Muyonga (2001)**. In mentioned studies, authors stated that important source of carotenoids are mainly orange sweet potato cultivars. **Alam, Rana and Islam (2016)** found the variability of TCC in nine orange cultivars of sweet potatoes from 3.8 to 72.4 mg.kg^{-1} f. w. Results found by **Tomlins et al. (2012)** also confirmed that orange cultivars (8.5 – 72.5 mg.kg^{-1} f. w.) are significantly richer sources of carotenoid in comparison with white cultivars of sweet potatoes (0.4 – 1.3 mg.kg^{-1} f. w.). Values of TCC, presented in both studies, were lower than results found in our experiments. The expressive variability of TCC in orange sweet potato cultivars was presented in study of **Ndah and Ojimelukwe (2018)** in which values of TCC was ranged from 18.01 to 180.98 mg.kg^{-1} f. w. Values of TCC in most of cultivars are comparable to orange cultivars tested in our study. **Tang, Cai and Xu (2015)** tested the effect of cultivars with different flesh colour on the TCC in sweet potatoes. The highest TCC was found in orange cultivars (157.9 mg.kg^{-1} f. w.), followed by yellowish-creamy (75.4 mg.kg^{-1}), light-purple (5.19 mg.kg^{-1}), white (4.46 mg.kg^{-1}) and dark-purple cultivars (2.85 mg.kg^{-1}) of sweet potatoes. In comparison to results of our study, TCC was higher in orange cultivars, comparable in purple cultivars and lower in white cultivars of sweet potatoes. **Grace et al. (2014)** found the significantly higher TCC in orange (95.00 mg.kg^{-1} f. w.) sweet potato cultivars compared to the cultivars with yellow (3.40 – 5.16 mg.kg^{-1}) and white (0.55 mg.kg^{-1}) flesh colour. Expressive differences of TCC among sweet potato cultivars, dependent on the colour of tuber flesh, were also found in the study of **Kammona et al. (2015)**. Values of TCC was ranged in following order of tuber flesh colour: orange (389.22 mg.kg^{-1} dry weight) > yellow (138.96 mg.kg^{-1}) > purple (116.28 mg.kg^{-1}) > white (115.18 mg.kg^{-1}). The strong interaction between flesh colour and TCC in sweet potatoes was also presented in studies of **Ellong et al. (2014)**, **Hussein, Billard and Adenet (2014)** and **Leighton. Schönfeldt and Kruger (2010)**.

The most important and dominant carotenoid substance in sweet potatoes is β-carotene **(USDA, 2019)**. According to **Kammona et al. (2015)**, β-carotene ratio from TCC, dependent on the sweet potato flesh colour, was following: purple flesh (97.9%) > orange flesh (93.8%) > yellow flesh (84.1%) > white flesh (79.0%). **Yildirim, Tokuşoğlu and Öztürk (2011)** tested the variability of β-carotene content in ten sweet potato cultivars and it was ranged from 50.1 (yellow) to 70.3 (orange) mg.kg^{-1} f. w. Compared to previous studies, **Suparno, Prabawardani and Pattikawa (2016)** found minimal variability of β-carotene content (62.98 – 64.69 mg.kg^{-1} f. w.) in sweet potatoes. **Wu et al. (2008)** found significantly higher content of β-carotene in orange sweet potato cultivars (55.9 – 231.1 mg.kg^{-1} f. w.) compared to the cultivars with white (23.0 mg.kg^{-1}), yellow (5.2 mg.kg^{-1}) and purple (0.60 mg.kg^{-1}) cultivars. The significant effect of cultivar on the content of β-carotene in sweet potatoes was found in the study of **Vimala et al. (2011)**. Authors tested 42 orange sweet potato cultivars and values of β-carotene was ranged from 10.4 to 143.7 mg.kg^{-1} f. w. Compared to the previous study, **Ukom, Ojimelukwe and Okpara (2009)** found lower β-carotene in orange and white sweet potatoes which was ranged from 5.23 to 11.77 mg.kg^{-1} f. w., dependent on the cultivar. Results presented by **Aywa, Nawiri and Nyambaka (2013)** confirm findings of previous studies. Authors found that sweet potato cultivars are significantly richer source of β-carotene (46.19 – 48.89 mg.kg^{-1} f. w.) compared to cultivars with different flesh colour (20.17 – 26.28 mg.kg^{-1} f. w.).

Vitamin C

The variance analysis of obtained results showed statistically significant (p <0.05) differences of vitamin C content among tested cultivars, except of relation between cultivars 'Višnjica white' and 'Višnjica purple' (Table 3). The average content of vitamin C was increasing in following cultivar order: 'Višnjica white' (179.66 mg.kg^{-1} fresh weight) < 'Višnjica purple' (187.75 mg.kg^{-1}) < 'Beauregard' (246.31 mg.kg^{-1}) < 'Dubaian' (325.99 mg.kg^{-1}).

Rautenbach et al. (2010) tested impact of cultivar on the vitamin C content in sweet potatoes and its values were ranged from 155 to 322 mg.kg^{-1} f. w. These values are comparable to our results. The significant differences of vitamin C content in sweet potatoes (8 different-coloured cultivars) were found in the study of **Ellong et al. (2014)**. The highest vitamin C content was found in yellow cultivars (178 – 291 mg.kg^{-1} f. w.), followed by cultivars with beige (143 mg.kg^{-1}), white (41 – 128 mg.kg^{-1}) and purple (54 mg.kg^{-1}) flesh colour. Compared to our study, vitamin C content was lower in white and purple sweet potato cultivars. The expressive effect of cultivar on the vitamin C content in sweet potatoes was presented by **Yildirim, Tokuşoğlu and Öztürk (2011)** who found its lower values in orange cultivars (252 – 386 mg.kg^{-1} f. w.) in comparison with creamy (252 – 386 mg.kg^{-1}) and yellow (237 – 381 mg.kg^{-1}) flesh colour. In orange cultivars, values of vitamin C content was comparable to our tested cultivars 'Beauregard' and 'Dubaian'. **Aywa, Nawiri and Nyambaka (2013)** found significantly lower values of vitamin C content in comparison with our study. Similarly, authors found higher vitamin C content in orange cultivars compared to white and purple cultivars of sweet potato. The higher content of vitamin C in orange-coloured sweet potatoes in comparison with purple cultivars was also stated by **Grace et al. (2014)**. Compared to our experiment, **Croitoru et al. (2017)** found lower vitamin C content (66 – 117 mg.kg^{-1} f. w.) in tubers of sweet potatoes. The lower values of vitamin C content (129 – 142 mg.kg^{-1} f. w.) was also presented by **Maria and Rodica (2015)**. **Krochmal-Marczak et al. (2013)** determined the vitamin C content in dependency on the flesh colour of sweet potatoes (white, orange, purple). The vitamin C content in orange sweet potato cultivar (242 mg.kg^{-1} f. w.) was lower compared to our tested orange cultivars. On the contrary, authors found higher vitamin C content in white (242 mg.kg^{-1}) and purple (203 mg.kg^{-1}) cultivars of sweet potatoes in comparison with results of our study. The

significantly higher vitamin C content in purple (727 mg.kg^{-1} f. w.) and white (672 mg.kg^{-1}) sweet potatoes was found in the study of **Suparno, Prabawardani and Pattikawa (2016)**.

Within study of **Barrera and Picha (2014)**, the average vitamin C content in cultivar 'Beauregard' (214 mg.kg^{-1} f. w.) was lower than in our experiment. **Mitra (2012)** determined the vitamin C content in 15 orange cultivars of sweet potato. Its values were ranged from 129 to 268 mg.kg^{-1} f. w.; only one of tested sweet potato cultivar was higher compared to orange cultivars in our experiment. **Gichuhi et al. (2014)** found nearly 4-fold lower vitamin C content in cultivar 'Beauregard' (64 mg.kg^{-1} f. w.) compared to this cultivar tested in our experiment.

Total soluble solids

According to **Cejpek (2012)**, the method for estimation of total soluble solids (TSS) are used for testing of sugar content in syrup, fruit and vegetable juices or dairy products and total concentration of monosaccharides and disaccharides in any solutions. **Hegedűsová et al. (2018)** define TSS as additive quantity which expresses the content of dissolved substances, mainly sugars, in vegetable extracts. As the unit of TSS, Brix degrees (°BRIX) are used.

The statistical analysis of gained results revealed statistically significant (p <0.05) differences of TSS content among all tested cultivars of sweet potato (Table 3). The highest average content of TSS was found in purple cultivar 'Višnjica purple' (10.13 °BRIX), followed by orange cultivars 'Dubaian' (9.72 °BRIX) and 'Beauregard' (8.52 °BRIX) and white cultivar 'Višnjica white' (5.57 °BRIX). **Nair et al. (2015)** found values of TSS content in sweet potatoes in the range from 7.9 to 8.8 °BRIX. In cultivar 'Beauregard', authors found lower TSS content (7.9 °BRIX) compared to value found in the same cultivar in our experiment.

The significant differences of sugar content in sweet potatoes were presented in several studies. **Krochmal-Marczak et al. (2013)** found significantly higher content of total sugars in white sweet potato cultivar (3.85 g.100g^{-1} f. w.) compared to cultivars with orange (2.90 g.100g^{-1}) and purple (2.16 g.100g^{-1}) flesh colour. In comparison to our study with TSS, it means opposite order of different coloured flesh of sweet potatoes. On the contrary to previous mentioned study, **Sanoussi et al. (2016)** determined the significantly higher sugar content in orange cultivars (22.45 g.100g^{-1} f. w.) compared to white (17.95 g.100g^{-1}) cultivars of sweet potatoes. **Ellong, Billard and Adenet (2014)** found higher sugar content in purple sweet potato cultivar (33.62 g.100g^{-1} f. w.) in comparison with white cultivars (26.79 – 33.12 g.100g^{-1}). The significant impact of cultivar on the sugar content in sweet potatoes was also found by **Yildirim, Tokuşoğlu and Öztürk (2011)**, **Mitra (2012)** and **Alam, Rana and Islam (2016)**. Compared to previous studies, **Salawu et al. (2015)** found minimal differences of sugar content between sweet potato cultivars with purple (65.17 g.100 g^{-1} f. w.) and white (65.10 g.100 g^{-1}) flesh colour.

CONCLUSION

The sweet potato (*Ipomoea batatas* L.) is relatively known vegetable species, but it is grown only on small area in the Middle European region. It belongs among very important and often used vegetable species in the world, mainly in Asia and Africa. The sweet potato cultivars are characterized by different colour of tuber flesh which can be white, beige, yellow, orange and purple. The most used and typical for sweet potatoes are orange cultivars. The aim of this study was to determine and compare selected qualitative parameters of tubers among orange, white and purple sweet potato cultivars. The highest total carotenoid content was found in orange (78.47 – 122.89 mg.kg^{-1} fresh weight) sweet potato cultivars and its values were multiple-fold higher in comparison with purple (4.22 mg.kg^{-1} f. w.) and white (10.71 mg.kg^{-1} f. w.) cultivars. The vitamin C content in orange cultivars (246.31 – 325.99 mg.kg^{-1} f. w.) was also significantly (p <0.05) higher compared to white (179.66 mg.kg^{-1} f. w.) and purple (187.75 mg.kg^{-1} f. w.) cultivars of sweet potatoes. The total soluble solids, expressing mainly sugar content, was higher in purple (10.13 °BRIX) cultivars of sweet potatoes, followed by cultivars with orange (8.52 – 9.72 °BRIX) and white (5.57 °BRIX) tuber flesh. Obtained results indicate that cultivar of sweet potato, characterized by tuber flesh colour, is very important factor from aspect of its composition, taste and contribution for human health.

THERMO-DEGRADATIVE CHANGES OF RAPESEED AND SUNFLOWER OILS DURING DEEP-FRYING FRENCH FRIES

Lucia Zeleňáková, Mária Angelovičová, Marek Šnirc, Jana Žiarovská, Stanislav Kráčmar, Branislav Gálik, Simona Kunová

ABSTRACT

The purpose of this study was to investigate changes in TPCs, acid value and peroxide value as well as fatty acids composition in edible oils during french fries production. Lower TPCs content was found in rapeseed oil (3.3%) and the threshold (24%) was achieved on the fourth day. The total time for the deterioration of deep-frying rapeseed oil was $23^{½}$ hours. On the contrary, in fresh sunflower oil at the first day was TPCs content 5.5% and the limit of 24% was reached on the third day. The total time for the deterioration of deep-frying sunflower oil was $17^{½}$ hours. The results indicated significant differences (<0.05) in TPCs content between rapeseed and sunflower oils during deep-frying process. At the beginning of deep-frying French fries in rapeseed oil, the acid number was 0.374 mg KOH.g^{-1} and 1.271 mg KOH.g^{-1} at the fourth day of deep-frying. The measured peroxide value was 4.3 mEq O_2.kg^{-1} at the beginning and at the end of deep-frying 10.5 mEq O_2.kg^{-1}. The initial peroxide and acid values were higher in sunflower oil compared with rapeseed oil, respectively. It should be note, then the acid values and peroxide values, respectively, in the two fresh oils used in this study were below the limit of refined oil according to Slovak legislation (peroxide value – not more than 10 mEq O_2.kg^{-1}, acid value – not more than 0.6 mg KOH.g^{-1}). However, detected values varied during deep-frying process. Monounsaturated fatty acids were predominantly observed in fresh rapeseed oil (61.22%) wherever in sunflower oil they were much lower (29.77%). A slight increase of MUFA was found in both oils. The initial content of saturated fatty acids in rapeseed oil was 6.94%, in fresh sunflower oil was observed slightly higher content of SFA (10.37%). The major groups of fatty acids in fresh sunflower oil were polyunsaturated fatty acids (PUFA) which have in principle a significant effect on oil deterioration. A slight decrease of PUFA was observed in both oils throughout the frying period. The content of PUFA was reduced by about 9.42% in rapeseed oil and by 10.8% in sunflower oil. The initial content was 28.14% and 58.91%, respectively.

Keywords: plant oil; deep-frying; total polar compound; peroxide and acid value; fatty acid methyl ester; oil deterioration

INTRODUCTION

Frying is a unit operation in which food is heated in oil to alter its eating quality, and destroy microorganisms to make safe of food, and for some foods to extend their shelf-life **(Romero et al., 2006; Tabee et al., 2009; Fellows, 2017)**.

Frying is a more efficient process in comparison with other cooking methods and has gained a high popularity both in restaurants and in industry. The benefits of the frying are its speed and operational simplicity. Even though deep-frying is an old and popular process, it is still poorly understood **(Ziaiifar et al., 2008; Zeleňáková et al., 2012; Gertz, 2014)**.

Temperatures used at frying are in the 150 – 200 °C range. In contrast to boiling in hot water the preparing of foods at elevated temperatures provides a desirable appearance (color), texture (crispness) and taste **(Erickson, 2007; Sebastian et al., 2014; Neethu et al., 2016).**

Deep frying is a cooking method in which food is submerged in hot fat, for example oil. Normally, a deep fryer or chip pan is used for this; industrially, a pressure fryer or vacuum fryer may be used **(Aladedunye and Przybylski, 2013; Srivastava and Semwal, 2015)**.

Deep frying food is a process where food is completely submerged in hot oil at temperatures typically between 350 °F (177 °C) and 375 °F (191 °C). Deep frying is commonly used for food preparations such as frozen pre-fried foods, snack foods and fast foods **(Fellows, 2009; Chen et al., 2013)**.

The nature and rate of decomposition products during frying depend mainly on the composition of the oil (fatty acids pattern, unsaponifiable matter content), the mode of frying (intermittent or continuous, shallow-, pan- or deep-frying), frying temperature, length of frying process, and type of food being fried. Many laboratory tests have been proposed for quality assessment of frying oils. There are also used a number of quick tests to screen oils easily at

the fryer **(Szabó et al., 2010; Crosa et al., 2014; Li et al., 2017)**.

The frying-process is a complex system depending on the chemical reactions like oxidation, polymerization of triglycerides (TAGs), and hydrolysis where the physical and chemical properties of the heated fat are altering. It is difficult to estimate the extent of influence of each factor and to keep the frying conditions at an optimum level. Excellent reviews are published in the scientific literature describing the oxidative and hydrolytic changes during frying process. Moisture in foods induces and accelerates oxidation with the hydrolytic compounds **(Gertz 2014; Perkins and Erickson, 2007; Tkáčová et al., 2015; Nieva-Echevarría et al., 2016)**.

Hydrolysis of TAGs occurs due to the presence of moisture from foods, releasing free fatty acids (FFAs), monoglycerides (MAGs) and diglycerides (DAGs). Unsaturated fatty acids in glycerides are prone to be oxidized under high temperature, generating oxidized glyceride compounds **(Dobarganes and Márquez-Ruiz, 2006)**. In addition, dimeric and oligomeric triglycerides are generated in the polymerization reactions **(Firestone, 2007; Choe and Min, 2007; Bansal et al., 2010)**.

TPCs content in deep-fried oils is a reliable indicator of oxidative degradation of frying oils **(Zribi et al., 2014; Aladedunye and Przybylski, 2013; Aniołowska and Kita, 2016)**.

Several authors **(Matthäus, Haase and Vosmann, 2004; Mareček et al., 2010; Sebastian et al., 2014; Crosa et al., 2014; Li et al., 2017)** have determined relative content of fatty acid methyl esters in vegetable oils such as soybean oil, sunflower oil, rapeseed oil, olive oil, coconut oil as well as palm oil (in fresh state and during deep-frying, respectively). Many of them have examined the effects of fatty acids profile on the formation of polar compounds and their retention in French fries, over deep-frying process.

The contents of free fatty acid (FFA) and total polar compounds is usually used for initial oil quality assurance and after-use frying oil quality assessment, respectively **(Lee, 2009; Chen et al., 2013)**.

In context with the above mentioned, the aim of this study was to examine the thermo-degradative changes of rapeseed and sunflower oils during deep-frying French fries.

Scientific hypothesis

The purpose of this study was to investigate thermo-degradative changes of rapeseed and sunflower oils during deep-frying French fries. In this context the purpose of our experiment was to examine the effect of deep-frying process on fatty acids composition, acid value, peroxide value and content of TPCs in used oils.

MATERIAL AND METHODOLOGY

Material

Deep-frozen French fries were purchased at a local supermarket and stored in the freezer at -18 °C until being analyzed. The total quantity of French fries that were used in the experiment was 2.5 kg. For deep-frying French fries were used edible rapeseed and sunflower oils bought from market. Both oils have wide spectrum of using in long-term and short-term thermal preparation of food (cooking, steaming, frying, baking) as well as in cold kitchen (salads, marinades, sauces etc.).

Deep frying French fries

A commercial deep-fat fryer (Siemens TG 15001/01 Kreis Pinneberg, Germany) of capacity 2 L was used for the frying of French fries' samples. Fresh rapeseed oil and sunflower oil was loaded into the fryer separately and heated to 170 °C before frying. The same batch of French fries (100 g) was deep-fried and the same frying conditions (4 min, 170 °C) were applied. Afterwards, the French fries were placed in a plate and extra oil was sucked using tissue paper. The frying procedure was held constantly for 4 continuous days (6 h per day according to reached 24% TPCs content). At the end of each day of frying the deep fryer was shut off and the oil was cooled down. Then, the oil was filtered to remove the solid residues. Time of oil sampling was different according to examined parameters (explained below). All experiments were done at least in duplicates. All analyzes oil samples were carried out at Department of food hygiene and safety, FBFS, SUA in Nitra and at Department of animal nutrition, FAFR, SUA in Nitra as well.

Experimental determinations

Examined parameters: TPCs – total polar compounds, acid value, peroxide value, fatty acids composition.

Measurement of TPCs content by oil tester Testo 270

TPCs estimation was based on dielectric constant changes directly measured on hot oil with deep frying oil tester Testo 270. The following measurements were performed with the Testo 270:

• Temperature of the deep-frying oil: Indicator for correct setting of the deep-fryer.

• TPCs content: Indicator for the deterioration of the deep-frying oil. The sensor works on a capacitive basis and determines the total amount of polar materials in % as the reading.

For quality analysis used oil samples (fresh and deep-fried) were taken every 30 min throughout the deep-frying process. Measurement of TPCs content in oils was carried out at an oil temperature 130 °C. Analyses were terminated when the TPCs content reached ≥24%, which means oil wear.

For quality analysis used oil samples were taken in fresh state as well as deep-fried every 30 min throughout the deep-frying process.

Determination of peroxide value according to ISO 3960:2007 (EN)

The oil samples were dissolved in isooctane and glacial acetic acid, and potassium iodide was added. The iodine liberated by the peroxides was determined iodometrically (visually) with a starch indicator and a sodium thiosulfate standard solution. The endpoint of the titration was determined iodometrically (visually). The peroxide value (PV) expressed in milliequivalents of active oxygen per kilogram (mEq $O2.kg^{-1}$) was calculated by the following equation:

$$PV = \frac{(V - V_0)\ x\ cthio\ x\ cstand\ x\ 1000}{m}$$

where:

V – is the volume of the 0.01 N sodium thiosulfate standard solution used for the determination, in millilitres.

V0 – is the volume of the 0.01 N sodium thiosulfate standard solution used for the blank test, in millilitres.

cstand – is the exact concentration of the 0.01 N sodium thiosulfate standard solution, in moles per litre.

cthio – is the approximate concentration of the 0.01 N sodium thiosulfate standard solution, in moles per litre (= 0.01)

m is the mass of the test sample, in grams.

Determination of acid value according to ISO 660:2009 (EN)

Acid value of fat was determined after dissolution of fat in the extract ethanol-diethyl ether in a 1:1 alkalimetric titration against phenolphthalein. The extracted fat was slightly heated, and fat was dissolved in 25.0 mL of ethanol-ether. The content in extraction flask was titrated with a few drops of the indicator with the potassium hydroxide solution until it turned to slight pink colour. An acid number of fat was expressed in mg KOH per g (mg $KOH.g^{-1}$). A fat acid value is the number of mg of potassium hydroxide required to neutralize free fatty acids per gram of fat extracted from the extracting agent.

For quality analysis used oil samples were taken in fresh state as well as deep-fried every 60 min throughout the deep-frying process.

$$AV = \frac{56.1\ x\ Vx\ c}{m}$$

Where:

AV : acid value

V – is the volume of the potassium hydroxide standard solution, in millilitres.

c – is the exact concentration of the potassium hydroxide standard solution, in moles per litre m is the mass of the test sample, in grams.

For quality analysis used oil samples were taken in fresh state as well as deep-fried every 60 min throughout the deep-frying process.

Determination of fatty acids composition by gas chromatography according to ISO 12966-1:2014

0.1 g oil samples were dissolved in 5 mL hexane; 1 mL 2 M KOH in methanol was added. The tubes were capped and stirred for 30 min to separate into two phases. The upper phase was analysed using gas chromatography. A 6890 GC with a Multi-Mode injector, a 7683B automatic liquid sampler and flame ionization detection (Agilent Technologies, Palo Alto, CA) were used. Separation was performed with a (60 m × 0.25 mm i.d. × 0.15 μm DB-23) column (Agilent 6890 GC). The temperature programme was an initial 50 °C with a 1 min hold, ramp 25 °C per min to 175 °C, then 2 °C per min to 230 °C with a 5 min hold, then 120 °C per min to 245 °C with an 8 min hold. Injector temperature was 250 °C. Carrier gas was H2 with a pressure of 238.96 kPa (2.225 $mL.min^{-1}$). Fatty acid analysis was performed by auto injection of 1 μL of each sample at a split ratio of 1.10^{-1}, constant flow mode, velocity 20.4 $cm.s^{-1}$. The flame ionization detector temperature was 280 °C with H2 35 $mL.min^{-1}$, air 350 $mL.min^{-1}$, and N2 make-up gas flow rates of 30 $mL.min^{-1}$, respectively. The run time for a single sample was 32 min. The fatty acid methyl esters were identified by comparing their retention times and mass spectrum with a mixture standard FAME.

For quality analysis used oil samples were taken in fresh state as well as deep-fried every day after 6-hour of deep-frying process.

Statistic analysis

Mathematical and statistical evaluation of the results was realized by the SAS Enterprise Guide Version 1.5 system program. Measurements of duplicate samples were expressed as means ± standard deviation. The data were subjected to the analysis of variance (ANOVA) in the general linear models (GLM), t-test, Scheffe´s test and Pearson correlation coefficients (rxy). The level of significance associated to the statistical test was 0.05.

RESULTS AND DISCUSSION

Deep frying is cooking method in hot-fat. Typically, deep frying cooks foods quickly: all sides of a food are cooked simultaneously as oil has a high rate of heat conduction **(Koh and Surh, 2015)**. However, only very few researches related to the influences of oil and food types on frying oil quality can be found.

Both goal setting and implementation of the experiment itself were based on requirements of Slovak legislation **(Decree No. 125/2017)**. It requires that deep-fat frying be carried out in accordance with good manufacturing practice and frying fats should not be heated above 180 °C (not longer than 24 hours of continuous frying). The law specifically forbids preparation of fried foods in equipment not provided with temperature control. However, practice shows that, especially, operators of fast food restaurants often violate these requirements and use "frying" oils for several days.

Our research was focused on analysis of thermo-degradative changes of rapeseed and sunflower oils during deep-frying French fries. The following indicators of excessive oil deterioration were investigated: content of total polar compounds, peroxide and acid value, fatty acids composition.

TPCs in oils during deep-frying French fries

The polar compounds were identified as oligomeric triglycerides, dimeric triacylglycerol, oxidized triacylglycerols, diacylglycerols, and free fatty acids **(Aladedunye and Przybylski, 2013; Aniołowska and Kita, 2015)**. Recommended and widely accepted limits are 24% for TPcs and 12% for PTG.

When oxidative alterations strongly predominate over thermal alterations, sensory defects can appear before TPCs and PTG reach recommended values. In that case additional parameters like anisidine value, carbonyl value, or epoxy fatty acids should be considered. There are many available physical and chemical rapid methods. Despite the limited informative value and the possibility of error of rapid tests, they are essential for fryer operators, because

they deliver information about fat quality in real-time **(Weisshaar, 2014)**.

Since the degradation of frying oil is greatly accelerated by foods, the frying condition should be controlled carefully. As is shown in Figure 1, TPCs values measured by Testo 270 grown in both oils continuously since the first deep-frying. Lower TPCs content was found in rapeseed oil (3.3%) and the threshold (24%) was achieved on the fourth day. The total time for the deterioration of deep-frying rapeseed oil was 23½ hours. On the contrary, in fresh sunflower oil at the first day was TPCs content 5.5% and the limit of 24% was reached on the third day. The total time for the deterioration of deep-frying sunflower oil was 17½ hours.

The results in this study indicate significant differences (p <0.05) in TPCs content between rapeseed and sunflower oils during deep-frying process (Table 1). The statistical analysis (Scheffe´s test) showed comparable results in both oils between days and hours of deep-frying French fries. TPCs content was similar or lower at 8 o´clock compared to previous day (at 14 o´clock). However, this finding was not statistically significant (p >0.05). Deeper analysis using Pearson correlation coefficients (rxy) by **Cohen (1988)** showed that between days and hours of deep-frying French fries in rapeseed oil was found high positive linear correlation (p <0.001) between A08 and B08, C14; B08 and C14; B14 and C08. The other linear correlations were other medium negative (p >0.05) or none. However, high positive linear correlation (p <0.001) according TPCs content in sunflower oil during deep-frying time was found at the end of the first frying day and B08, C14, as well as at the beginning of the second frying day and C14 (at the end of the third frying day). In other results were no linear correlations. However, it can be said that deep-frying process directly increases TPCs content (p <0.05).

Similar research was realized by **Zeleňáková et al. (2012)**. Two kinds of rapeseed vegetable oils were used for continuously deep-frying French fries and outside deep-frying process were stored in the room temperature and in the refrigerator, respectively. The both rapeseed oils were from different producers and had different composition related to fatty acid. These factors have significantly affected achieved TPCs amounts. The oil with higher content of oleic acid achieved the 24% TPCs after 22 hours (at room temperature) and 26½ hours (in the refrigerator) of deep-frying. The low erucic acid rapeseed oil was less stable (19 hours and 22½ hours, respectively).

For public health concerns, the content of total polar compounds in frying oil is regulated at not more than 25%, in Taiwan **(Lee, 2009)**. **Chen et al. (2013)** published that the contents of TPCs in soybean oil and palm olein, respectively, were shown to exceed the limit of 25% after 48 h of frying with foods.

Table 1 Changes in TPCs, peroxide value and acid value in sunflower and rapessed oils during deep-frying French fries.

As it was mentioned, over the frying process, TPCs increased linearly with the frying time in both oils. The progress of each linear function was defined by regression equation and the reliability of all determinations was expressed by determination coefficients (R^2). As shown Figure 1, level of detection reliability (99.4 and 99.1%, respectively) was comparable for both oils. In context with this, between the time of deep-frying and TPCs content was found high positive linear correlation r = 0.997 (rapeseed oil) and r = 0.995 (sunflower oil). The slope of regression line over time for rapeseed oil frying with French fries was 0.794 and that for sunflower oil was 0.936, indicating that the rate of TPCs formation in rapeseed oil frying with foods was lower than that of sunflower oil (Table 2).

Similar results were also recorded by **Chen et al. (2013)** during frying French fries, chicken leg fillets and pork chops. The content or TPCs in both soybean oil and palm olein increased linearly with frying time. The influence of oil type on the content of TPCs in used oils was significant. It is important to mention that TPCs was measured by standard method (column chromatography) and two rapid-measuring devices (Ebro FOM 310 and Testo 270). They found that Testo 270 was suitable for palm oil while Ebro FOM 310 was more suitable for monitoring the quality of soybean oil.

The kinetics of wide spectrum of oxidation products and acrylamide formation depend on the temperature and time of frying determine. This formation starts at temperatures above 120 °C and the maximum rate takes place at temperatures higher than 170 – 180 °C **(Pedreschi and Moyano, 2005; Knol et al., 2009)**. The same batch of French fries (100 g) was deep-fried and the same frying conditions (4 min, 170 °C) were applied in our research.

Polar compounds and TAG oligomers which created during deep-fat frying course with content range of 20 – 27% and 10 – 16%, respectively have been proposed to determinate the rejection of used frying oil **(Zhang et al., 2012)**. However, the measurement of polar compounds doesn't represent the whole content of reaction products formed during the deep-fat frying. Some products were considered as potential detrimental substances to the human body from the nutritional aspect **(Saguy and Dana, 2003; Totani et al., 2008)**.

Organoleptic as well as chemical changes in French fries during frying were investigated by **Andrés et al., 2013; Bingol et al., 2014; Ignat et al., 2015**.

Acid and peroxide value in oils during deep-frying French fries

As was discussed in the **(EFL, 2011)** for fresh oils, the acid value is routinely used as a selective indicator for the degradation status.

Oxidation may be initiated by the formation of lipid peroxides. Initial phases of lipid oxidation can be detected by measuring the peroxide value, which quantifies the levels of peroxides and hydroperoxides formed at that stage **(Bennett et al., 2014)**.

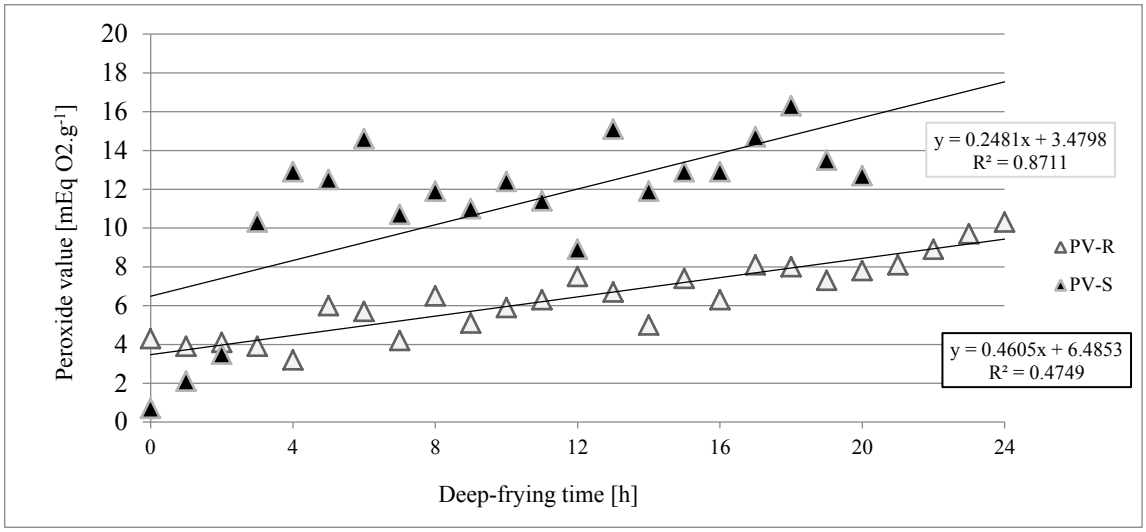

Figure 2 Determination of peroxide value in rapeseed (R) and sunflower (S) oils during deep-frying French fries.

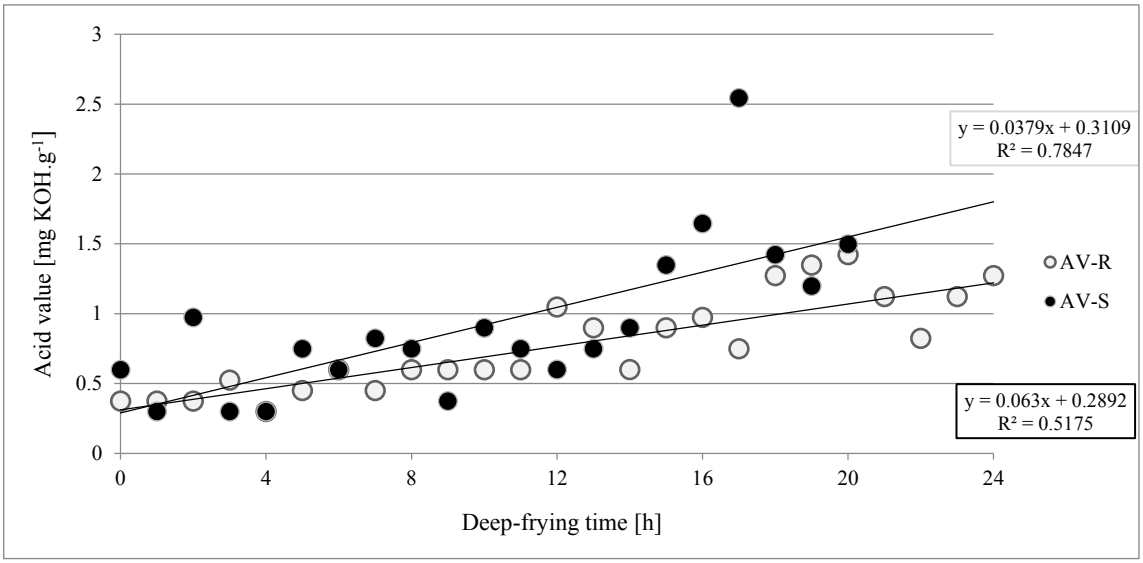

Figure 3 Determination of acid value in rapeseed (R) and sunflower (S) oils during deep frying French fries fries.

Throughout the deep-frying process were in rapeseed oil and sunflower oil measured acid values and peroxide values. At the beginning of deep-frying French fries in rapeseed oil, the acid number was 0.374 mg KOH.g^{-1} and 1.271 mg KOH.g^{-1} at the fourth day of deep-frying. The measured peroxide value was 4.3 mEq O2.kg^{-1} at the beginning and at the end of deep-frying 10.5 mEq O2.kg^{-1}. The initial peroxide and acid values, respectively, were higher in sunflower oil compared with rapeseed oil. The initial acid value in deep-fried sunflower oil was 0.598 mg KOH.g^{-1} and at the end of deep-frying French fries (third day) 1.497 mg KOH.g^{-1}. The measured peroxide value was 0.7 mEq O2.kg^{-1} at the beginning and at the end of deep-frying 12.7 mEq O2.kg^{-1}. It should be note, that the acid values and peroxide values, respectively, in the two fresh oils used in this study were below the limit of refined oil according to Slovak legislation **(Decree No. 424/2012)**. This regulation laying down requirements for edible vegetable fats and edible vegetable oils and their products (peroxide value – not more than 10 mEq O2.kg^{-1}, acid value – not more than 0.6 mg KOH.g)$^{-1}$. However, detected values varied during deep-frying process.

Peroxides are known to be unstable and volatile, as can be seen from Figure 2. It follows that sunflower oil is responsible to thermal degradation and is not suitable for long-term heat treatment.

As it was mentioned, over the frying process, TPCs increased linearly with the frying time in both oils. The linear regression was also used in evaluating the reliability of peroxide and acid value detection (Figures 2 and 3). However, unlike TPCs detection, in these detections was found a lower reliability indicated by R^2. The determination coefficients were 0.8711 (peroxide value) and 0.7847 (acid value) in rapeseed oil and 0.4749 (peroxide value) and 0.5175 (acid value) in sunflower oil. The other parameters of linear regression for both values are shown in the Table 2. This finding is explained by many authors **(Alander and Lidefelt, 2007; Nieva-Echevarría et al., 2016; Li et al., 2017)**.

During deep-frying process (125 °C), rapid oxidation occurs (accumulation of hydroperoxides) and peroxide value increased. However, but upon further heating at high frying temperatures, the peroxide value again decreases, because accumulated hydroperoxides are decomposed

more rapidly and other secondary degradation products are formed. The rise of the peroxide value therefore occurs at a time when the oil cools and is not used.

It can be concluded that measurement of the peroxide value is more suitable for measuring the quality of fresh oil than for measuring the quality of oil during frying and deep-frying, respectively **(Koh and Surh, 2015; Naz et al., 2005; Juárez et al., 2011)**. For public health concerns, the acid value in frying oil is regulated at not more 2.0 mg KOH.g^{-1}, in Taiwan **(Lee, 2009)**.

From the results of **Chen et al. (2013)** soybean oil contained 0.03 mg KOH.g^{-1} of acid value, while palm olein contained slightly higher acid value (0.071 mg KOH.g^{-1}).

Other studies **(Gerde et al., 2007; Tabee et al., 2009)** also showed that the acid value in palm olein were higher than those in soybean oil.

Table 1 lists the acid value and peroxide value in both analysed oils with statistical evaluation. The influence of oil type on the peroxide value in used oil was significant (p <0.05), but the effect of oil type on acid value was not observed (p >0.05).

Our results partially correspond with those from **Chen et al. (2013)**, who used palm and soybean oil for frying French fries. They found significant influence of oil type on acid value in these oils.

The One-way ANOVA test was used to determine the statistical significance between two types of frying oils according to changes of peroxide value and acid value during the frying time. Post-Anova (Scheffe´s test) was used where the F value was significant.

No significant differences in the peroxide value of rapeseed oil were observed in the first two days of frying. The first significant differences were found between B14 and A08, B08. Interestingly, no significant differences in the peroxide value were observed at the beginning of the third frying day and A08, A14, B08 and B14, but there were significant differences at the end of the third frying day and A08, A14, B08, C08. At the beginning of the last frying day, there were observed significant differences compared with A08, A14, B08 and C08. The peroxide value was significant different at the end of the last frying day compared with the first three frying days.

In sunflower oil, there is a significant difference in peroxide value measured at the beginning of frying (A08) and all other measurements. There were observed no significant differences between A14, B08, B14, C08, C14.

In the determination of acid value in both oils, there were no significant differences among days and hours of deep-frying rapeseed oil and sunflower oil, respectively.

Fatty acid methyl esters composition in oils during deep-frying French fries

Fatty acids composition is one of the most crucial factors determining the oxidative stability of oil. Fatty acids profile changed during frying process.

In the present study, fatty acid profiles in rapeseed and sunflower oil were analysed and compared over the deep-frying process of French fries at temperature 170 °C. As is shown in the Table 3, the content of PUFA, MUFA, and SFA in fresh oils was different but other changes in quantity due to the deep-frying in these oils were comparable (increasing and decreasing, respectively).

Monounsaturated fatty acids (MUFA) were predominantly observed in fresh rapeseed oil (61.22%) wherever in sunflower oil they were much lower (29.77%). A slight increase of MUFA (from 61.22 to 62.1 and from 29.77 to 32.03%) was found in both oils. Moreover, the saturated fatty acids (SFA) in fresh oils were determined and the trend of increasing due to deep-frying was quite similar to MUFA. The initial content of saturated fatty acids in rapeseed oil was 6.94%, over the deep-frying process increased to 7.14, 7.33, 7.59 and 8.03%. In fresh sunflower oil was observed slightly higher content of SFA (10.37%) and it increased with the increase of frying time (to 13.63%).

The major groups of fatty acids in fresh sunflower oil were polynusaturated fatty acids (PUFA) which have in principle a significant effect on oil deterioration. A slight decrease of PUFA was observed in both oils throughout the frying period. The content of PUFA was reduced by about 9.42% in rapeseed oil and by 10.8% in sunflower oil. The initial content was 28.14% and 58.91%, respectively.

The impact of the fatty acid composition on lipid oxidation was evaluated by measuring the relative percentage of unsaturated, polyunsaturated and saturated fatty acids. **Roman et al. (2013)** reported a higher reactivity of PUFA than MUFA (-linolenic acid > linoleic acid > oleic acid) in sunflower oil, as had previously been shown by different studies **(Parker et al. 2003; Martin-Polvillo et al., 2004)**.

The major fatty acid in fresh rapeseed oil was oleic acid (59.64 ±0.00%) while in fresh sunflower oil dominated linoleic acid (58.82 ±0.00%). A slight increase of oleic acid (C18:1) was observed in both fried oils examined. At the end of frying period, oleic acid increased by 1.5% in rapeseed oil and by 7.79% in sunflower oil. Initial content of oleic acid in sunflower oil was 29.51 ±0.01%.

In contrary, amount of oleic acid decreased slightly from 38.70% to 32.06% in palm oil over the frying process. However, oleic acid content in the other two kinds of oils (palm kernel oil and coconut oil) remained unchanged (approximately 17% and 8%, respectively) during frying period **(Li et al., 2017)**. The high oleic acid is reported as a better oil compared to regular sunflower, soybean, corn and peanuts oils due to its good thermal and oxidative stability during traditional frying **(Smith et al., 2007; Marmesat et al., 2012)**. Chemometric analysis showed, that there was no correlation between the polar compounds level and saturated fatty acids profile. It can be also assumed that high-oleic oils show a lower polar compounds level after a period of deep-frying compared to the oils with less oleic acid **(Abdulkarim et al., 2007; Zribi et al., 2014)**. Among frying oils, those with high oleic acid content such as palm olein have better health profile and heat stability **(Tabee et al., 2009)**.

In the case of palmitic (C16:0) and stearic acids (C18:0), they increased with the increase of frying time as well in both kinds of oils (from 4.52 to 5.11% and 1.49 to 1.75%, respectively, in rapeseed oil; from 6.13 to 8.59% and 3.05 to 3.43% in sunflower oil). Notably, even though no caprylic acid was observed in fresh rapeseed and sunflower oils, it increased to 0.12% and 0.17%, respectively, at the end of the frying procedure. The similar results were found in content of myristic acid (C14:0).

Caprylic acid and capric acid were observed reduced in refined palm kernel oil and refined coconut oil. The medium-chain fatty acids are volatile under the high temperature **(Amri, 2011)**. According to **Zribi et al. (2014)**, the fatty acids composition influences the generation of polar compounds over the frying process. Higher percentage of unsaturated fatty acids (UFAs) in the oils resulted in a higher level of polar compounds during the frying process. However, this was inconsistent with the present study.

Figure 4 French fries prepared by rapeseed oil (A) and sunflower oil (B).

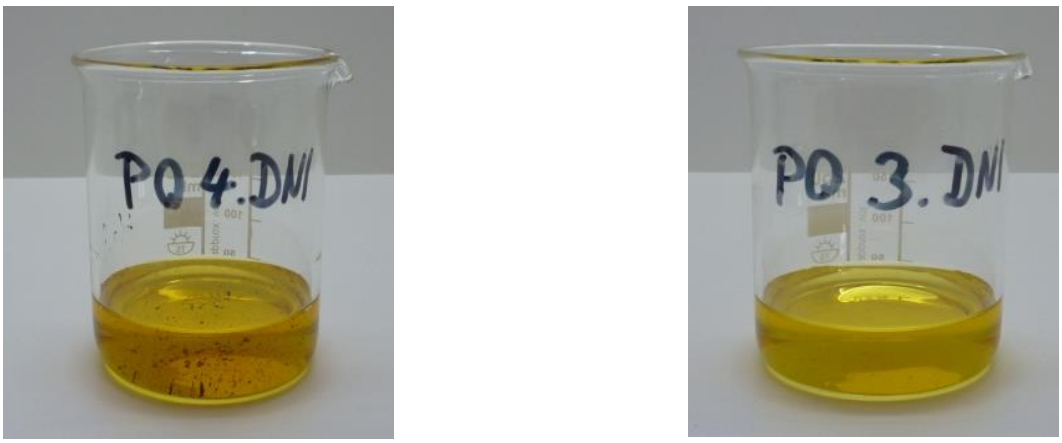

Figure 5 Visual changes in rapeseed oil (A) and sunflower oil (B) after 4 and 3-day deep-frying French fries.

In our study fresh rapeseed oil was found to have 18.96% of linoleic acid (C18:2) and 9.19% of linolenic acid (C18:3). The level of linoleic acid in fresh sunflower oil (58.82%) was higher than this in the rapeseed oil analysed. On the contrary, fresh sunflower oil contained only 0.09% of linolenic acid. The linoleic acid content was almost unchanged during frying process in rapeseed oil. Slight decrease was found in sunflower oil (from 58.82 to 52.55%).

It is necessary to note, that linolenic acid concentration was not detectable from the second day of deep-frying French fries in sunflower oil. The deterioration of (α) linolenic acid was more pronounced, with its contents being decreased by 30.25% in the last day of deep-frying French fries in rapeseed oil. Similar results were found by **Chen et al. (2014)** who detected by 20.86% lower linolenic acid content in palm oil. **Aladedunye and Przybylski (2009)** reported decreases of 13.3% in linoleic acid and 47.1% in linolenic acid when fresh canola oil was heated at 215 °C for 7 days.

Fresh soybean oil was reported to have 21.5% of oleic acid (C18:1), 53.4% of linoleic acid (C18:2) and 5.1% of linolenic acid (C18:3) and saturated fatty acid **(Juárez et al., 2011)**. It is important to note that soybean oil is commonly used for deep fat frying by Korean school meal services.

In our study, rapeseed oil has n-6/n/3 ratio around 2. This result is similar to this from **Dubois et al. (2007)** who analysed soybean oil (around 6). Flaxseed oil stands out for containing high levels of n-3, and sunflower oil stands out for introducing high n-3 values. The mixture of these oils can result in a mix with higher concentrations of polyunsaturated fatty acids and different n-6/n-3 ratios.

Recent studies have been demonstrated that mixtures of vegetable oils might modify the fatty acid profile and improve the stability of oils **(Wang et al., 2006; Meinhart et al., 2017)**.

Industrial food producers should understand the thermo oxidative changes in their frying oils, especially below 15% polar compounds. In fast food restaurants where the products are prepared for the direct consummation the limits of degradation are much higher (i.e. 24% polar materials) and may be monitored by units that measure and related dielectric constant to the degree of degradation **(EFL, 2011)**.

Finally, there is a discussion of the effect of frying on the sensory characteristics of foods, changes to their nutritional value, healthy concerns over fried foods and methods to reduce their fat contents.

CONCLUSION

Good understanding of the frying process helps in optimizing the manufacturing processes with regard to quality of food and use life of fat and of energy consumption. To guarantee a good quality of the fried end product it is necessary to install a management system which includes all critical points of the frying process. Variables involved in the process include frying conditions, replenishment of fresh oil, original oil quality, food materials, and fryer type. Oil for frying should be selected by its performance during the frying process. Nowadays, besides thermal-oxidative stability, handling (good melting profile), availability and price, the

nutritional-physiological features (good fatty acid balance, low trans-fatty acids, no allergens, no GMO) are important points of decision. There is no ideal fat suitable for all frying applications.

Our results, supported by other studies, provided the basis for choosing the suitable vegetable oil as well as rapid-measuring device to control the quality of frying oil in restaurants.

Based on our findings, we suggest:

- for frying and deep-frying to use only oils for that purpose,
- to keep the set temperatures and time with respect to the type of food,
- to keep the established ratio between food and oil,
- to filter the used oil at the end of the frying day to remove food debris,
- to store the oil in a dark and cool place,
- regularly check the oil quality,
- immediately to change oil showing the deterioration (exceeded smoke point and TPCs of 24%).

GOAT YOGHURT DRINKS WITH ELEVATED α-LINOLENIC ACID CONTENT AND ENRICHED WITH YACON FIBER

Markéta Borková, Miloslav Šulc, Alena Svitáková, Klára Novotná, Jana Smolová, Jitka Peroutková, Ondřej Elich

ABSTRACT
Goat milk and goat milk products are very valuable in human nutrition because of their favorable nutrient composition which can be further boosted by the addition of prebiotic fiber and probiotic bacteria. It has also been possible to change the fatty acid profile of goat milk through feed composition. The aim of this study was to increase the nutritional value of goat milk by producing a probiotic yoghurt drink made from milk with elevated omega-3 fatty acids and enriched with natural yacon prebiotics. Goat nutrition is one of the key factors how we can naturally increase omega-3 fatty acid content in goat milk. In our study, twenty four White Shorthair goats were divided into the control and experimental group which was supplemented with 55 mL of linseed oil per day for eight weeks to increase the monounsaturated and polyunsaturated fatty acid content in the milk. The yoghurt milk drinks were formulated from individual goat milk samples with added bifidobacteria and yacon prebiotics. Our results showed that goat feed supplementation with linseed oil indeed positively changed fatty acid profile of goat milk in which α-linolenic acid content increased while, at the same time, lauric, myristic and palmitic acid contents decreased. Also, yoghurt drinks enriched with yacon prebiotics have shown higher bifidobacteria counts compared to the control.

Keywords: fatty acid; goat milk; α-linolenic acid; linseed oil; yacon

INTRODUCTION
In the last few years, the number of goat farms (in particular operating under organic farming practices) has been increasing not only in the Czech Republic but also worldwide leading to greater production of goat milk **(Josrová, 2018)**. Therefore, farmers and dairy producers are actively seeking to develop new products and formulas which would attract consumers' attention. Goat milk represents a welcome alternative to products made from cow's milk. For instance, products made from goat milk are considered to be healthier because goat milk shows better nutritional characteristics like digestibility due to smaller diameter of fat globules (3.5 μm in goat milk compared to 4.5 μm in cow's milk) which causes the fat to be better dispersed in the milk **(Park et al., 2007)**. Goat milk contains also a higher amounts of caproic, caprylic and capric acids (in total 15 – 18% compared to 5 – 9% in cow's milk) that were shown to be beneficial to humans **(Sanz Sampelayo et al., 2007)**. These short-chain fatty acids have been proven to help patients with malabsorption syndrome, intestinal disorders, coronary heart diseases, cystic fibrosis and other conditions **(Haenlein, 2004; Ribeiro and Ribeiro, 2010)**. Furthermore, it is possible to increase the content of omega-3 fatty acids in goat milk by supplementing regular goat feed with moderate amounts of linseed oil which is rich in α-linolenic acid as described in **Borková et al. (2018)**. Differences in milk casein content were also found to impact human health. Goat α_{S1}-casein content is lower (typically 10 – 13% of total casein content) compared to cow's milk and depends on the particular genetic variant for α_{S1}-casein. The presence of null alleles for α_{S1}-casein such as 0_1, 0_2, 0_4 and N cause the absence of α_{S1}-casein in goat milk **(Caboni et al., 2016)** which is an important factor in decreasing the allergic sensitation of α_{S1}-casein **(Ballabio et al., 2011; Hochwallner et al., 2014)**.

Many more possibilities are available to boost nutritional impact of goat milk products as using milk high in omega-3 essential fatty acids, probiotic bacteria and prebiotics. Probiotic bacteria are well known for their antimicrobial, antioxidant and immunomodulatory effects **(Lee et al., 2011; Tomáška et al., 2015)**. Prebiotics are more or less indigestible components of foods comprising fructooligosaccharides (FOS) which positively influence the growth and activity of probiotic bacteria in the gastrointestinal system **(Valcheva and Dieleman, 2016)**. FOS are oligosaccharides consisting of D-fructose chains connected by β-(1→2) glycosidic bonds and capped by glucose. The yacon (*Smallanthus sonchifolius*) plant belongs to the *Asteraceae* family and grows in eastern Andes from Venezuela to northern Argentina **(Caetano et al., 2016)**. Yacon tuber is a great source of FOS **(Topolska**

et al., 2015) which do not undergo hydrolysis by human intestinal enzymes and are instead selectively fermented by bacteria in the colon leading to a more balanced composition of gut microbiota. Dry yacon tubers contain up to 50% (very rarely up to 70%) of FOS **(Velez et al., 2013)**.

The aim of this study was to increase the nutritional value of goat milk by producing a probiotic yoghurt drink made from goat milk with elevated omega-3 fatty acids and enriched with natural yacon prebiotics.

Scientific hypothesis

This research aimed to confirm the fact that milk from goats supplemented with linseed oil can be successfully used to produce dairy products with elevated polyunsaturated fatty acids. A special interest was paid to the use of natural yacon prebiotics to elevate the numbers of bifidobacteria in such products to increase their health benefits.

MATERIAL AND METHODOLOGY

Animals, animal diet, feed analysis

The experiment was carried out on a private organic farm near Liberec (Czech Republic) using the following set-up: Twenty four White Shorthaired dairy goats (on their third lactation) were selected based on age (3 years), date of kidding (between March and April 2017) and litter size (2 kids) and divided into experimental (LO) and control (C) groups, each comprising twelve animals. The goats were housed indoors and their feed consisted of: hay (*ad libitum*), haylage (3 kg per animal per day) and grain mix of 50% corn, 25% barley and 25% oat (1 kg per animal per day). Goats in the LO group were fed basic ration supplemented with 55 mL of linseed oil (LO) per animal per day and the C group was fed the same diet without LO supplement. The LO supplementation begun on May 17 and lasted for eight weeks till July 11, 2017. LO was supplied by 1. zemědělská a.s. (Chorušice, Czech Republic).

The animal feed was sampled on July 11, 2017 and analyzed according to methods published in **Regulation (EC) No 152/2009** for dry matter, ash, crude protein, ether extract and crude fiber. The fatty acid analysis in feed including lipid extraction was carried out as described by **Kubelková et al. (2013)**. Results are given in Table 1.

Milk sampling and analysis

Individual milk yield measurements and milk analyses were carried out at three time points – at the beginning (week 0), in the middle (week 4) and at the end (week 8) of the experiment. Results are shown in Table 2. Milk samples were analyzed for fat, protein and total solids by IR milk analyzer DairySpec FT (Bentley Instruments). The instrument has been calibrated using a set of goat milk samples which were simultaneously analyzed by reference methods in accredited laboratory (MILCOM a.s., Prague).

Two pooled milk samples were created to mimic standard practices on the farm. Pooled samples were created from individual milk samples (taken on July 11, 2017) obtained from the C and LO goat groups. One pooled sample was created from milk in the control group (to produce one PCY drink) and another one from milk in the experimental group fed linseed oil (to produce one PLY drink).

The fat in yoghurt drinks was extracted according to **ČSN EN ISO 1211 (2011)**. Fatty acids (FA) were then re-esterified into the corresponding methyl esters (FAME) and were analyzed by gas chromatography according to method described by **Borková et al. 2018**. FAME were identified using external analytical standard (Supelco, USA). The content of a particular fatty acid was calculated as a ratio of its peak area.sum^{-1} of peak areas of all fatty acids and given in g.100 g^{-1} total fatty acids.

Yoghurt drink formulation

Milk samples for yoghurt drinks were taken the last day of the experiment (July 11, 2017) during morning milking. Twelve yoghurt drinks (denoted as ILY) from the group fed linseed oil and twelve yoghurt drinks (denoted as ICY) originating from the control group were individually produced. All these yoghurt drinks in both groups contained 5 g of yacon tuber powder (see below). Also, twelve individual yoghurt drinks were prepared from the group fed linseed oil but without the addition of yacon tuber powder (denoted as IL) to enable the investigation of yacon powder addition on bacterial growth. Both yoghurt drinks made from pooled samples (PLY or PCY) contained each 5 g of yacon tuber powder.

Yoghurt drinks were prepared as follows: 5 g of lyophilized Peruvian yacon tuber powder (Gloobe corp., Czech Republic) were added into 95 g of goat milk, pasteurized at 84 °C for 10 min and fermented using 0.1% CCDM 528 (*Streptococcus thermophilus* and *Lactobacillus delbruckii* ssp. *Bulgaricus*, Laktoflora®) and 1% *Bifidobacterium animalis* ssp. *lactis* (Bb12, Chr. Hansen) at 30 °C for 16 – 18 h.

Yoghurt bacteria counts (in colony forming units, CFU) were estimated according to **ČSN ISO 7889 (2004)**, bifidobacteria counts (in CFU) according to **ČSN ISO 29981 (2010)** and FOS analysis as described in **Bohačenko and Pinkrová (2014)**.

Statisic analysis

The data were analyzed in Statistica (ver. 12, StatSoft). Milk yield and milk composition were tested by repeated measures ANOVA. The FA content, the numbers of CFU of yogurt bacteria and bifidobacteria were tested by one-way ANOVA. Tukey's *post-hoc* HSD test (p <0.05) was used to evaluate differences between groups. Results are expressed as mean value with the standard error of mean (*SEM*).

RESULTS AND DISCUSSION

Our previous work **(Borková et al., 2018)** revealed that feed supplemented either with linseed oil or linseed extrudate increased the amounts of omega-3 fatty acids in goat milk which can be successfully used to produce yoghurt drinks with added value. We found out that feed supplemented with linseed oil yields better results than linseed extrudate. Therefore, we decided to modify the previous experiment using feed supplementation with linseed oil to get enriched omega-3 goat milk which was used to produce yoghurt drinks with added yacon prebiotics to boost the drink's health benefits. We also

Note: NS = not found to be significantly different ($p > 0.05$); C = goats in the control group (N = 12); LO = goats fed linseed oil (N = 12); *SEM* = standard error of mean.

increased the length of linseed oil supplementation to goats to eight weeks to prove that it has a long-lasting effects on omega-3 fatty acid elevation (and other quality indicators) in goat milk. Our last experiment published in 2018 found a minor (but statistically insignificant) increase in milk yield, milk fat and total milk solids in milk samples from goats fed linseed oil. Results from the current study revealed that after four weeks of linseed oil supplementation the milk yield has increased ($p < 0.05$) and this effect lasted until the end of experiment. The linseed oil supplementation did not affect other quality parameters like fat and protein content or total solids (Table 2). Thus, the increased milk yield and quality (see below) after linseed oil supplementation may positively impact farm's economy offsetting the costs for feed supplementation.

From Table 3 (listing some major and nutritionally important minor fatty acids) it is evident that linseed oil supplementation (ILY) changes fatty acid profile in the final product. To sum up the results, saturated fatty acid (SFA) levels were significantly decreased ($p < 0.001$) while the levels of monosaturated fatty acids (MUFAs) and polyunsaturated fatty acids (PUFAs) increased ($p < 0.01$, $p < 0.001$ resp.). Contrary to our 2018 study, linseed oil supplementation was able to reduce short-chain SFAs and C12:0 in yoghurt drinks (in particular C6:0, $p < 0.05$; C8:0, $p < 0.05$; C10:0, $p < 0.01$; C12:0, $p < 0.05$). These are interesting results because the data in scientific papers so far either found an increase of short-chain SFA levels as in **Bernard et al. (2009)** or no change at all **(Martínez Marín et al., 2011)** after linseed oil supplementation. In the case of medium-chain SFAs (C14:0 and C16:0), we saw their levels to decrease ($p < 0.01$) after linseed oil supplementation which is in accordance with the data published in scientific literature **(Bernard et al., 2009; Martínez Marín et al., 2011)** and our last paper **(Borková et al., 2018)**. According to **Martínez Marín et al. (2011)** the observed reduction of short and medium-chain SFAs was likely caused by the increased intake of PUFAs from linseed oil added to the feed which might have affected some crucial enzymes in the *de novo* fatty acid synthesis pathway such as acetyl-CoA carboxylase and fatty acid synthase. The *de novo* synthesis in the mammary gland is the major source of fatty acids with less than sixteen carbon atoms. Unlike our previous short-term supplementation experiment, the long-term supplementation with linseed oil decreased the levels of C14:0, C16:0 and also the levels of C6:0 to C12:0.

The increased amounts of *trans*-C18:1 and *trans*-C18:2 isomers, ALA and conjugated linoleic acid contributed to the elevated levels of MUFAs and PUFAs. These results are in accordance with findings of **Martínez Marín et al. (2011) and Bernard et al. (2009)** who also observed such increases after linseed oil supplementation. The increase of the unsaturated fatty acids mentioned above in yoghurt drinks was caused by the ALA present in linseed oil. Fatty acids longer than eighteen carbons get into milk from lipoproteins present in blood plasma (which themselves originate from food or animal's fat depots). The PUFAs present in feed undergo biohydrogenation in rumen during digestion which leads to the formation of C18:0 and other isomers like *t*11-C18:1 (vaccenic acid) and *t*11,*c*15-C18:2 **(Chilliard et al., 2007)**. These fatty acids are subsequently absorbed in the colon and transported through blood into the mammary gland where they might be desaturated by stearoyl-CoA desaturase activity. Contrary to our previous report in **Borková et al. (2018)**, the linseed supplementation did not decreased *c*9-C18:1 in yoghurt drinks. The PUFAs biohydrogenation in goat rumen is a very complex process influenced by many external and internal factors. The composition of metabolites resulting from biohydrogenation process is dependent on the supplement type and feed itself which both impact the lipogenesis in the mammary gland and the activity of key enzymes. Unlike our previous experiment, we did not see the desaturase activity to drop significantly in the yoghurt drinks (see the desaturase index in Table 3) made from the experimental group (ILY). This fact is the likely cause why we did not observe the *c*9-C18:1 fatty acid to decrease. It is worth to mention that the present study confirmed again that ALA levels in yoghurt drinks remained increased.

From the nutritional perspective it is important to underscore the increased content of *trans*-fatty acids in the ILY drinks. As a matter of fact, *trans*-fatty acids in food can negatively influence consumers' health. However, this notion is not true for all *trans*-fatty acids **(Anadón et al., 2010; Jacome-Sosa et al., 2014; Ganguly and Pierce, 2015)** like vaccenic acid (*t*11-C18:1) which is the main biohydrogenation intermediate of ALA.

All our yoghurt drinks (with or without the addition of yacon tuber powder) made from enriched omega-3 milk (LO goat group) have met the requirements of the **Regulation no. 397/2016 Col. of Czech Republic** specifying that all yoghurt products must contain at least 7 log CFU.g^{-1} (which equals to 10^7 CFU.g^{-1}). Yoghurt drinks containing yacon tuber powder (ILY) showed significant increase in the number of bifidobacteria than yoghurt drinks without the yacon addition (IL) (Table 4). This result is likely due to the presence of fructooligosaccharides in the yoghurt drinks which are a welcomed substrate for the probiotic bacteria leading to their increased counts.

Two pooled milk samples (one from the experimental, the other from control group) were created to mimic standard practices on the farm because farmers usually do not have access to individual milk samples but only to the pooled milk from the herd. Both pooled samples were used to manufacture yoghurt drinks with yacon tuber powder (one drink per each pooled sample denoted as PLY and

PCY) because we were interested if there is any difference in fatty acid profile in yoghurt drinks made from the pooled sample versus yoghurt drinks made from individual milk samples. The results for both groups are shown in Table 5. The yoghurt drinks made from pooled milk samples from goats supplemented with linseed oil (PLY) had increased contents of MUFAs, PUFAs and a lower content of SFAs similar to findings for ILY yoghurt drinks. PLY yoghurt drinks had 66% higher ALA content (compared to the PCY group used as a control). The same comparison for yoghurt drinks from individual milk samples (ILY and ICY) has shown only 53% increase in ALA content. The higher amount of ALA in the pooled samples (66%) was caused by some goats having higher milk yield with the highest ALA content (unpublished results). Fructooligosaccharide content in yoghurt drinks from the pooled samples was 0.73 – 0.81 g.100 g^{-1} of yoghurt drink thus these yoghurt drinks can be a valuable source of prebiotics, probiotics and α-linolenic acid.

CONCLUSION

Goat yoghurt drinks with bifidobacteria and yacon tuber powder are novel products that might be interesting for health conscious consumers providing them with added value. These drinks are a good source of fructooligosaccharides and bifidobacteria compared to regular products without any added prebiotics. In case of the milk produced by goats fed linseed oil it is possible to manufacture a product which has an increased omega-3 fatty acid content and decreased content of saturated fatty acids. These yoghurt drinks eventually contained significantly higher amounts of α-linolenic acid and lower levels of lauric, myristic and palmitic acid.

UNUSUAL ASPECTS OF THE FAT CONTENT OF MEALWORM LARVAE AS A NOVEL FOOD

Martin Adámek, Jiří Mlček, Anna Adámková, Marie Borkovcová, Martina Bednářová, Zuzana Musilová, Josef Skácel, Jiří Sochor, Oldřich Faměra

ABSTRACT

The work focuses on some aspects of content and properties of the fat in mealworm as a novel food. The total fat content of this species is a markedly variable nutritional value that is significantly dependent on the breeding conditions. In this work, the fat content of a mealworm from various Czech suppliers ranged from 202 g.kg^{-1} to 282 g.kg^{-1} dry matter, determined using the Soxhlet extraction method. The total average value from all suppliers was 235.8 ±40.8 g.kg^{-1}. This is a range that can be expected by the customer when buying mealworm larvae from a random Czech supplier. Furthermore, the work graphically compares the values of the total fat content with other comparable commodities of animal origin, e.g. chicken or fish. Finally, the aim was to obtain initial information about the comparison of the sensory properties of the mealworm fat with other fats of animal origin using a simple electronic nose. There was a difference between the fat obtained from insect larvae and the conventional unprocessed fats. This work brings a wider view of fat as a taste carrier in a new food - a mealworm.

Keywords: mealworm; fat; breeder; electronic nose

INTRODUCTION

The inclusion of edible insect as novel foods in human nutrition is affected by several factors such as nutritional value, consumer gastronomic requirements, as well as economic and ecological aspects **(Cerritos, 2011; Chae et al., 2012; Fontaneto et al., 2011; Mariod, Abdel-wahab and Ain, 2011; Premalatha et al., 2011)**. The attitude of consumers towards entomophagy varies in different parts of the world. In developing countries, the edible insect is a common basic food with an interesting nutritional value, such as protein and fat content. On the contrary, in the developed world, especially in Europe and North America, it is predominantly an enjoy-ment food **(De Foliart, 1992; Ramos-Elorduy et al., 2011)**. By changes of European legislation, edible insect became a novel food that is being increasingly promoted on European markets **(EFSA 2015; EFSA, 2018)**. The reason is the growing consumer interest in repeated eating of edible insect, not only because of its interesting nutritional value but also for its specific sensory properties **(Adámek et al., 2018)**.

Insect is consumed mostly culinary processed (baked, blended into rice, soups, pasta, or salads) **(van Huis, 2015)**. Fat as a carrier of taste is generally rich in edible insect. However, its quantity varies considerably among species. Its value for mealworm (*Tenebrio mollitor*) is most often in the range of 150 to 300 g.kg^{-1}. Not only the amount of fat but also the fatty acid profile is dependent on various aspects (diet, developmental stage, breeding temperature). In terms of purchasing insect in native state, however, many aspects are unknown for the consumer. Information on total fat content is important to consumers because of the use of edible insect material as part of food products and meals. The fat content can determine the final product properties. In the case of including insect in the food basket of the Czech consumer, it is important to compare it with commonly consumed foods of animal origin. For the consumer, not only the nutritional value but also the organoleptic properties play an important role. The primary assessment of a consumed food is its visual appearance and aroma, on the basis of which the consumer chooses to consume. A firmly defined state of a food with a certain flavor can be recorded using the electronic nose to distinguish this firmly defined state of the food (commodity) from other states. This can be used, for example, to determine the authenticity and safety of foods, the maturity of a particular raw material, and so on.

Scientific hypothesis

A) Average values of the total fat content of the mealworm as a novel food by individual breeders do not differ by more than ±10% from the total average fat content of all selected suppliers. B) The total fat content of the mealworm as a novel food is comparable to other commodities of animal origin from common livestock. C) The results of

comparison of the fat sensory evaluation of mealworm as novel food with other fats of animal origin using a simple electronic nose will be different.

Aim

The aim of this work was to evaluate some aspects gained and analyzed during the monitoring of nutritional values of mealworm, especially for fat. The work observes and compares the total fat content of mealworm from different breeders including the determination of its average value and the standard deviation and its comparison with other fats of animal origin commonly used. Furthermore, the aim was to obtain initial information on the comparison of the sensory properties of the fat of the mealworm with other fats of animal origin using a simple electronic nose.

MATERIAL AND METHODOLOGY

Material

Mealworm (*Terebrio mollitor*) larvae in the last and the penultimate developmental stages (full length of the body just before the pupae) were used. The larvae were taken from the breed, left to starve for 48 hours, killed with boiling water (100 °C) and immediately dried at 105 °C. The samples prepared this way were homogenized and stored in a refrigerator at 4 – 7 °C until analysis.

The larvae were purchased from three companies in the Czech Republic. In addition, the data of the author described in **(Adámková et al., 2016; Adámková et al., 2017)** were used for comparison. Furthermore, the average values and standard deviations from available literature were compared with a focus on breeding and sales in the Czech Republic.

Methods

Determination of fat content using Soxhlet extraction method

Determination of fat content was carried out by Soxhlet extraction method **(Soxhlet, 1879)** using Gerhardt Soxtherm machine (C. Gerhardt, Germany). 5 g of dried and homogenized samples (with an accuracy of 0.0001 g) were placed in the extraction cartridge and extracted with 150 ml petroleum ether (program: 70 °C for 120 minutes). The extracted sample was then dried at 103 °C and repeatedly weighed to a constant weight.

E-nose

Fat samples were further analyzed using the simple electronic nose described in **Adámek et al. (2018)**. Samples were analyzed at 20 °C – 23 °C.

Statisic analysis

The data were analyzed using Excel 2013 (Microsoft, USA). Results were expressed by average ± standard deviation. For the calculation of the general average fat values for mealworm and their comparison, also the values from the available literature complemented by the optimal conditions of breeding focused on the breeding area in the Czech Republic were used together with the measured values.

In case of measurement by E-nose, data was evaluated using Excel 2013 (Microsoft, USA) and Gnuplot 5.0: an interactive plotting program **(Williams et al., 2016)**.

RESULTS AND DISCUSSION

Comparison of the total fat content in samples from each supplier

To determine the overall value of the total fat content of the mealworm larvae and its comparison, the total fat content in samples from three suppliers (2 direct breeders + 1 supplier with unknown breeder) was determined in the first step. The basic results determined by the Soxhlet method are shown in Table 1.

From the results shown in Table 1. average values and standard deviations for individual suppliers were calculated and these values were compared with other literary sources focusing on the area of the Czech Republic, as shown in Table 2.

Table 2 shows that even under optimal breeding conditions, the total dry fat content of mealworm larvae (*Tenebrio molitor*) samples may differ statistically, even if the breeders are from one geographical area. By random purchase, the consumer gained insect with a total fat content ranging from 170 $mg.g^{-1}$ to 360 $mg.g^{-1}$ of fat in dry matter. The mean value calculated from the experimental values and available literature sources for Europe for the optimal breeding conditions stated is 243 ±57 $mg.g^{-1}$.

Table 1 Basic results of total fat content determination in samples from three breeders.

Supplier / Number of sample	Weight (g)	Cartridge (g)	Cartridge with fat (g)	Fat (g)	Fat (%)

From a standard deviation of 23.4% of the average total fat content, it can be estimated that the consumer is not able to estimate the amount of fat in a particular insect sample with sufficient accuracy. The real extreme values can occur in breeds where welfare is not respected by the breeder and especially the seller **(Adámková et al., 2017)**.

The analyzed data show the total fat content of mealworm is not affected by the area of breeding. The content of the fat will be influenced by the breeding temperature, seasons, stress and nutrition in managed breeds **Broekhoven et al. (2015); Nowak et al. (2016)**. Here, too, it is confirmed that nutrition is one of the important factors influencing the quantity and variability of fat as it is for other commodities of animal origin (patent). The fat content of mealworm can be compared with the fat content of the parts of the body of common livestock (Figure 1) **(Pipek, 1995; Steinhauser, 1995)**. Due to the size of the insect, from the whole body of the insect, whereas in common livestock it is possible to extract the fat from individual parts thereof. In addition, it is necessary to consider that fat consumption from ordinary livestock can take place after a short heat treatment or even in the raw state, insect fat can be used for food purposes only after chemical extraction. This increases the cost of this raw material. On the other hand, in the longterm storage process there are no significant biochemical and microbiological changes and no specific storage conditions **(Adámek et al., 2018)**.

When comparing the total fat content in the dry matter of the mealworm with the total fat content of the conventional meat, the analyzed values for the mealworm are in a wide range from 16% to 36%. This can be compared with both lean chickens (14%) and, for example, salmon (37.6%). This range includes, for example, beef sirloin, mackerel or turkey meat.

From the health point of view, not only the total fat content but also the fatty acid profile, especially linoleic acid and linolenic acid, is important. EFSA Recommendation on fat and other lipophilic substances ingestion from 2010 **(EFSA, 2010)** no longer state recommendation for the n-6: n-3 ratio but, indicate that linoleic acid intake should not fall below 4% and linolenic acid below 0.5% of total energy intake. In the case of mealworm meal consumption and required energy intake of 10,000 $kJ.day^{-1}$, linolenic acid in the amount of 205 g and 708 g of linolenic are needed. Considering the linolenic acid intake, the quantity contained in the dry matter is insufficient and must be supplemented from other sources. On the contrary, the amount of linoleic acid is sufficient, and the dry matter can serve as the source of this acid **(Adámková, 2017)**. Although mealworm is included among livestock since 2015 **(EFSA, 2015)**, it must be considered a specific species with special biological properties. For this reason, insect has to be bred under the defined breeding conditions to achieve the desired properties.

In the next part, the flavor of raw pork and beef fat was measured with a simple electronic nose and compared with fat obtained by the extraction from mealworm larvae. The results in Figure 2 show the difference between insect fat and pork and beef fat.

The most significant difference was recorded by the MQ-8 type sensor, which responds in particular to Hydrogen (H_2), next to alcohol, LPG and cooking fumes. Therefore, the difference between fats can be caused by the treatment of fat from insect during extraction or different fat composition.

In today's food industry, modern techniques such as electronic nose, eye or tongue are used to capture sensory properties. The disadvantage of these techniques is that they cannot replace the human sensory organ in full. The

advantage is good repeatability even in longterm measurements (human can be tired) and in some cases a better sensitivity, resolution or range wider than a human can possess (e.g. electronic eye). An electronic nose used to record flavors from commodities of animal origin is described, for example, by **Gopal (2015)**, who in his study used the Peres' electronic nose to assess the freshness and durability of the meat. The electronic nose plays another important role in detecting food counterfeiting and assessing its authenticity **(Peris and Escuder-Gilabert, 2016)**. In the case of edible insect as a novel food that is being introduced to the market, however, this technology has been used only minimally. The introduction of this technology is one of the arguments for persuading the Czech (European) consumer that food from edible insect is safe and has properties similar to other commodities of animal origin. It is necessary to bear in mind that the insect fat is extracted.

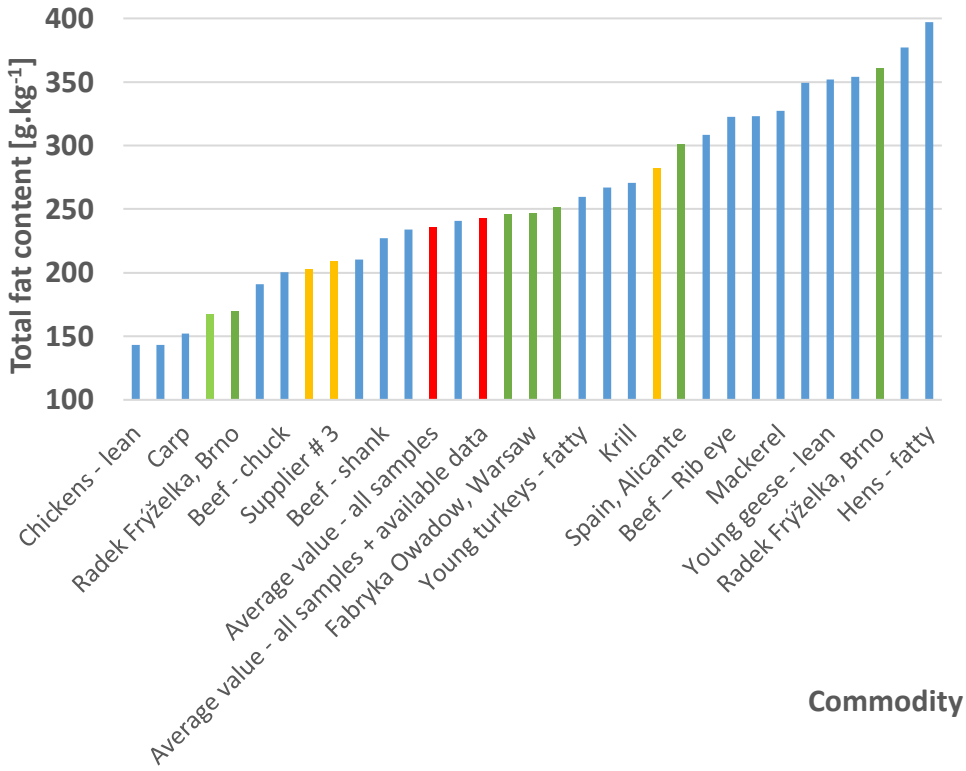

Figure 1 Comparison of total fat content in mealworms and conventional meat **(Pipek, 1995; Steinhauser, 1995)**.

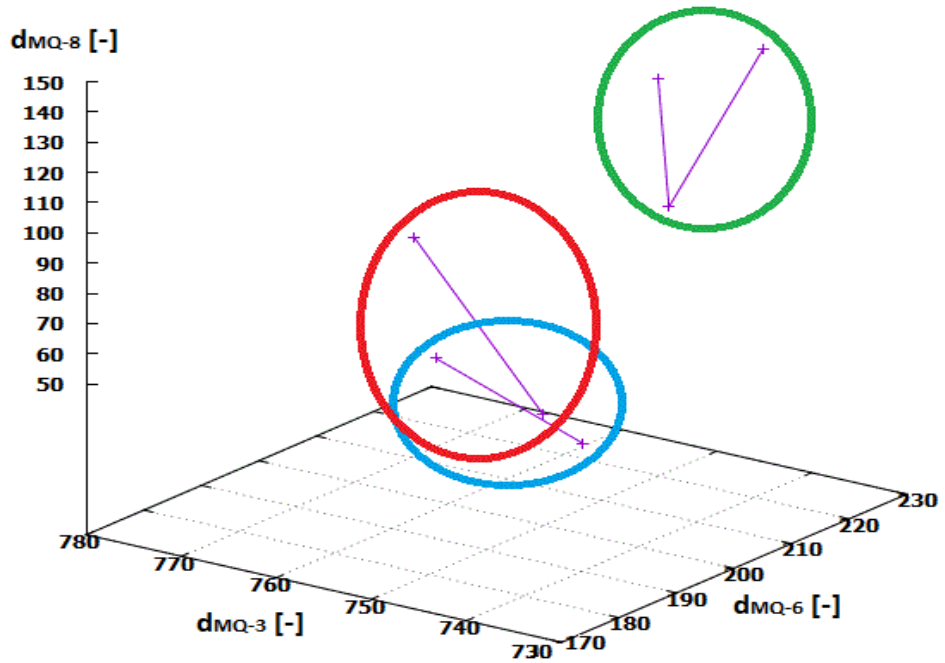

Figure 2 Comparison using a simple electronic nose of pork (blue) and beef (red) crude fat with fat obtained by extraction from mealworm (green).

CONCLUSION

The total fat content of the mealworm is a significantly variable nutritional value, which is highly dependent on the breeding conditions.

In this work, the fat content of the mealworm from various Czech suppliers ranged from 202 $g.kg^{-1}$ to 282$g.kg^{-1}$ dry matter. The overall mean value of all suppliers 235.8 ±40.8 $g.kg^{-1}$ does not confirm the hypothesis that the fat content of the dry matter will not differ by more than 10% of the average fat value. The result demonstrated the wide range of fat content even though the supplier has stated the optimal breeding conditions for the species. If a consumer needs to obtain insect with a specific fat content, the solution to this problem can be to communicate directly with the breeder and ensure adequate breeding conditions to achieve the required nutritional value. Considering the wide range of fat content in mealworm samples it is possible to compare the fat content with, for example, lean chickens (14%) and salmon (37.6%). This range includes, for example, beef sirloin, mackerel or turkey meat. On the other hand, measurement using an electronic nose demonstrated the differences between insect fat and unprocessed (raw) pork and beef fat. The article brings some new information on some aspects of edible insect as a source of fat.

Characteristics of flour and dough from purple and blue wheat grain

Iva Burešová, Václav Trojan, Martin Helis

ABSTRACT
The characteristics of flours and doughs prepared from wheat grains containing purple pericarp (variety PS Karkulka and Jumiko) and wheat grain containing blue aleurone (variety Skorpion) were tested and compared with commercial wheat to evaluate the applicability of colored wheat in bread making. The fine flours prepared from colored wheat grains significantly differed in the activity of the amylase enzyme, expressed as Hagberg falling number. Zeleny sedimentation volume of flour prepared from grains of the PS Karkulka variety (36 mL) was significantly higher than the values of AF Jumiko and Skropion (34 mL) varieties. The results of uniaxial deformation test indicated that doughs prepared from wheat varieties PS Karkulka and Skropion can be elongated; the dough is, however, weak and can be expected to rupture more easily than dough prepared from variety AF Jumiko, as well as commercial flour. Even if some variations in the values of farinographic dough development time and stability were also observed, clear differences in the behavior of doughs prepared from colored and commercial flours were not found. The differences in dough behavior during heating test were also negligible. It can be concluded that none of the tested colored wheat grains exhibited characteristics completely different from the others or the commercial one. The results may indicate the applicability of all tested colored wheat grains in yeast-leavened bread production.

Keywords: fine flour; rheology; quality; bread making

INTRODUCTION
Wheat is grown on more land than any other commercial crop and continues to be the most important food grain source for humans. Global production is about 700 million tons per year. Wheat provides 20% of daily protein and is a significant source of calories for 4.5 billion people **(FAO, 2014)**. The unusual properties of wheat storage proteins (gluten proteins) allow flour to be transformed into dough with suitable properties for bread making **(Goesaert et al., 2005)**.

Wheat grain may also be a good source of phytochemicals, compounds with health-promoting effects. When taken regularly and in adequate amounts, these molecules can have long-term benefits on human health through reducing the likeliness of obesity, diabetes, and cancer and degenerative diseases, such as cardiovascular disease **(Borrelli and Trono, 2016)**. Some of these phytochemicals significantly influence grain color. Anthocyanins are accumulated in the aleurone or pericarp layer resulting in or a combination of blue and purple. Phlobaphenes present mainly in the outer layer are responsible for a reddish color **(Lachman et al., 2018)**.

Colored wheat grains can be used in food production. Since the phytochemicals are situated in the aleurone or pericarp layer, whole grain products are preferred. The applicability of purple wheat grain in biscuit and pasta production has already been studied. Biscuits prepared from whole wheat extracted from purple grains exhibited higher antioxidant activity than biscuits prepared from common wheat grain. Purple biscuits, moreover, showed lower levels of lipid-derived carboxylic acids and higher levels of alcohols and aldehydes than common biscuits, indicating lower oxidative degradation of lipids **(Pasqualone et al., 2015)**.

Ficco et al. (2016) found the sensory properties of pasta from the purple genotype not to be significantly different from commercial whole wheat pasta. In vitro glycemic index was also lower.

Wheat grain with purple pericarp (PS Karkulka and Jumiko) and wheat grain with blue aleurone (Skorpion) **(Lachman et al., 2018; Martinek et al., 2013)** were studied. The aim of this study was to compare the characteristics of flour and dough prepared from colored wheat grain with commercial wheat flour and dough, and to evaluate the applicability of these wheats' grains in the production of yeast-leavened bread.

Scientific hypothesis
The doughs prepared from colored wheat grains exhibit different behavior than dough made from commercial wheat during uniaxial deformation, farinographic and heating tests, which may limit their use in the production of yeast-leavened bread production.

MATERIAL AND METHODOLOGY

Material

Fine flours from wheat grain with purple pericarp (PS Karkulka and Jumiko) and wheat grain with blue aleurone (Skorpion) were used in this study. Fine flours are characterized by being made up of at least 96% of particles that pass through a 257 μm sieve opening and a maximum of 75% of particles passing through a 162 μm sieve opening **(Decree No. 333/1997)**. The Babiččina volba commercial fine flour manufactured by GoodMills Česko s.r.o. was bought in a local supermaket.

Flour characteristics

The flours were characterized by Hagberg falling number and Zeleny sedimentation volume. Hagberg falling number is used to describe the activity of flour amylase enzymes. It was determined according to **ČSN EN ISO 3093 (2011)**. Zeleny sedimentation volume is a key factor of the wheat quality. It is used to predict the baking strength of flour. This parameter was determined according to **ČSN EN ISO 5529 (2011)**.

Dough rheological characteristics

Uniaxial deformation test was performed on dough samples made by mixing flour, water (according optimal farinograph water absorption) and salt (1.5%). The dough was made into thin rolls, put onto the lubricated surface of a Teflon mold and compressed with a lubricated top plate. Test pieces were formed into 5 cm long chunks with a trapezoidal cross-section (3 mm, 5 mm, 4 mm). The doughs were left resting for 40 ±1 min at 30 ±1 °C. The test was performed using textural analyzer TA.XT plus (Stable Micro Systems, UK) equipped with an SMS/Kieffer Dough and Gluten Extensibility Rig. During testing the dough sample was stretched by the hook until it fractured. Test speed of the hook was 3.00 $mm.s^{-1}$, trigger force 5 g. The force required to stretch the dough sample and the displacement of the hook were recorded as a function of time. The values of resistance to elongation *R* (N), extensibility *E* (mm) and extension area *A* (N.mm) were calculated. Force *R* represents the dough resistance to extension, extensibility *E* represents the distance at which this peak force occurs, and extension area *A* is the area under the curve which is related to the energy required to stretch the test piece to its rupture. Each test was performed on dough samples prepared at least in six replicates. The given results are represented as mean values.

Dough behavior during mixing was studied using Mixolab (Chopin Technologies, Paris, France). The dough was prepared by mixing flour with distilled water. Chopin S protocol simulated the operation conditions of the Farinograph. The obtained parameters were: flour water absorption *WA* (%), dough development time *DT* (min), dough stability *ST* (min) and degree of softening *DS* (FU). The standard Chopin+ protocol was used to test dough behavior during heating and cooling, following a 30 – 90 – 50 °C pattern. The extent of dough weakening α ($Nm.min^{-1}$), starch gelatinization β ($Nm.min^{-1}$) and cooking stability γ ($Nm.min^{-1}$) were evaluated. Each test was performed on dough samples prepared at least in six replicates. The given results are represented as mean values.

Statistical analysis

The results were statistically analyzed using analysis of variance (ANOVA). The differences were tested on $p = 0.05$ significance level using Fisher LSD test. The analysis was performed using Statistica 13 software (StatSoft, CR).

RESULTS AND DISCUSSION

Flour characteristics

The flours were characterized by Hagberg falling number and Zeleny sedimentation volume (Table 1). The flour prepared from Skorpion variety was the only one exhibiting optimal value (251 s) for bread making **(Kurt and Evers, 2017)**. The flours from the AF Jumiko and PS Karkulka varieties exhibited significantly (p <0.05) higher values (407 – 460 s), indicating low activity of amylase enzymes **(Ranken, Kill and Baker, 1997)**. Zeleny sedimentation volume of flour prepared from grains of PS Karkulka variety (36 mL) was significantly (p <0.05) higher than the values of AF Jumiko and Skropion (34 mL) varieties. This higher value of sedimentation volume can be explained by better swelling and flocculating properties of the insoluble proteins associated with good bread making characteristics **(Kurt and Evers, 2017)**.

Dough behavior during uniaxial deformation

Dough extensibility *E* did not significantly (p <0.05) differ among the tested doughs (Table 2). Dough resistance to elongation *R* was significantly lower in doughs prepared from colored wheat grain (0.17 – 0.30 N) than in the dough from commercial wheat flour (0.34 N). The recorded weak resistance to extension can also be related to the decrease in the extension area values *A* recorded in dough from colored wheat flours. The decrease was, however, significant (p <0.05) only in the dough prepared from Skorpion variety. The combination of good resistance to elongation and extensibility, expressed as *R/E* ratio, is expected in doughs with good bread making quality **(Burešová and Hřivna, 2011; Goesaert et al., 2005; Tsiami et al., 1997a, b)**. The dough prepared from AF Jumiko variety exhibited an *R/E* ratio similar to dough from commercial flour. The values obtained in dough from PS Karkulka and Skorpion varieties were significantly (p <0.05) lower. Significantly weak resistance to extension recorded in these samples can be the factor decreasing the values of *R/E* in these doughs. The results of uniaxial deformation test indicated that doughs prepared from PS Karkulka and Skropion varieties can be elongated; these doughs are, however, weak, and can be expected to rupture more easily than doughs prepared from AF Jumiko variety, as well as commercial flour.

Farinographic characteristics

Farinographic characteristics are used to describe dough formation and behavior during kneading at constant temperature. The amount of water required to prepare dough with optimal consistency of 500 FU, expressed as water absorption, is also obtained.

Table 1 Hagberg falling number (*FN*) and Zeleny sedimentation volume (*SEDI*) of flours from colored wheat grains.

Flour	FN (s ±SD)	SEDI (mL ±SD)
AF Jumiko	460 ±10^{c}	34 ±2^{a}
PS Karkulka	407 ±9^{b}	36 ±2^{b}
Skorpion	251 ±3^{a}	34 ±2^{a}

Table 2 Dough behavior during uniaxial deformation test.

Flour	R (N ±SD)	E (mm ±SD)	A (N.mm ±SD)	R/E (10^{-3} N.mm^{-1} ±SD)
AF Jumiko	0.30 ±0.04^{c}	44 ±9^{a}	9.9 ±0.7^{ab}	7.0 ±0.9b
PS Karkulka	0.21 ±0.02^{b}	56 ±9^{a}	9.2 ±0.9^{ab}	3.8 ±0.7a
Skorpion	0.17 ±0.04^{a}	47 ±9^{a}	8.2 ±0.7^{a}	3.6 ±0.6a
Commercial	0.34 ±0.03^{d}	52 ±9^{a}	12.4 ±0.9^{b}	6.5 ±0.9b

Note: Dough resistance to elongation (*R*), extensibility (*E*), extension area (*A*), *R/E* ratio.

Table 3 Rheological characteristics of dough.

Flour	WA (% ±SD)	DT (min ±SD)	ST (min ±SD)	DS (FU ±SD)
AF Jumiko	60.0 ±0.4^{b}	4.9 ±0.3^{b}	36 ±2^{b}	46 ±7^{a}
PS Karkulka	61.4 ±0.4^{c}	3.6 ±0.4^{b}	28 ±1^{a}	44 ±3^{a}
Skorpion	62.4 ±0.8^{d}	1.0 ±0.4^{a}	39 ±5^{b}	38 ±9^{a}
Commercial	57.6 ±0.5^{a}	2.9 ±0.1^{ab}	29 ±1^{a}	44 ±5^{a}

Note: Farinographic water absorption (*WA*), dough development time (*DT*), dough stability (*ST*) and degree of softening (*DS*).

Table 4 Rheological characteristics of dough. Mixolab dough weakening (α), gelatinization rate (β) and stability (γ).

Flour	α (10^{-3} Nm.min^{-1} ±SD)	β (Nm.min^{-1} ±SD)	γ (Nm.min^{-1} ±SD)
AF Jumiko	-69 ±9^{a}	0.09 ±0.05^{a}	-0.07 ±0.02^{a}
PS Karkulka	-113 ±9^{a}	0.39 ±0.02^{ab}	-0.06 ±0.03^{a}
Skorpion	-94 ±6^{a}	0.48 ±0.06^{b}	-0.08 ±0.01^{a}
Commercial	-57 ±4^{a}	0.22 ±0.09^{ab}	-0.05 ±0.04^{a}

The water absorption WA of all tested flours prepared from colored wheat grain was significantly (p <0.05) higher than the absorption of commercial flour (Table 3). Dough development time DT was significantly higher in dough prepared from AF Jumiko and PS Karkulka varieties than in dough from Skorpion and commercial flour. Dough stability ST of dough prepared from PS Karkulka was closer to the commercial flour. The stability of dough ST prepared from PS Karkulka and AF Jumiko was, however, significantly (p <0.05) higher. Dough softening DS did not differ among tested flours. The farinographic test revealed that the flours from colored wheat required a higher amount of added water to reach optimal consistency of 500 FU. Even if some variations in dough development time and dough stability were also observed, clear differences in the behavior of doughs prepared from colored and commercial flours were not found.

Dough behavior during heating

Changes of dough viscosity during baking significantly impact dough ability to trap and hold gas in enclosed cells and expand along with it. Thus, optimal dough viscosity is essential for obtaining high quality, spongy bread crumb **(Collar, Bollain and Rosell, 2007; Mondal and Datta, 2008)**. Viscosity changes occurring in dough during baking are generally attributed to protein breakdown, gelatinization rate and cooking stability.

At the beginning of heating (30 – 50 °C), doughs exhibited weakening indicated by negative values of α (Table 4). Dough weakening can be partially related to water released from proteins after reaching the temperature of their denaturation, and partially to water released from dough macromolecules due to mechanical stress applied on the sample. Dough viscosity rose in the temperature range of 60 – 80 °C, which is evident from positive values of β, indicating dough strengthening. While in the previous phase of heating, the dough characteristics were mainly affected by protein denaturation, starch gelatinization occurred in this heating phase. Light dough weakening was observed during the final phase of the heating test, which is evident from negative values of γ. Although the doughs exhibited some differences during the heating test, these differences were not significant during the initial and final phase of the test. The only significant (p <0.05) differences were found during the gelatinization phase in which dough from AF Jumiko variety exhibited reduced gelatinization extent (0.09 Nm.min^{-1}) than dough from Skorpion variety

(0.48 Nm.min^{-1}). The differences in gelatinization rate among the other doughs were not significant.

CONCLUSION

The fine flours and doughs prepared from wheat grains with purple pericarp (PS Karkulka and Jumiko varieties), along with wheat grain with blue aleurone (Skorpion variety) were tested and compared with commercial flour to evaluate the applicability of colored grain wheat in bread making. The flours prepared from colored wheat grains exhibited variations in the values of Hagberg falling number and Zeleny sedimentation volume. The dough behavior during uniaxial deformation, farinographic and heating tests also varied. The differences were, however, generally weak. None of the tested colored wheat grain exhibited characteristics completely different from the others or the commercial one. The results may indicate the applicability of all tested colored wheat grains in bread making. Experimental baking tests, however, are yet to be performed to finally confirm it.

NATURAL FRUIT BEVERAGES FORTIFIED BY BIOLOGICALLY ACTIVE SUBSTANCES OF GRAPE VINES

Lukáš Snopek, Jiří Mlček, Vlastimil Fic, Irena Sytařová, Soňa Škrovánková

ABSTRACT

Based on the study of general knowledge of biochemical and all subsequent developmental studies of organic matter, especially products of grapevine and selected fruit products, a comprehensive study of processing technologies is prepared. Use of a combination of vine products and fruit products in the form of natural grapes. Beverages are researched and developed to be purely natural on the basis of grape musts, blue and white, either individually and again separately in targeted combinations, both biochemically, organoleptically and colorfully, with fruit sources. The core of grape value of biologically active substances is an integral and essential new part and condition of designing these beverages. Their increased biological values, which create the preconditions for containment and if properly managed on the basis of scientific knowledge, may in some cases almost result in the elimination of synthetic additives. It should be noted that 20 – 25% of the adult population suffers from many unexpected allergies, for example, to the sulphite content, although its content in the final product does not exceed the health-approved normatives. And there are many other, interrelated relationships. Beverages are technologically dealt with both without alcohol fermentation and with this fermentation, but only based on their compositional natural resources. They are therefore suitable for the entire population profile. The whole set contains 7 variants and a combination of natural beverages from different fruits. Including natural beverages with or without alcoholic fermentation from the must of white wine grapes, the juice of apple puree with those of biologically active substances from the products grapevine. Three months of monitoring and determination of basic (oenological) values and biologically active substances were performed on these products. The high-performance liquid chromatography method with a refractometric detector determined amount of sugar and alcohol, whilst titrating determined total and volatile acids and free sulfur dioxide. Yeast assimilable nitrogen, total anthocyanins and polyphenols were determined by spectrophotometry, antioxidant activity by DPPH and ABTS methods.

Keywords: biologically active substances; natural stability; isolation of selected substances; natural beverages with or without alcohol

INTRODUCTION

The values of biologically active substances are monitored by biochemical analysis in connection with the determination of the oenological, microbiological and other characteristics. Critical points of instability of the biologically active substances value are determined, possibilities of restraint until the causes of this instability are eliminated. Values of endogenous sulfur dioxide content and possibilities of reduction until its elimination **(Wells and Osborne, 2011; Ivanova, Petruseva and Mitrev, 2015)**. Correlation of concurrent laboratory and organoleptic values, which create the first sense of customer interest and interest in manufacturing and commercial applications. The equilibrium of the total polyphenol values demonstrates the stability of the biologically active substances values, thus demonstrating the correctness of the design of the technological processes **(Mlček et al., 2016; Tarko et al., 2015)**. The protein content test proves their stability, which is a measure of protection against sunburn.

In this case, however, completely different technological processes, due to the prepared conditions for yeast activity, are also of completely original origin **(Hernández et al., 2018)**. The yeast for the preparation of the fermentation support comes from the same variety and locality, including agrotechnical practices and technology for the cultivation of grapevine **(Lachman et al., 2009)**. The fermentation process is prepared from grapes harvested 5 to 7 days before the harvest for the entire production process. The exact start date of the preparation of the

fermentation support is determined by the temperature relations of the habitat and the duration of the preparatory processes for the technological process of fermentation and its course **(Yu et al., 2018)**. The temperature sessions need to be regulated in the range of 18 – 28°C and YAN conditions (assimilable N). In the case of unfermented must in the range of 120 – 200 mg.L^{-1} (on the experimental parcels of the submitted project, it ranged in three sampling times at 177 – 166 – 134 mg.L^{-1}, the yeasts were not referred to as "life", they did not consume nitrogen). In fermentation, nitrogen value has fallen further since the beginning of the fermentation process and reached 50 – 44 – 40 mg.L^{-1}. However, it is necessary to emphasize that the resources for obtaining the raw material needed for its processing are consistent but the technological procedures for the respective goals are quite varied.

The technological bond of the basic raw material, ie the apple pulp, has been created to obtain apple juice and the sources of tripenten biological substances contained in apple peel. Apples contain a range of substances that the technologist must register and monitor their development **(Baron, Dénes and Durier, 2006; Valdramidis et al., 2009)**. Mutual relationships of organic acids and sugar content, which is represented by fructose, glucose. During fruit maturation, sucrose passes gradually into fructose. Ripening also creates conditions for the transformation of starch (in immature fruit) into sugar. Furthermore, it is necessary to monitor proteins, pectin substances, fiber and others, especially vitamins and aromatics **(Qin, Petersen and Bredie, 2018)**. Biological activity is heavily enriched with biologically active substances from grape vines, which which belongs to high-incidence plants. The combination of both components – i.e. apples and natural additives, i.e. biologically active substances from grapevine products, creates a value that is purposefully controlled on the basis of the relevant analyzes **(Vrancheva et al., 2018)**.

Scientific hypothesis

The aim of the research is to increase the share of biologically active substances and to increase their stabilization throughout the technological processes from the stage of their sources, the analytical procedures in the course of research and development and the complete observance of the development rules throughout the production process. Monitor biological agents and their development during storage and validate values using appropriate matrix-adapted methods.

MATERIAL AND METHODOLOGY

Materials

The whole set contains 4 variants and a combine natural beverages from different fruits. Includes natural beverages with or without alcoholic fermentation from the must of white wine grapes, the juice of apple puree with those of biologically active substances from the products grapevine.

Methods

Determination of free SO_2 by OIV-MA-AS323-04B : R 2009

The modified method of **Snopek et al. (2018)** which is based on the methodology of **OIV (1990)**. 50 mL of wine sample is pipetted into a 500 mL volumetric flask, we add 3 mL of 16% H_2SO_4 (Penta, Prague, Czech Republic), 1 mL EDTA 3 solution having a concentration of 1%, 5 mL of starch solution is titrated against a white background I_2 (Ing. Petr Lukeš, Uherský Brod, Czech Republic) solution having a concentration of 0.02 mol.L^{-1} to blue color.

Spekctrophotometric methods

Spectrophotometric measurements were performed on a Lambda 25 UV-VIS spectrophotometer (PerkinElmer, USA) in 10 mm optical quartz cuvettes.

Determination of total polyphenol content (TPC)

The spectrophotometric method using the Folin-Ciocalteau reagent is used to determine the total phenolic compound (TPC) content. The essence is the reduction of the phosphomolybdate-tungsten complex by phenolic substances in an alkaline environment. The modified method of **Singleton and Rossi (1965)** according to **Snopek et al. (2018)** was used. Determination is carried out after a 30 min incubation at a wavelength of 765 nm. TPC of substances was expressed as gallic acid equivalent (GAE) in mg.L^{-1}. For the preparation of calibration solutions, use distilled water (20 mL), four volumetric flasks (volume 50 mL) and a micropipette. Split the standard solution, then the Folin-Ciocalteau (Penta, Prague, Czech Republic) reagent (1 mL) and mix. After 2 minutes, 5 mL of 20% sodium carbonate solution are added. The volumetric flask thus prepared is filled with distilled water to the mark. Incubation is followed (60 minutes) and we measure dye intensity in a 10 mm diameter cell at 765 nm against a blank. In the same way, determine the absorbance of the samples. According to the regression curve equation we calculate the content of polyphenols, expressed as mg of gallic acid equivalent (GAE).L^{-1}.

Determination of total antioxidant activity (TAA) by DPPH metod

Total antioxidant activity was assessed by modification method of **Rop et al. (2010)** according to **Snopek et al. (2018)**. The stock solution is prepared by dissolving 24 mg of 1,1-Diphenyl-2-picryl-hydrazyl (DPPH) (Penta. Ing. Petr Švec, Prague, Czech Republic) in 100 mL of methanol (Penta, Prague, Czech Republic). To prepare the working solution, use 10 mL of stock solution and 45 mL of methanol. The working solution is measured spectrophotometrically at a wavelength of 515 nm against methanol as blank. A sample of 450 µL of beverage is pipetted into a test tube. 8.55 mL of DPPH working solution are added. Incubation is followed (60 min) in the dark and then the sample is measured at the indicated wavelength. Absorption loss was recalculated using the linear regression equation to equivalent Trolox (TE).L^{-1}.

Determination of total antioxidant ativity by ABTS metod

The analysis was performed using the modified method of **Re et al. (1999)** and **Hosu, Cristea and Cimpoiu, (2014)**. The $ABTS^{+}$ cationic radical was obtained by reacting a 7 mmol.L^{-1} 2,2'-azino-bis(3-

ethylbenzothiazoline-6-sulphonic acid) ABTS (Merck KGaA, Darmstadt, Germany) solution of a diammonium salt with a solution of 2,45 mmo.L^{-1} $K_2S_2O_8$ mixed 1:1 (v/v). The solution was incubated for 16 hours at room temperature in the dark. Subsequently, 0.5 mL of the sample was added to 3 mL of $ABTS^+$ solution diluted to give an absorbance of less than 0.800. Absorbance was measured at 734 nm for 30 minutes. Absorption loss was recalculated using a linear regression equation to the Trolox equivalent (TE).L^{-1}.

Determination of total anthocyanins content (TAC)

A sample extract was prepared for the assay, to which 5 mL of the extraction mixture (70 methanol : 29 distilled water : 1 acetic acid) was added to 1 mL sample. Subsequently, they were placed in a water bath and shaken for 1 hour at 50 °C and placed for ultrasound for 20 minutes. The extract thus prepared is pipetted in a volume of 0.5 mL into two tubes. To one was added 2.5 mL of 0.025 M KCl buffer of pH 1 (0.186 g of KCl was dissolved in 98 mL of distilled water, followed by pH adjustment by concentrated HCl), and the same quantity of 0.4 M acetate buffer pH 4.5 (5.443 g of sodium acetate trihydrate was dissolved in 96 mL of distilled water, the pH value checked by pH meter and optionally adjusted with HCl). Absorbance was measured in all tubes on a spectrophotometer at a wavelength of 510 nm (absorption maximum of major cyanidine-3-glucoside) and at 700 nm against the extraction mixture. This determination was carried out by a modified method according to **Giusti and Wrolstad (2001)** and **Orsavová et al. (2019)**

Determination of sugar and alcohol

Before sampling, samples were diluted 1:10 with distilled water and then filtered through nylon micro filters (Syringe Filter, Nylon 13 mm x 0.45 μm). The determination of ethanol was carried out using a high performance liquid chromatography (RP-HPLC) method on UltiMate 3000 (Dionex, Sunnyvale, CA, USA) using a Phenomenex Rezex RCM-Monosaccharide Ca + 2 (100 x 7.8 mm, 8 μm) Torrance, CA, USA) with a RI detector. Water, isocratic elution, with a flow rate of 0.4 mL.min^{-1}, was used as the mobile phase. Column temperature 80 °C. Detector temperature RI 35 °C.

The qualitative evaluation was performed on the basis of analysis of the individual sugars and ethanol standards. A quantitative evaluation where the resulting value was determined as the average of the six measurements was performed by the calibration curve method and subsequent calculation of the concentration of the substance in the sample. The fructose, glucose and sucrose content was expressed as the equivalent amount of g standard in a 1 liter sample. The alcohol content was expressed as volume %.

Determination of volatile and total acids

To measure total acids, measure 30 mL of water, 1 mL of indicator and 20 mL of sample (CO_2-free) into a conical flask. We will titrate in green blue with a standard 0.1 M NaOH solution (pH = 7.0). All titratable acids are calculated as the tartaric acid content in g.L^{-1}.

The Berh S2 apparatus is used for volatile acids, a 25 mL sample (CO_2-free) is dripped into the distillation vessel. The heated distillate is heated to 60 – 70 °C, add 2 drops of phenolphthalein and titrate with 0.1 M NaOH to pink color. Calculate the volatile acid content as acetic acid in g.L^{-1}.

Determination of yeast assimilable nitrogen (YAN)

According to **Gump et al. (2002)** and **Petrovica et al. (2018)** free amine nitrogen and ammonia as well as YAN components are measured separately by an enzymatic test using K-PANOPA Megazy (Ireland) and ammonia using Enzytec Fluid Ammonia (R-Biopharm). This was done spectrophotometrically on a 20XT instrument (Thermo Fisher Scientific, Walthan). These individual values for free amine nitrogen and ammonia provide the total amount of available YAN and expressed as the nitrogen content in mg .L^{-1}.

Statisic analysis

The data obtained was expressed as mean value ± standard deviation (SD) and the Microsoft Office Excel program (Redmond, WA, USA) was used to calculate them. All analyzes were performed five times in two replicates. Differences between observed results were detected by t-test (Statistica, 2018, StatSoft, USA). A $p < 0.05$ was considered statistically significant.

RESULTS AND DISCUSSION

Samples of natural beverages from grape vines and apple juice were supplemented with biologically active substances from grapevine and free sulfur dioxide, total antioxidant activity (TAA) by methods using DPPH and ABTS, total polyphenol content (TPC), total anthocyanins content (TAC), sugar (fructose, glucose and sucrose), alcohol (ethanol), free and volatile acids and yeast assimilable nitrogen (YAN) were determined at regular monthly intervals during beverage storage under the prescribed conditions at 5 ° C.

Free sulfur dioxide in test samples of natural beverages (Table 1 – 4) ranges from 1.84 to 15.05 mg.L^{-1}. The smallest content was found in the natural beverage from apple juice with values of biologically active substances from vine products without alcoholic fermentation after 3 months of storage, on the contrary, the highest value was in natural beverage from white grape must with alcoholic fermentation after the first determination. If we compare the achieved values for free SO_2 (Table 1 – 4) with a study of sulfur dioxide **(Snopek et al. 2018)** the measured values are compared to those in organic quality.

To determine the total polyphenols content, a spectrophotometric method using Folin-Ciocalteau reagent was used in samples of a natural beverages of grape vines and fortified beverages of apple juice, using gallic acid as a standard. For beverages tested, the higher value of total polyphenols in fortified apple beverages was made by biologically active substances from grapevine and its change during storage was only fractionally. For alcoholic beverages, they exceeded 677.26 mg GAE.L^{-1} after first measurement to 619.54 mg GAE.L^{-1} after 3 months of storage.

Table 1 Results of individual provisions for natural beverage from white grape must without alcoholic fermentation.

Length of storage [month]		1st	2nd	3rd

Note: Table 1 to 4: SO_2 – sulfur dioxide; TPC – total polyphenol content; TAA – total antioxidant ativity using DPPH and ABTS – radical scavenging activity; TE – trolox equivalent; GAE – gallic acid equivalent; C3G – cyanidine-3-glucoside equivalent; fru – fructose; glu – gluctose, suc – sucralose; YAN – yeast assimilable nitrogen; ±standard deviation. The different superscripts in rows indicate statistically significant differences between data groups (statistically tested on level of significance $\alpha = 0.05$).

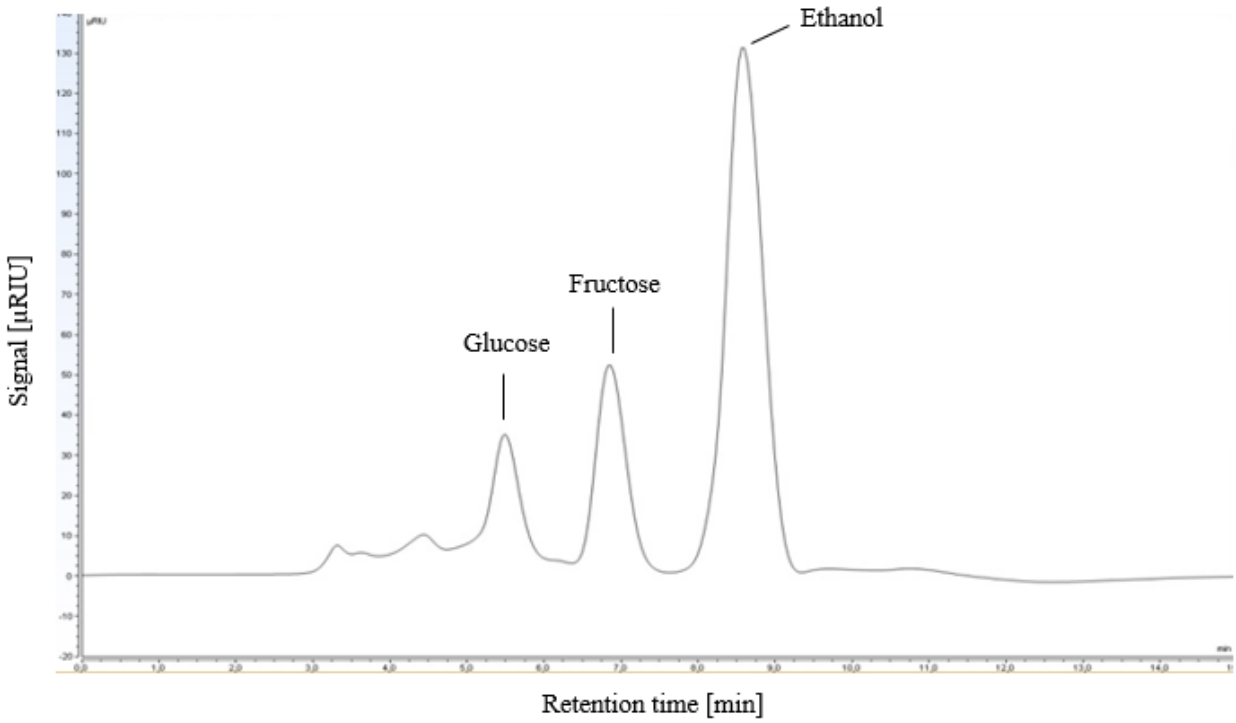

Figure 1 Chromatogram of determination of sugars and alcohol in a sample of white grapes (HPLC – RID).

The least total polyphenols were determined for a natural drink of white grape vines with alcoholic fermentation. It reached from 305.03 mg GAE.L^{-1} after the first measurement to 306.58 mg GAE.L^{-1} after three months of storage.

Paixao et al. (2007) evaluated the content of polyphenols in a fermented beverage of white grape vines. The average measured content was 369 mg GAE.L^{-1}, another study **(Hurtado et al., 1997)** reported the TPC of the beverage of 292 mg of GAE.L^{-1}. These published values are comparable to our values. The results of the work by **Ricci, Parpinello and Versari (2017)** for a TPC were reported at 222 mg GAE.L^{-1} which is in correlation with our results. Fortified beverage achieved above-average results and can be evaluated very positively. **Tarko et al. (2015)** published comparable values for apple juice, indicated as raw materials with high TPC.

To determine the antioxidant activity of natural beverage samples, the DPPH method was used, based on the reaction of the test substance with a stable 1,1-diphenyl-2-picrylhydrazyl radical. In addition, the ABTS method was used. It is characterized by reacting the test substance with 2,2'-azino-bis (3-ethylbenzothiazoline-6-sulfonic acid). Both methods used trolox as standard. The highest antioxidant activity in natural beverages (Table 1 – 4) was determined by both methods in non-alcoholic natural beverage from apple juice with fortified bioactive substances from white grape vines. The value ranged from 655.58 – 644.48 mg TE.L^{-1} determined by the DPPH method and 975.73 – 956.89 mg TE.L^{-1} using the ABTS method during storage. The smallest antioxidant activity was determined in a beverage sample of white grapes without alcohol.

The determination of total anthocyanins content was another of analyzes that support the high content of biologically active substances in a natural beverage based on fortified apple juice. Its content ranged from 9.51 mg C3G.L^{-1} to 8.29 mg C3G.L^{-1}. There followed a non-alcoholic natural drink of white grape vines with values ranging from 5.95 mg C3G.L^{-1} to 6.14 mg C3G.L^{-1}. A decrease in total anthocyanin values was observed for alcohol drinks during a three-month storage period with a white grape drink from 4.35 mg C3G.L^{-1} to 3.23 mg C3G.L^{-1} and for fortified apple juice with alcohol then 3.31 mg C3G.L^{-1} to 2.66 mg C3G.L^{-1}. Our measured values of the content of anthocyanin in apples reached the published values by **Wolfe, Wu and Liu (2003)**. Losses were attributed primarily to the technological modifications that took place during the production of the beverage.

Chromatographic techniques were most suitable and accurate for the identification and quantification of mono- and oligosaccharides in food **(Duarte-Delgado et al., 2015)** and according to the guidelines of the Association of Official Analytical Chemists **(AOAC, 1993; Sims, 1995)** for quantification of sugars. Table (1 – 4) lists the sugars (fructose, glucose and sucrose) content in natural beverages samples at the beginning of storage determined by the HPLC method. Figure 1 shows the chromatogram of determination of sugars and alcohol in a sample of white grapes (HPLC – RID). When the highest peak is ethanol, the other peaks represent the individual sugars. Table 1 – 4 shows that alcohol-free beverages contain up to ten times more sugars than alcohol drinks. Most of the sugars were determined for a grape wine without alcohol 226.64 g.L^{-1}, which was retained after 3 months of storage and the alcohol content fluctuated between 0.19% (vol.) and 0.22% (vol.). In fortified apple juice the sugar value dropped from the initial 156.54 g.L^{-1} to 147.65 g.L^{-1}, and its alcohol content also reduced from 0.12% (vol.) to 0.09% (vol.). Conversely, for a white grape alcohol drink,

which reached an average of 11.74% (vol.) alcohol content, it contained only 9.37 g.L^{-1} to 10.44 g.L^{-1} of sugars.

Fortified apple juice contained less alcohol from 9.02 – 9.37% (vol.), the sugar content ranged from 25.78 – 22.97 g.L^{-1}. **Pickering et al. (1998)** determined the effect of ethanol concentration (range 0-14% vol.) on perception of the "fullness" of beverages. It has been found that ethanol concentrations were highly correlated with perceived intensity, physical viscosity and density measurements **(Nurgle and Pickering, 2005).**

Volatile and total acids were also determined. Volatile acids were determined in very small amounts in all analyzed samples. Most of them were determined for fortified apple juice with an alcohol of 0.52 – 0.54 g.L^{-1}, on the other hand, the least amount in the same sample without alcohol, and in the range of 0.01 – 0.03 g.L^{-1} during the three month storage. Total acids were at highest as measured for fortified apple juice without alcohol in the range of 10.45 – 10.47 g.L^{-1}. For all other beverages, the total acid value was approximately the same as 9 g.L^{-1}.

Asymilatable nitrogen were considered to be the initiator of fermentation, affecting its kinetics, aromatic content, acetic acid and others. Table 1 – 4 shows the results of determining the amount of assimilable nitrogen in natural beverages. Highest values of assimilated nitrogen were determined for non-alcoholic beverage variants. The highest was determined for a drink from white grapes wine 177.04 mg.L^{-1} and dropped to 134.45 mg.L^{-1}. The fortified apple juice was 156.42 mg.L^{-1} and dropped to 124.37 mg.L^{-1} during 3 month storage. Conversely, for alcoholic beverages, the values were lower. Table 2 shows a decreasing value from 50.15 mg.L^{-1} to 40.18 mg.L^{-1}. Table 4 shows a high drop from 99.45 mg.L^{-1} to 76.34 mg.L^{-1}.

This confirmed **(Steidl, 2002)** that the more ammonium ions are in the environment, the more yeast consume them.

CONCLUSION

It is essential to select and evaluate sources to prepare raw material base for the production of natural beverages without and with alcoholic fermentation using exclusively natural starting values. During production it is necessary to assess natural values and quality of these basic rescources.

The high content of biologically active substances from grape vines and their incorporation into all musts is an integral part of the entire technological, production process and in combination with the corresponding fruit sources it appears to be a positive step towards enriching food with natural additives.

MICROBIOTA OF DIFFERENT WINE GRAPE BERRIES

Miroslava Kačániová, Simona Kunová, Soňa Felsöciová, Eva Ivanišová, Attila Kántor, Jana Žiarovská, Czeslaw Puchalski, Margarita Terentjeva

ABSTRACT

The wine grape berries share a complex microbial ecology including filamentous fungi, yeasts and bacteria. The microbiota reveals different physiological characteristics and depends on the grape ripening stage and the availability of nutrients with different effect on wine production. The microbiota of grape berries (n = 12) was isolated and identified in the present study. The samples were collected in September 2018. Grape berries were obtained from Vrbovo vineyard located in Slovakia. The grape berries investigated belonged to Blue Frankish, Cabernet Sauvignon, Chardonnay, Dornfelder, Feteasca regala, Green Veltliner, Irsai Oliver, Müller Thurgau, Pálava, Pinot Blanc, Rhinriesling and Welschriesling varieties. The microorganisms were cultivated on Malt extract agar (MEA) at 25 °C for five days in aerobically for microscopic filamentous fungi and Tryptone Soya agar (TSA) at 37 °C for 24 – 48 h aerobically for bacteria and yeasts. Total bacterial counts on different wine grape berries ranged from 2.57 ±0.09 in Chardonnay to 4.39 ±0.21 log CFU.g^{-1} in Pálava. Microscopic filamentous fungi count ranged from 1.18 ±0.03 in Blue Frankish to 2.60 ±0.17 log CFU.g^{-1} in Welschriesling. MALDI-TOF MS Biotyper mass spectrometry was used for identification of microorganisms (bacteria and yeasts) and microscopic filamentous fungi with manuals. The most identified microscopic fungal species was *Alternaria* sp., for yeasts *Issatchenkia orientalis* and *Leuconostoc mesenteroides* subsp. *mesenteroides* for bacteria.

Keywords: microbiota; grape berries; identification; MALDI-TOF MS Biotyper

INTRODUCTION

The *V. vinifera* phyllosphere is colonized by bacteria and fungi which modulate health, development and quality of grape and the produced wine characteristics **(Barata, Malfeito-Ferreira andLoureiro, 2012)**. The grape surface inhabiting microorganisms are sensitive to environmental changes during wine fermentation and cannot survive in low pH, ethanolic and anaerobic conditions. At the same their metabolic activity on the grape surface can have consequences for wine quality, e.g. metabolic changes produced by phytopathogenic fungi **(Hong et al., 2011)**.

The grape microbiota more often demonstrates the beneficial effect, and the participation of microbiota in wine fermentations can improve the sensory characteristics of wines **(Ciani et al., 2010)**. Studies of microbiota involved in wine fermentations allowed a discovery of microbial species, which show positive enological properties. The application of those microorganisms with *Saccharomyces* yeasts was commercialized in winemaking **(Ciani et al., 2010)**. With improvement of detection and identification methods in winemaking, a growing number of microorganisms were recognized as active contributors in wine fermentations with significant improvement of sensory qualities of wine **(Ciani et al., 2010)**.

Regional wines characteristics potentially are influenced by microbial biogeography, which is another important factor for winemaking. Traditional winemaking relies mostly on native grape microbiota for fermentations. This practice thought to enhance the regional typicity. The role of microorganisms is well described for grape health, fruit and wine quality **(Barata, Malfeito-Ferreira and Loureiro, 2012)**, but the effect of grape microbiota on regional characteristics of wines is still of limited knowledge. The effect of geographic region, grape variety, and climatic factors influence the bacterial and fungal communities of wine grapes was shown through the growing years **(Bokulich et al., 2014)**. The regional fungal biodiversity of grapes was demonstrated also globally **(Taylor et al., 2014; Gayevskiy and Goddard, 2012; Pinto et al., 2015)**. The local *Saccharomyces cerevisiae* strains, the principal yeast species for wine fermentations purposes, resulting in distinct wine chemical compositions, thus the role of regional microbiota is important for winemaking **(Knight et al., 2015).**

Study of microbiota of grape berries was conducted in Slovakia **(Kačániová et al., 2018).** A total of 33 species of 8 Gram-negative (G$^-$, 20.72%) and 10 Gram-positive (G$^+$, 31.53%) bacteria and 10 yeasts species of 8 genera (47.74%) were identified with MALDI-TOF Mass Spectrometry. These results show that the yeasts were the most common group pf microorganisms isolated from grapes, but the yeasts and bacteria were isolated from each

grape variety. Bacteria counts were higher than yeast. The highest counts of yeast species were identified in Irsai Oliver (10.06%), Pálava, Pinot Blanc and Rheinriesling (9.43%) grape varieties **(Kačániová et al., 2018).**

Scientific hypothesis

Grape berries contain bacteria, yeasts and moulds, which could be identified with MALDI-TOF mass spectrometry. Microbial ecology of grapes could affect the wine grape berries health. Accurate identification of wine grape berries microbiota is essential to understand the grape microbial ecology.

MATERIAL AND METHODOLOGY

Wine grape berry samples

Twelve grape samples from wineyard in Vrbové located in the Small Carpathian wine region were used in this experiment. Ripe grape bunches were collected into sterile polyethylene bags and transported to the laboratory for microbiological analyses. The grape samples of following varieties were investigated: Blue Frankish, Cabernet Sauvignon, Chardonnay, Dornfelder, Feteasca regala, Green Veltliner, Irsai Oliver, Mūller Thurgau, Pálava, Pinot Blanc, Rhinriesling and Welschriesling.

Microbiological analyses of grape berries samples

Five grams of grape berries from each variety were diluted with 45 mL of sterile physiological saline (0.85%). Berries were stirred on a horizontal shaker for 30 min. After that, the dilutions of 10^{-2} and 10^{-3} were prepared for cultivation of sampled with spread plate method. A 0.1 mL of each dilution (10^{-2}, 10^{-3}) was cultivated on Plate count agar (PCA) (Oxoid, UK) and on Malt extract agar base (MEA) (Oxoid, UK) supplemented with bromocresol green (0.020 g.L^{-1}) (Centralchem®, Slovakia). Inoculated PCA agars were cultivated at 37 °C for 24 – 48 h aerobically. Microscopic filamentous fungi were cultivated at 25 °C for five days aerobically. The identification of fungal species was done according to the manuals of **Samson et al. (2002)**, **Samson and Frisvad (2004)**, **Pitt and Hocking (2009)**.

Growing colonies with macroscopic morphological differences were recultivated on TSA (Tryptic Soya agar, Oxoid®) and inoculated plates were cultivated at 30 °C or 25 °C for 24 h for bacteria and yeasts, respectively. After cultivation, the proteins were extraction was done.

Sample preparation and MALDI-TOF MS measurement

One colony of each bacterial and yeast isolate was transferred into an Eppendorf vial and mixed with 300 µL of sterile water. After addition of ethanol (900 µL), the suspension was mixed and centrifuged (13 000 g, 2 min). After removal of supernatant, the pellets were dried at room temperature at least for 5 min. The bacterial and yeast pellets were resuspended in 20 – 50 µl of formic acid (70%) and the same amount of acetonitrile. After centrifugation (2 min at 13 000 g), a 1 µL of supernatant was spotted onto a sample position of a polished steel MALDI target plate and dried at room temperature. A 1 µL of MALDI matrix (solution of α-cyano-4-hydroxycinnamic acid (HCCA) in 50% acetonitrile / 2.5% trifluoro-acetic acid) was added to the spot and dried.

The MALDI target plate was introduced into the MALDI-TOF mass spectrometer for automated measurement and data interpretation. MALDI-TOF profile mass spectra were imported into the MALDI Biotyper 3.0 software and processed automatically after measurement. The logarithm of the score (log[score]) was displayed as the matching result. The MALDI Biotyper output was a log(score) between 0 and 3.0, which was calculated from a comparison of the peak list from an unknown isolate with the reference MSP in the database. A log(score) ≥1.7 indicated identification at the genus level, log(score) ≥2.0 was set as the threshold for a match at the species level. Isolates with ≥2.0 were accepted as a correct identification **(Kačániová et al., 2018)**.

Climatic conditions during the wine grape harvest

Climatic conditions during the harvest were characterized by air temperature (Figure 1), soil temperature (Figure 2), and cumulative rainfall (Figure 3).

Statistic analysis

All experiments were carried out in triplicate and standard deviations for replication were calculated. The experimental data were subjected to analysis of variance (Duncan's test) at a 95% confidence level (software XL STAT, 2019).

RESULTS AND DISCUSSION

In our study, the total bacteria counts isolated from different wine grape berries ranged from 2.57 ±0.09 in Chardonnay to 4.39 ±0.21 log cfu.g^{-1} in Pálava (Table 1). Microscopic filamentous fungi count ranged from 1.18 ±0.03 in Blue Frankish to 2.60 ±0.17 log cfu.g^{-1} in Welschriesling. **Kántor et al. (2015)** found the bacteria counts on Acetobacter agar (AA) from 1.76 to 2.80 log cfu.mL^{-1}. The highest counts of acetic acid bacteria on AA agar was found in grape variety Blaufränkisch (2.80 log cfu.mL^{-1}). Lactic acid bacteria (LAB) counts on MRS agar ranged from 0.48 to 2.06 log cfu.mL^{-1}, but the LAB was not isolated from white grape varieties.

Table 1 Microorganisms counts isolated from wine grape berry varieties in log cfu.g^{-1}.

Grape type	TSA	MEA
Blue Frankish	4.42 ±0.16^{a}	1.18 ±0.03^{c}
Cabernet Savignon	4.42 ±0.09^{a}	2.51 ±0.09^{ab}
Chardonnay	2.57 ±0.09^{d}	2.35 ±0.16^{b}
Dornfelder	3.77 ±0.12^{b}	1.25 ±0.06^{c}
Feteasca regala	3.75 ±0.07^{b}	2.44 ±0.11^{ab}
Green Veltliner	3.43 ±0.20^{c}	2.35 ±0.17^{b}
Irsai Oliver	3.85 ±0.09^{b}	2.37 ±0.14^{ab}
Mūller Thurgau	3.55 ±0.07^{bc}	2.49 ±0.06^{ab}
Pálava	4.39 ±0.21^{a}	1.18 ±0.04^{c}
Pinot Blanc	3.64 ±0.13^{bc}	2.44 ±0.15^{ab}
Rhinriesling	3.78 ±0.19^{b}	2.43 ±0.08^{ab}
Welschriesling	3.41 ±0.16^{c}	2.60 ±0.17^{a}

Note: TSA-Tryptic Soya agar , MEA-Malt extract agar; mean ± standard deviation; different letters in column mean that values were significantly different

Table 2 Microorganisms isolated from different wine grape berries varieties

Grape variety	Isolated microorganisms
Blue Frankish	*Alternaria* sp., *Arthrobacter koreensis, Bacillus cereus, Candida magnoliae, Escherichia coli, Hanseniaspora uvarum, Issatchenkia orientalis, Kazachstania exigua, Kluyveromyces marxianus, Lactobacillus acidophilus, Lactobacillus paracasei, Leuconostoc mesenteroides* susp. *mesenteroides, Pantoea agglomerans, Rhodotorula glutinis, Staphylococcus epidermidis, Stenotrophomonas maltophilia, Yarrowia lipolytica*
Cabernet Savignon	*Alternaria* sp., *Arthrobacter koreensis, Bacillus cereus, Botrytis cinerea*, *Cladosporium* sp., *Enterobacter cloacae, Hanseniaspora uvarum, Ignatzschineria indica, Issatchenkia orientalis, Kazachstania exigua, Lactobacillus acidophilus, Leuconostoc mesenteroides* subsp. *mesenteroides, Metschnikowia pulcherrima, Micrococcus luteus, Staphylococcus epidermidis, Stenotrophomonas maltophilia, Yarrowia lipolytica*
Chardonnay	*Alternaria* sp., *Bacillus endophyticus, Escherichia coli, Hanseniaspora uvarum, Issatchenkia orientalis, Kazachstania exigua, Lactobacillus fermentum, Leuconostoc mesenteroides* subsp. *mesenteroides, Metschnikowia pulcherrima, Pantoea agglomerans, Stenotrophomonas maltophilia, Yarrowia lipolytica*
Dornfelder	*Alternaria* sp., *Arthrobacter koreensis, Bacillus cereus, Hanseniaspora uvarum, Ignatzschineria indica, Issatchenkia orientalis, Lactobacillus fermentum, Lactobacillus paracasei, Leuconostoc mesenteroides* susp. *mesenteroides, Pantoea agglomerans, Rhodotorula glutinis, Yarrowia lipolytica*

Table 2 Microorganisms isolated from different wine grape berries varieties (continue)

Grape variety	Isolated microorganisms
Feteasca regala	*Bacillus endophyticus, Candida magnoliae, Escherichia coli, Hanseniaspora uvarum, Kazachstania exigua, Lactobacillus fermentum, Lactobacillus paracasei, Leuconostoc mesenteroides* subsp. *mesenteroides, Micrococcus luteus, Penicillium expansum, Staphylococcus epidermidis*
Green Veltliner	*Alternaria* sp., *Bacillus cereus, Hanseniaspora uvarum, Issatchenkia orientalis, Lactobacillus fermentum, Lactobacillus paracasei, Leuconostoc mesenteroides* subsp. *mesenteroides, Metschnikowia pulcherrima, Pantoea agglomerans, Stenotrophomonas maltophilia, Yarrowia lipolytica*
Irsai Oliver	*Bacillus endophyticus, Cladosporium* sp., *Hanseniaspora uvarum, Issatchenkia orientalis, Kazachstania exigua, Kluyveromyces marxianus, Lactobacillus fermentum, Lactobacillus paracasei, Leuconostoc mesenteroides* subsp. *mesenteroides, Metschnikowia pulcherrima, Penicillium expansum, Rhodotorula glutinis, Staphylococcus epidermidis*
Mūller Thurgau	*Bacillus cereus, Cladosporium* sp., *Hanseniaspora uvarum, Ignatzschineria indica, Issatchenkia orientalis, Kazachstania exigua, Kluyveromyces marxianus, Lactobacillus paracasei, Leuconostoc mesenteroides* subsp. *mesenteroides, Metschnikowia pulcherrima, Micrococcus luteus, Penicillium expansum, Stenotrophomonas maltophilia*
Pálava	*Aeromonas hydrophila, Alternaria* sp., *Aspergillus niger, Cladosporium* sp., *Hanseniaspora uvarum, Issatchenkia orientalis, Lactobacillus fermentum, Lactobacillus paracasei, Metschnikowia pulcherrima, Pantoea agglomerans, Staphylococcus epidermidis, Stenotrophomonas maltophilia, Yarrowia lipolytica,*
Pinot Blanc	*Bacillus endophyticus, Botrytis cinerea, Cladosporium* sp., *Hanseniaspora uvarum, Ignatzschineria indica, Kazachstania exigua, Kluyveromyces marxianus, Lactobacillus paracasei, Leuconostoc mesenteroides* susp. *mesenteroides, Metschnikowia pulcherrima, Penicillium expansum, Stenotrophomonas maltophilia*
Rhinriesling	*Alternaria* sp., *Bacillus endophyticus, Hanseniaspora uvarum, Issatchenkia orientalis, Lactobacillus fermentum, Lactobacillus paracasei, Metschnikowia pulcherrima, Pantoea agglomerans, Penicillium expansum, Rhodotorula glutinis, Staphylococcus epidermidis, Stenotrophomonas maltophilia*
Welschriesling	*Alternaria* sp., *Bacillus licheniformis, Candida magnoliae, Hanseniaspora uvarum, Issatchenkia orientalis, Kazachstania exigua, Lactobacillus fermentum, Lactobacillus paracasei, Leuconostoc mesenteroides* susp. *mesenteroides, Metschnikowia pulcherrima, Staphylococcus epidermidis, Stenotrophomonas maltophilia*

The highest LAB counts were found in grape variety Cabernet sauvignon of 2.06 log cfu.mL^{-1}, and the highest counts of LAB were detected in Blaufränkisch grape variety. The yeasts count on Sabouraud dextrose agar (SDA) ranged from 2.47 log cfu.mL^{-1} to 2.76 log cfu.mL^{-1}, and the highest counts were on Blaufränkisch grape variety surface. In generally, limited yeast diversity and low bacteria counts (10 – 10^3 CFU.mL^{-1}) were detected on immature grape berries, but the yeasts count increased to 10^4 – 10^6 CFU.mL^{-1} as the grapes were ripe enough to harvest. During ripening, the sugars diffuse from the inner tissues of the grape to the surface, that facilitating yeast

growth. Unripe grapes mostly harbour *Rhodotorula, Cryptococcus* and *Candida* species. These species could be isolated from mature, ripe grapes, however, the apiculate yeasts as *Hanseniaspora* (anamorph *Kloeckera*) and *Metschnikowia*, were mostly distributed. *Hanseniaspora* (*Kloeckera*), *Candida* and *Metschnikowia* species, as well as species of *Saccharomyces* and *Zygosaccharomyces* has increased incidence on the damaged grapes **(Fleet, 2003)**.

In our samples, different bacterial, yeasts and fungal species were found (Table 2). The most abundant microscopic filemanous fungi were: *Alternaria* sp., *Aspergillus niger, Botrytis cnerea, Cladosporium* sp. and *Penicillium expansum*. *Alternaria* sp. was found in 8 (66.7%) wine grape berries samples. Altogether nine yeast species were isolated: *Candida magnoliae, Hanseniospora uvarum, Ignatzschineria indica, Issatchenkia orientalis, Kazachstania exigua, Kluyveromyces marxianus, Metschnikowia pulcherrima, Rhodotorula glutinis* and *Yarrowia lipolityca. Issatchenkia orientalis* was the most abundant yeast, which was found in 10 grapes varieties (83.33%). In total, 14 bacterial species were isolated: *Arthrobacter koreeniss, Bacillus endophyticus, B. cereus, B. licheniformis, Escherichia coli, Enterobacter cloacae, Lactobacillus acidophilus, L. paracasei, L. feremntum, Leuconostoc mesenteroides* subs. *mesenteroides, Micrococcus luteus, Pantotea agglomerans, Staphylococcus epidermidis* and *Stenotrophomonas maltophilia.* The most distributed bacterial species was *Leuconostoc mesenteroides* subs. *mesenteroides*, which was isolated from 10 grape berry varieties (83.33%).

The microorganisms can contaminate from different environmental sources. The origin of microorganisms could be the vineyard, can be residents of the winery flora, or can be transmitted with insects such as fruit flies and, bees **(Fleet et al., 2002)**. Over twenty yeast species have been identified in wines **(Renouf et al., 2007)**. *Hanseniaspora uvarum* (anamorph: *Kloeckera apiculata*), *Metschnikowia pulcherrima* (anamorph: *Candida pulcherrima*), and *Candida stellata* are thought to be the principal yeasts of grapes. In some studies, *Hanseniaspora* was reported to be the dominant species **(Beltran et al., 2002; Combina et al., 2005; Hierro et al., 2006)**, while *Candida* assumed to be widespread as well **(Clemente-Jimenez et al., 2004)**. Majority of *Candida stellata* isolates from wine are actually *Candida zemplinina* **(Csoma and Sipiczki, 2008)**.

Kačániová et al. (2018) isolated from the surface of grape berries different species of microorganisms. The most abundant G^- bacteria were *Stenotrophomonas maltophilia* and *Ignatzschineria indica.* Same results were found in the present study with wine grape berries. Within 22 different species of G^+ bacteria, *Bacillus endophyticus, Paenibacillus glucanolyticus, Paenibacillus lautus* and *Staphylococcus succinus* were the most isolated among bacteria *Rhodotorula mucilaginosa* was the most abundant among yeasts.

Kunová et al. (2018) found fungal counts ranged from 2.85 log cfu.g^{-1} in Cabernet Sauvignon to 4.83 log cfu.g^{-1} in Feteasca regala. After identification of 627 isolates of microscopic fungi, moulds belonged to genera *Alternaria* and *Penicillium* were the most widespread and were isolated from 100% of samples. *Alternaria* sp. was the most abundant fungal species in our study also. The high prevalence of *Aspergillus* (76.92%) and *Cladosporium* (76.92%) was found (Table 2).

Alternaria, Cladosporium and *Penicillium* were the most abundant moulds after identification of 1377 cultures of microscopic fungi isolates **Felsöciová et al. (2017)**. The identified prevalence found was similar to our results (100%). The higher prevalence was detected for *Fusarium* (100%), *Epicoccum*, *Rhizopus* (87.5%), *Botrytis*, *Aspergillus* (75%) and *Mucor* (62.5%). Different fungal genera with higher prevalence in comparison with our study were identified. **Kántor et al. (2017)** found 11 genera of G^- (11%), 11 of G^+ (27%) bacteria and nine genera of yeasts (62%) among 200 isolates of 19 Slovak grape samples. The most frequently isolated G^- bacteria were *Acinetobacter* (22%), *Pseudomonas* (22%) and *Sphingomonas* (13%). The most common genera of G^+ bacteria were *Bacillus* (20%), *Lactobacillus* (19%), *Leuconostoc* and *Staphylococcus* (11%). The most common yeasts genera were *Hanseniaspora* (37%), *Metschnikowia* (31%), and *Rhodotorula* (10%). Our results on diversity of microbial species in grape samples corresponded to **Kántor et al. (2017)** results.

Similar results were described in **Kántor et al. (2016)** study, who studied similar grape wine varieties as sampled in our study. The most dominant species was *Saccharomyces cerevisiae* isolated from all 15 new wine samples, that was a very good wine quality indicator. Altogether, seven different *S. cerevisiae* strains were identified with mass spectrometry, the second most common species was *Kloeckera apiculata (Hanseniaspora uvarum)* found in seven new wine samples. Also, other non – *Saccharomyces* yeasts such as *Metschnikowia pulcherrima*, *Pichia occidentalis* and *Pichia kluyveri* were identified.

CONCLUSION

Natural microflora of grape berries is very diverse. In our study, the bacteria were the most distributed in comparison with other groups of microorganisms. The highest bacterial counts were found in Palava grape variety, followed by Welschriesling. In our study, 5 different yeast, 9 moulds and 14 bacteria species on grape berries were identified.

QUALITATIVE PARAMETERS OF PROTEIN GELS FROM ALBUMEN BASE

Sylvie Ondrušíková, Šárka Nedomová, Alžbeta Jarošová, Vojtěch Kumbár

ABSTRACT
The aim of this research was to monitor strength of egg albumen gels depending on addition additives - salt, sugar, corn syrup, citric acid, citric acid in combination with sugar, whey protein and apple fiber. The egg albumen gel was prepared under two temperature limits at 70 and 90 °C. The highest strengths of egg albumen gel were achieved at 90 °C in the albumen gel with the addition of 1% citric acid and 3.5% sugar with a strength of 7.38 N, with the lowest strength of 1.61 N being achieved with the albumen gel with 0.1% salt. For an egg albumen gel prepared at 70 °C, the strength ranged from 1.34 N (0.1% salt) to 6.63 N (1% citric acid + 3.5% sugar). On average, the pH of egg albumen gels ranged from 4.67 (1% citric acid + 3.5% sugar) to 9.05 (0.1% salt). For the strength of egg albumen gel and pH with additives of various additives at a given concentration, a statistically significant difference was found.

Keywords: hen eggs; albumen gel; strength; additives; texture analysis; temperature; pH

INTRODUCTION
Egg albumen is one of the most important sources of animal proteins that make up the main component of dry matter, and their content ranges from 10 to 12% in native protein. Egg albumen is rich in ovalbumin (about 54%), ovotransferrin (about 12%), ovomucoid (about 11%), and lysozyme (about 3.4%) **(Mine, 2002)**. It is gelation is a complex process involving protein denaturation, aggregation and formation of gel network **(Mine, 1995)**. Egg proteins are especially valuable for the high content of essential amino acids that are essential for humans because they cannot synthesize themselves in the body. The digestibility of egg proteins is in the range of 98 – 100%.

Eggs, especially egg albumen, have several functional properties that are used in the food industry. These properties include mainly gel forming ability, foaming capability and emulsifying properties. Changes in egg albumen during egg storage affect its functional properties **(Mine and Yang, 2010; Wang et al., 2010)**. Most functional properties of egg white depend on exposure of hydrophobic groups, molecular surface and interactions of these groups **(Li-Chan, Powrie and Nakai, 1995)**. Proteins produce gels by polymerization in a number of molecules, providing a three-dimensional network, and this process takes place by transforming a viscous liquid into a viscous elastic matrix **(Hermansson, 1979)**. The formation of the gel structure takes place in two phases where the first phase involves changes in conformation (mostly induced by heat) or partial denaturation of protein molecules. In the protein dispersion thus formed, the first features of the elastic solid appeared. In the second stage, aggregation of denatured proteins results in increased viscosity and formation of a fixed network. The second phase should be slower to make a gradual build-up of the organized grid network, because if accelerated at this stage, a non-organized structure would form, a coagulum that would not be able to retain water, which would lead to syneresis. The nature and properties of egg whites may be affected by several factors, predominantly protein concentration and pH values of the solution. Egg albumen gel formation can be conditioned by the use of both heating and cooling, depending on the nature of the protein and the process itself **(Alleoni, 2006)**.

The ability to coagulate egg albumen is used in many food products – such as surimi, baker's products, desserts, meat products and currently in very popular foods called "superfoods" with a high protein content, which important especially for athletes or people with alternative diets. Commercially available egg albumen products have a wide range of uses and are produced in various shapes (dice, burgers, rollers). These products can be enriched with other nutritionally valuable substances, such as fiber **(Zayas, 1997)**.

Egg albumen coagulates at pH 7 from 65.0 °C and at pH 9 to 69.5 °C. The ability of egg albumen coagulation is utilized in many food products **(Croguennec, Nau and Brulé, 2002)**. The albumen is brought to a solid state at a temperature of 61 – 70 °C. At 70 – 74 °C, the gel increases elasticity and stabilizes the gel at 89 °C. The strongest albumen gels are in the temperature range of 71 – 83 °C **(Simeonovová et al., 2013)**. Factors influencing gel formation are temperature, warm-up time, pH value and ionic strength. Egg protein properties change due to chemical changes in glycoprotein and ovomucin **(Kirunda and McKee, 2007)**. These changes lead to

a decrease in the height of the solid egg by lowering its viscosity and losing its gel-like structure **(Hammershøj and Quist, 2001; Lomakina and Míková, 2006)**. The egg albumen gels are produced without flavour and with flavours in a salty and sweet form. They can be used in cold kitchens (e.g. grated, salad cuts) or in hot kitchens (they can be baked, choked, cooked). The addition carbohydrates and/or salt in products are common in the food industry and therefore it is important to consider their effect with respect to protein gel formation **(Raikos, Campbell and Euston, 2007)**.

Gelling traditionally requires warming, but can also be caused by high pressure, acidification, enzymatic amplification, salt or urea use. The characteristics of each gel are different and depend on the degree of degradation and protein concentration **(Kaewmanee, 2010)**.

Texture is one of the major quality factors in foods in addition to appearance, flavour and nutrition. In many cases, sensory texture is correlated with rheological properties measured by instruments **(Pollak and Peleg, 1982)**. The quality of the resulting egg albumen gel is evaluated mainly by its strength.

Scientific hypothesis

The main hypothesis of this work is detection of dependence of egg albumen gel strength, pH and height on species and amount of addition.

MATERIAL AND METHODOLOGY

For the determination of the strength of the egg albumen gel were use hen eggs, hybrid Hisex Brown from a commercial breeding from South Moravia, Czech Republic. The hens were fed a complete feed mixture. Hen eggs were imported on a laying day and stored at 4 °C and 75% relative humidity. For fortification was used different salt additions (0.1 and 0.4%), sugar (10%), corn syrup (10%), citric acid (1%), citric acid in combination with sugar (1 + 3.5%), whey protein (1 and 3%), apple fiber (1 and 3%), where the strength of the egg gel was determined.

The egg albumen gel was made from the fresh eggs, where the egg was manually crushed, and the individual egg components were separated. The egg albumen was thoroughly homogenized, and the additive was added thereto at a certainly concentration. The albumen protein preparation thus prepared was poured into the sampler and placed in a water bath at 90 °C for 30 min and for comparison at 70 °C for 30 min. For measuring the strength of the gel, a universal instrument for measuring physical characteristics – TIRAtest (type 27025, TIRA, Germany) was used. A flat-plate pressure test with a crossbar speed of 100 mm.min^{-1} was performed using this instrument. From each gel was cut 8 cylinders with a height and a diameter of 1 cm.

The concentration of hydrogen ions is expressed by the hydrogen exponent (pH), which is negative logarithm of hydrogen ion concentration. Digital pH was used for determination PORTAMESS 911 pH KNICK with injection electrodes and the height of the egg albumen gels was measured with a sliding gauge.

Statistic analysis

Statistical analysis of the differences was based on Statistica12 (StatSoft, Czech Republic), namely single-factor ANOVA – Duncan's test. Microsoft Excel version 2010 (Microsoft, USA) was used to evaluate the results. The statistically inconclusive difference was considered to be a result whose probability value reached $p > 0.05$.

RESULTS AND DISCUSSION

In this study, we focused on proteins precisely albumen gels on egg albumen base. Additives were added to the homogeneity of the egg albumen mixture at a given concentration. As standard in this case, the egg albumen was used without any addition. The strengths of the egg albumen gel at a preparation temperature of 90 °C are shown in Table 1. Strengths was observed in the specimens thus prepared, when the result showed that the highest value was achieved by the gels with the addition of 1% citric acid + 3.5% sugar (7.38 N) and the lowest values were achieved in egg albumen gels with the addition of 0.1% salt (1.61 N).

Compared to the standard pure egg albumen gel, the highest value increased by 4.71 N and the lowest value dropped by 1.05 N. When using a lower sample temperature (70 °C), there were very similar results when the highest strength of the egg albumen gel was achieved in the sample with 1% citric acid + 3.5% sugar and the lowest value in the sample with 0.1% salt. **Raikos, Campbell and Euston (2007)** says that the highest achieved strength of the egg albumen gel with the addition of 3% sugar + 3% salt when the value is 14.21 N, which is higher than our results by 48%. Adding 1% apple fiber to albumen gel strength increased by 1.56 N over egg albumen gel without addition at 90 °C. Higher amounts of fiber resulted in a decrease in the strength of the protein by 0.61 N. Similarly, an albumen gel prepared at 70 °C was obtained when the addition of 1% of apple fiber increased the egg albumen gel strength by 2.03 N against the gel without addition.

When comparing the results of the egg albumen gel strength at 90 and 70 °C, it can be seen that the lower strength of the resulting albumen gel occurred at a lower sample preparation temperature. On the other hand, the lowest value was achieved by in its results in the sample with the addition of 6% salt, where the value was 4.66 N **(Raikos, Campbell and Euston, 2007)**. This value approximated our results for egg albumen gels with the addition of 1% whey protein (4.60 N) at 90 °C and at 70 °C for samples with 1% citric acid (4.86 N) added.

Holt et al. (1984) showed egg albumen gel strength were highest in gels with a treatment combination of 85.2 °C, pH 9.0, and 0.08 M NaCl. Temperature had the greatest effect on all three rheological parameters. Gels heated above 80 °C were of unusual character, exhibiting syneresis and shrinkage. The average pH values of egg albumen gel with additive additions in a given concentration are shown in Table 2. **Croguennec, Nau and Brulé (2002)** states that the highest strength of the egg albumen gel occurs at pH 5, resulting in gross aggregation, and the resulting coagulate has a low viscoelastic property whereas egg albumen gels at pH 7 and 9 are more viscoelastic. The highest strength values for egg albumen gel were obtained at pH 9.05 (0.1% salt) and the lowest ones at pH 4.67 (1% citric acid + 3.5% sugar).

Handa et al. (1998) showed that at pH 7 and 9 had egg albumen gels a fine and uniform network structure that may have contributed to the excellent gel properties. It is clear from our results that the additive additives we have chosen, have a significant effect on the measured pH values, when compared to the standard which was 9.04 for the egg albumen gel without addition, the average pH values ranged from 9.05 to 4.67. **Li et al. (2018)** states that pH values also had affect eggs' other functional properties as a foam and foam stability.

Egg albumen gel height values (Table 3) were also observed, with the highest value achieved by the albumen gel with the addition of 1% citric acid + 3.5% sugar (4.23 cm) and the lowest value of 1.98 cm protein albumen gel with the addition of 10% corn syrup.

Between individual samples a statistically significant difference was observed due to different pH values. Adding 1% whey protein reduced the egg albumen gel height by 0.8 cm. However, after the addition of 3% whey protein, the height increased by 0.31 cm in the sample at 90 °C. Egg albumen gel height results correspond to pH values, where it can generally be said that lower height albumen gel has been reached in the alkaline environment than in the acidic environment.

Table 1 Effect of type and amount of addition additives on egg albumen gel strength at 90 and 70 °C.

Quantity and type of addition	Strength [N] 90 °C	Strength [N] 70 °C
Without addition	$2.66^{b,c}$	1.98^{b}
0.1% salt	1.61^{e}	1.34^{c}
0.4% salt	2.55^{b}	1.76^{a}
10% sugar	$3.13^{a,c}$	$2.56^{a,b}$
1% apple fiber	4.22^{d}	4.01^{d}
3% apple fiber	3.61^{a}	3.15^{c}
1% citric acid	5.56^{f}	4.86^{e}
1% citric acid + 3.5% sugar	7.38^{g}	$6.63^{c,e}$
1% whey protein	4.60^{d}	4.11^{d}
3% whey protein	$3.35^{a,d}$	$2.57^{a,c}$
10% corn syrup	3.38^{a}	3.08^{a}

Note: a, b, c, d, e, f, g – different superscripts in a line indicate a statistically significant difference at $p < 0.05$.

Table 2 Effect of type and amount of addition additives on pH value egg albumen gel.

Quantity and type of addition	pH [-]
Without addition	9.04^{a}
0.1% salt	9.05^{a}
0.4% salt	9.04^{a}
10% sugar	8.94^{a}
1% apple fiber	8.77^{c}
3% apple fiber	8.23^{b}
1% citric acid	5.08^{d}
1% citric acid + 3.5% sugar	4.67^{a}
1% whey protein	6.75^{c}
3% whey protein	7.23^{b}
10% corn syrup	6.79^{b}

Note: a, b, c, d – different superscripts in a line indicate a statistically significant difference at $p < 0.05$.

Table 3 Effect of type and amount of addition additives on height of the egg albumen gel.

Quantity and type of addition	Height of the egg albumen gels 90 °C [cm]	Height of the egg albumen gels 70 °C [cm]
Without addition	2.45a,b	2.38a,b
0.1% salt	2.43a,b	2.42a,b
0.4% salt	2.51a,b	2.48a,b
10% sugar	2.49a,b	2.47a,b
1% apple fiber	2.52a,b	2.50a,b
3% apple fiber	2.75a	2.73a
1% citric acid	3.78c	3.78c
1% citric acid + 3.5% sugar	4.23d	4.22d
1% whey protein	2.37a,b	2.33a,b
3% whey protein	2.68a	2.66a
10% corn syrup	1.98b	2.00b

Note: a, b, c, d – different superscripts in a line indicate a statistically significant difference at $p < 0.05$.

CONCLUSION

There was monitored the effect of influence of the type and amount of additive additions on the rheological properties especially strength, height and pH of the egg albumen protein gels using two temperature stages of sample preparation.

Average egg albumen gel strength values ranged from 1.61 N (0.1% salt) to 7.38 N (1% citric acid + 3.5% sugar) for samples prepared at 90 °C. A native egg albumen gel sample was considered as standard without an additive addition having an average strength of 2.66 N. The closest to this strength was a sample of the albumen gel with the addition of 0.4% salt with an average value of 2.55 N.

For egg albumen gels prepared at 70 °C, average gel strengths were in the range of 1.34 N (0.4% salt) to 6.63 N (1% citric acid + 3.5% sugar). As a standard, native albumen gel was using again without addition of additives with an average value of 1.98 N, which was again most closely approximated by egg albumen gel with the addition of 0.4% salt (1.76 N).

Changes in pH values were also observed for samples after the addition of selected additives, with an average value of 9.04 in the non-admixture of the albumen gel sample. The same values were obtained with a sample of 0.4% by the addition of salt. The highest average pH was achieved by the sample with 0.1% salt addition and the lowest pH sample with 1% citric acid + 3.5% sugar (4.67).

It can be stated that the various additive additives significantly affect the functional properties of hen egg masses and the egg albumen gel, which can be used in innovations and the creation of new recipes for the food industry.

GLUTEN-FREE RICE MUFFINS ENRICHED WITH TEFF FLOUR

Lucia Minarovičová, Michaela Lauková, Jolana Karovičová, Zlatica Kohajdová, Veronika Kepičová

ABSTRACT

In recent years, demand for gluten-free products has grown. More and more people suffer from allergies, so the market should expand to products for this group of people. It is also important to improve the gluten-free nutritional content diets by incorporating alternative gluten free grains that are naturally rich in nutrients. Teff is a valuable ingredient of gluten-free products because it increases their nutritional quality. Teff is rich in fibre, carbohydrates and has a complete set of essential amino acids, is also high in iron and has more copper, zinc and calcium than other cereal grains. The effect of teff flour addition (25, 50 and 75%) to rice muffins on qualitative and sensory parameters was evaluated. The antioxidant activity of raw materials and products was also determined. Utilization of teff flour up to 50% provided satisfactory results. Incorporation of higher addition levels of teff flour (75%) negatively affected qualitative and textural properties of muffins; the muffins were harder, crumbly and less springy. High antioxidant potential of teff was reflected in increasing antioxidant activity of baked products. Muffins enriched with teff flour had pleasant flavor, sweet and nutty taste. Sensory evaluation revealed that rice muffins incorporated with teff flour at level 25% were the most acceptable for assessors.

Keywords: muffin; gluten-free; teff flour; rice flour, sensory

INTRODUCTION

In recent decades, gluten has attracted great attention due to the increasing number of diagnosed patients with intolerance to this protein fraction, relating to the improved sensitivity of the detection methods and the increasing awareness of the existence of the disease. Three pathologies are associated with gluten intake, which appear to be increasing in importance: i) food allergy, ii) coeliac disease, which is an autoimmune disorder caused by the ingestion of gluten not only from wheat, but also rye, barley and some varieties of oats and iii) gluten sensitivity, a pathology of intolerance to gluten **(Rosell et al., 2014)**.

Celiac disease is a cell-mediated autoimmune disease whereas wheat allergy is an immunoglobulin E (IgE) – mediated reaction. The symptoms of these disorders may vary, depending on individual sensitivity and disease severity. Celiac disease causes villous atrophy of the small intestine, resulting in various gastrointestinal and extraintestinal/systemic complications. Like other food allergies, depending on the severity, the symptoms of wheat allergy may range from mild itching to life-threatening anaphylaxis. Since there is no cure available, avoidance of gluten/wheat in the diet is the best option for patients **(Sharma, Pereira and Williams, 2015)**. The production of high-quality leavened baked goods made from ingredients other than wheat flour represents a major technological challenge, due to the absence of the visco-elastic gluten compound **(Hager and Arendt, 2013)**.

Teff is a cereal native to Ethiopia and Eritrea. It has an excellent adaptability to harsh environmental conditions and plays an important role in food security. In recent years, teff is becoming globally popular due to the attractive nutritional profile such as gluten free and high dietary fiber content **(Zhu, 2018)**.

Teff (*Eragrostis tef*) is a tropical cereal that belongs to the family of *Poaceae*, subfamily *Eragrostoidae*, tribe *Eragrosteae* and genus *Eragrostis*. About 350 species are known in the genus *Eragrostis*, of which teff is the only cultivated species **(Gebremariam, Zarnkow and Becker, 2014)**. There are about 33 improved tef varieties and hundreds of farmers' local varieties in Ethiopia, differing in seed size and color from milky-white to almost dark-brown **(Shumoy and Raes, 2017)**. For marketing purposes, teff is classified on the basis of seed color: netch (white), qey (red/brown) and sergegna (mixed) **(Gebremariam, Zarnkow and Becker, 2014)**.

Teff is the smallest grain in the world, taking 150 grains to weigh as much as one grain of wheat. The extremely small grains are 1 – 1.5 mm long and there are 2500 – 3000 seeds to the gram. Because of its small size, teff is made into whole-grain flour (bran and germ included), resulting in a very high fiber content and high nutrient content in general **(Mohammed, Mustafa and**

Osman, 2009; Gebremariam, Zarnkow and Becker, 2014).

Teff grain is gluten free and has great potential to be formulated into a range of food/beverage products to aid people with celiac disease. As a result of the unique chemical composition and the whole grain form, a range of health benefits have been associated with teff. For example, teff showed in vitro anti-oxidative activities, and can improve the haemoglobin level in human body and help to prevent malaria, and incidence of anaemia and diabetes **(Zhu, 2018)**.

Scientific hypothesis

The purpose of this study was to prepare gluten-free muffins with known additions of teff flour, determine the physical and textural properties of muffins, the antioxidant activity and the color of individual raw materials and products. It was also important to perform a sensory analysis of finished products.

MATERIAL AND METHODOLOGY

Fine rice flour (moisture 8.17%), whole grain teff flour (moisture 9.56%) and other ingredients (vegetable oil, salt, sugar, milk, eggs and baking-powder) were purchased in local market.

Muffins were prepared according to **Tess et al. (2015)**. Rice flour was replaced with 0%, 25%, 50% and 75% teff flour. Milk (174.2 g), oil (53.4 g) and egg (76 g) were mixed together with an electric hand mixer. Flour (200 g), sugar (51 g), baking powder (5.6 g) and salt (4 g) were mixed together in a separate bowl, and then were mixed into with the wet ingredients. Muffin pans were filled with the butter and were baked for 21 minutes at 190°C in a preheated oven (Mora MB05103GX, Czech Republic). Then were muffins removed from the pans and allowed to cool on wire racks for one hour after which analyses were performed. Baked muffins are presented in Figure 1.

Qualitative parameters of muffins

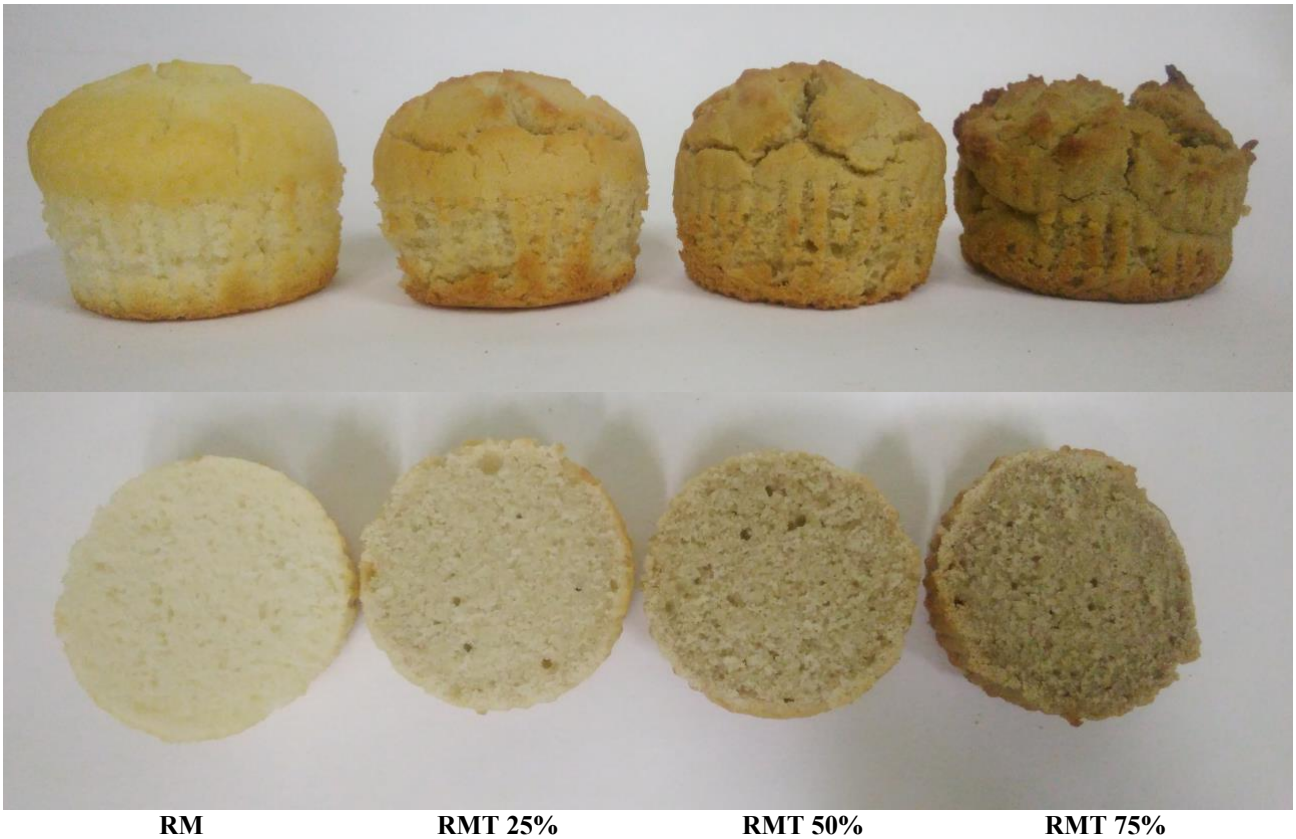
Qualitative parameters of muffins were evaluated 2 h after baking.

The muffin height and width was measured from the highest part of the muffin to the bottom part and at the widest point using a calliper **(Martínez-Cervera, Salvador and Sanz, 2015)**.

Cambering of muffins was calculated as a ratio of muffin height and width **(Lauková, Kohajdová and Karovičová, 2016)**.

Moisture of muffins was determined according to method AACC 44-19.01 **(AACC, 2000)**.

Baking loss (%) is characterized as the muffin weigh reduction after baking. The muffins were weighed before (W3) and after baking and 2 h cooling (W4). The weighting mean mass loss during baking was calculated as follows: weight loss = (W3-W4)*100/W3 **(Martínez-Cervera, Salvador and Sanz, 2015)**.



RM **RMT 25%** **RMT 50%** **RMT 75%**

Figure 1 Photo of muffins.
Note: RM – rice muffins without teff flour. RMT – rice muffins with teff flour (25, 50 and 75%)

Textural analysis

Muffin firmness was determined according to modified method described by **Acosta, Cavender and Kerr (2011)** using a texture analyzer (TA-XT Plus, Stable Micro Systems, Godalming, Surrey UK). Firmness and springiness were measured using Method MUF1/P36R. Firmness was defined as the force (in grams) required compressing the product by a pre set distance. A simple way of looking at the springiness property is to record the force after 30 seconds and divide this by the maximum force and then multiply by 100%. The closer the resulting value is to 100% the more like a „spring" the product is. Cross sections of 2.5 cm thickness were cut from the center of each muffin and subjected to a modified compression test fitted with a 36 mm diameter cylindrical probe. Each sample was compressed to 40% of the sample's initial height at a probe speed of 1.0 $mm.s^{-1}$.

The textural profile analysis (TPA) was conducted on the muffins using a texture analyzer. The quality attributes measured were hardness, springiness, cohesiveness and chewiness **(Gupta, Sharma and Sharma, 2007)**. Hardness is defined as the maximum peak force during the first compression cycle (first bite). Springiness is related to the height that the food recovers during the time that elapses between the end of the first bite and the start of the second bite. Cohesiveness is defined as the ratio of the positive force during the second compression to that during the first compression **(Tess et al., 2015)**. Chewiness is obtained by multiplying harness, cohesiveness and springiness **(Cornejo and Rosell, 2015)**. Gumminess is defined as a product of hardness x cohesiveness **(Bourne, 2002)**. The test was performed on cubes (2.5 cm side) taken from the center of the muffin. The test speed was 1.7 $mm.s^{-1}$; the post test speed was 10 $mm.s^{-1}$ and there was a 5 s interval between the two compression cycles. A trigger force of 5 g was selected. The compression of 40% was performed with a 36 mm cylindrical probe, and the cubes were compressed twice **(Tess et al., 2015)**.

Color measurement

The color was determined using a Cary 300 Spectrophotometer (Agilent Technologies, USA). The color of the rice flour, teff flour and muffins from these flours was measured. A crumb of muffins was dried and grinded with a kitchen robot (Eta 0010, Czech Republic) before measuring. The individual color values were expressed using CIELab* and Metric L*Ch*. The color parameters were L* (L* = 0, black and L* = 100, white), a* (-a* = greenness and +a* = redness), b* (-b* = blueness and +b* = yellowness), C – Chroma and h* – hue angle. The spectrophotometer was calibrated with a white calibration tile **(Kraithong, Lee and Rawdkuen, 2018)**. The total color difference (ΔE) was determined using the equation according to **Ghanem et al. (2012)**.

Determination of antioxidant activity

Antioxidant activity was evaluated by measuring free radical 2,2-diphenyl-1-picrylhydrazyl (DPPH) scavenging capacity according to **Cai et al. (2014)**. Sample (0.1 g) was extracted with 1 mL of pure methanol at 25 °C for 2 h with continuous shaking under a dark environment and centrifuged at 1,200 × g for 10 min. The extract (0.05 mL) was reacted with 1 mL of 0.1 mM DPPH solution at 25 °C for 30 min, and absorbance was measured at 517 nm. Antioxidant activity was calculated as percent discoloration of DPPH = $[1 – (A1/A0)] \times 100$, where $A1$ is the absorbance of sample extract at the end of the reaction (t = 30 min) and $A0$ is the absorbance of the pure methanol control at the beginning of the reaction (t = 0). Measurements were conducted in duplicate, and the data were reported as percentage of discoloration.

Sensory evaluation of muffins

The sensory evaluation of muffins was made by five point hedonic scale which ranged from 5 = most liked to 1 = most disliked. The panel was made up of staff and students of the Faculty of Chemical and Food Technology, Slovak University of Technology, Bratislava, Slovakia. The overall acceptability of muffins was determined using 100 mm graphical non-structured abscissas with the description of extreme points (minimal or maximal intensity, from 0 to 100%) according to **Lauková, Kohajdová and Karovičová (2016)**.

Statistic analysis

All measurements were carried out in triplicate and the average values were calculated. The results were expressed as mean value ± standard deviation. Significant differences between mean values at significance level $p < 0.05$ were compared using Student`s test. Microsoft Excel version 2010 was used as the statistical analysis software.

RESULTS AND DISCUSSION

The qualitative (cambering, moisture and baking loss) and textural (firmness and springiness) parameters of muffins are shown in Table 1.

The cambering value of control sample (RM) was 0.79. From the results concluded that addition of teff flour increased the cambering of muffins up to 0.88 (RMT 75%).

Moisture content of muffins showed no significant differences after addition 25 – 50% of teff flour. Addition of 75% of teff flour increased muffins moisture to 41.20%. A high level of moisture content may be indicating short self life of composite muffins as they encourage microbial growth leads to spoilage **(Man et al., 2014)**.

Determining the actual baking losses is very important as the finished product after baking must have a defined weight. The loss by baking is influenced mainly by the weight of the product; by shape and moisture content **(Minarovičová et al., 2018)**. Increasing level of teff flour caused decreasing of baking loss values.

In baking industry, the products having a specific shape and definite texture determine the acceptance or rejection of the product by the consumers. Texture of product shows its quality **(Younas et al., 2015)**. Texture evaluation demonstrated that muffins including 25 and 50% of teff flour had similar firmness compared to control sample (RM). However, the 75% replacement of rice flour resulting in 39.15% increase of muffin firmness. Similar trend was observed when the hardness was measured using TPA (Table 2). Comparable results were also described by

Table 1 Qualitative and textural parameters of muffins.

	Cambering	Baking loss (%)	Moisture of crumb (%)	Firmness (g)	Springiness (%)	Overall acceptance (%)

the authors **Tess et al. (2015)** in muffin enriched with teff flour.

Springiness is associated with freshness in a product with a high quality muffin having higher springiness values **(Tess et al., 2015)**. The increase in the muffin firmness is related to the decrease in muffin springiness. With higher addition levels of teff flour the muffins were less springy.

TPA parameters of muffins are summarized in Table 2. Gumminess is defined as the energy required to disintegrate a semisolid food to a state of readiness for swallowing **(Bourne, 2002)**. In this study was observed that addition of teff flour at higher levels (50 and 75%) caused significantly lower gumminess of muffins.

Springiness is a measurement of how much the crumb springs back after being compressed once and it can be defined as the elasticity of the crumb, it is also an important parameter to determine the staling degree of product **(Lauková et al., 2017)**. Substituting of rice flour in muffins with teff flour resulted in lower springiness, similarly to the protocol MUF1/P36R which was used in textural analysis.

Cohesiveness is defined as how well the product withstands a second deformation relative to how it behaved under the first deformation **(Boz and Karaoğlu, 2013)**. It was noticed that muffins with 25% of teff flour had comparable cohesiveness with control sample (RM). Higher substitution levels caused lower cohesiveness. These results are in agreement with study of **Tess et al. (2015)**.

Chewiness is related to the work needed to chew a solid sample to a steady state of swallowing **(Boz and Karaoğlu, 2013)**. Results in Table 2 also showed that increasing level of teff flour led to significantly lower chewiness of muffins.

The color of bakery products is affected by ingredients, process, and ingredient process interactions, such as Maillard or caramelization reactions **(Kırbaş, Kumcuoglu and Tavman, 2019)**. Color also depends on the concentration of a certain ingredients **(Bhadury, 2013)**. Rice flour is white in color and teff flour can range in color from ivory to light brown. This fact was confirmed with result presented in the Table 3. The highest lightness (L*) was observed in rice muffins (RM). Significant decrease of this parameter was detected in samples containing 50 and 75% of teff flour, which is the consequence of darker color of initial teff material. Incorporation of teff flour caused in higher a* and b* color parameters. Chroma (C*), considered the quantitative attribute of colorfulness, is used to determine the degree of difference of a hue in comparison to a grey color with the same lightness. The higher the C* value, the higher is the color intensity of samples perceived by humans **(Granato and Masson, 2010)**. Higher color intensity (C*) of muffins was related to high C* value identified in teff flour. These findings are reflected in color differences (ΔE), which had increasing trend up to 90.42 (RMT 75%).

The antioxidant activity (percentage of discoloration) was measured in raw material and also in baked products

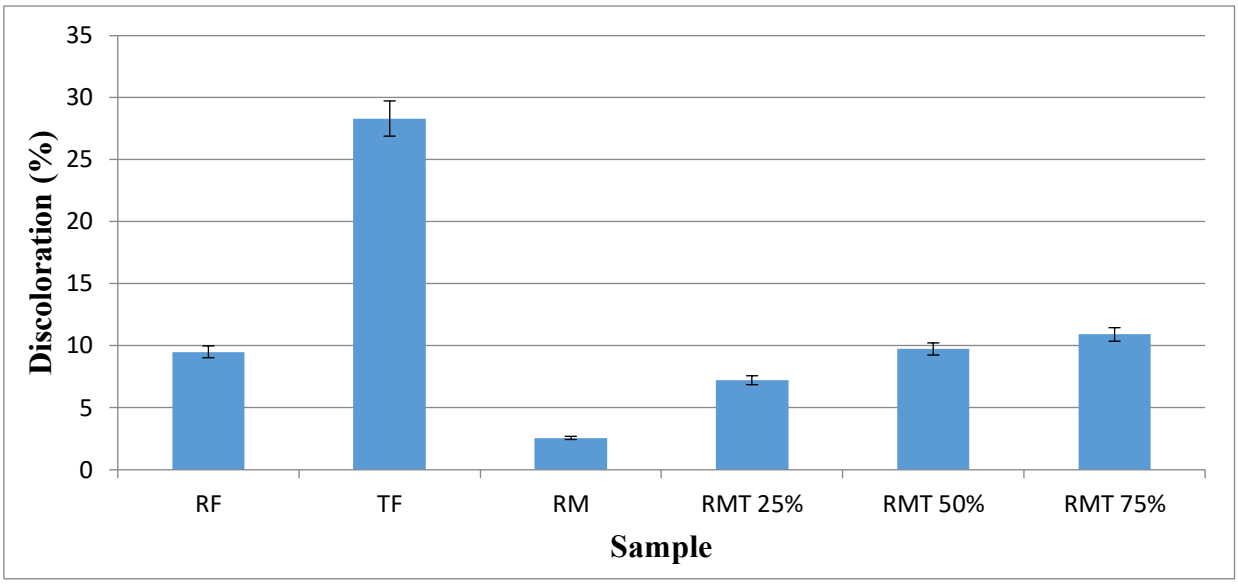

Figure 2 Antioxidant activity of raw materials and muffins.
Note: RF – rice flour, TF – teff flour, RM – rice muffins without teff flour, RMT – rice muffins with teff flour (25, 50 and 75%).

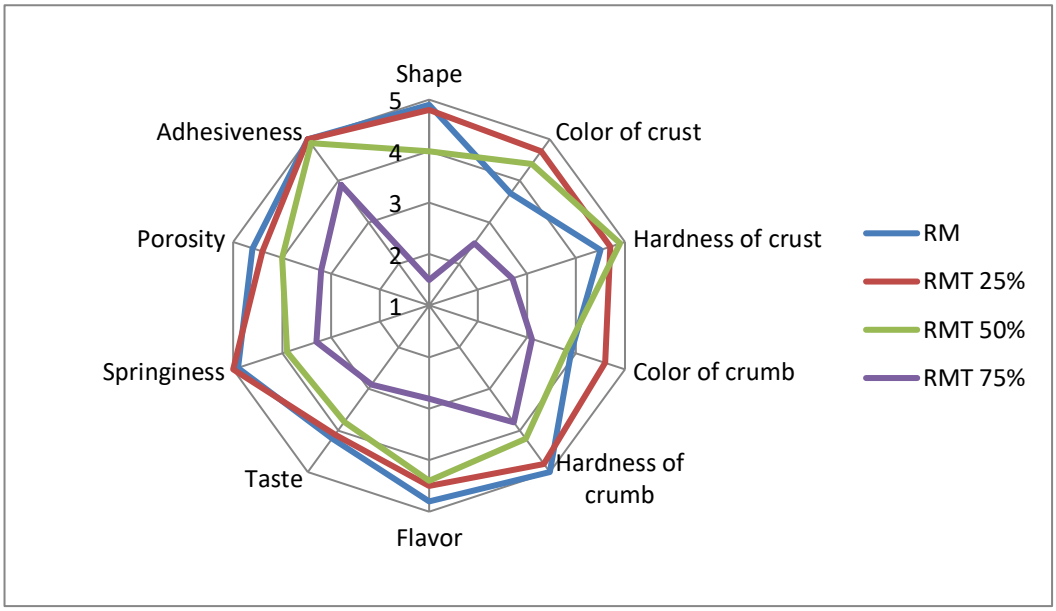

Figure 3 Sensory evaluation of muffins.
Note: RM – rice muffins without teff flour. RMT – rice muffins with teff flour (25, 50 and 75%)

(Figure 2). As can be seen from the results, teff flour had about 3-times higher antioxidant activity (28.32%) than rice flour (9.51%). Thereupon the teff enriched muffins also had higher antioxidant activity (7.22 – 10.91%). The effects of teff flour on sensory parameters of muffins are presented in Figure 3. Generally, teff supplementation of rice flour resulted in decreasing of shape score of muffins. The highest addition level of teff led to cracked and less compact shape of muffins. Color is an important attribute of the baked food products because it affects to the consumer's perception to the acceptability of the product **(Bhadury, 2013)**. The results showed that color of enriched muffins, both for crust and crumb, was more acceptable for assessors up to addition level 50% than control sample (RM). The score for flavor of muffins was not significantly affected by teff addition, except for sample including 75% of teff. The muffins enriched with 25 and 50% of teff flour had similar sensory score of taste with control sample (RM). Moreover, the assessors describe the pleasant sweet and nutty taste of teff incorporated muffins. The assessors also described that muffins contained high levels of teff were harder and less springy compared to control sample (RM). Results also showed that incorporation of teff at higher levels caused that muffins had less porosity.

The overall acceptance results of muffins are summarized in Table 1. It was concluded that the most acceptable enriched muffins (91.10%) were prepared with 25% of teff flour, which was comparable with overall acceptability of control sample RM (91.73%), while higher supplementation level caused the lower acceptance of muffins. Similar decreasing trend was described by **Tess et al. (2015)** for rice muffin enriched with teff flour.

CONCLUSION

In this study it was noticed that lower addition of teff flour in the muffins had similar quality parameters like control rice muffins. Moreover, enriched muffins had better color, flavor and taste. In general, it was concluded that muffins with acceptable qualitative and sensory parameters can be prepared by addition of teff flour at level 25 and 50%.

MYCOTOXIN-PRODUCING *PENICILLIUM* SPP. AND OTHER FUNGI ISOLATED FROM GRAPES FOR WINE PRODUCTION IN SMALL CARPATHIANS WINE REGION

Soňa Felšöciová, Miroslava Kačániová

ABSTRACT
The diversity of mycobiota associated with grapevine in Vrbove, Slovakia at the harvest time in 2018 was evaluated. Fourteen samples of grapes were analyzed by plating methods and by plating methods with surface disinfection. The identification of fungi was performed using the morphological and microscopical characteristics. From the 1001 strains detected and identified from exogenous mycobiota, the most frequent genera were *Alternaria, Rhizopus* and *Sordaria*. Their relative density was low, except *Alternaria*. The most frequently encountered moulds and with the highest relative density from endogenous mycobiota were *Alternaria, Cladosporium* and *Penicillium*. Most of all genera had relative density less than 1%. *Penicillium* contributed small proportion in both sources. *Penicillium citrinum* was the most dominant species in exogenous and endogenous mycobiota. *Penicillium expansum* and *P. glabrum* were recorded in exogenous source and *P. hordei, P. chrysogenum* and *P. griseofulvum* in endogenous. Potentially toxigenic *Penicillium* species were tested for their toxigenic ability by thin layer chromatography method. Out of 15 tested isolates representing five potentially toxigenic species 11 produced at least one mycotoxin. Positive toxinogenity was detected in all tested strains of *Penicillim citrinum* (9/9).

Keywords: grapes; *Penicillium*; microfungi; mycotoxins; TLC

INTRODUCTION
Fresh grapes are prone to fungal contamination in the fields, during harvesting, transporting, marketing and during storage under domestic conditions. If the spoiling fungi are toxigenic or pathogenic, they could pose a health risk for the consumer. Grape fruit contain high levels of sugars and other nutrients, and they possess and ideal water activity for microbial growth, their low pH makes them particularly susceptible to fungal spoilage **(Tournas and Katsoudas, 2005)**.

The most frequent filamentous fungi found in grapes were species of *Cladosporium, Penicillium, Botrytis, Alternaria* and *Aspergillus* **(Serra et al., 2005; Fredj et al., 2007)**. The grape mycrobiota may change in response to various factors such as: the climate, grape variety and geographical region **(Raspor et al., 2006)**.

Penicillium species are one of the most common fungi occurring in a diverse range of habitats, from soil to vegetation, air, indoor environments and various food products **(Visagie et al., 2014)**. Species of *Penicillium* are economically, ecologically and medically important microorganisms playing vital roles in natural ecosystems, agriculture and biotechnology **(Visagie, 2008)**. Many species of the *Penicillium* are among the common postharvest pathogens on a wide range of fruits and vegetables. *Penicillium expansum*, the main cause of green (blue) mold of apple, pear and fruits of other deciduous trees, is an example of destructive pathogens that causes much of post-harvest economic losses on food during storage and marketing stages **(Barkai-Golan, 2008)**. Two main genera are responsible for mycotoxin production in grapes: *Aspergillus* and *Penicillium*. The mycotoxin production is characteristic of the species and therefore by identifying the species one can predict potential mycotoxin hazards **(Serra et al., 2006)**. Green mould produces mycotoxins for example patuline which is however degraded during fermentation and by sulphurization. Berries affected by green mould have an off-flavour and even a small amount of infected berries add a mouldy taste to the wine **(Kassemeyer and Berkelmann-Löhnertz, 2009)**. Ochratoxin A (OTA) producing fungi are members of the genera *Aspergillus* and *Penicillium*. Natural occurrence of OTA has been reported from temperate to tropical climates mainly on cereals and their products, beverages such as bread, beer, coffee, dried fruits, grape juice and wine among others. Only some OTA producing species are known to be a potential source of OTA contamination of these commodities, including *A. niger* aggregate, *A. carbonarius, A. ochraceus, A, westerdijkiae,*

A. steynii, Penicillium verrucosum and *P. nordicum* **(Cabañes et al., 2010)**.

In our work the goal was to assess the fungi present on the surface and inside of healthy grapes destined for commercial winemaking at harvest time. Emphasis was given to *Penicillium* species due to their relevance for mycotoxin production.

Scientific hypothesis

During maturation of grapes, the spoilage agents, *Aspergillus, Penicillium* and *Rhizopus*, increase their incidence. When the temperature is higher then 37 °C, species in *Aspergillus* section *Nigri* become predominant **(Valero et al., 2007)**. At harvest time, the conditions are optimal for fungal invasion, especially if physical damage had occurred on grape. Certainly the *Aspergillus* species are present worldwide, in all the grape products and under all environmental conditions.

MATERIAL AND METHODOLOGY

Study area

The grapes (*Vitis vinifera*) used in this study originated from a small family winery founded in 2002. Their goal is to produce quality wines mainly from grapes from their own production. The farm is situated in Vrbovsky subregion, in the village of Vrbove, which is part of the Small Carpathians wine region. In the years 2014 – 2016, 10 ha of their own vineyards were planted in Vrbove. Young vineyards are great advantage because they had the opportunity to choose many varieties according to the climate, soil type, but also their own experience so that they could obtain a high-quality raw material for the production of unique wines. They planted old varieties that were grown in Vrbove in the past, for example Green Veltliner, Müller Thurgau, Sauvignon, but also modern varieties such as Pálava, Cabernet Sauvignon and Alibernet.

The Small Carpathians wine region has a medium climate and abundant moisture. The spring of 2018 was an extremely abnormal temperature in Slovakia. April and May were two recordable warm months in Hurbanovo. The average monthly air temperature reached 16.2 °C in April and 19.7 °C in May. Summer was extremely hot with the absence of longer, cooler days. Intense rainfall occurred at the beginning of September **(Siman, 2019)**.

Grape samples

Wine company provided the grapes grown for commercial winemaking. A total of 14 samples were taken: ten from white varieties (Green Veltliner, Seteasca Regala, Chardonnay, Rheinriesling, Welschriesling, Sauvignon, Pálava, Pinot Blanc, Irsai Oliver, Müller Thurgau and the remaining 4 from red varieties: Dornfelder, Blaufränkisch, Alibernet, Cabernet Sauvignon, during the period from the end of August to the beginning of September 2018, in the maturation stages corresponding to harvest. The samples comprised 10 bunches of grapes collected across two diagonal transects. Grape samples were put directly each into a sterile plastic bag. Samples were brought into the laboratory and kept at 5 °C till fungal analysis.

Isolation and identification of fungi

A total of 50 berries (7 – 8 berries per bunch) from each sample were plated in Dichloran Rose Bengal Chloramphenicol agar medium (DRBC) and incubated at 25 ±1 °C in the dark for one week. The detection of fungi in grape samples was also made by plating methods with surface disinfection. The whole 50 grapes were surface-disinfected in 1% NaClO for 1 min according methods of **Magnoli et al. (2003)**. After thorough washing with sterile distilled water (3 times, total amount 1L), and drying were inserted on the agar surface DRBC as a whole fruit and incubated at 25 ±1 °C in the dark for 5 – 7 days.

The identification of fungal taxa based on macroscopic and microscopic features, with guidelines by **Pitt and Hocking (2009)**.

Media used for isolation of fungi were:

a) Dichloran Rose Bengal Chloramphenicol agar medium (DRBC, MERCK, Germany) to which rose bengal (25 $\mu g.mL^{-1}$) was used to inhibit rapidly growing fungi and chloramphenicol (100 $\mu g.mL^{-1}$) was used as bacteriostatic agents.

Penicillium strains were isolated and cultivated on these medias:

b) Malt extract agar (MEA),
c) Czapek yeast agar (CYA),
d) Creatine-Sucrose agar (CREA),
e) Yeast Extract agar (YES) **(Samson et al., 2010)**.

Genus *Penicillium* was identified to species level based on morphological characters according to special mycological literature of **Pitt and Hocking (2009), Samson and Frisvad (2004)** and **Samson et al. (2002a, 2010)**.

Mycotoxins analysis

A total of 15 different isolates of filamentous fungi from different samples belonging to *Penicillium* spp. were examined for their ability on mycotoxins production by thin layer chromatography (TLC) according to **Samson et al. (2002b)**, modified by **Labuda and Tančinová (2006)**. Extracellular metabolites – citrinin, griseofulvin and patulin were carried out on YES agar and intracellular roquefortine C and cyclopiazonic acid on CYA agar. A few pieces of mycelium with approximate size 5 x 5 mm were cut from colonies and placed in an Eppendorf tube with 500 µL of chloroform:methanol – 2:1 (Reachem, Slovak Republic). The content of the tubes was stirred for 5 min by Vortex Genie ® 2 (MO BIO Laboratories, – Carlsbad, CA, USA).

Mycotoxins detection

Mycotoxins extracted from fungal isolates cultures were determined by thin layer chromatographic technique on pre-coated silica gel plate (Alugram ® SIL G, Macherey – Nagel, Germany). The volume 30 µL of liquid phase of extracts along with 10 µL standards (Sigma, Germany) was applied on TLC plate. The plate was put into TEF solvent (toluene:ethyl acetate:formic acid – 5:4:1, toluene – Mikrochem, Slovak Republic; ethyl acetate and formic acid – Slavus, Slovak Republic). After elution the plate was air-dried. Mycotoxins were identified by comparison with appropriate reference standards of mycotoxins.

Table 1 Fungi identified in Slovak wine grapes from 2018 by the direct plating method.

Fungal taxa	No.	Fr (%)	RD (%)
Alternaria	868	100	87
Aspergillus	5	14	<1
Aureobasidium	1	7	<1
Botrytis	18	43	2
Cladosporium	4	21	<1
Epicoccum	7	36	<1
Mucor	3	14	<1
Penicillium	5	21	<1
from this			
P. citrinum	3	7	
P. expansum	1	7	
P. glabrum	1	7	
Rhizopus	49	93	5
Sordaria	13	71	1
Trichoderma	1	7	<1
Mycelia sterilia	19	71	2
Total isolates	**1001**		

Note: No. – number of isolates, Fr – isolation frequency, RD – relative density.

Table 2 Fungi identified in Slovak wine grapes from 2018 by the direct plating method with surface disinfection.

Fungal taxa	No.	Fr (%)	RD (%)
Alternaria	414	100	81
Aspergillus	1	7	<1
Botrytis	1	7	<1
Cladosporium	49	79	10
Epicoccum	3	21	<1
Fusarium	2	14	<1
Penicillium	14	43	3
from this			
P. citrinum	6	21	
P. griseofulvum	1	7	
P. hordei	4	7	
P. chrysogenum	3	21	
Rhizopus	7	29	1
Trichoderma	1	7	<1
Mycelia sterilia	17	64	3
Total isolates	**509**		

Note: No. – number of isolates, Fr – isolation frequency, RD – relative density.

Table 3 Toxinogenity of selected *Penicillium* strains, isolated from exogenous and endogenous mycobiota of wine grapes.

Species/Exo	C	G	P	CPA	RC
P. citrinum	3*/3**				
P. expansum	1/1		0/1		0/1
Species/Endo					
P. citrinum	6/6				
P. griseofulvum		1/1	1/1	0/1	0/1
P. hordei					0/1
P. chrysogenum					0/3

Note: * - number of isolates with ability to produce mycotoxin, ** - number of tested isolates, C – citrinin, G – griseofulvin, P – patulin, CPA – cyclopiazonic acid, RC – roquefortin C.

Roquefortine C was visible after spraying with $Ce(SO_4)_2$ x 4 H_2O as an orange spot. Cyclopiazonic acid was visible directly in daylight after spraying with the Ehrlich reagent as a violet-tailed spot. Patulin by spraying with 0.5% methylbenzothiazolone hydrochloride (MBTH), (Merck, Germany) in methanol and heating at 130 °C for 8 min and then detectable as a yellow-orange spot. Directly under UV light with a wavelength of 365 nm were visualized citrinin as a yellow-green-tailed spot and griseofulvin as a blue spot.

Statisic analysis

The obtained results were evaluated and expressed according to relative density (RD) and isolation frequency (Fr). The relative density (%) is defined as the percentage of isolates of the species or genus, occurring in the analyzed sample **(Guatam et al., 2009)**. These values were calculated according to **González et al. (1999)** as follows:

$$RD\ (\%) = (ni / Ni) \times 100$$

where ni – number of isolates of a species or genus; Ni – total number of isolated fungi.

The isolation frequency (%) is defined as the percentage of samples within which the species or genus occurred at least once. These values were calculated according to **González et al. (1999)** as follows:

$$Fr\ (\%) = (ns / N) \times 100$$

where: ns – number of samples with a species or genus, N – total number of samples.

RESULTS AND DISCUSSION

A survey study was conducted on 14 samples of fresh grape which collected from Vrbove, Slovakia. Isolation of fungi contaminated fresh grape resulted in collecting of 1001 fungal isolates. Data in Table 1 show that, eleven fungal genera namely *Alternaria, Aspergillus, Aureobasidium, Botrytis, Cladosporium, Epicoccum, Mucor, Penicillium, Rhizopus, Sordaria, Trichoderma* and *Mycelia sterilia* (unidentified fungus without creation fruiting bodies) were identified from fresh grape samples.

Data in the same Table 1 showed that, *Alternaria* was the most frequently occurring genus (100 %) which record 868 isolates, with the highest relative density 87%. *Rhizopus* was the second predominant genus which recorded frequency of 93%, but low relative density (5%), followed by *Sordaria* (71% Fr, 1% RD). *Botrytis, Epicoccum, Penicillium, Cladosporium, Aspergillus, Mucor Aureobasidium* and *Trichoderma* were less fungal frequency occurred in all grape samples.

Khashaba et al. (2018) reported that prevalence of *Alternaria* was moderate fungal frequency (50%) and *Aspergillus* was the most frequently occurring genus (100%) in Egypt. *Penicillium* was the second predominant genus which recorded frequency of 92.5%. In our study *Aspergillus* and *Penicillium* were less fungal frequency occurred in all grape samples. Similar results that *Aspergillus* is the main fungal genus were obtained by several studies **(Alisa et al., 2007; Fredj et al., 2007)**. *Alternaria, Botrytis* and *Cladosporium* were three of the most frequent genera in all four winemaking regions in Portuguese **(Serra et al., 2006)**, representing 16, 17 and 24% of the total identified strains, respectively.

Figure 1 *Penicillium expansum.*

Figure 2 *Penicillium chrysogenum.*

According to the region considered, other frequent fungi were *Aureobasidium pullulans, Aspergillus niger, Epicoccum nigrum, Penicillium brevicompactum, P. thomii* and *Rhizopus*. *Aspergillus* and *Penicillium* were also an important part of the mycobiota representing 15 and 24%, respectively, of all the fungi found in the regions. *Aspergillus* was more frequent than *Penicillium* in almost all regions. In our samples *Botrytis* represented 2% of the total identified strains and *Cladosporium* less than 1%, but *Alternaria* was the most frequent genus, too. **Serra et al. (2006)** described that the most frequent *Penicillium* species were *P. brevicompactum, P. thomii* and *P. glabrum* which together accounted for approximately 71% of the strains identified in the genus. Five species of *Penicillium* including *P. brevicompactum*, *P. citrinum, P. echinulatum, P. expansum* and *P. solitum* reported from grapes in Korea **(Won et al., 2007)**. **Serra and Peterson (2007)** described two new species of *Penicillium*, namely, *P. astrolabium* and *P. neocrassum* from contaminated grapes in Portugal. The reports on *Penicillium* species occurring on grape and raisin from Iran are very rare **(Rahmani et al., 2012; Maulani et al., 2012)**, mainly *P. expansum*, *P. brevicompactum* and *P. glabrum* **(Houbraken et al., 2014)**. Five species represent new records for the mycobiota of Iran are *Penicillium crocicola*, *P. olsonii, P. sumatrense, Talaromyces atroroseus* and *T. minioluteus* **(Khodaei et al., 2016)**. During our survey, five isolates belonging to three *Penicillium* species (*P. citrinum, P. expansum* and *P. glabrum*) were isolated and identified from exogenous colonisation (Table 1). Their occurrence was very sporadically. On the other hand, *Penicillium* were between the most common species identified in grape from Small Carpathian area during harvesting 2011 to 2013 **(Felšöciová et al., 2015)**. From 13 different *Penicillium* species with high frequency (93%) were 4 main species: *P. chrysogenum, P. crustosum, P. expansum* and *P. griseofulvum*. *Penicillium citrinum* was less common species identified in grape samples.

By the endogenous (surface-disinfected) plating method were identified nine different genera from the 509 fungal strains (Table 2): *Alternaria, Aspergillus, Botrytis, Cladosporium, Epicoccum, Fusarium, Penicillium, Rhizopus, Trichoderma* and *Mycelia sterilia*. The three most abundant genera found by descending order and with the highest relative density were *Alternaria, Cladosporium* and *Penicillium*. Most of all genera had relative density less than 1%.

Most of the fungi found are ubiquitously distributed, such as the field fungi *Alternaria, Cladosporium* and *Epicoccum*, which occur commonly in the air, plant surfaces, debris and soil **(Serra et al., 2006)**. Fungal species capable of causing rot in grapes (e.g. *Aspergillus niger, Botrytis cinerea, Rhizopus*) were not common inhabitants of the berry surface.

Four *Penicillium* species were found: *Penicillium citrinum, P. griseofulvum, P. hordei* and *P. chrysogenum* (Table 2). According **Felšöciová et al**. **(2013)** some similar species but in lower number of abundances were isolated from the Nitra wine growing region in 10 analysed samples, namely *P. citrinum, P. corylophilum, P. crustosum, P. decumbens, P. expansum, P. chrysogenum* and *Penicillium* spp. The occurrence of most was also very sporadically, except *P. crustosum, P. chrysogenum* and *P. expansum*. Nine *Penicillium* species (*P. canescens, P. citrinum, P. crustosum, P. expansum, P. funiculosum, P. glabrum, P. griseofulvum, P. chrysogenum* and *P. variabile*) were found from grapes grown in the Central Slovak wine region, but there occurrence was also very sporadically except two *P. expansum* and *P. chrysogenum* **(Felšöciová et al., 2015)**.

As shown in Table 3, thin layer chromatographic analysis of 15 tested isolates representing 5 potentially toxigenic species showed that 11/15 (73%) produced at least one mycotoxin. Positive toxigenity was detected in *P. citrinum* (9 out of 9 strains screened). *Penicillium expansum* (Figure 1) produced only citrinin, did not produce patulin and roquefortin C, *Penicillium griseofulvum* produced griseofulvin and patulin, the production of cyclopiazonic acid and roquefortin C was not confirmed. Negative toxigenity were detected in *Penicillium hordei* and *P. chrysogenum* (Figure 2) on roquefortin C.

Penicillium spp. in our samples was generally low (3% RD). On the other hand, *Penicillium* was a common component of the grapes mycobiota from 2011 to 2013 in the Small Carpathian area **(Felšöciová et al., 2015)**. Ninety three percent of samples were colonies by the genus *Penicillium*. During the survey, 251 isolates belonged to 14 *Penicillium* species. Out of 124 strains, 84% produced at least one mycotoxin by TLC method. The most frequent was *P. chrysogenum*. Interesting was, that almost all tested strains on roquefortin C were producted (100 out of 102). No mycotoxin (RC) was formed by the examined four species (*P. expansum, P. griseofulvum, P. hordei* and *P. chrysogenum*) isolated from our grape samples.

CONCLUSION

The present work indicated that the examined grape fruits were contaminated with several fungi especially members of *Alternaria*. Members of *Aspergillus* and *Penicillium*, fungi capable of producing mycotoxins such as aflatoxins and ochratoxin A, were very rare. These findings indicate that strict hygiene microbiological must be applied during different stages of harvest, transport, storage and handling to avoid the harmful effects on human health.

THE INFLUENCE OF SELENIUM ON SELECTED HEAVY METALS CUMULATION IN OYSTER MUSHROOM FRUITING BODIES

Marcel Golian, Alžbeta Hegedűsová, Marianna Trochcová, Adriána Maťová, Miroslav Šlosár

ABSTRACT

Food safety is a very frequent topic. The article deals with the problems of fortification of the most grown mushroom in Slovakia, and the 3rd most grown mushroom in the world, *Pleurotus ostreatus*. Due to the high environmental pollution of soils and air, there is a risk of the production of dangerous fruiting bodies with high heavy metals content. It is known that these substances can promote serious health effects on human body, such as bone weakness or kidney damages (cadmium) and negative process of cognitive developing (lead). The experiment was focused on biofortification with selenium to reduce the accumulation of selected heavy metals (lead, cadmium) in oyster mushroom, grown with intensive cultivation under artificial conditions. This work confirms that the application of sodium selenate to the growing substrate with straw as the main component can reduce the accumulation of cadmium (by 22.45%) and lead (by 64.81%). Research by various authors reported the ability of the oyster mushroom to embed selenium from the substrate into the fruiting bodies. Based on the results of the experiments, we propose to fortify the growing substrate for the production of oyster mushroom by selenium. This way we produce a food with a high antioxidant potential.

Keywords: oyster mushroom; *Pleurotus ostreatus*; heavy metals; food safety; mushrooms; lead; cadmium

INTRODUCTION

Oyster mushroom is popular especially because of its delicious taste. Its composition is also very important. Oyster mushroom contains high amounts of proteins and carbohydrates, minerals such as calcium, phosphorus, iron and other, vitamins like thiamine, riboflavin and niacin as well as low fat **(Sturion and Oetterer, 1995; Justo et al., 1998; Manzi et al., 1999)**.

According to **Silveira et al. (2006)** energy value of *P. ostreatus* is between 139.36 and 213.05 kcal.100 g^{-1} fresh mushrooms. Hyphae are composed of cell wall components such as chitin, other hemicelluloses and β-glucans, which often play a key role in the pharmacological use of mushrooms. For example, in enhancing macrophage function, resisting many bacterial, viral, fungal and parasitic infections, activating non-specific immune stimulation, lowering blood cholesterol levels and blood glucose levels **(Cheung, 2009)**. Although the mushrooms are not plants, they are often included between vegetables in terms of dietary properties. Most species of the genus *Pleurotus* are known for their healing potential.

Selenium (Se) is an essential element with antioxidant effects. It is an important component of several major metabolic reactions, including synthesis of thyroid hormones, antioxidant defence systems and immune functions **(Köhrle and Gärtner, 2009; Gandhi, Nagaraja and Prabhu, 2013)**. The essentiality of selenium was demonstrated in 1957 **(Hegedűs et al., 2006; Hegedűs, Hegedűsová and Šimková, 2007)**. In 1976, the necessity of selenium for humans was proven, despite the fact that previously were highlighted his negative effects **(Hegedűs et al., 2008; Jakabová et al., 2008; Jakabová et al., 2009)**.

It is therefore clear that mushroom enriched with inorganic forms of selenium can produce functional foods with positive effects on human health, anti-inflammatory and anti-tumour effects **(Clark et al., 1996)**.

Cultivation of saprophytic fungi on substrates rich in selenium may be an effective means of producing food with built-in selenium. The content of selenium in mushrooms is generally higher than most vegetables **(Rayman, Infante and Sargent, 2008)**, but this indication is very variable. In contrast with biologically available selenium concentrations in the soil and the related content of selenium in wild mushrooms, in cultivated mushrooms is the content of the embedded selenium variable depending on the species and their maturity. Its content is also dependent on the type and quality of the substrate **(Kalac, 2009)**. The concentration of selenium in the fruiting bodies of the favourite edible mushroom is in the range from <1 – 20 μg $Se.g^{-1}$ dry weight of the fruiting bodies.

The concentration of selenium in the fruiting bodies of mushroom *P. djamor* produced on high selenium substrates

compared to the control substrate without selenium contamination exceeds 800 times the amount, i.e. 141 μg $Se.g^{-1}$ weight of dried mushroom. It has been confirmed that as well as other species of genus *Pleurotus* are able to cumulate selenium **(Wang et al., 2005; Estrada et al., 2009; Da Silva et al., 2012)**.

Scientific hypothesis

Application of sodium selenate into the substrate will reduce the lead and cadmium content in oyster mushroom fruiting bodies.

MATERIAL AND METHODOLOGY

Establishment of experiments to produce oyster mushroom fruiting bodies

In the experiment was used the production strain of oyster mushroom *(Pleurotus ostreatus)* KRYOS B. Mushroom production was based on controlled cultivation conditions, in the premises of The AgroBioTech Research Centre, in two cultivation periods. The production of mushrooms proceeded in the following phases:

- inoculum preparation,
- preparation of the substrate,
- inoculation by inoculum and incubation at 25 °C about 2 weeks,
- initiation of the fruiting bodies at 11 °C for one day,
- fructification (12 hours, 16 °C in dark and 12 hours, 16 °C under light).

The experiment consisted of 4 variants, each variant had 10 repetitions. The whole experiment was carried out in two cultivation periods in the following terms:

- First cultivation period (1. CP) – from 04. April 2016 to 26. May 2016.
- Second cultivation period (2. CP) – from 09. June 2016 to 27. July 2016.

Created variants of experiments:

Preparation of all substrates consisted of wetting of dry straw pellets in water in a weight ratio of 1:2.6.

C – control – without selenium;

X – 0.5 $mg.dm^{-3}$ Se – with addition of 0.5 $mg.dm^{-3}$ Se in the form of sodium selenate aqueous solution;

Y – 1.0 $mg.dm^{-3}$ Se – with addition of 1.0 $mg.dm^{-3}$ Se in the form of sodium selenate aqueous solution;

Z – 2.0 $mg.dm^{-3}$ Se – with addition of 2.0 $mg.dm^{-3}$ Se in the form of sodium selenate aqueous solution.

After the end of the incubation, the containers were evenly bleached, overgrowth with mushroom mycelium, and no visible signs of contamination. In the next step the cultivation containers were covered with transparent plastic layers with a 3 cm hole in the middle of the lid. The microthene foil was cut in the shape of a cross in the place of hole. The initiation of fruiting bodies production was carried out by repeated substrate cooling in two cycles.

The fruiting following after the phase of fruiting bodies germ initiation was similar in 2 cycles from 12 May (1. CP) and from 17 July (2. CP).

Collection and processing of oyster mushroom fruiting bodies

Oyster mushroom fruiting bodies were harvested in the optimal growth phase. Fruiting bodies were lyophilized on a LYOVAC GT2 (Germany) for 24 – 30 hours. The lyophilizate was then homogenized by grinding to a fine powder and further used to determine the selected qualitative parameters.

Analytical methods for determining selected qualitative factors

Quantitative determination of the content of selected risk metals except mercury was carried out in the mineralized samples by AAS (AAS Varian AA Spectr DUO 240 FS/240Z/UltrAA) flame technique. The results were evaluated by the calibration curve method.

Ready-made CertiPur stock calibration solutions (Merck, Germany) was used with well-known concentrations of the heavy metals to be monitored. The final values of the measured parameters were subsequently obtained by software translating the calibration curve with the absorbance of the monitored analyte in the sample.

Statistic analysis

The statistical evaluation of the results was carried out by standard methods using statistical software Statgraphics Centurion XVII (StatPoint, USA) – multifactor analysis of variance (MANOVA), LSD test.

RESULTS AND DISCUSSION

It is generally known that different species of mushrooms tend to accumulate different substances from the substrate and from the environment, with no exception for risk metals. We evaluated the content of selected risk metals (lead and cadmium) during our experiment. For each cultivation period 40 samples of lyophilized fruiting bodies grown on selenium fortified substrates were analysed. Average values for individual variants are given in Table 2. Dehydrated samples of the control substrate without sodium selenium application were also analysed for the presence of metals (Table 1).

In terms of contamination of the oyster mushroom fruiting bodies by risk metals, currently applicable regulations and decrees set the highest limits only for two risk elements - cadmium and lead. According to **Commission Regulation (EU) 2015/1005** of 25 June 2015 amending Regulation (EC) No 1881/2006 as regards maximum levels of lead in certain foodstuffs, the maximum allowed limit for oyster mushroom fruiting bodies intended for consumption is till 0.30 $mg.kg^{-1}$ Pb of fresh matter of the fruiting bodies. As regards **Commission Regulation (EU) No 488/2014** of 12 May 2014 amending Regulation (EC) No 1881/2006, as regards maximum levels of cadmium in foodstuffs, they were determined at levels of up to 0.20 $mg.kg^{-1}$ Cd of fresh fruiting bodies. Since the samples analysed by us were lyophilized, we carried out a conversion to fresh matter of the fruiting bodies. The results are shown in Table 3.

After the calculation we can state, that the critical limits of heavy metals set by the applicable food quality regulations were not exceeded.

Table 1 Average content of metals in samples of dehydrated substrate.

Variant	Pb (mg.kg^{-1})	Cd (mg.kg^{-1})
C	2.20	0.21

Table 1 Average content of metals in lyophilized samples of fruiting bodies*Pleurotus ostreatus* KRYOS B fortified by selenium.

Variant	Dry matter (%)	average periods
	Pb (mg.kg^{-1})	
C	11.44	0.18
X	10.46	0.19
Y	10.69	0.16
Z	11.69	0.11
	Cd (mg.kg^{-1})	
C	11.44	0.02
X	10.46	0.02
Y	10.69	0.01
Z	11.69	0.02

Note: C – 0.0 mg.dm^{-3} Se; X – 0.5 mg.dm^{-3} Se; Y – 1.0 mg.dm^{-3} Se; Z – 2.0 mg.dm^{-3} Se.

Therefore, these fruiting bodies can be considered as a safe food product for the consumer also after application of selenium. In the case of the interaction of selenium and selected heavy metals, it was statistically proven in both cases that the increased content of selenium in the substrate reduces the accumulation of lead and cadmium. Average for both cultivation periods pointed out that in the variant with 2.0 mg.dm^{-3} Se was the lead accumulation statistically significant reduced by 64.81%. Reduction in accumulation occurred after application of 1.0 mg.dm^{-3} Se (2.47%) too, but it was not statistically significant. In a variant with 0.5 mg.dm^{-3} Se, lead accumulation was increased by 19.75%, but it was not statistically significant (p >0.05).

Similar results were also found in the case of cadmium accumulation in fortified oyster mushroom fruiting bodies, on average for both cultivation periods. In variant with 2.0 mg.dm^{-3} Se was statistically proven lower cadmium accumulation by 24%, while in a variant with 0.5 mg.dm^{-3} Se, its accumulation grew by 4%, but statistically not significant. In variant with 1.0 mg.dm^{-3} Se, accumulation of cadmium was statistically not significant decrease by 16%. Based on the above results it can be stated, that the fortification of substrates with selenium not increases the accumulation of selected risk metals statistically significantly in any of the experimental variants. On the other hand, in the variant with 2.0 mg.dm^{-3} Se, was statistically proven decreased accumulation of lead and cadmium in the fruiting bodies of edible oyster mushroom. **Lepšová (2001)** argues that the oyster mushroom cultivated in the wood can accumulate only a small amount of heavy metals from the environment; therefore, there is no need to fear their increased level in the harvested fruiting bodies. The opposite phenomenon can occur in the intensive production of edible mushrooms, where the grain is used as a substrate, which is a by-product of intensive agricultural production.

Stihi et al. (2011) in their study found that wild oyster mushroom in Romania, distant 0.5 km from the source of pollution contained Cr (1.81 mg.kg^{-1}), Mn (12.4 mg.kg^{-1}), Fe (387.00 mg.kg^{-1}), Ni (1.85 mg.kg^{-1}), Cu (12.5 mg.kg^{-1}), Zn (41.30 mg.kg^{-1}), Se (2.64 mg.kg^{-1}), Cd (0.95 mg.kg^{-1}) and Pb (0.64 mg.kg^{-1}) in lyophilized samples. Fruiting bodies in a location 10.5 km distant from the same source of pollution contained only slightly lower concentrations of

the monitored elements, namely Cr (1.08 mg.kg^{-1}), Mn (11.8 mg.kg^{-1}), Fe (284.00 mg.kg^{-1}), Ni (1.29 mg.kg^{-1}), Cu (10.20 mg.kg^{-1}), Zn (37.90 mg.kg^{-1}), Se (2.57 mg.kg^{-1}), Cd (0,87 mg.kg^{-1}) and Pb (undetectable) in lyophilizates. These results confirm the ability of oyster mushroom to accumulate risk metals. In samples of fruiting bodies fortified with selenium, which were analysed in our work, many lower concentrations of the elements were found. The findings can be explained by a better quality of the production substrate.

Siwulski et al. (2017) on the basis of their research indicate that the lowest levels of Al, Fe, Mn, P and Se were observed in the *P. ostreatus* 930 strain. The lowest concentrations of Ca, Cr, K, Nd, Te and Zn were determined in *P. florida*, while in *P. pulmonarius*, were observed trace amounts of Er, Rh, Sc, Tm and Zr. On the other hand, *P. ostreatus* strain 930 contained the highest content of Cu and Lu, whereas *P. florida* of the Rh element. Significant differences were observed in *P. ostreatus* K 22, *P. citrinopileatus* and *P. eryngii*. The highest content of Al, Cr, Er, Fe, Pt, Th, Ti and Tm was determined in *P. ostreatus* K 22, the elements Mg, Mn, P, Re, Se and U were most represented in *P. Citrinopileatus,* and *P. eryngii* accumulated the highest concentration of As, B, Ca, In, Na, Nd and Sr. *P. ostreatus* strain K 22 contained the lowest concentration of In, *P. citrinopileatus* lowest concentration of Na and *P. eryngii* the lowest concentration of Th. From other tested species and strains contained *P. ostreatus* HK 35 lowest content of As and highest level of Te, *P. ostreatus* H 195 lowest content of Cd, Pb and U and highest level of Sc. The authors emphasize that the highest concentration of Pb and Cd was determined in fruiting bodies of *P. ostreatus* 80. The high cumulative potential of the said strain can be specifically used in the soil myco-remediation processes. *P. djamor* was rated as the most efficient K and Zn accumulator. We confirm the fact that the individual strains of edible oyster mushroom are different from each other in the ability to accumulate selected compounds.

Quarcoo and Adotey (2013) monitored the accumulation of selected heavy metals by oyster mushroom fruiting bodies in Ghana. They found that the fruiting bodies contained on average 0.04 mg.kg^{-1} Pb, 0.04 mg.kg^{-1} As, 43.77 mg.kg^{-1} Fe, 0.35 mg.kg^{-1} Cd and 0.04 mg.kg^{-1} Hg in a lyophilized mass. Our samples of the fortified fruiting bodies contained lower concentrations of these elements.

Kaya and Bag (2010) analysed 24 species of mushrooms occurring in Turkey. In the case of *Pleurotus ostreatus*, significant levels of heavy metals were found, namely 20.87 mg.kg^{-1} Al, 0.41 mg.kg^{-1} B, 2.11 mg.kg^{-1} Cd, 0.90 mg.kg^{-1} Co, 0.21 mg.kg^{-1} Cr, 39.36 mg.kg^{-1} Cu, 40.57 mg.kg^{-1} Fe, 4.22 mg.kg^{-1} Mn, 1.23 mg.kg^{-1} Ni, 2.14 mg.kg^{-1} Pb and 86.83 mg.kg^{-1} Zn in lyophilizate. Again, we conclude that the concentration of selected elements was lower in our experiment.

Demirbas (2001) found in the dry matter fruiting bodies of the edible oyster mushroom Pb (3.24 mg.kg^{-1}), Cd (1.28 mg.kg^{-1}), Hg (0.42 mg.kg^{-1}), Cu (13.6 mg.kg^{-1}), Mn (6.27 mg.kg^{-1}), Zn (29.8 mg.kg^{-1}) and Fe (81.6 mg.kg^{-1}).

Tuzen, Ozdemir and Demirbas (1998) determined in the dry matter of edible fruiting bodies Pb (0.11 mg.kg^{-1}), Cd (0.55 mg.kg^{-1}), Hg (0.31 mg.kg^{-1}), Fe (48.6 mg.kg^{-1}), Cu (5.0 mg.kg^{-1}), Mn (10.3 mg.kg^{-1}) and Zn (19.3 mg.kg^{-1}).

Lasota, Florezak and Karmanska (1990) prove Cd (11.2 mg.kg^{-1}), Hg (1.2 mg.kg^{-1}), Zn (0.8 mg.kg^{-1}) and Pb (0.0 mg.kg^{-1}) in lyophilized fruiting bodies of oyster mushroom.

All of the above-mentioned findings of a large number of authors point to the fact that edible mushrooms are able to accumulate heavy metals from the environment and the from the substrate into the fruiting bodies, which can greatly worsen the quality of the production. Our argument explains the different concentrations of the rated elements compared to the cited authors, as the content of the selected elements in the concrete fruiting bodies is directly related to the content of the analysed element in the growing substrate. For the intensive production of edible mushroom is important to use only high-quality lignocellulosic material analysed for the content of risk metals. From the point of view of the accumulation of selected metals, we recommended to fortify the cultivation substrate of oyster mushroom with the selenium in order to produce a functional and uncontaminated foodstuff.

CONCLUSION

At work we monitored the accumulation of risk elements – lead and cadmium in the oyster mushroom fruiting bodies. We found that the limit set by the European Commission Regulations, which concern about the content of lead and cadmium in oyster mushroom fruiting bodies has not been exceeded. Fruiting bodies are of satisfactory quality and are suitable for daily consumption.

In the experiment, the reduction of lead and cadmium accumulation was statistically confirmed after application of 2.0 mg.dm^{-3} Se. Cadmium content decreased by 22.45% and lead by 64.81% compared to the control variant. From the results it is clear that by fortification of the substrate (the main component of which is straw) by selenium, we produce not only a high-quality food with a high antioxidant potential, but we can also prevent the accumulation of risk elements of lead and cadmium from the substrate.

QUALITY OF BISCUITS AS AFFECTED BY ADDITION OF FIBRE

Viera Šottníková, Radka Langová, Luděk Hřivna, Šárka Nedomová, Miroslav Jůzl

ABSTRACT
The aim of the study was to propose formulas with addition of bamboo and hemp fibre and grape seed flour in an amount of 3, 6 and 9% and then assess the effect of added fibre on the quality of biscuits. A total of 20 samples were baked, in half of the samples the basic ingredient was wheat flour, and in the rest of samples spelt flour was used. During a baking experiment, it was found that the best effect on the product volume and the weight after baking had bamboo fibre. Minor baking losses occurred in biscuits with wheat flour. The best sensory results were attained with the sample having 3% of grape seed flour with a spelt flour base. The crispiest was the sample made from spelt flour with 3% of hemp fibre and the wheat samples with bamboo fibre were of the lightest colour. Control samples had the highest nutritional values and biscuits with added bamboo fibre contained the lowest energy in both formulas.

Keywords: fibre; biscuit; baking experiment; sensoric assessment; nutritional value

INTRODUCTION
Biscuits are very popular in the food industry. **Kumar et al. (2015)** indicate in their study that annual consumption of biscuits per person is 10 to 15 kg in developed countries. The biscuits are popular owing to their sensory attributes, long shelf life, relatively low price, suitable packaging sizes and availability **(Vitali, Dragojević and Šebečić, 2009; Brownlee et al., 2017)**. Due to competition in the market and increased demand for healthy, natural and functional products, the aim is to improve the nutritional value and functionality of biscuits by changing their nutritional composition. The beneficial properties and positive effect of fibre on the human organism are known for decades. Many studies show its association with body weight and insulin levels in the blood. Foods rich in fibre are digested more slowly and absorption of nutrients takes longer, which increases the feeling of satiety and consequently longer breaks between meals and lower energy intake. Although the energy gain from fibre is small, its main function is to protect and act as prevention against many non-infectious diseases of mass occurrence, such as heart and blood vessel diseases, colon cancer and tumours, obesity, and diabetes. It affects the excretion of hormones by glands with internal secretion, including cholecystokinin, which is secreted by cells in the small intestine, stimulates pancreatic secretion, and controls the central feeling of satiety. It helps to reduce postprandial glucose levels, unsaturated fats, blood triacylglycerols, and LDL cholesterol **(Marko, Rakická and Šturdík, 2015; Van Der Kamp et al., 2010)**.

Enriching biscuits with different types of fibre not only improves viscosity, texture, sensory properties and product durability with its physicochemical properties, but also reduces the energy value of the product **(Vitali, Dragojević and Šebečić, 2009; Brownlee et al., 2017)**. Through the formula adjustment and fortification, they are made to suit different uses, such as for sick, children, athletes or army **(Kadlec, Melzoch and Voldřich, 2012)**.

Scientific hypothesis
We are expecting the significant effect of added fibre on the quality of biscuits. Based on spectrophotometric color measurement it was assumed that the lightest colour would have the samples with bamboo fibre and the darkest color would have samples with grape seed flour.

According to sensoric analysis we assumed that the best evaluated sample would be the sample containing 6% of bamboo fibre even if both flours were used.

Based on the strength measurement we assumed that the smallest strength would be measured at samples enriched with hemp fiber.

MATERIAL AND METHODOLOGY
Biscuits of two kinds of flour were baked. The base consisted of wheat and spelt flour to which bamboo and hemp fibre and grape seed flour were added in an amount of 3, 6 and 9%. Subsequently, the quality of durable bakery products affected by the fibre was examined. Biscuits were baked and assessed in the pilot plant and laboratory of the Institute of Food Technology at Mendel University in Brno.

Two formulas were proposed (Table 1 and Table 2). The standard mixture consisted of wheat and spelt flour to which the selected fibre was added, always in the same proportion – 3, 6 and 9%.

Table 1 Proposed formula with a wheat flour base.

Sample no.		1	2	3	4	5	6	7	8	9	10

Note: **Eggs were of size M (53 – 63 g). **The numbers in brackets indicate the actual fibre content declared by the manufacturer on the individual fibre packaging, converted to the percentage of the given formula.
Sample no. 11: control without fibre.
Samples no. 12 – 14: bamboo fibre in an amount of 3, 6, and 9%.
Samples no. 15 – 17: hemp fibre in an amount of 3, 6, and 9%.
Samples no. 18 – 20: grape seed flour in an amount of 3, 6, and 9%.

The technology of production started with sifting flour and then mixing it with other loose ingredients (powdered sugar, vanilla sugar, fibre, and lemon zest). In the next step, softened butter and eggs (both yolks and whites) were added. All ingredients were worked together and kneaded for 7 minutes to develop smooth dough that was left to restin a cool place (10 °C) for 2 hours; meanwhile other doughs were prepared.

After the maturation phase, the dough was rolled with a special rolling pin having an adjustable dough sheet thickness set to 4 mm, so that all biscuits were of even height. Biscuits were cut out from all the doughusing round stamps with embossed patterns of 5.5 cm in diameter; the edges of shaped biscuits were higher due to the embossing pattern used. The cut-out biscuits were placed on a baking tray lined with parchment paper and put in a preheated hot air rotary oven at 160 °C for 15 minutes.

The baked biscuits were laid on stainless steel tables and left to cool freely. After cooling, on the same day, the physical measurement was carried out, followed, on the next day, by sensoric assessment using the proposed questionnaire and colour measurement using a spectrophotometer.

Sensoric assessment of biscuits

All samples were assessed the next day after baking. A panel of 10 trained judges completed the sensory questionnaire. A total of 20 samples with different fibre added were assessed. The questionnaire was composed of 10 questions and biscuit samples were assessed for colour, hardness (break strength), aroma, surface, shape and homogenity, taste, ease of bite, adhesion to palate, bite swallowing, and overall impression.

Hardness measurement

The biscuit strength was measured using the TIRATEST 27025 (TIRA Maschinenbau GmbH, Germany) on the day of their technological production. A penetration test at a rate of 100 mm.min^{-1} was used to determine the brittleness of biscuits, with a stick of 3 mm diameter used as extension and a path of 5 mm. The strength was measured in [N].

Colour measurement using a spectrophotometer

The colour of biscuits was measured the day after the technological production, using the Konica Minolta CM-3500d spectrophotometer with a 30 mm measuring aperture and D65 illumination mode, in the reflectance mode with SCE (specular component excluded). The samples were measured from the bottom of the biscuit, each twice by attaching.

Determination of nutritional value

To determine the nutritional value of baked biscuits, the nutritional values per 100 g of ingredient used as declared by the manufacturer on the package were needed. The measured values were recalculated to the amount of ingredient used in the formula. The final data was converted to the weight of biscuits after baking and the results were again indicated per 100 g of baked biscuits.

Statisic analysis

Statistical comparison of samples using the Duncan's test was done separately for each kind of flour. Dependencies between measurements of individual sensory characteristics were assessed by factor analysis, with factor rotation according to a simple VARIMAX method Statistical test results were calculated using the STATISTICA CZ 12 software, the chosen significance level was 0.05. Statistical test results were calculated using the STATISTICA CZ 12 software, the chosen significance level was 0.05.

RESULTS AND DISCUSSION

Baking experiment

From the results of baking experiment measurements the following summary of characteristics was evaluated: weight of biscuits after baking [g], baking loss [%], product volume (mL.100 g^{-1}) and index number [-].

The weight of individual samples after baking differed based on the fibre used and its physicochemical properties. In the wheat-based formula, the control sample weighed 596 g, the highest weight showed the biscuits with addition of bamboo fibre (no. 2, 3, 4) and the sample no. 10 (with 9% of grape seed flour); other samples weighed under 600 g.

Among the samples no. 11 to 20, the highest weight had the control sample (608 g). The weight of samples no. 12, 13, and 14 was higher than 590 g, other samples weighed less. In both formulas, the percentage weight of biscuits increased with the increasing amount of bamboo fibre and grape seed flour added. On the contrary, the weight of hemp fibre samples decreased with the decreasing amount added. In contrast, **Gómez et al. (2010)** found no significant influence of the fibre type on the weight of the products, and no significant differences were foundas regarded the percentage of added fibre.

The highest value of the weight lost by baking in samples no. 1 to 10 showed sample no. 8 (with the addition of 3% of grape seed flour) with a loss of 15.41% and the lowest loss (10.51%) was also calculated for the addition of grape seed flour in sample no. 10. In samples no. 11 to 20, sample no. 17 (with 9% of hemp fibre) had the greatest loss in baking (21.01%), while sample no. 14 (with 9% of bamboo fibre) had the smallest (11.69%). In both wheat and spelt-based formulas, the lowest value of baking loss showed samples to which bamboo fibre was added; the loss in baking diminished with its enrichment. This is due to the binding capacity of bamboo fibre of up to 700%. At higher binding capacity, the dough was tough and poorly workable.The same result was obtained by **Gómez et al. (2010)**. Thus, with adding more fibre, it is necessary to improve the technological development which incorporates into the dough other ingredients inhibiting the water absorption **(Raymundo, Fradinho and Nunes, 2014)**. In the case of hemp fibre, on the other hand, the losses increased with higher percentage added due to the higher fat content in fibre. In general, smaller baking losses occurred in samples no. 1 to 10, due to the wheat flour that contains less fibre as compared to the spelt flour, which is whole grain. As also stated in study by **Frakolaki et al. (2018)**, higher fibre content in spelt flour negatively affects the dough rheology and product quality**.** Losses higher than 18% were recorded only in samples with spelt flour, samples no. 16, 17 and 18, and higher losses were also obtained in sample no. 15 (17.41%) which may mean that hemp fibre in an amount of 3, 6 and 9% and the addition of 3% of grape seed flour has a negative effect on the physical properties of the dough.

The smallest volume in samples no. 1 to 10 was observed for sample no. 10 (with 9% of grape seed flour) and the largest volume in sample no. 4 (with 9% of bamboo fibre). In the case of spelt flour biscuits, the sample no. 17 (with 9% of hemp fibre) had the lowest volume, i.e. 11.2% less compared to the control, while the sample no. 14 with the addition of bamboo fibre had the largest volume, 14% more than the sample no. 11, which was the control sample without fibre.

In both formulas, the largest volumes were observed in biscuits enriched with bamboo fibre that increased their volume with the addition of fibre. By contrast, in the case of hemp fibre and grape seed flour, the volume of samples decreased with their addition. The volumes of spelt flour-based samples (no. 11 to 20) were generally smaller.

Contrary to this, **Hrušková and Švec (2016)** found that biscuits with the addition of hemp seed flour, both fine and wholemeal, had their shape and volume unchanged.

Regarding the index number, arching slightly increased in wheat and spelt flour formulas (samples no. 1 to 20) with the addition of bamboo fibre. In samples no. 1 to 10, the most flattened was the fibre-free control (no. 1) with an index number of 0.1. In samples where the basic ingredient was spelt flour, all samples had the value of 0.09, except samples no. 13 and 14 with the addition of bamboo fibre (0.1 points) which were the most arched. Index numbers ranged from 0.09 to 0.12, meaning that fibre does not affect the shape and arching of biscuits too much.

Sensoric assessment of biscuits

The best impression from the wheat-based samples gave the sample no. 3 enriched with 6% of bamboo fibre (21 points), while the sample no. 10 with 9% of grape seed flour was the worst. In the second formula, the sample no. 18 was the best with 18.7 points and the worst overall impression was given by sample no. 14 with 28.1 points. The samples of both formulas were classified into one homogeneous group according to the Duncan's

test, i.e. no statistical differences were found between them ($p > 0.05$).

In grape seed flour and hemp fibre samples, the colour was the worst from the sensoric properties, and the surface was the best rated, while in the bamboo fibre samples the surface was the third worst rated property and the colour was the best rated descriptor. Unlike the wheat flour samples, the colour of all spelt flour samples was the worst rated of all of the selected attributes. It is, however, noticeable that the colour in the bamboo fibre samples was rated better than that in the hemp fibre and grape seed flour samples. Another observed difference is that samples with grape seed flour and bamboo fibre have the ease of bite as the second worst-rankedin the displayed properties, while in hemp fibre, rating of this property is comparable to that of the surface, shape and taste.

The relationships between the ratings of individual sensoric properties were determined using the factor analysis with a simple VARIMAX method of factor rotation (Table 3).

Based on the method, three significant factors were identified. The first factor was based on the close relationship of taste, adhesion, swallow ability, and overall impression. From a connection with the overall impression it can be concluded that taste, adhesion and swallow ability can be the main sensoric properties upon which the judge assesses the food in question. The second factor was based on an assessment of hardness, ease of biting and aroma. The third factor revealed the continuity of surface and shape assessments.

Measuring the colour of biscuits on a spectrophotometer

The results were expressed in accordance with the CIE L*a*b colour scheme with respect to D65 illumination. The higher the L* values in the graph, the lighter the colour of the sample.

In terms of the L* variable, which determines lightness from black to white, Duncan's test found that samples no. 5 to 10 had significantly lower values ($p < 0.05$) and the sample no. 4 had statistically significantly higher ($p < 0.05$) values, which statistically differs from all other samples from group 1 to 10. As the bamboo fibre amount increased, the biscuits were lighter in colour. Among the spelt flour samples, it was found that the samples no. 15 to 20 had statistically significantly lower values ($p < 0.05$) of the L* variable. The lightest sample (59.2%) was the sample with 6% bamboo fibre added.

For both formulas, the Duncan's test divided samples into five homogeneous groups with alpha significance level = 0.05. The darkest samples were the result of grape seed flour – sample no. 9 with 51.3% and sample no. 20 with 43%. Also **Maner, Sharma and Banerjee (2015)** found that grape seed flour gave biscuits their brown colour.

Biscuit strength assessment

For samples with wheat flour (1 – 10), the Duncan's test found that samples no. 3, 5 and 10 had statistically significantly lower ($p < 0.05$) hardness values compared to the control and the sample no. 8 had statistically significantly higher value than the control.

According to **Cappa, Lucisano and Mariotti (2013)**, the fibre binds water and retains it in the product during baking, so the fortified products are softer compared to the control, which corresponds to samples no. 2, 3, 4, 5 and 10 with the wheat flour base and samples no. 15, 16, 17, 18 and 20 with the spelt flour base. If the water content in the product is small, as with durable baking products, the ingredients compete with each other for water, and the fibre cannot perform its function as well as hydrocolloids that increase the dough's ability to bind water.

When comparing samples no. 11 to 20 in terms of hardness N, samples no. 15 and 17 showed statistically significantly lower values of hardness compared to the control and samples no. 12, 13 and 14 statistically significantly higher ($p < 0.05$) values. Samples of both formulas (1 to 20) were classified in five homogeneous groups using the Duncan's test with alpha significance level of 0.05. Furthermore, it was demonstrated that in both groups the smallest strength was measured in samples containing 3% of hemp fibre (no. 5 and 15) with average values of 23.9 and 20.8 N respectively. **Mancebo et al. (2017)** found that all fibre-enriched biscuits showed greater strength than the control and the biscuits with bamboo fibre added were the hardest.

Table 3 Factor analysis with a simple VARIMAX method of factor rotation.

Variable	Factor 1	Factor 2	Factor 3
Colour	0.35	0.14	-0.45
Hardness	-0.29	**0.79**	-0.07
Aroma	0.26	0.66	-0.08
Surface	0.12	-0.08	**0.84**
Shape and homogeneity	0.28	0.09	**0.81**
Taste	**0.81**	0.11	-0.11
Ease of bite	0.34	0.62	0.20
Adhesion	**0.74**	-0.07	0.33
Swallowability	**0.86**	-0.10	0.18
Overall impression	**0.75**	0.14	0.31

Nutritional values of biscuits

The calculated nutritional values per 100 g of wheat-based biscuits are shown in Table 4. The highest energy value, in addition to the control sample no. 1 (1,980.83 kJ), contained sample no. 8 (1,978.11 kJ) with 3% of grape seed flour. The least energy was contained in sample no. 4 (1,887.72 kJ) with the addition of 9% of bamboo fibre.

Table 5 shows the nutritional values per 100 g of spelt-base biscuits. The highest calorific values were calculated for the control sample no. 11 (1,929.64 kJ) and for sample no. 18 (1,927.52 kJ) with 3% of grape seed flour and the lowest energy values were reported for samples with bamboo fibre added (no. 11 to 14).

In both formulas, the control sample (no. 1 and no. 11) without the addition of fibre had the highest energy value because the formulas contained 100 percent of the flour amount. Samples no. 11 to 20 contained more fibre due to the spelt flour in which the amount of dietary fibre per 100 g is higher than in the wheat flour.

Bamboo fibre samples contained the most fibre due to the amount of fibre contained (97%) per 100 g of fibre. Biscuits enriched with grape seed flour contained the least fibre, but data from the study by **Maner, Sharma and Banerjee (2015)** clearly indicate that products enriched with grape seed flour have a positive effect on consumer health. Flour made from grape seeds and press cakes is nutritious and has antioxidant properties. It can be deduced from the results of the study by **Bilgiçli, İbanoglu and Herken (2007)** that fibre as a substitute for wheat flour reduces energy intake, but also the digestibility of proteins.

CONCLUSION

The aim of the study was to create formulas and subsequently to determine the effect of fibre additions on the quality of biscuits. Bamboo and hemp fibre and grape seed flour were used in the amounts of 3, 6 and 9 %. The basis of the first formula was wheat flour, while the second formula contained the spelt flour as the primary ingredient.

We performed a baking experiment, sensory evaluation, hardness measurement by TIRA test, spectrophotometric color measurement and a nutritional value was calculated.

It can be concluded from the results that the fibre as a substitution for the flour used reduces the energy intake, but also the digestibility of proteins, improves the functionality and nutritional value of the biscuits by changing their composition.

FUNCTIONAL PROPERTIES OF MUFFIN AS AFFECTED BY SUBSTITUING WHEAT FLOUR WITH CAROB POWDER

Libor Červenka, Michaela Frühbauerová, Helena Velichová

ABSTRACT

Carob (*Cerationa soliqu*a L.) pod is the good source of dietary fiber, minerals and polyphenolic substances. The aim of this study was to prepare muffin where wheat flour was substituted with carob powder, and determine some physicochemical properties. Carob powder was prepared by milling dry carob pods to particles smaller than 600 μm. Then wheat flour in muffin dough was replaced by carob powder in 5, 10, 15 and 20% (w/w) and subsequently baked at 180 °C for 20 min. It was found that the height of the muffin fortified with carob powder decreased in comparison with that in control muffin sample. Although the height of muffins decreased with the increase in level of carob powder, the differences were not statistically significant. Weight loss was similar for all the muffin samples in this study. Moisture content of muffins with carob powder was significantly higher than that in control. Addition of carob powder had also effect on water activity of muffin. While 0.905 a_w was observed in control sample, significantly higher a_w values were determinated in fortified muffins (0.912 – 0.923 a_w). The antioxidant characteristics were determinated using spectrophotometric assays for total phenolics (TPC), total flavonoids (TFC), radical scavenging activities (DPPH, ABTS) and hydrogen peroxide scavenging (HPS). TPC values gradually increased with the increase in level of carob powder from 348.1 to 829.1 μg gallic acid.g^{-1} dry matter but TFC values significantly increased in muffin with 15 and 20% (w/w) of carob powder. All the antioxidant assays showed strong and positive association with the increase in level of carob powder. Addition of carob powder resulted in the increase of browning index and FAST index as a metrics of the formation of Maillard products.

Keywords: fortification; phenolics; antioxidant; browning

INTRODUCTION

Carob powder or flour is the product of the fruit of *Ceratonia siliqua L.* Carob powder is usually prepared from mature, dried carob pod (without seed) after milling to desired particle size. Carob powder is a good source of sucrose and other simple sugars (maltose, mannose), unsaturated fatty acids and minerals such as calcium, potassium and iron **(Ayaz et al., 2009)**. High content of dietary fibre, both soluble and non-soluble, is the most important parameter, which makes the carob powder applicable in various food products such as bread **(Durazzo et al., 2014)** and cookies **(Roman et al., 2017)**. Carob powder is also used as a replacer of cocoa in cocoa and chocolate-based products decreasing the content of caffeine and theobromine but keeps the cocoa-like aroma, particularly when roasting **(Loullis and Pinakoulaki, 2018)**. In addition, carob powder is the rich source of polyphenolic substances exhibited promising pharmacological actions such as antioxidant, antibacterial, anti-inflammatory and anti-diabetic activities **(Rtibi et al., 2017)**.

In a recent work of **Pawlowska et al. (2018)**, the effect of substitution of cocoa powder for carob powder at 5% (w/w) level in muffin dough was examined. Improved antiradical activity and higher content of phytosterols have been observed in their study. However, their research was focused on substitution of cocoa powder at a single level. Replacing wheat flour for carob flour/powder may lead to both cocoa-like aroma and gluten-free products **(Roman et al., 2017; Lauková, Kohajdová and Karovičová, 2016)**.

Scientific hypothesis

Increasing content of polyphenolic substances and increasing antioxidant status of muffins prepared by partial substitution of wheat flour for carob powder are expected.

MATERIAL AND METHODOLOGY

All the solvents (methanol, ethanol and acetone) and acids (sulphuric and acetic acids) were purchased from Lach-Ner s. r. o. (Neratovice, Czechia). Folin-Ciocalteau reagent solution, gallic acid, quercetin hydrate, (+)-catechin, vanillin, aluminium chloride, 2,2-diphenyl-1-

picrylhydrazyl (DPPH), 2,2´-azino-bis-3-ethylbenzthiazoline-6-sulphonic acid (ABTS), potassium persulphate, hydrogen peroxide, ferrous ammonium sulphate, 1,10-phenanthroline and (±)-6-hydroxy-2,5,7,8-ramethylchromane-2-carboxylic acid (Trolox) were obtained from Sigma-Aldrich Chemical Co., St. Louis, MO, USA). All the chemicals were of analytical grade.

Sample preparation and baking procedure

Dry carob pods (*Ceratonia silique* L.) without seed were purchased in local supplier. Pods were milled using knife mill Grindomix GM 200 (Retsch®, Haan, Germany) to obtain powder. Particles smaller than 600 μm were separated by passing through analytical sieve and used for subsequent experiments. Carob powder was stored in evacuated plastic bag at room temperature until used.

Muffin formulation dough was adopted from the study of **Ambigaipalan and Shahidi (2015)** The control sample (without carob powder) contains 65 g of wheat flour and 37.5 g of sugar (Castello, Lidl Stiftung, Germany), 3.0 g of baking powder (Dr. Oetker, Bielefeld, Germany), 0.62 g of salt, 60.0 mL of 2.5% fat milk (Pilos, Louny, Czechia), 20.0 mL of canola oil (Promienna, Lidl Stiftung, Germany) and 1 egg (large). A portion of wheat flour was substituted for carob powder at 5, 10, 15 and 20% (w/w) levels to obtain fortified muffin. When carob powder content had been 25% and 30% (w/w), unacceptable taste was observed by three panelists. A dough was prepared by mixing all the ingredients, a batter (30 g) was transferred into muffin paper cups and baked in pre-heated oven at 180 °C for 20 min. Muffins were baked in quadruplicate, cool to room temperature and moisture content, water activity, weight and height loss were immediately determined. Thereafter, muffins were mixed and stored in evacuated plastic bag at -20 °C.

General chemical and physical analysis

Moisture content of carob powder samples and muffins was determined in moisture analyser (Kern MLB 50-3, Kern & Sohn GmbH, Balingen, Germany) at 103 °C to a constant weight. Water activity was measured at 25 °C in Aw Sprint TH 500 (Novasina AG, Lachen, Switzerland). Weight loss was calculated from the weight difference between dough and muffin using balance (sensitivity 0.001 g). Height loss was measured using digital caliper (sensitivity 0.01 mm) in three random positions. For measurement of those parameters, muffin samples were cooled down after baking for 1 h at ambient temperature.

Preparation of extracts

Aqueous-organic extracts of muffin or carob powder were prepared according to **Durazzo et al. (2014)** with slight modification. About 3 – 4 g of muffin or carob powder was placed in plastic tube with 20 mL of methanol/water (1:1, v/v). The tubes were placed in vertical shaker for 60 min followed by centrifugation at 5000 rpm for 10 min. The supernatant was removed and 20 mL of acetone/water (70:30, v/v) was added to pellet. After shaking for another 60 min, both methanolic and acetonic extracts were combined, centrifuged (5000 rpm, 5 min) and stored at -20 °C.

Determination of phenolics

Total phenolic content (TPC) was determined using Folin-Ciocalteau procedure as was provided in our previous study **(Brožková et al., 2018)**. The methanol/acetone extract (1.0 mL) was mixed with 0.5 mL of Folin-Ciocalteau reagent and 5.0 mL of distilled water followed by addition of 1.0 mL of 5% Na_2CO_3. After 60 min of incubation in a dark cabinet, the absorbance was measured at 765 nm. The same volume of distilled water was added instead of sample extract to obtain control measurement. The results were expressed as gallic acid equivalent (mg GA.g^{-1}) of dried matter (DM).

Total flavonoid content (TFC) was measured after formation of flavonoids-$AlCl_3$ complex in acetate solution followed by recording absorbance at 415 nm **(Brožková et al., 2018)**. The results were expressed as quercetin equivalent (mg QE.g^{-1} DM).

Determination of antioxidant capacity

Three various methods were used to assess antioxidant capacity of carob powder and muffin. Two assays are based on both electron and hydrogen atom transfer mechanisms involving the reaction of antioxidants with stable chromogen radical DPPH or ABTS. The procedures were adopted from our previous study **(Brožková et al., 2018)**. Briefly, 5.0 mL of DPPH methanolic solution (25 mg.L^{-1}) was mixed with 0.5 mL of methanol/acetone extract and the decrease of absorbance was observed after 35 min at 517 nm. ABTS radical cation (ABTS•+) was prepared from ABTS solution (5.0 mL, 50 mg.L^{-1}) and 100 μL of potassium persulphate (64 mmol.L^{-1}). The mixture was stored in a dark for 12 – 16 hours at laboratory temperature before use. Diluted ABTS•+ solution (3.0 mL) was mixed with 0.5 mL of methanol/acetone extract and the decrease of absorbance was recorded at 734 nm after 50 min of incubation. For both DPPH and ABTS assays, the results were expressed as Trolox equivalent antioxidant capacity (TEAC) in μg Trolox.g^{-1} DM.

Hydrogen peroxide scavenging (HPS) assay represents the method describing the effect of antioxidant against reactive oxygen species **(Mukhopadhyay et al., 2016)**. Extract (0.5 mL) was mixed with 0.25 mL of 1.0 mM ferrous ammonium sulphate and 62.5 uL of 5.0 mM H_2O_2. After 5.0 min of incubation in a dark cabinet at laboratory temperature, 1.5 mL of 1.0 mM 1,10-phenanthroline was added and subsequently incubated for 10 min. The absorbance was red at 510 nm against blank. Distilled water was added to control sample instead of extract and H_2O_2 (total volume 1.562 mL). The increase in HPS activity was reflected by the decrease of absorbance. The % of H_2O_2 scavenging ability was calculated as $(A_{test}/A_{blank}).100$, where A_{test} is the absorbance of the solution containing sample extract, ferrous ammonium sulphate, H_2O_2, 1,10-phenanthroline and A_{blank} is the absorbance of solution containing only ferrous ammonium sulphate and 1,10-phenanthroline.

Determination of Maillard products

The reaction of reducing sugars and tryptophan during roasting of carob powder and baking of muffin may result in formation of advanced Maillard products. Those

products were determinated according to the FAST (Fluorescence of Advanced Maillard products and Soluble Tryptophan) method of **Birlouez-Aragon et al. (2001)**. Briefly, sample extract was prepared by sonication (30 min) of 1.0 g of sample in 40 mL 0.1 M borate buffer solution (pH 8.2). The extract was filtered through filter paper (Whatmann no. 2) and fluorescence of advanced Maillard products (F_{amp}) was recorded at excitation and emission wavelengths of 353 nm and 438 nm, respectively. The decrease of tryptophan amount (F_{trp}) was monitored at excitation and emission wavelengths of 353 nm and 438 nm, respectively. Acryl cuvettes and fluorimeter Fluorat® 02 Panorama (Lumex Instruments, Mission, Canada) were used. FAST index was calculated as (F_{amp}/F_{trp}).100 and the results were expressed in %.

The formation of brown pigment resulted in Maillard reaction was measured in 80% of ethanol at 420 nm against distilled water according to **Krishnan et al. (2010)**. The results were expressed as browning index (BI) in absorbance unit (A_{420}). UV/VIS Spectrophotometer DU 530 (Beckman Coulter Inc., Brea, CA, USA) was used for all colorimetric measurements.

Statistic analysis

The results were expressed as the average means with standard deviations of 4 replicates (n = 4). Non-parametric statistical tests were used throughout this study. *i.e.* Tukey´s multiply comparison method was to find differences between means. Association between carob powder levels and selected variables were determined using Spearman´s correlation coefficient (*r*). Statistical treatment was performed on the probability level of p = 0.05 (Statistica CZ, StatSoft CR s. r.o., Prague, Czechia).

RESULTS AND DISCUSSION

The main composition of carob powder was as followed (in g.100g^{-1} DM): crude protein (7.37 ±0.80), crude fat (0.43 ±0.05), reducing sugar (13.12 ±0.4), crude fiber (26.30 ±0.25), ash (3.29 ±0.22) and moisture (7.20 ±2.00), similarly to those found by **Mohamed, Hamed and Al-Okbi (2008)** for carob pods. Concerning fibre content, lower amount was found in our study (~26%) in comparison with carob powder dried in microwave oven (~50%) **(Tounsi et al., 2017)**. Those differences may be attributed to the different methods, which were used for fibre determination (enzymatic or chemical) or it may be caused by the variability in processing technology and particle size of powder **(Benković et al., 2017)**. Nevertheless, the crude fibre content found in this study fits to the range of 7.6 – 38% previously presented in a review article of **Loullis and Pinakoulaki (2018)** for carob pulp composition.

Weight loss and height of muffins fortified with carob powder

The height and weight loss of the control sample was 3.57 cm and 5.69 g, respectively. The general decrease in height was presented in Table 1. As can be seen, the addition of carob powder caused the reduction of height in comparison with the control. The height of muffin fortified with carob powder significantly decreased from 3.38 to 3.03 cm (p <0.05) with the increase of carob powder level. The decrease in height may be attributed to the dilution of gluten and disruption of gluten network as was previously described by **Lauková, Kohajdová and Karovičová (2016)**, who observed the decrease in diameter and volume of biscuits enriched with apple powder. Similarly, addition of chicory syrup to muffin dough significantly reduced the loaf volume of the products **(Zacharová et al., 2018)**. Incorporating of dietary fibre into dough formulation also exhibited reduction in volume and height of muffin fortified with red capsicum pomace powder **(Nath et al., 2018)**. Although the content of crude fibre in fortified muffins was not evaluated in this study, the content of carob powder with 25% of crude fibre should not be omitted and it requires further investigation. Weight losses of fortified muffins were not statistically significant for all the carob powder samples in comparison with the control muffin sample in the present study.

Moisture content and water activity of muffins fortified with carob powder

Weight loss occurs usually due to the evaporation of water during baking and reflects the changes in moisture content. As can be seen from Table 1, moisture content of muffin samples with carob powder (except of muffin with 15% (w/w)) was significantly higher than this in control. Some authors also observed small but significant increase in moisture content of bread fortified with 10% and 20% of carob flour **(Salinas et al., 2015)**. In a study of **Karaca, Saydam and Guven (2012)**, addition of carob molasses in yogurt significantly increased water-holding capacity of samples. The addition of carob powder to muffin formulation significantly increased water activity from 0.905 (control) to 0.912 – 0.923 a_w for muffins with carob powder (Table 2). Despite those findings, a_w values still fell within the safe water activity range.

Table 1 Weight loss, height, moisture content and water activity of muffin with different levels of carob powder.

Level (%, w/w)	Height (mm ±SD)	Weight loss (g ±SD)	Moisture content (g.100 g^{-1} ±SD)	Water activity
control	3.57 ±0.1^{d}	5.69 ±0.17^{a}	30.19 ±0.84^{a}	0.905 ±0.001^{a}
5	3.38 ±0.11^{bd}	5.71 ±0.18^{a}	31.52 ±0.55^{b}	0.914 ±0.002^{b}
10	3.23 ±0.16^{c}	5.62 ±0.15^{a}	32.41 ±0.19^{b}	0.923 ±0.001^{c}
15	3.22 ±0.05^{c}	5.51 ±0.14^{a}	29.76 ±0.43^{a}	0.918 ±0.001^{b}
20	3.03 ±0.13^{c}	5.58 ±0.16^{a}	31.12 ±0.41^{b}	0.912 ±0.002^{b}

Note: Average mean ± standard deviation (n = 4); significant difference between means in column is indicated by different small letters (p <0.05).

Table 2 Antioxidant properties of muffin with different levels of carob powder.

Level (%, w/w)	TPC	TFC	$TEAC_{DPPH}$	$TEAC_{ABTS}$	HPS
control	193.2 ±18.1[a]	35.7 ±7.1[a]	ND	198.2 ±4.4[a]	5.5 ±0.4[a]
5	348.1 ±6.9[b]	49.6 ±3.3[a]	222.9 ±6.1[a]	1048.8 ±58.5[b]	19.8 ±0.3[b]
10	435.7 ±4.9[c]	49.1 ±2.0[a]	393.5 ±8.6[c]	1683.4 ±18.7[c]	30.6 ±0.2[c]
15	670.0 ±1.2[d]	73.0 ±7.8[b]	1099.5 ±23.9[e]	3137.5 ±4.9[d]	45.8 ±0.2[d]
20	829.1 ±8.8[e]	81.7 ±1.7[b]	1228.3 ±65.6[e]	3599.4 ±21.7[e]	74.6 ±0.2[e]

Note: TPC, Total phenolics content (μg gallic acid.g^{-1} DM); TFC, total flavonoids content (μg quercetin.g^{-1} DM); TEAC, Trolox equivalent antioxidant capacity (μg Trolox.g^{-1} DM); HPS hydrogen peroxide scavenging (%); significant difference between means in column is indicated by different small letters (p <0.05).

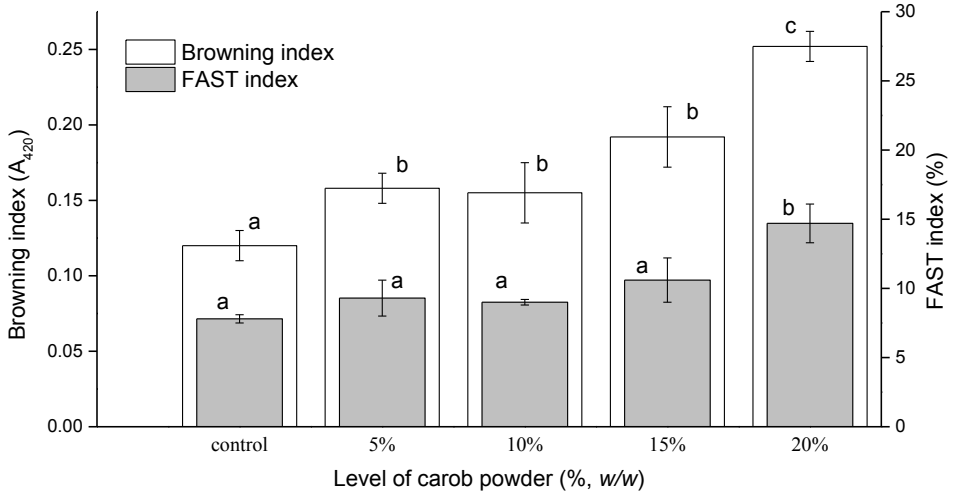

Figure 1 The effect of substitution of carob powder for wheat flour on browning index (white bars) and FAST index (gray bars) in muffin. Average mean ±standard deviation (n = 4).

Total phenolic, total flavonoid and condensed tannin contents in muffins fortified with carob powder

Total phenolic content of fortified muffins significantly increased in comparison with that in control (Table 2). While 193.2 μg GAE.g^{-1} DM was found in control sample, the substitution of wheat flour for carob powder resulted in gradual increase in TPC values from 348.1 to 829.1 μg GAE.g^{-1} DM with the increase of carob powder levels from 5% to 20% (w/w) (p <0.05). **Seczyk, Swieca and Gawlik-Dziki (2016)** also demonstrated that increase addition of carob flour to pasta resulted in the increase of total phenolic content. TFC values were significantly higher than in control (35.7 μg QE.g^{-1} DM; p <0.001) for all fortified muffins without regard of carob powder level. However, the increase in TFC values was not proportional to addition of carob powder. The addition of 5% and 10% (w/w) of carob powder led to the similar TFC values 49.6 – 49.1 μg QE.g^{-1} DM and to 73.1 – 81.7 μg QE.g^{-1} DM when 15% and 20% (w/w) of powders were added.

Antioxidant capacity of muffins fortified with carob powder

Antioxidant characteristics are presented in Table 3. While control muffin sample did not exhibit antioxidant capacity in terms of DPPH assay, the addition of carob powder at 5% (w/w) level to muffin recipe resulted in sharp increase to 222.9 μg Trolox.g^{-1} DM. Then, $TEAC_{DPPH}$ values increased with the increase in carob powder level. The highest $TEAC_{DPPH}$ values were obtained for muffin with 15% and 20% (w/w); *i.e.* 1099.5 and 1228.3 μg Trolox.g^{-1} DM (p <0.01), respectively. Antioxidant capacity measured by ABTS assay is based on similar principle as DPPH assay. Both radicals are able to accept hydrogen atoms or electrons provided by phenolic compounds in the extract. ABTS assay gave higher TEAC values than those in DPPH assay, probably due to the steric hindrance or different solubility of active substances in solutions, which were used for the preparation of stable radicals **(Apak et al, 2016)**. As can be seen from Table 3, ABTS assay always exhibited higher TEAC values at the same level of carob powder in comparison with those determined using DPPH assay (pairwise comparison test was not provided) in current study. It is known that each phenolic constituent contributes in different manner to total antioxidant capacity. We have found that rutin exhibited pro-oxidative effect during drying of buckwheat-based products **(Brožková et al., 2018)** and the same pattern was observed for quercetin, rutin or chlorogenic acid during processing of tomato paste **(Jacob et al., 2010)**. The addition of carob powder significantly increased the ability to scavenge H_2O_2 from initial 5.5% (control) to 19.8% followed by further increase with the increase of carob powder level (Table 3).

Table 3 The correlation analysis of increasing carob powder level *vs.* selected variables in muffin.

Maillard reaction products in muffins fortified with carob powder

The higher content of reducing sugars and specific amino acids in food matrix may lead to the formation of various Maillard reaction products, which can be measured, in general, at specific wavelength or determination of compounds can be provided using HPLC techniques. Since carob powder is rich in reducing sugars (fructose, glucose) and reactive amino acids such as lysin or proline **(Ayaz et al., 2009; Benkovic et al., 2017)**, the formation of Maillard reaction products should be under control. With the increase in roasting temperatures and roasting times (130 – 150 °C for 5 – 30 min), the coloured Maillard reaction products, fluorescent compounds and hydroxymethylfurfural significantly increased in carob powder as was described in a study of **Cepo et al. (2014)**. The browning and FAST indices were determined in the present study. Addition of carob powder resulted in significantly higher BI when compared with the control muffin sample (p <0.05). BI values increased with the increase of the amount of carob powder up to 0.252 (A_{420}) for muffin with 20 % of carob powder (Figure 1). Surprisingly, FAST index did not differ in muffins fortified with carob powder from that found in control muffin sample (p >0.05) except in muffin with 20% level of carob powder, where significantly higher value was found (p <0.01).

The results of correlation analysis

The correlation analysis revealed that addition of carob powder instead of wheat flour to muffin recipe in the range from 5% to 20% (w/w) did not have effect on the weight loss, moisture content and water activity (Table 3). Strong and positive correlation coefficients ranged from 0.824 to 0.974 for antioxidant properties in terms of TPC, TFC, both TEAC values and hydrogen peroxide scavenging assay were obtained. While browning index showed strong positive correlation with the increase of carob powder level (r = 0.892, p <0.001), FAST index exhibited weak but significant association with the carob powder level (r = 0.692, p <0.01). However, this association is rather statistical than practical. It was evident from multiply comparison (see Figure 1) that FAST index values were not statistically different for control sample and muffins with 5 – 15% (w/w) of carob powder.

CONCLUSION

The additions of carob powder significantly affect the height of the muffins but not weight. Significant differences in moisture content of muffin samples were observed but it was not proportional to the level of carob powder. The addition of carob powder significantly increased water acitivity of muffins in comparison with the control sample. It was found that TPC gradually increased with the increase level of carob powder while TFC significantly increased in muffins fortified with higher levels of carob powder. Antioxidant capacity has increased with the increase level of carob powder in terms of DPPH, ABTS, and hydrogen peroxide scavenging assays. On the other hand, the addition of carob powder was associated with the formation of Maillard products. Browning index was significantly higher for muffin with the lowest carob powder level than that in control sample, but FAST index was significantly higher in muffin with the highest level of carob powder.

The results of this study showed that the replacement of wheat flour with carob powder increased the antioxidant status of muffins, however the higher the level of carob powder, the higher the potential to the formation of Maillard products.

COMPARISON OF ANTIOXIDANT ACTIVITY, CONTENT OF POLYPHENOLS AND FLAVONOIDS IN LITURGICAL AND COMMON WINES

Jiří Mlček, Anna Adámková, Soňa Škrovánková, Martin Adámek, Monika Ondrášová

ABSTRACT

This article deals with the comparison of biologically active substances (antioxidant capacity, content of polyphenols and flavonoids) in samples of common and liturgical wines. For determination were chosen these varieties Pinot Noir, Red Traminer and Chardonnay. The total content of polyphenols and flavonoids were found by visible diode array spectrophotometer. For determination of total antioxidant capacity was used the DPPH test. Results of this paper did not prove a general difference between liturgical and common wines, although between individual samples a statistically significant difference was found. Furthermore, the results show considerably higher values of biologically active substances in red wines Pinot Noir against white wine Red Traminer and Chardonnay – the total antioxidant capacity was considerably in excess of values up to 30 times, the total content of polyphenols up to 50 times and the total content of flavonoids up to 50 times. From the content of biologically active substances point of view, the red wine is recommended for human health.

Keywords: altar wine; kosher wine; antioxidant activity; polyphenols; flavonoids

INTRODUCTION

Wine is a very popular beverage over the world. The traditional production of wine is already known several thousands of years. For example, the ancient Romans knew wine and popularised wine consumption for its health benefits **(Lukacs, 2012)**. Since time immemorial, wine is also used at various religious ceremonials to pay tribute to gods at rituals of corresponding church. In Christian religion wine symbolizes Jesus Christ blood **(Bible, 1991)**. The production of altar wine using as „blood of the Lord" at Eucharist is followed the rules, that are set down by Czech Bishop Conference for the Czech Republic **(Koudelka, 2010)**. According to instructions of **Congregation for Worship and the Discipline of the Sacraments (2004)** the altar wine must be natural from grapevine, without other additives and chemically treated. First of all, Czech Bishop Conference requires that wine was made only from grapes coming from Bohemia and Moravia. It is possible to give another rule, that used grapes must have 20 degrees of sugar content at least **(Koudelka, 2010)**.

Not only in Christianity, but also in other religions the liturgical wine, which is used for religious purposes, must meet the requirements of relevant religion and must be approved by a relevant religious authority. For example, at Jewish religious ceremonies wine is used much more than in Christian religion and rules for its production are more stringent. In Jewish religion Tóra looks at wine and bread as at „good things of life" and „things for pleasure of gods and people" **(Torah, 2012a,b,c; Divecký, 2005; Bondyová and Sliva, 2008)**. Wine is divided into several groups **(Mlček et al., 2018)**. Apart from boiled wine, non-Jew cannot touch kosher wine or open it due to the maintenance of kosher quality. Strict rules, that are apply to the manipulation with wine, are valid even for its growing and processing. For example, according to the commandment in the third book of Moses it is necessary to let a vineyard fallow and rest every seventh year (sabbatical year).

The wine grape is a basis for the production of grape wine. During processing of wine, the large amount of substances convenient for human health arise or get directly into final beverage from grapes. That is why wine is a significant source of biologically active substances such as antioxidants, polyphenols, flavonoids or mineral substances **(Mlček et al., 2018)**. The content of biologically active substances in grapes and wine depends on the variety of wine, locality, climate conditions, used agrotechnology and technology of processing and storage. Important biologically active substances are antioxidants, which prevent or reduce the oxidative destruction of substances, in which are contained in small amount. The substances with high antioxidant capacity have especially plant origin. Wine is the rich source of substances with antioxidant capacity, that can prevent damaging of DNA, peroxidation of lipids and formation of free radicals. So, it can be one of prophylaxis instruments before lifestyle diseases, especially cardiovascular **(Anastasiadi et al., 2010; Snopek et al., 2018b)**. Another biologically active substances in wine are

polyphenols, that arise as secondary metabolites. They have an important role in reducing the risk of cardiovascular diseases similarly to antioxidants **(Snopek et al., 2018a)**. Flavonoids are classified to group of polyphenols according to type of reaction. They are very reactive and affect the wine oxidation. In case of gentle processing of grapes and of careful pressing the polyphenols content ranges under 200 $mg.L^{-1}$ in white wine. In red wine the polyphenols content is 3 – 10 times higher. The total daily intake of polyphenols is estimated at 1 g **(Pavloušek, 2010)**. Due to positive effects of biologically active substances in wine on human health it is necessary to observe their content **(Valášek et al., 2014)**. Due to stricter conditions at the production of liturgical wine it can come about the variability of these biologically active substances content and difference from common wines.

Scientific hypothesis

Scientific hypothesis is: The total antioxidant capacity and the content of polyphenols and flavonoids in Czech liturgical and common wines are differed.

The aim of the study was a comparison of the antioxidant capacity and the content of polyphenols and flavonoid in Czech liturgical and common wines. Wine samples were selected with respect to their comparability of vintage, subregion and attribute.

MATERIAL AND METHODOLOGY

Wine samples

For analysis of total antioxidant capacity and the total content of polyphenols and flavonoids in sacramental wines were selected wines Pinot Noir and Red Traminer, Chardonnay was used for comparison in kosher wines. For each variety, 2 samples of common wine and 2 samples of liturgical wine were tested. Samples were chosen to ensure the highest comparability possible (vintage, sub-area and attribute), but different producers. Due to the difficulty of acquiring the comparable samples, their gathering took 15 months.

Samples were bought gradually in the common market, specialized wine shops and directly from the producers. Two bottles of each wine were bought and analysed. The samples in Table 1 were tested.

Table 1 Wine origin and category.

Sample	Category	Vintage	Sub-area, village, track	Quality
			Pinot Noir

Total antioxidant capacity assay

To determine total antioxidant capacity (TAC) DPPH (1,1- diphenyl -2 picrylhydrazyl) assay was used according to the study by **Brand-Williams et al. (1995)**. The stock solution was prepared by dissolving 24 mg of DPPH with 100 mL of methanol and then stored at -20 °C until needed. The absorbance of DPPH radical without wine was measured daily. The sample solution was obtained by mixing 10 mL of the stock solution with 45 mL of methanol to obtain the absorbance of 1.1 ±0.02 units at 515 nm using the spectrophotometer LIBRA S6 (Biochrom, Cambridge, UK). The wine (210 µL) was allowed to react with 4 mL DPPH solution for 1 hour in the dark. Then, the absorbance was taken at 515 nm. Antioxidant capacity was calculated as a decrease of the absorbance value using the formula:

Antioxidant capacity (%) = (A0 - Ai/A0) x 100%, where A0 is the absorbance of a blank (without the sample) and Ai is the absorbance of the mixture containing the sample. Calculated antioxidant capacity was converted using a calibration curve of the standard and expressed in ascorbic acid equivalents (AAE) **(Rupasinghe, Jayasankar and Lay, 2006)**.

Total phenolic content assay

To measure total phenolic content (TPC) Folin-Ciocalteau reagent was used. 0.1 mL of wine was taken and mixed with water in a 50 mL volumetric flask. There-after, 0.5 mL of Folin-Ciocalteau reagent and 1.5 mL of 20% solution of Na_2CO_3 were added. The resulting absorbance was measured by LIBRA S6 spectrophotometer (Biochrom, Cambridge, UK) at the wavelength of 765 nm. Water was used as reference **(Thaipong et al., 2006)**. The results were expressed as grams of gallic acid (GAE) per kg of fresh mass (FM).

Total flavonoid content assay

Total flavonoid content (TFC) was determined by using 0.85 mL of juice mixed with 8.5 mL of 30% ethanol, 0.375 mL of $NaNO_2$ (c = 0.5 mol.dm^{-3}) and 0.375 mL of $AlC1_3.6H_20$ (c = 0.3 mol.dm^{-3}) as is described by **Park et al. (2008)**. The mixture was measured at the wavelength of 506 nm by LIBRA S6 spectrophotometer (Biochrom, Cambridge, UK). Total flavonoid content was calculated from a calibration curve by using rutin as the standard. The results were expressed in mg.kg^{-1} of FM.

Statistic analysis

The data were analysed using Excel 2013 (Microsoft Corporation, USA) and STATISTICA Cz version 12 (StatSoft, USA). Results were expressed by average ± standard deviation. Comparison of the results was performed using by Kruskal-Walllis test (α = 0.05). The samples of individual varieties were compared to each other. Furthermore, all samples of individual varieties of liturgical wines were compared against common wines.

RESULTS AND DISCUSSION

Total Antioxidant Capacity

In the study basic biologically active substances were determined in wine of these varieties – Pinot Noir, Red Traminer and Chardonnay. The basic measured results of the total antioxidant capacity, the content of polyphenols and flavonoids are given in Table 2.

The highest values of total antioxidant capacity were determined for variety Pinot Noir and these ones significantly exceed values of another observed varieties (up to 30x between sample RM1 a TR1). For variety Pinot Noir average values were measured over 2600 mg.L^{-1} AAE for every sample, while for another two varieties Red Traminer and Chardonnay were found below 900 mg.L^{-1} AAE. This finding confirms the fact, that antioxidant capacity is much higher for red wines than for white wines. This is due to the fact that in red wines substances with antioxidant capacity, for example phenolic substances, are in a significantly higher amount. In these more general facts results are in accordance with **Rupasinghe and Clegg (2007)** and **Szajdek and Borowska (2008)**. **Špakovská (2012)** in her study presents the higher antioxidant activity in red wines than in white wines. Average values were measured for each sample for variety Pinot Noir.

Results, presented in Table 2, were used for a comparison between each sample for given wine variety. Results of the comparison of total antioxidant capacity are shown in Table 3. Even though between many compared samples the statistically significant difference (p <0.05) was found out for each variety, the difference between liturgical and common wines was not generally proven. For example, for variety Pinot Noir the statistically significant differences were calculated for all samples.

However, total antioxidant capacity in common and altar wine is in the same range of values (Table 2) so the statistically significant difference between these varieties of wine was not confirmed.

Total Phenolic Content

Similarly, to total antioxidant capacity, the values of polyphenolic substances are significantly higher than for other observed varieties. For varieties Pinot Noir the total phenolic content was above 6300 mg.L^{-1} and for varieties Red Traminer and Chardonnay, average values of total phenolic content were set to 500 mg.L^{-1}. Statistical results of comparison for the total content of polyphenols are shown in Table 4. Again, the statistically significant difference (p <0.05) was found between many samples of each variety, but the difference between liturgical and common wines was not generally proven.

The phenolic substances are mainly contained in a grape peel. White wines are not macerated with peels in the production process, but peels are immediately removed and for this reason white wines contain fewer phenolic substances. In this aspect, the results are consistent with **Rupasinghe and Clegg (2007)** and **Faitova et al. (2004)**. **Špakovská (2012)** presents the content of polyphenols in the range of 299 to 407 mg.L^{-1} for white wines and for red wines in the range of 2130 to 650 mg.L^{-1}, which is consistent with our measured values.

Jančářová et al. (2013) states that the total polyphenol content is gradually decreasing with increasing time. Similarly, **Andjelkovic, Radovanović and Radovanović (2013)** also states, that the total polyphenol content grows during maturation and then decreases, ranging from 74.04 to 315.45 mg GAE.g^{-1}. The result of the above studies is finding, that the total polyphenol content varies with time.

Due to the method of agrotechnical processing of altar wines, which should have the sugar content 20 °NM and more, later harvesting is supposed. Harvest time may be affected by the amount of polyphenols, their content can be lower.

On the other hand, the content of fragrances can increase, and organoleptic properties can improve.

Total flavonoid content

The last observed group of biologically active substances was group of flavonoids and their total content. Similarly,

to the two previous observed parameters, values of total flavonoid content for variety Pinot Noir were significantly higher compared to other varieties.

For variety Pinot Noir the content of flavonoids ranged above 5200 mg.L^{-1}, but for varieties Red Traminer and Chardonnay values were measured below 1000 mg.L^{-1}. Comparison between each sample for observed varieties is given in Table 5. However, one can conclude here (to take account of total values), that the statistically significant difference between liturgical and altar wines cannot be established, but the difference between the individual samples can be established.

As stated by **Rupasinghe and Clegg (2007)**, the nature and concentration of flavonoids in wine samples could influence both the wine variety and damaged grapes during harvest and the differences in processing methods. **Sandler and Pinder (2003)** states, that flavonoid content in red wines can exceed 1200 mg.L^{-1}. This reality is in line with our obtained results. In case of white wines, the content of flavonoids is up to several times lower due to their technological processing.

CONCLUSION

This study deals with the content of biologically active substances in samples of liturgical and common wines and their comparison, which did not show the difference between liturgical and common wines, although the statistically significant difference between the individual samples was found. The total content of polyphenols and flavonoids and the total antioxidant capacity of samples were measured. The biologically active substances are important for the impact on human health. Results documented significantly higher values of biologically active substances in red wine for variety Pinot Noir against white wines for varieties Red Traminer and Chardonnay. The article also mentions the fact, that the content of individual biologically active substances changes and it is necessary to balance these quantities according to the requirements of the producer and the customer.

CHICKEN SKIN GELATINE AS AN ALTERNATIVE TO PORK AND BEEF GELATINES

Petr Mrázek, Pavel Mokrejš, Robert Gál, Jana Orsavová

ABSTRACT

Poultry meat-processing industry produces considerably large amounts of by-products (such as chicken skins, heads, feathers, viscera, bones and legs) containing significant volumes of proteins, particularly collagen. One of the possibilities of advantageous utilization of these under-used by-products can be their application as a raw material rich in collagen for preparation of gelatine, a partial hydrolysate of collagen. In the present study, chicken skins obtained as a by-product from the chicken-breast processing were purified from non-collagen proteins, pigments and fats. Collagen was treated with proteolytic enzymes and the gelatine extraction was performed in distilled water at temperatures of 40, 50, 60, 70 and 80 °C during the constant extraction time of 60 min. The influence of the technological conditions on gelatine functional properties including viscosity, clarity, water holding and fat binding capacity, emulsifying and foaming properties was explored. Certain functional properties of prepared gelatines were significantly affected by the extraction temperature, while on some other properties the extraction temperature had no significant effect. Viscosity of prepared chicken skin gelatines was in the range from 3 to 5.7 $mPa.s^{-1}$, clarity from 1.5 to 2%, water holding capacity from 3.8 to 5.6 $mL.g^{-1}$, fat binding capacity from 0.9 to 1.3 $mL.g^{-1}$, emulsion capacity from 35 to 50%, emulsion stability from 73 to 88%, foaming capacity from 18 to 61% and finally foaming stability was from 4 to 39%. Chicken skin gelatines were compared with commercial food grade pork and beef gelatines. Prepared chicken skin gelatines showed better viscosity, fat binding capacity and foaming stability than mammalian gelatines, while water holding capacity, emulsifying stability and foaming capacity were not as good as in beef and pork gelatines. Emulsifying capacity was comparable with commercial gelatines. Therefore, chicken skin gelatine has the potential as an alternative to traditional gelatines from mammalian sources, such as pork or beef bones and skins.

Keywords: chicken skin; collagen; food grade gelatine; functional properties; poultry by-products

INTRODUCTION

Extensive manufacture of poultry meat produces large amounts of by-products such as viscera, feet, heads, bones, blood, feathers or skins **(Zhu et al., 2010)**. These by-products are normally composted or used for the production of livestock feed. Unfortunately, a common practise in some developing countries is unfortunately to landfill or incinerate them. On the other hand, in some countries poultry by-products, such as heads, paws and stomachs, are cooked, fried and consumed as traditional meals **(Toldra, Mora and Reig, 2016)**. Poultry by-products are rich in proteins, enzymes and lipids **(Ockerman and Hansen, 2000; Raju, Rose and Rao, 1997)** and thus possess nutritional and economic potential **(Salminen and Rintala, 2002)**.

Traditional sources of collagen for the production of gelatines are skins, connective tissues and bones from beef or pork origin **(Morrison et al., 1999)**. Gelatine gained from pig skin accounts 46% of the production, from beef skin 29%, from bones 23% and 2% accounts gelatine made from other sources **(Ahmad and Benjakul, 2011)**. Pork gelatine is prohibited to use in Kosher and Halal foods, whereas beef gelatine cannot be consumed by Hindus **(Kaewruang et al., 2013)**. That is why, alternative sources of collagen, such as fish bones, skins and scales, are becoming more important. Another alternative source can also be poultry by-products including chicken, turkey or duck skin. It is estimated that chicken skins represents about 15% of live weight of the animal **(Sheu and Chen, 2002)**. Thus, chicken skins should be considered as by-products with significant economic potentional. One of the further options of the application of chicken skins, by-products from the conversion of chicken meat to chicken breast, is to use it as a raw material for gelatine extraction.

Gelatine is a partial hydrolysate of collagen with a wide range of potential functions based on its specific structure

(Norziah et al., 2009). This unique biopolymer supply elasticity, viscosity and stability in foods **(Zhou, Mulvaney and Regenstein, 2006)**. Gelatine gel has the ability of "melt in the mouth" which gelatinous agents of plant origin, such as starch, alginate, pectin, agar and carrageenan lack **(Bazawine and He, 2003)**. If the concentration of gelatine solution is suitable for network forming, transition from sol to gel occurrs **(Kaur et al., 2002)**. Gelatine is, due to its unique properties, used as a food ingredient in various types of products to modify e.g. elasticity, slicability and cohesion, (for example in desserts, lunch meats, aspics, marshmallows, ice creams, coating, puddings, sauces, yogurts), in the biomedical field (e.g. wound dressing and three-dimensional tissue regeneration products) or in numerous non-food applications (e.g. photography, paper manufacture, matches, coating, sizing) **(Chatterjee and Bohidar, 2005; GMIA, 2012; Petrášová et al., 2016)**. Gelatine also finds its application in the pharmaceutical industry in the production of soft and hard capsules **(Karim and Bhat, 2008)**. The global consumption of gelatine in 2011 was 348,000 tons and in 2018 it was expected to be as much as 450,000 tons **(Sheela, 2014)**.

Gelatine quality is determined mainly by gelatine gel strength expressed in the Bloom value **(Binsi et al., 2009)**. Further functional characteristics of gelatine including viscosity, clarity, water holding and fat binding capacity, emulsifying and foaming properties are also important, mainly in the food industry.

Viscosity of gelatine and other protein solutions depends on internal characteristics, such as molecular weight, amino acid content or surface charge **(Masuelli, 2011)**. Several studies devoted to viscosity of gelatine solutions have been published recently. **Masuelli and Sansone (2012)** studied intrinsic viscosity of gelatine. **Qiao et al. (2013)** determined viscosity of gelatine in solutions of monovalent and divalent salts.

Clarity of gelatine gel may be a significant feature in products which are required to be transparent **(Bower et al., 2006)**. It is an important organoleptic property and determines mainly acceptability of final products **(Zarai et al., 2012)**. Clarity is the opposite of turbidity. Turbidity is influenced by inorganic, protein and mucosubstance contaminants which remain in gelatine unless they have been completely removed during the gelatine preparation.

Water holding capacity (WHC) is the elemental gelatine characteristic and desirable property in food products including sausages, custards and dough because it is supposed to draw water without dissolving proteins and thus attaining products thickening and viscosity. The ability of gelatine to bind water is one of the most significant properties, which is benefitial in numerous food applications. WHC is an important feature for reducing water losses and juiciness of frozen fish or meat products while they are being cooked **(Rawdkuen, Thitipramote and Benjakul, 2013)**. Better WHC may be connected with a higher quantity of hydrophilic groups and affected by many factors, such as a protein concentration and ionic strength **(Kinsella, 1976; Li, Jia and Yao, 2009; Ninan, Joseph and Aliyamveettil, 2014)**. Higher WHC is also related with desired rheological and textural characteristics and reduction in dehydration during the storage **(Simões et al., 2014)**.

Fat binding capacity (FBC) is required property in minced meat formulations helping retain flavour and palatability and prolong the shelf life of baked goods, soups and meat products **(Rawdkuen, Thitipramote and Benjakul, 2013)**. FBC is a significant functional property specifically important in the production of meat and confectionary products **(Souissi et al., 2007)** as it determines the ability of collagen to bind fat through non-polar chains of macromolecules **(Bhaskaracharya, Kentish and Ashokkumar, 2009)**. FBC of proteins is related to hydrophobicity of the surface and to the level of exposure of hydrophobic residues inside gelatine molecule. It may be influenced by various factors, such as a type of protein and degree of hydrolysis **(George, Joseph and Zynudheen, 2010; Kristinsson and Rasco, 2000)**.

Emulsifying capacity (EC) and emulsifying stability (ES) of gelatine are especially utilized in the cosmetic industry during the preparation of ointments and creams. **Kinsella (1976)** defined EC of gelatine as the volume of oil that can be emulsified by gelatine and hydrolysates. Gelatines and hydrolysates are surface active substances and encourage to form oil-in-water emulsions since they are soluble in water and have functional groups both hydrophilic and hydrophobic **(Wilding, Lilliford and Regenstein, 1984)**. It is generally presumed that emulsifying properties of gelatines/hydrolysates are probably affected by difference in their peptide composition, molecular size and lipophilic–hydrophilic arrangement **(Li, Jia and Yao, 2009)**. Gelatines with high gelatine gel strength improves emulsifying properties if they are added to final products **(Gómez-Guillén et al., 2011)**.

The capability of forming stable gelatine foam is crucial in the preparation of confectionery products including marshmallows or other whipped products. This may be explained by probable presence of a large molecules of peptides in chicken skin collagen which can form stable films around gas bubbles **(Souissi et al., 2007)**. In order to create a stable foam on water-air interface, molecules must contain hydrophobic regions that appear during the unfolding of proteins **(Gómez-Guillén et al., 2011)**. Foaming properites of gelatine may be important in the bakery industry as they help to stabilize foaming products, such as pies, breads and cakes **(Djagny, Wang and Xu, 2001)**.

The aims of this study

This paper continues in the previous research of authors focusing on designing of the proper technological conditions for the chicken skin gelatine preparation, testing the effects of the extraction temperature on gelatine gel strength.

The aims of this paper are as follows:

1. Preparation of chicken skin gelatines at different extraction temperatures according to the method described in the previous work **Mrázek et al. (2019 – in press)**.
2. Testing of functional properties of chicken skin gelatines in relation to food applications: viscosity, clarity, water holding and fat binding capacity, emulsifying capacity and stability and foaming capacity and stability.

3. Comparison of functional properties of gelatine prepared from chicken skin with commercial food grade pork and beef gelatines.
4. Evaluation of extraction conditions affecting the functional properties of prepared gelatines.

Scientific hypotheses

There were presumptions that technological conditions during the extraction of gelatines (e.g. temperature) affect the functional properties of prepared gelatines and that functional properties of chicken skin gelatines will be comparable with functional properties pork and beef gelatines.

MATERIAL AND METHODOLOGY

Appliances, tools and chemicals

Stevens LFRA Texture Analyser for measuring gelatine gel strength (Leonard Farnell and Co ltd., England), SPAR Mixer SP-100AD-B meat grinder (TH Industry RD, Taiwan), Rotina 35 centrifuge (Hettich, Germany), IKA T 25 digital Ultra-Turray desintegrator (IKA-Werke, Germany), Memmert ULP 400 drying device (Memmert GmbH+Co. KG, Germany), LT 43 shaker (Nedform, Czech Republic), Kern 440-47 electronic scale, Kern 770 electronic analytical balance (Kern, Germany), A 10 labortechnik analytical mill (IKA-Werke, Germany), ULP 400 drying oven (Memmert GmbH+Co. KG, Germany), Samsung fridge-freezer (Samsung, South Korea), Thermo Haake C 10 thermometer (Thermo Fisher Scientific, USA), Helios Epsilon spectrophotometer (Thermo Fisher Scientific, USA), Whatman No. 1 paper (Sigma Aldrich, UK), a metal filter sieve with the size of pores 1 and 2 mm (Labor-komplet, Czech Republic). Chemicals: NaCl, NaOH, petroleum ether, ethanol and chloroform (Verkon, Czech Republic); all chemicals were of analytical grade. Proteolytic enzyme Polarzyme 6.0 T-serine endoprotease manufactured by fermentation of microorganisms that are not present in the final product (Novozymes, Denmark) with declared enzyme activity of 6 KPU.g^{-1} (kilo protease unit.g^{-1}). Commercial gelatines, pork DO12119 260 Bloom (type A) and beef D529 260 Bloom (type B) of the grain size of 2 mm. Virgin sunflower oil (Via Naturae, Czech Republic).

Preparation of chicken skin gelatines

Chicken skins were purchased from Raciola (Uherský Brod, Czech Republic). The composition of chicken skins was as follows: dry matter: 53.6 ±1.5%; in dry matter: proteins: 16.5 ±1.3, collagen: 92.6 ±0.1, fats: 85.0 ±2.4, inorganic solids: 0.9 ±0.3 **(Davídek et al., 1981; ISO 3496-1994)**. The raw material was processed into gelatines according to the method described in **Mrázek et al. (2019 – in press**). The raw material was ground to the size of particles of 3 mm and separation of non-collagen parts was performed using 1 M NaCl and 0.5% NaOH. After filtration and rinsing with water, raw material was dried at 35 °C. Separation of fats was performed using the mixture of solvents of petroleum ether and ethanol at the ratio of 1:1 (w/w). The filtration process was followed by proteolytic enzyme pre-treatment using 0.5% Polarzyme 6.0T in distilled water at pH 7.5. After filtration and rinsing with water, 5 experiments of gelatine extraction were realized in distilled water at 40, 50, 60, 70 and 80 ±0.5 °C for 60 min. After filtration of gelatine solution using Whatman no.1 paper (Sigma Aldrich, UK) and drying it in a thin layer at 45 °C ±0.3 °C. Gelatine powder was prepared by grinding of the gelatine film to the size of particles of 1 – 2 mm using A 10 labortechnik analytical mill (IKA-Werke, Germany). Samples of gelatines were then subjected to further analysis.

Testing of functional properties of gelatines

Prepared gelatine samples were analysed in order to compare the functional properties of gelatines produced under different extraction temperatures. Results were compared with the analyses of two types of commercial food grade gelatines (pork and beef).

Viscosity

Viscosity of gelatine solution was measured according to the method described at **GMIA (2013)**. 6.67% gelatine solution was prepared as follows: 7.5 g of gelatine was mixed with 105 mL of distilled water and maintained at room temperature for 2 h in order to swell. The sample was afterwards dissolved in 65 °C water bath for not more than 10 min. Gelatine solution was transferred to the viscosity pipette placed inside thermometer Thermo Haake C 10 (Thermo Fisher Scientific, USA). The temperature of 60.00 ±0.05 °C was maintained. Time required for 100 mL of gelatine solution to pass through the capillary tube of the pipette by draining gelatine solution was measured. Viscosity of gelatine sample was calculated from the following equation:

$$\nu = k \cdot t - \frac{B}{t}$$

ν – kinematic viscosity [mm^2.s^{-1}]
k – the viscosity constant detected by calibration fluid (0.5)
t – arithmetic mean of measured flow times [s]
B – correction constant for kinetic energy determined from dimensions of the viscometer (2.8)

Kinematic viscosity was converted to dynamic viscosity according to the following equation:

$$\eta = \nu \cdot \rho$$

η – dynamic viscosity [mPa.s]
ρ – gelatin solution density [g.cm^{-3}]

Density of gelatine was 1.003 g.cm^{-3} ±0.005 and it was determined by pycnometric method.

Clarity

Clarity of gelatine solution was determined according to the method described at **GMIA (2013)**. The same gelatine solution as for viscosity measurement was used. It was heated at the temperature of 45 °C in water bath and transmittance value at λ = 640 nm using Helios Epsilon spectrophotometer (Thermo Fisher Scientific, USA) was recorded.

Water holding capacity

Water holding capacity (WHC) was determined in conformity with the method described by **Nasrin, Noomhorm and Anal (2015)**. Gelatine sample (1 g) was weighed and dispersed in 25 mL of distilled water in test tube by vortexing for 5 min at room temperature. After that, it was centrifuged using Rotina 35 centrifuge (Hettich, Germany) at 3,000 rpm for 30 min. Supernatant was filtered with Whatman no. 1 paper and the sample was then weighed again.

Water holding capacity was calculated using a formula:

$$WHC = \frac{w_1}{w_0}$$

WHC – water holding capacity [mL.g^{-1}]
w_1 – weight of sample after analysis [g]
w_0 – weight of sample before analysis [g]

Fat binding capacity

Fat binding capacity (FBC) was determined according to the method by **Li, Jia and Yao (2009)**. Gelatine sample (0.1 g) was weighed and dispersed in 10 mL sunflower oil in test tubes and properly mixed by vortexing for 1 min and allow to stand for 30 min at room temperature. Afterwards, gelatine was dispersed in oil and centrifuged at 3,000 rpm for 30 min. Free oil was decanted and FBC was calculated using the following formula:

$$FBC = \frac{w_1}{w_0}$$

FBC – water holding capacity [mL.g^{-1}]
w_1 – weight of sample after analysis [g]
w_0 – weight of sample before analysis [g]

Emulsifying properties

Emulsifying capacity and stability were determined according to the method by **Neto et al. (2001)**. 5 mL of gelatine solution (prepared by heating at 45 °C) at concentration of 10 mg.mL^{-1} was homogenized with 5 mL of sunflower oil for 1 min. Thereafter, the mixture of gelatine and oil was centrifuged at 1,100 rpm for 5 min. Emulsifying capacity was determined using the following formula:

$$EC = \frac{H_1}{H_0} \cdot 100$$

EC – emulsifying capacity [%]
H_1 – height of emulsion layer [mm]
H_0 – height of the total content [mm]

After that the emulsion of fat and gelatine was heated in 55 °C water bath followed by centrifugation at 1,100 rpm for 5 min. Emulsifying stability was calculated using the formula:

$$ES = \frac{H_1}{H_0} \cdot 100$$

ES – emulsifying stability [%]
H_1 – height of emulsion layer after heating [mm]
H_0 – height of emulsion layer before heating [mm]

Foaming properties

Foaming capacity and foaming stability were determined according to the method by **Sathe, Deshpande and Salunkhe (1982)**. 0.6 g of gelatine and 30 mL distilled water was mixed and heated at 60 °C. Foam was prepared by homogenization at 10,000 rpm for 5 min using IKA T 25 Digital Ultra-Turray desintegrator (IKA-Werke, Germany).

Foamed gelatine solution was poured into 250 mL measuring cylinder and foaming capacity was calculated using the formula:

$$FC = \frac{V_1 - V_0}{V_0} \cdot 100$$

FC – foaming capacity [%]
V_1 – volume of foamed liquid [mL]
V_0 – initial volume of liquid [mL]

Thereafter foaming stability was determined. The principle was based on measuring the volume of foamed gelatine solution after 30 min; foaming stability was calculated according to the following formula:

$$FS = \frac{V_2 - V_0}{V_0} \cdot 100$$

FS – foaming stability [%]
V_2 – volume of foamed liquid after 30 min
V_0 – initial volume of liquid [mL]

Statistical analysis

All analyses were performed in triplicate; linear regression, 1-sample and 2-sample t-test testing on the significance level of p 0.05 were applied to all results using Minitab 18 statistical software for Windows (Minitab 213 Inc., USA).

RESULTS AND DISCUSSION

Testing of functional properties of chicken skin gelatines

Tables 1 and 2 show obtained values of viscosity, clarity, water holding capacity (WHC), fat binding capacity (FBC) emulsifying capacity (EC), stability (ES), foaming capacity (FC) and stability (FS) of gelatines prepared at different extraction temperatures.

Viscosity

The relationship between viscosity and extraction temperature is not statistically significant ($p>0.05$). Viscosity moderately decline with an increasing extraction temperature as can be seen in Figure 1. It plummet from 50 °C to 60 °C. At 60 °C the values reached the minimum.

Table 1 Viscosity, clarity, water holding capacity (WHC) and fat binding capacity (FBC) of prepared chicken skin gelatines at different extraction temperatures. CSG – chicken skin gelatines.

CSG (°C)	Viscosity (mPa.s ±SD)	Clarity (% ±SD)	WHC ($mL.g^{-1}$ ±SD)	FBC ($mL.g^{-1}$ ±SD)
40	5.2 ±1.51	1.51 ±0.51	3.85 ±0.30	0.97 ±0.20
50	4.4 ±1.87	1.95 ±0.75	3.99 ±0.15	1.15 ±0.25
60	2.7 ±0.14	1.45 ±0.35	4.59 ±0.19	1.26 ±0.22
70	3.0 ±0.15	1.61 ±0.31	5.00 ±0.19	1.06 ±0.07

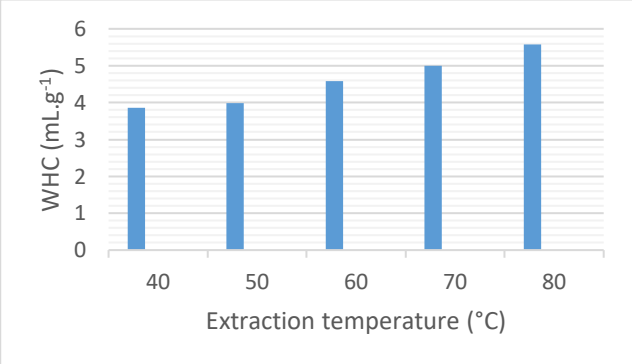

Figure 3 Water holding capacity (WHC) of chicken skin gelatines prepared at different extraction temperatures.

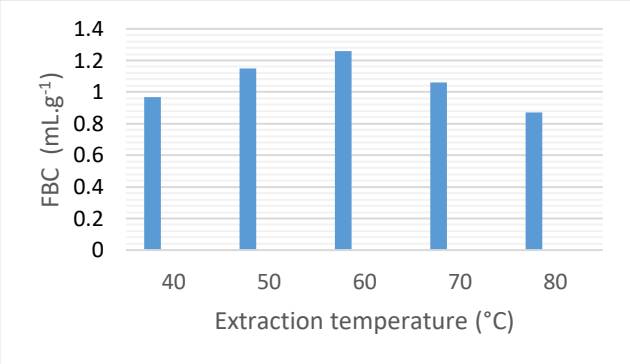

Figure 4 Fat binding capacity (FBC) of chicken skin gelatines prepared at different extraction temperatures.

An upward trend is observed between the extraction temperatures of 60 °C and 70 °C. However, at 80 °C viscosity soar slightly above the level registered at 40 °C. Viscosity of gelatine solutions is the highest at the extraction temperature of 80 °C and lowest at 60 °C. This may be explained by the fact that at the temperature of 60 °C the level of hydrolysis is the highest and collagen chains have the lowest molecular mass resulting in lower viscosity. This assumption was proved by the highest

gelatine yield recorded at this extraction temperature in the previous study **Mrázek et al. (2019 – in press)**.

Ninan, Joseph and Aliyamveettil (2014) anounced viscosity of grass carp skin gelatine of 7.07 mPa.s. **Rafieian, Keramat and Kadivar (2011)** reported viscosity of chicken gelatine from deboner of 5.85 mPa.s. **Bichukale et al. (2018)** stated that viscosity of poultry skin and bone ranged from 3.83 to 9.10 mPa.s. Therefore, viscosity of prepared chicken skin gelatines is comparable with data obtained in other studies.

Clarity

No significant influence of the extraction temperature on clarity has been observed (p >0.05). As depicted in Figure 2, clarity values is in a range from 1.5 to 1.9% which represents very low level of clarity. This may be attributed to residual impurities in gelatine. **Mad-Ali et al. (2017)** reported turbidity of gelatine solution from 1.8 to 2% depending on drying method.

Water holding capacity (WHC)

The effect of extraction temperature on WHC is statistically significant (p <0.05). WHC increases almost linearly with an increasing extraction temperature as Figure 3 depicts (R^2=97.23). WHC of gelatine has been extensively examined during the last few years. **Omar and Sarbon (2016)** studied the effect of drying method on functional properties and antioxidant activities of chicken skin gelatine hydrolysate and recorded WHC values from 8.4 mL (vacuum oven dried) to 63.7 mL.g^{-1} (freeze dried) depending on drying method and pH of gelatine. **Dhakal et al. (2018)** investigated optimal conditions of collagen extraction from chicken feet by papain hydrolysis and synthesis of chicken feet collagen based biopolymeric fibres and determined WHC of 1.9 mL.g^{-1}. **Surangna and Anal (2016)** discussed the optimization of extraction of functional protein hydrolysates from chicken egg shell membrane (ESM) by ultrasonic assisted extraction (UAE) and enzymatic hydrolysis and reported values of WHC varying from 1.9 to 2.9 mL.g^{-1} depending on the type of pre-treatment. Therefore, prepared gelatines analysed in this study are similar to these results.

Fat binding capacity

The relationship between FBC and extraction temperature is not statistically significant (p >0.05). As can be seen in Figure 4, FBC rises with an increasing extraction temperature until reaches the peak at 60 °C; then it decreases to a slightly lower value than it was observed at 40 °C. This may stem from the fact that at the extraction temperature of 60 °C the rate of hydrolysis is the highest resulting in more hydrophobic residues exposed for bonding with fat molecules. Several studies have been proceeded in order to determine FBC of gelatine. **Li, Jia and Yao (2009)** examined amino acid composition and functional properties of collagen polypeptide from Yak (Bos grunniens) bone and reported FBC of only 0.21 to 0.29 mL.g^{-1}. **Surangna and Anal (2016)** determined FBC from 2.5 to 4.4 mL.g^{-1} and **Dhakal et al. (2018)** reported FBC of 5.3 mL.g^{-1} which is in accordance with the results of this study.

Emulsifying capacity and stability (EC and ES)

The influence of extraction temperature on EC is statistically significant (p <0.05). Figure 5 shows that there is a decrease of EC between the extraction temperatures of 40 °C and 60 °C. However, EC remains nearly steady from 60 °C to 80 °C. This trend may be caused by changes in gelatine structure affected by the temperature rise.

The mean of ES were significantly higher than the mean of EC (p <0.001). ES soars between the extraction temperatures of 40 °C and 50 °C and fluctuate from 50 °C to 80 °C. The highest emulsifying capacity and stability was recorded at the extraction temperatures of 40 °C and 50 °C, respectively. Several studies have been conducted to determine emulsifying properties. **Li, Jia and Yao (2009)** studied amino acid composition and functional properties of collagen polypeptide from Yak (*Bos grunniens*) bone and stated EC of yak bone collagen of 57.3% which is slightly higher than EC of chicken skin gelatine extracted at 40 °C. **Shahidi, Xiao-Qing, Synowiecki (1995)** investigated production and characteristics of protein hydrolysates from Capelin (*Mallotus-villosus*) and reported EC of lyophilized capelin protein hydrolysates of 50.9% and ES of 92% which is comparable with the present study. **Omar and Sarbon (2016)** examined the effect of drying method on functional properties and antioxidant activities of chicken skin gelatin hydrolysate and registered EC and ES of chicken skin gelatine of approx. 56% which is very similar to the results by **Li, Jia and Yao (2009)**.

Foaming capacity and stability (FC and FS)

The relationship between FC and extraction temperature is not statistically significant (p >0.05). Figure 6 shows that between the extraction temperatures of 40 and 60 °C there is a steep decrease of FC. From 60 °C to 70 °C it remained steady followed by a dramatic soar between 70 °C and 80 °C. This thermal behaviour can be explained by the fact that the level of hydrolysis is probably the highest at the temperature of 60 °C (as it was mentioned previously); therefore, collagen molecules contain shorter chains and are unable to form a stable foam.

The mean of FS is not significantly different from the mean of FC (p =0.141); however, the effect of extraction temperature on FS is statistically significant (p <0.05). FS values were slightly lower at 50 °C compared to FC; however, decrease of FS is more obvious at 40, 60 and 70 °C in comparison with FC and the extreme difference was recorded at 80 °C. It is obvious that an increasing temperature causes a decline in FS. The most appropriate extraction temperature for the best foaming properties seems to be 40 °C due to the significantly high FC value and highest FS value. Several studies have been performed in order to investigate foaming properties.

Haddar et al. (2011) studied physicochemical and functional properties of gelatin from tuna (*Thunnus thynnus*) head bones and reported FC from 64 to 80% and FS from 41 to 60% depending on the concentration of gelatine. **Jain and Anal (2016)** investigated optimization of extraction of functional protein hydrolysates from chicken egg shell membrane (ESM) by ultrasonic assisted extraction (UAE) and enzymatic hydrolysis and reported FC of protein hydrolysate prepared from eggshell

Table 3 Comparison of viscosity, water holding capacity (WHC), fat binding capacity (FBC), clarity of chicken skin gelatine extracted at 40 °C with commercial food grade pork and beef gelatines.

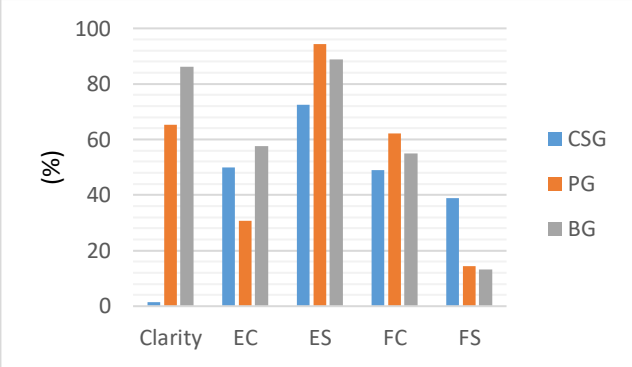

Figure 7b Comparison of clarity, emulsifying capacity (EC), emulsifying stability (ES), foaming capacity (FC) and foaming stability (FS) of chicken skin gelatine (CSG) prepared at 40 °C with commercial pork (PG) and beef (BG) gelatine.

membrane in the range from 21.7% to 28.3% and FS from 8.3 to 25% depending on the applied method of preparation. **Dhakal et al. (2018)** examined optimization of collagen extraction from chicken feet by papain hydrolysis and synthesis of chicken feet collagen based biopolymeric fibres and reported FC of 16.7% and FS of 11.7% which is in accordance with the results of this study.

Comparison of functional properties of chicken skin gelatines with commercial food grade pork and beef gelatine

The mean of viscosity of chicken skin gelatines (CSG) is significantly higher than the viscosity of pork gelatine (p <0.05), whereas it is not significantly different in comparison with viscosity of beef gelatine (p >0.05). The mean of clarity of CSG is significantly less than the viscosity of pork and beef gelatines (p <0.05). The mean of WHC of CSG is not significantly different from WHC of pork gelatine (p >0.05); however in contrast to beef gelatine it is significantly less (p <0.05). The mean of FBC of CSG is significantly greater than WHC of pork and beef gelatines (p <0.05). The mean of EC of CSG is significantly greater than EC of pork gelatine (p <0.05), while the mean of EC of CSG is significantly less than EC of beef gelatine (p <0.05). The mean of ES of CSG is significantly lower than ES of pork gelatine (p <0.05), however the mean of ES of CSG is not significantly different from ES of beef gelatine (p >0.05). The mean of FC of CSG is significantly less than FC of pork and beef gelatines (p <0.05). The mean of FS of CSG is not significantly different from FS of pork and beef gelatines (p >0.05).

Gelatine extracted at the temperature of 40 °C was chosen for the illustration of comparison with commercial food grade beef and pork gelatine because this gelatine has the highest gel strength as described in the previous study, **(Mrázek et al., 2019 – in press)**, emulsifying capacity, foaming capacity and stability, and significantly high viscosity of all prepared samples. Tables 3 and 4, Figures 7a and 7b display obtained data. Viscosity of prepared chicken skin gelatine is higher by 53% and 31% than viscosity of pork and beef gelatine, respectively. WHC of chicken skin gelatine is lower by 67% and 15% than WHC of beef and pork gelatine, respectively. FBC of prepared gelatine is higher by 57% and 27% than FBC of pork and beef gelatine, respectively. On the other hand, clarity of prepared gelatin is considerably lower than clarity of pork and beef gelatine. This may be attributed to difficulty in the cleaning process in laboratory conditions. EC of chicken skin gelatine is 15% lower than EC of beef gelatine whereas it is by 39% higher than the value of pork gelatine, which are comparative results. ES of chicken skin is 30% lower than ES of pork gelatine and 23% lower than beef gelatine. FC of prepared gelatine is lower by 27% and 13% than FC of pork and beef gelatine, respectively; while FS is higher by 63% and 66% than FS of pork and beef gelatine, respectively, which are excellent results. In addition, FS is 4.3 times lower than FC in commercial gelatines, whereas only 1.3 times lower in prepared chicken skin gelatine. This may be ascribed to the difference in intrinsic properties and composition of proteins in various gelatine sources **(Damodaran, 2005)**.

CONCLUSION

Chicken skin gelatines were prepared by extraction in distilled water at 5 different temperatures of 40, 50, 60, 70 and 80 °C at constant extraction time of 60 min. Functional properties of gelatines (viscosity, clarity, water holding capacity, fat binding capacity, emulsifying capacity/stability and foaming capacity/stability) were investigated. Results revealed that the extraction temperature has an influence on the properties of gelatine. With respect to the highest emulsifying capacity, foaming stability and high viscosity of gelatine, the extraction temperature of 40 °C appears to the most appropriate; in addition, this gelatin has the highest gel strength. The most suitable extraction temperature for the highest viscosity, water holding capacity and foaming capacity was 80 °C; however, for the highest fat binding capacity it was 60 °C and for emulsion stability 50 °C.

Functional properties of chicken skin gelatine extracted at 40 °C were compared with those of commercial food grade pork and beef gelatine. Viscosity, fat binding capacity and foaming stability of chicken skin gelatine were higher in comparison with mammalian gelatines. Water holding capacity, emulsifying stability and foaming capacity of chicken skin gelatine were lower than those of mammalian gelatines. Clarity of chicken skin gelatines were significantly lower than clarity of mammalian gelatines; this will be a subject of the following research. All tested gelatines showed comparable emulsifying capacity.

The results of experiments have proven that it is possible to prepare chicken skin gelatine with comparable functional properties to food grade beef and pork gelatine. Chicken skin gelatine has a promising potential to be an alternative to mammalian gelatines.

THE IMPORTANCE OF MILK AND DAIRY PRODUCTS CONSUMPTION AS A PART OF RATIONAL NUTRITION

Ľubica Kubicová, Kristína Predanocyová, Zdenka Kádeková

ABSTRACT

The paper is focused on the issue of consumption of milk and dairy products as an important part of the rational nutrition of the population of the Slovak Republic. The aim of the paper is to highlight the development of consumption of drinking milk and selected dairy products, including cheese and acid-based products, in the last 20 years in the conditions of the Slovak Republic. Furthermore, the paper focuses on comparing current consumption of milk and dairy products with recommended intakes resulting from the rationalization of diet. Based on the results, it can be stated that the consumption of milk and dairy products is insufficient at the level of 70% of the recommended consumption intakes of the selected food group. In connection with this, it is important to note that the consumption of drinking milk is low. The results obtained by processing the secondary data were supplemented with the primary data obtained from the questionnaire survey. Based on the results, we have conclude that most consumers are trying to maintain a healthy lifestyle and rational diet, which is just the consumption of milk and dairy products. Consumers especially prefer drinking milk, cheese and yoghurt, whose consumption is still low, which the respondents attribute to the high prices of the monitored products as compared to their income. On the other hand, the results showed the main factors determining the consumption of milk and dairy products, among which we can include quality, composition, price, durability and nutrition data. Based on the results obtained by processing secondary data and primary research, we suggest informing and educating consumers about the positive health effects and highlighting the recommended benefits to a greater extent.

Keywords: milk; dairy product; consumption; recommended intake; rational nutrition

INTRODUCTION

The aim of rational nutrition is to ensure the necessary intake of nutrients that are relevant to the health of the human organism **(Golian et al., 2018; Holienčinová et al., 2013)**. However, at present consumers do not have enough information to make reasonable decision when buying the food. Important food, which consumption is inadequate in the conditions of the Slovak Republic and which are essential for health, includes milk and dairy products. For this reason, the aim of the paper is to highlight the basic issues and issues related to milk and dairy products, with an emphasis on the importance of consumption and its sufficiency in relation to the recommended intakes resulting from the rationalization of eating.

Milk and dairy products represent one of the most elemental foods for all age categories of the population because of its biological component, which is the basis for the promotion and maintenance of rational nutrition of the population, regarding to which it has got a significant position **(Michaelidou, 2008; Pereira, 2014)**. Milk is a multicomponent blend, with its primary components, which are proteins, fat, lactose, vitamins and minerals, involved in the formation of a complex food **(Keresteš, 2016; Čuboň, Haščík and Kačániová, 2012; Nicklas, O'Neil and Fulgoni, 2009)**.

Milk proteins present in the milk are made of casein and whey proteins, which are nutritionally and technologically essential and represent an irreplaceable amino acid intake for humans. Another milk constituent is carbohydrates that do not form a significant portion, but lactose is the primary ingredient. Lactose is a hydrocarbon that can only be found in milk and has a significant role in energy production. Milk fat, representing an easily digestible emulsion containing lecithin and a relatively low level of cholesterol, is another important ingredient in milk. According to **Beck and Coad (2017)** the main minerals are calcium, phosphorus and potassium, with iron and copper having a less pronounced presence. In the context of this, there is an important ratio of calcium and phosphorus, which should be 1:1.3, and the magnesium content for the optimal skeleton development in child and juvenile consumers. In addition to the ingredients, milk also consists vitamins that can be diversified into two categories, water-soluble vitamins and fat-soluble vitamins. In cow´s milk, there is enough of vitamin A, B1, B2, B6 and

B12, biotin and lower amount of vitamin C **(Zeleňáková and Golian, 2008)**.

On the basis of the mentioned above, we can conclude that milk is an important food because milk and dairy products take an irreplaceable place in the intake of nutrients that are essential for the growth of the human organism and can be considered as a medicine for all age categories of consumers with different levels of their health condition **(Košičiarová, Nagyová and Holienčinová, 2017; Herian, 2006)**.

Nouzovská (2007), based on studies by several experts who regard milk as an exceptional food for its ingredients, highlights its need for body building. She also points to substances that provide the human body with energy in the required amount and essential elements that body cannot produce by itself, vitamins, minerals, hormones, enzymes with a positive aspect of non-stressing the body. In the context of the individual components of milk and their beneficial effects, we can define the basic benefits of consuming dairy products for the health of consumers **(Koca et al., 2017)**.

Regular consumption of milk and dairy products has, in the first place, beneficial effects on health of bones and teeth. We state that cow´s milk is an important source of calcium and minerals **(Prentice, 2014)**. Furthermore, the milk also contains vitamins that positively influence the health of the bones. An inadequate amount of calcium and vitamin D can lead to negative health consequences, in particular can cause osteoporosis and osteopenia. For this reason, it is beneficial and necessary for people to include milk and dairy products in their daily diet. On the other hand, it is important to note that cow's milk consumption is not sufficient to prevent osteoporosis, it is important to maintain also the physical activity, strength training, absence of smoking and drinking alcohol, complex healthy eating with a focus on diet containing low sodium and a significant amount of potassium **(International Osteoporosis Foundation, 2015)**.

Consumption of milk and dairy products as part of a rational, healthy diet also has positive effects on optimal blood pressure. Cow's milk, which is an important source of potassium and contains a low sodium content, is effective in preventing and promoting the elimination of the risk of cardiovascular disease. However, milk and dairy products should be consumed according to recommended intakes, since their over-consumption may have adverse health effects for consumers. As we have already mentioned, cow's milk contains not only high amounts of potassium but also saturated fat and cholesterol, whose excessive consumption can cause an increased risk of heart disease. If the consumers have the high blood pressure and cardiovascular disease reported for the longer time, they should consider cholesterol intake, when milk and dairy products with low fat and salt content are recommended **(Ware, 2016)**.

Ware (2016) consider as a significant positive of cow's milk its content of a wide range of proteins, including all essential amino acids that have a beneficial effect on the growth and recovery of human muscle tissue. Cow's milk and high-fat milk products contain a sufficient amount of saturated fat, which can be considered as the energy source needed to increase the muscle mass in the body. Maintaining a healthy amount of muscle in the body is one of the basic prerequisites for promoting metabolism and ensuring optimal body weight **(Geng, Qi and Huang, 2018)**. It can be said that by consuming of milk, consumers can increase their muscular mass and receive the energy they need to exercise and promote a healthy lifestyle.

Several studies confirm that cow's milk has, in addition to the above-mentioned benefits, other aspects contributing to the positive health of humans. Cow's milk and dairy products due to its high content of minerals act preventively against the development of colon cancer. Experts also point to a sufficient amount of vitamin D in cow's milk, which has a beneficial effect on hormones associated with mood, appetite and sleep, which can lead to the elimination of depression of consumers. Various studies aimed at examining the positive effects of cow's milk on the human organism also emphasize its importance in brain and nerve tissue development, regulation of body temperature, bowel movement, bile acid reduction, good vision, and resistance to infections of various kinds **(Herian, 2006)**.

Analysis of individual milk components leads us to the conclusion that cow´s milk and dairy products have demonstrated beneficial effects on human health, therefore are set the recommended intake of consumption.

Table 1 Composition of cow´s milk %.

Ingredient	%
Water	87.0
Dry matter	13.0
Protein	3.2
Lactose (carbohydrate)	4.8
Fat	4.2
Minerals	0.8

Note: own processing based on **Obermaier and Čejna, 2013**.

Table 2 Recommended intake for milk and dairy products consumption.

Milk and dairy product	Recommended annual intake in kilograms per person	Recommended daily intake in grams per person
Milk and dairy products	220.0	602.7
of which: Cheese and curd	10.1	27.7
Drinking milk	91.0	249.3
Sour-milk products	14.0	38.3

Note: own processing based on **Kajaba et al., 2012**.

Recommended intake of milk and dairy products are formulated with regard to recommended dietary intake to give the consumer daily basic nutrients, minerals and vitamins. In the context of the above, recommended intake of milk and its consumption are set at 220 kg per capita per year, with an intake for adequate consumption between 206 kg and 240 kg. Receipt of the analysed commodity is necessary due to its positive effects on consumer health. The following table shows the recommended annual and daily consumption of individual dairy products.

Milk and dairy products can be generally considered as recommended food for all age categories of consumers that are very difficult to substitute, and with regard to children's consumers, their intake is irreplaceable **(De Pelsmaeker, Schouteten and Gellynck, 2013)**. For this reason, it is important to draw attention to children and the need to include milk and dairy products into their daily meals. Recognizing the need for milk by children of low age can lead to a positive relationship and a regular consumption of dairy foods even in adulthood.

As already mentioned, consumption of milk and dairy products is beneficial for consumers and can be considered as a form of prevention against various diseases. **Lecerf (2013)** considers milk as a food from which the child obtains 51% of calcium, 31% of phosphorus, 27% of zinc, 41% of iodine, 15% of selenium, 39% of vitamin B2, 42% of retinol, 20% of vitamin B12, 24% of protein and 18% of magnesium from the recommended daily dietary intake. In the case of adults, the proportion of milk and dairy products is different from the recommended daily dietary intake. Adult consumers obtain, by consuming the recommended daily dietary intake of milk and dairy products, 45% of calcium, 24% of phosphorus, 20% of zinc, 32% of iodine, 11% of selenium, 29% of vitamin B2, 30% of retinol, 20% of vitamin B12, 18% of protein and 11% of magnesium.

Scientific hypothesis

The aim of the paper is to point out the consumption of milk and dairy products in the conditions of the Slovak Republic, with an emphasis on the development of consumption of individual types of dairy products compared to the recommended intake and the identification of factors affecting the level of consumption.

For a deeper analysis of the research objectives, the following hypotheses were formulated:

Hypothesis 1: We assume that there is a dependence between respecting health principles in rational nutrition and selected demographic characteristics of respondents (age, gender, education).

Hypothesis 2: We assume that there is a difference in the evaluation of higher prices as a main reason of low consumption of milk and dairy products between respondents from households with different monthly incomes.

Hypothesis 3: We assume that consumers assess the importance of the individual criteria for choosing milk and dairy products differently.

MATERIAL AND METHODOLOGY

Regarding the development of the consumption of milk and dairy products in comparison with the recommended intake, the secondary data had been obtained from the Statistical Office of the Slovak Republic and the Research Institute of Agriculture and Food Industry.

The primary data was obtained from questionnaire survey, implemented in an electronic version and conducted on a sample of 516 respondents from April to December 2018 in the Slovak Republic.

Respondents participating in the survey were diversified into 9 categories by gender (women 64.1%, males 35.9%), age (up to 25 years 43.0%, 26 – 35 years 23.3%, 36 – 50 years 19.2%, 51 – 60 years 8.5%, more than 61 years 6.0%), education (basic 1.7%, secondary school 45.9%, university 52.3%), permanent residence (countryside 48.6%, city 51.4%), economic status (student 36.2%, employed 48.3%, the self-employed person 4.7%, unemployed 1.2%, maternity leave 2.9%, retired 6.8%), monthly household income (less than 1,000 Euro 19.8%, 1,001 – 2,000 Euro 54.7%, 2,001 – 3500 Euro 23.1%, 3,501 – 4,500 Euro 2.1%, more than 4,501 Euro 0.4%) and by the number of members of the household (1 member 3.7%; 2 members 18.8%; 3 members 22.9%; 4 members 37.6%; 5 members 12.0%; more than 5 members 5.0%).

Statistic analysis

Collected data was processed by using Microsoft Excel and then evaluated in the statistical program XL Stat. The formulated hypotheses were tested by applying the following statistical methods:

- Contingency table chi-square test,
- Fisher's exact test,
- Cramer's coefficient,
- Mann-Whitney test,
- Friedman test,
- Nemeny's method.

In hypothesis testing, if the *p*-value is lower than significant level, in case of XL Stat software, it is 0.05, the null hypothesis is rejected, and the alternative hypothesis is confirmed **(Witek, 2016)**.

RESULTS AND DISCUSSION

In the Slovak Republic, the development of consumption of milk and dairy products per capita was accompanied by a fluctuating trend in the period 1997 – 2017 (Figure 1) **(Statistical Office of the Slovak Republic (SO SR), 2018)**. In 2003, the consumption of milk and dairy products began to decline. In 2010 there was an increase in consumption of the monitored food, but the average consumption did not reach the recommended intake level resulting from rationalization of meals. This trend persisted until 2017, so it is necessary to point out the possible reasons for the relatively low consumption of milk and milk products that could be caused by the living conditions of the population of the Slovak Republic, by unconfirmed information about the negative effects of milk consumption on human health or by the diagnosis of lactose intolerance **(Zingone et al., 2017)**. At present, the consumption of milk and dairy products is 176.1 kg per capita, which represents lower consumption by 20.0% compared to the recommended intake. The consumption of milk and dairy products was mainly due to drinking milk, cheese and sour-milk products.

Development of consumption of drinking milk is not proportional to the total consumption of milk and dairy products in the analysed period 1997 – 2017 (Figure 2). We predict this on the basis of the downward trend in milk consumption in the long run. In the first reference year, consumption was 75.8 kg per capita and in 2017 only 46.3 kg. Of course, the fluctuations in milk intake by Slovak consumers were also recorded. The largest increase was registered in 2010, which was determined by the state's support activities for milk consumption. However, in the context of the above, it is also important to note the elimination of consumption from 2011 to the present. Consumption of drinking milk does not cover the recommended intake and falls by almost 50%, which we consider to be a very significant lack of rational nutrition. In the next two years, we expect an even lower consumption of drinking milk based on the determinant coefficient (R^2), which should reach an annual level of about 40 kg per capita in the Slovak Republic. Low milk consumption contributes to increasing milk prices and to constantly expanding supply of other dairy products such as cheese, yoghurt, or other sour-milk products **(Kubicová, 2008; Kubicová and Habánová, 2012)**.

Note: questionnaire survey, 2018.

The consumption of cheese is directly proportional to the total milk and dairy consumption. In the monitored period, a gradual increase in the consumption of cheese was recorded (Figure 3). In 1997, consumption was 6.3 kg and in the last analysed year up to 11 kg, which represented an increase in consumption by 74.6%. On the basis of the determinant (R^2), a slight decrease in cheese consumption is estimated to approximately 10.5 kg per person in the following two years, but with a view to rationalizing the diet

and the recommended intake, cheese consumption will still be at a sufficient level.

Consumption of sour-milk products is similar to consumption of cheese. In the analysed period 1997 – 2017 there was a gradual increase in the intake of sour-milk products by Slovak consumers (Figure 4). In connection with mentioned, it is important to highlight the favourable consumption growth of 212.5% from 8.0 kg in 1997 to 17 kg in the last reference year.

By 2011, the consumption of dairy food was below the recommended dose of 14 kg, but it is slightly higher than in 2012 and currently stands at around 21.4% above the rational diet recommendations.

In view of the above, the consumption of sour-milk products is expected to increase and in 2019 it should reach an annual level of approximately 17.5 kg per inhabitant of the Slovak Republic. **Kubicová and Dobák (2012)** emphasize that the increase in consumption of sour-milk products was mainly determined by the increased and varied range of products of domestic and foreign production associated with marketing communication and a wider range of price levels.

The question of the adequacy of current consumption of milk and dairy products can be judged by the level of recommended intake. Excessive consumption, i.e. consumption higher than the recommended intake, is recorded in the case of cheeses and sour-milk products. The consumption of sour-milk products is 21.4% higher compared to the recommended intake and the consumption of cheeses is 8.9% higher compared to the recommended intake. On the other hand, inadequate consumption, i.e. consumption lower than the recommended intake, is recorded in a case of drinking milk, which is 49.13% lower compared to the recommended intake (Figure 5).

Consumption of milk and dairy products is influenced also by the level of retail prices in relation to the average income of the population **(Bousbia et al., 2017)**, the gross domestic product and its distribution among the population, the standard of living, structure of the market, intensity of international trade or the individual consumer behaviour **(Matošková and Gálik, 2016; Skořepa, 2009)**. Consumer behaviour can be considered as one of the main factors determining the consumption of milk and dairy products. We identified these on the basis of a questionnaire survey focused on consumers of milk and dairy products, aimed at identifying consumers' attitudes towards rational eating, the positive health effects of milk consumption from the point of view of consumers, preferences in milk and dairy products and factors determining consumer behaviour when choosing milk and dairy products. In relation to health and a healthy lifestyle resulting from rational diets, it was necessary to point to the percentage of consumers adhering to this trend. Based on the research results (Figure 6), it can be stated that 25% of respondents adhere to regular health principles in rational nutrition and 54.1% of consumers follow rational diets on an irregular basis. As a result, almost 80% of respondents are nutritionally focused on the health aspect and try to follow recommended intakes.

Regarding to this question several dependences between the selected socio-demographic variables of respondents and respecting the health principles in rational nutrition (Hypothesis 1). Applying the statistical tests Contingency table chi-square test and Fisher's exact test, statistically significant dependency has been proved between respecting health principles in rational nutrition and gender (p-value = 0.008), age (p-value = 0.024) and education (p-value = 0.001). From the aspect of dependence tightness, there is a slight dependence demonstrated by the calculation of the Cramer coefficient (Table 3).

Recommended intake of milk consumption is also result from its positive effects on consumer health. The positive health effects of drinking milk and dairy products are recognized by 88.4% of respondents involved in consumer survey. Respondents have highlighted milk as a very good food, containing calcium, protein, iron and zinc, which greatly affects bones, teeth, nails or skin. In addition, the polls evaluated milk and dairy products as an excellent source of vitamins and minerals. The positive effect of milk consumption is also perceived by respondents who consume milk, especially because of the proven effects related to the growth of the organism, the support of the immune system. Other beneficial effects assessed by consumers include support for better digestion, energy intake, preventive effects against osteoporosis, memory support and brain function, prevention of high blood pressure, elimination of sleep problems as well as ensuring proper functioning of the thyroid gland. Several studies show that the consumers were made aware of the good health benefits and reducing risk for exposing to diseases **(Peng, West and Wang, 2006; Alwis, Edirisinghe and Athauda, 2011)**. On the other hand, **Krešić et al. (2010)** emphasize, that consumers do not have adequate knowledge about the health benefits of milk and dairy products consumption.

As most consumers involved in the questionnaire survey are aware of the positive effects of drinking milk and dairy products and are trying to keep their consumption in line with the recommended intakes, we were interested in reason of the lower consumption in the Slovak Republic in comparison with the requirements for rationalization of meals. Consumers should rank 5 reasons of low consumption, 1 being the most important reason and 5 the least important reason and the reasons were ranked according to the average order. On the basis of the results of the survey (Figure 7), consumers consider the higher price of the monitored products as the main reason for lower consumption of milk and milk products compared to the past (1.62) followed by a lower quality (2.00), an extended offer substitution product (3.13), inadequate education (3.62), and unconfirmed information on harmful substances in milk (3.62). Regarding to this question the difference in the evaluation of higher prices as a main reason of low consumption between respondents from households with different monthly incomes was examined (Hypothesis no. 2). Applying the statistical test of Mann-Whitney U test it could be concluded that the calculated p-value (0.901) is more than significance level $\alpha = 0.05$, which means, that the null hypothesis was accepted and there is not statistically significant difference in evaluation of higher prices as a main reason of low consumption between respondents from households with the monthly income less than 2,000 euro and respondents from households with the monthly income more than 2,000 euro In connection with the questionnaire survey, up to 23.4% of respondents are aware of insufficient consumption of the selected food group.

The questionnaire survey shows that all respondents consume milk and dairy products at least in a minimum amount, mainly because of rational diet (20.3%) and nutritional content (14.0%).

In the context of the above, the objective of the questionnaire survey was to identify which dairy products are most preferred among consumers. The results of the consumer survey (Figure 8) proved that the respondents engaged in the questionnaire survey purchased all kinds of dairy products, with milk and cheese as the most preferred ones. This is confirmed by the fact that milk (56.4%), cheese (57.0%), butter (51.7%) and yogurt (51.4%) are most commonly bought and consumed by consumers in regular intervals. **De Graaf et al. (2016)** found out that Most participants consumed milk and dairy products at least once per day (54.1%), or multiple times per week (27.3%). **Kapsdorferová and Nagyová (2005)** and **Pinto et al. (2016)** identified milk, yoghurt and cheese as the most commonly preferred dairy food among consumers. On the other hand, other sour-milk products are least preferred, which was confirmed by their purchase by 70% of respondents in irregular intervals, followed by curd (66.3%) and cream (63.8%).

Based on the results (Figure 9) can be concluded that quality (98.8%), price (91.4%), composition (90.3%), durability (89.3%) and nutrition data (79.1%) are the most important factors for consumers when choosing the specific dairy products. **Kumar and Babu (2014)**, **Paraffin, Zindove and Chimonyo (2018)** and **Kurajdová et al. (2015)** confirm our results and identify quality, nutritional value and price as the main factors determining the purchase of milk and dairy products. **Zajác et al. (2012)** highlights the quality and safety of raw cow´s milk as a factor that consumers of dairy products increasingly focus on. **Nagyová et al. (2019)**, concluded within their research that consumers consider as healthy food products those with a positive effect on human organism and food, which is subject to rigorous control requirements for quality of food products. On the other hand, the promotion of the product (72.9%), the appearance of the packaging of the product (65.5%) and the size of the packaging (28.9%), consumers do not consider as important criteria when deciding to buy a given product. **Bytyqi et al. (2008)** concludes that consumer behaviour in the purchase of milk and dairy products is not affected by factors connected with the packaging of milk and dairy products. The **GfK survey (2017)** has shown that for the Slovak consumers is still a very important price when deciding about purchasing chosen food, including milk and dairy products, but the emphasis on quality is clearly rising. 59% of consumers say they closely monitor the prices of food in different stores and shop where the best deal is offered. As a result, consumers are focusing on quality, but at the same time they are looking for quality for the best price.

In relation to the assessment of the various factors influencing the choice of milk and dairy products by consumers, we found differences in the assessment of these criteria among the respondents (Hypothesis No. 3). Based on the Friedman test, it is possible to identify differences in factor evaluation confirmed by the statistical calculation of the p-value (<0.0001), which is lower than the alpha significance level (0.05). By using Nemeny's method and based on the data in the following Table 4, we conclude that quality is the most important criterion when choosing milk and dairy products (Group A), another group of significant factors is created by price, durability and composition (Group B), followed by a set of criteria created by the nutrition data and country of origin (Group C), the other group of factors consisted from the country of origin, the manufacturer and the package size (group D), and the last group of factors is the appearance of packaging and the promotion of the product (Group E). By dividing the factors determining consumer behaviour when choosing milk and dairy products into these groups, it is possible to point to the differences in the assessment of individual criteria (groups) by consumers. The country of origin criterion is placed in two groups (Group C and Group D), which can be explained by the fact that there is no statistically significant difference in their ratings among Group C and Group D factors. However, between groups C and D there is a difference in the assessment of factors by consumers.

CONCLUSION

Paper focuses on the consumption of milk and dairy products and its importance within the rational nutrition of the population of the Slovak Republic. Based on the results, it can be stated that at present the consumption of milk and dairy products is at the level of 70% of the recommended consumption of the given food group. Consumption of cow´s milk is alarmingly low, covering only about 50% of the recommended milk consumption, while consumption of cheese, curd and sour-milk products has risen in recent years and slightly exceeds the recommended consumption intakes. Other dairy products, cream, powdered milk and condensed milk or butter do not represent a significant share of total consumption. Regarding previous, a consumer survey was conducted, in which we identified that 80% of consumers are aware of a healthy lifestyle that also includes consumption of milk and dairy products in view of their proven positive effects. In the context of this question, there the formulated hypothesis was proved, and it means that there exists the dependence between the respecting of the health principles in rational nutrition and selected demographic characteristics of respondents (gender, age and education). Consumers attribute importance to milk consumption, especially due to calcium, protein, iron and zinc content, which greatly affect bone, teeth, nails or skin, and the overall positive effect on the human body. However, consumers are aware of the inadequacy of consumption of the monitored food, which is justified by the high prices of milk and dairy products. In the context of this question there was formulated hypothesis, which was rejected and there is no statistically significant difference in the evaluation of higher prices as a main reason of low consumption of milk and dairy products between respondents from households with monthly incomes of less than 2,000 euro and respondents from households with monthly incomes of more than 2,000 euro. Despite above mentioned, consumers consume the milk and dairy products at regular intervals, with the most preferred milk, cheese and yogurt. The choice of specific dairy products is determined by different criteria, which respondents evaluate differently, and it means the proved hypothesis related to consumer assessment of the importance of individual criteria for choosing milk and dairy product. The most important criteria for milk and dairy products consumption are quality, composition, price,

durability and nutrition data. Nutrition information is becoming more and more noticeable to consumers when choosing dairy products, which we consider to be an important aspect in the direction of rational nutrition. Due to the obtained results, we note that it is essential to address consumers in particular with regard to information and education in the selection of cow´s milk and dairy products. Consumers need to be permanently aware of recommended doses of consumption of a given commodity in terms of its beneficial effects due to the strengthening of bones, teeth, muscle mass, prevention of cardiovascular diseases, colon cancer and other positive effects.

ASSESSMENT OF LIPID PEROXIDATION IN DAIRY COWS WITH SUBCLINICAL AND CLINICAL MASTITIS

František Zigo, Juraj Elečko, Milan Vasiľ, Zuzana Farkašová, Ladislav Takáč, Jana Takáčová, Martina Zigová, Jolanta Bujok, Ewa Pecka-Kiełb

ABSTRACT

Mastitis is still one of the major causes of economic losses in dairy sector. The routine application of bacteriologic examination of milk samples is often insufficient and for this reason, alternative parameters are used to identify trends in the development of the udder health. Therefore, the objectives of this study were to determine the relationship of oxidative product levels, using malondialdehyde (MDA) as a marker on occurrence of mastitis and its causing pathogens. Dairy herd of 223 Slovak spotted cattle were tested for etiology and occurrence of mastitis based on assessment of clinical signs, abnormal udder secretions, Californian Mastitis Test (CMT) with subsequent collecting of milk samples for bacteriological examination. From 892 quarter milk samples were selected for MDA detection 51 subclinical (SM) and 26 clinical mastitis (CM) quarters with positive CMT score and positive bacteriological examination of *Staphylococcus* spp. and *Streptococcus* spp. as well 40 healthy quarters. Results showed that among the current pathogens of the mammary gland belong CNS, *S. aureus, S. sanguinis, S. uberis* and *E. coli,* which were the most frequently isolated from SM and CM. The highest MDA level was observed from clinical cases of mastitis however, increased MDA levels were detectable from subclinical cases. Bacterial isolates from subclinical quarter milk samples are different levels of MDA. In this study, we found that quarter milk samples infected with *S. uberis* were higher compared to other pathogens. In conclusion, differences in both severity of mastitis and mastitic pathogens were associated with differences of oxidative products in infected udders.

Keywords: cows; lactation; mastitis; lipid peroxidation; *S. uberis*; coagulase negative staphylococci

INTRODUCTION

The quality and quantity of milk obtained from the cows is important for the dairy sector. Infection of mammary gland - mastitis is one of the biggest problems of dairy producers causes great losses every year in the livestock economy. The disease is usually local but may become systemic, although rarely, in immunocompromised animals **(Tančin et al., 2006; Shari, Umer and Muhammad, 2009; Andrei et al., 2010; Vršková et al., 2015)**.

Mastitis is characterized by several physical and chemical alterations of the milk and corresponding pathological changes in the mammary tissue depending on the type of the disease. Intramammary infection (IMI) is caused by interaction of various factors associated with the animal, pathogens and the environment, so nature and duration of the disease varies accordingly **(Taponen et al., 2006; Suriyasathaporn et al., 2006; Zajác et al., 2012)**.

More than 140 different microorganisms are recognized to cause mastitis. Infectious agents like bacteria, viruses, fungi and algae are mostly the primary causes of the disease.

Authors **Vasil' et al. (2009)** and **Tenhagen et al. (2006)** indicate that up to 95% IMI is caused by bacterial pathogens. At routine bacteriological examination of milk from suspect cows, or secretion of the cow udder with clinical mastitis we can detect *Staphylococcus aureus*, *Streptococcus uberis*, *Streptococcus dysgalactiae*, CNS, *Escherichia coli*, *Enterobacter* spp., *Klebsiella* spp., *Serratia* spp., *Pseudomonas* spp. and others.

During a bacterial infection the number of somatic cells in milk increases, especially that of polymorphonuclear cells (PMN). The antibacterial activity of PMN cells is partially mediated through reactive oxygen species (ROS); an excess of these species correlating with the absence of optimal amounts of antioxidants can lead to oxidative stress. It was shown that the occurrence of oxidative stress in cattle may contribute to some periparturient disorders (retained fetal membranes, udder edema, mastitis) or metabolic diseases **(Castillo et al., 2006; Sharma et al., 2011)**.

Oxidative stress in veterinary medicine and particularly in ruminant health is a relatively young field of research. Early identification of udder health problems is essential for dairy farmers and veterinarians to ensure not only the animal well-being but also the milk quality and dairying productivity. Economic aspects interfere with the routine application of bacteriologic examination of quarter milk samples. For this reason, alternative indicators of oxidative stress are used to identify trends in the development of the udder health in a dairy herd. Although these parameters belong detection of lipid peroxidation reactive aldehydes such as malondialdehyde (MDA) **(Suriyasathaporn et al., 2012; Sharma et al., 2016)**.

MDA is one of the several low molecular weight end products formed during the radical induced decomposition of polyunsaturated fatty acid. MDA modifies the physical structures of cell membranes and is indirectly involved in the synthesis of protein, DNA, and RNA. In addition, it has mutagenic and carcinogenic properties **(Turk et al., 2017; Kapusta et al., 2018)**.

Scientific hypothesis

Lipid peroxidation reactive aldehydes have been identified as a key factor in numerous pathologies, including udder inflammation. Detection of MDA may be helpful in the health management of cows. Therefore, the goal of this study was to evaluate the etiology of mastitis and to assess of lipid peroxidation by measuring milk malondialdehyde level in raw cows' milk.

MATERIAL AND METHODOLOGY

Animals and milking

The experiment was carried out in dairy herd of 270 Slovak Pied cattle in north of the Slovakia. Dairy cows from monitored herd were kept in a free housing system with a separate calving barn and equipped with individual boxes with bedding and were allowed *ad libitum* access to water. Their diet was formulated according to international standards **(NRC, 2001)** to meet the nutritional requirements of a 600 kg cow, yielding 15 - 25 kg of milk per day. The cows were milked twice a day at 4:30 a.m. and 4:30 p.m. in the fishing-milking parlour (FarmTec) 2x10. Milking and pulsation vacuum were set at 42 kPa. Pulsation ratio was 60:40 at a rate of 52 c.min^{-1}.

Examination of health status

The examination of health status included clinical examination of the mammary gland, examination fore-strip of milk, with CMT reaction, subsequent collecting of milk samples for bacteriological examination, subsequent cultivation and identification of pathogenic bacteria. Clinical examination consisted of heart rate, body temperature, respiratory rate, udder health including the mammary gland palpation, evaluation of macroscopic changes in milk, and evaluation of somatic cell count in milk using the CMT (Indirect diagnostic test, Krause, Denmark). CMT was performed from the 223 milked cows on 892 quarter milk samples and the score was evaluated (Table 1) according to **Jackson and Cockcroft (2002)**. Following washing and drying the mammary teats, 70% ethanol was sprayed, and a few streams of milk were discarded. Afterwards, quarter milk samples of the secretion (10 mL) were then collected with aseptic techniques in accordance with **National Mastitis Council guidelines (2001)**. The samples were cooled and immediately transported to the laboratory.

Laboratory analyses

Bacteriological examinations were performed according to commonly accepted rules **Malinowski et al. (2006)**. Milk samples (10 μL) were cultured at the respective veterinary practice according to their routine procedures, usually employing Columbia Blood Agar Base with 5% of defibrinated blood, Staphylococcal medium N° 110, Baird-Parker agar, Edwards Medium, Mac Conkey Agar (Oxoid, (OXOID Ltd., Basingstoke, Hants, UK) incubated at 37 °C for 24 h (Figure 1).

Figure 1 Bacteriology analysis cultured on selectives medium. Note: *S. aureus* (1A - 1B), *S. warneri* (2A - 2B), *S. uberis* (3A - 3B), *E. coli* (4), *A. viridans* (5).

Beside evaluation of bacterial growth characteristics another assays were used to bacterial species determination: pigment and coagulase production, catalase activity, haemolysis, Gram staining and other virulence factors. Bacteria *Staphylococcus* spp. were selected for the tube coagulase test (Staphylo PK, ImunaPharm, SR). Suspect colonies *Staphylococcus* spp., *Streptococcus* spp. and *Enterobacteriaceae* spp. were isolated on blood agar and cultivated at 37 °C for 24 h and detailed identified biochemically using the Staphy test, Strepto test, resp. Entero test and identification by software TNW Pro 7.0 (Erba-Lachema, CZ) according to the manufacturer's instructions. Identification of typical *Trueperella pyogenes* colonies derived from pure or mixed culture were distinguished by colony morphology, post incubation haemolysis, Gram staining, catalase test. Specific colonies were plated on defibrinated sheep blood agar (5%) and incubated aerobically at 5% CO_2 atmosphere at 37 °C for 72 hours. Colonies morphologically compatible with *T. pyogenes* were subjected to a conventional phenotypic assay API Coryne strips (BioMe'rieux, France).

MDA determination from quarter milk samples

For milk MDA detection were selected three groups from all monitored cows. The first group of 10 healthy cows (40 quarters milk samples) without clinical signs, negative score of CMT and negative bacteriological examination. From the 29 cows (51 quarters milk samples) on the basis of positive CMT score, without clinical signs and positive bacteriological examination of *Staphylococcus* spp. and *Streptococcus* spp. were selected second group with subclinical mastitis.

The third group of 11 cows (26 quarters milk samples) was selected on the basis of clinical signs, positive CMT score and positive bacteriological examination of *Staphylococcus* spp. and *Streptococcus* spp.

Milk MDA level from selected milk samples was measured by the photometric method based on a reaction with thiobarbituric acid (TBA) described by **Andrei et al. (2010)**.

Briefly, one hundred microliters of milk sample were properly mixed with 1 mL of trichloroacetic acid with a vortex mixer. Afterwards 400 mL of TBA was added. The mixture was boiled for 30 min and subsequently cooled down by tap water. The solution was duplicate analysed by UV spectrophotometry at 532 nm against its blank reaction mixture. The results were expressed in $nmol.mL^{-1}$ milk.

Statistical analysis

The data of milk MDA level from selected groups of cows and selected mastitis pathogens are presented as the mean (M) ±standard error of the mean (SEM). Difference between groups and pathogens causing subclinical mastitis were analysed by using analysis of variance (ANOVA) followed by Tukey comparison test and minimum criteria for statistical significance was set at $p \leq 0.05$ for all. Approximate probabilities were evaluated with Post Hoc Test for the statistical analysis of MDA level between selected pathogens.

RESULTS AND DISCUSSION

Table 1 shows the health status udder of 223 lactating dairy cows. From (892 quarter milk samples were recorded in 161 positive samples (18.1%) with CMT score trace or 1 - 4. Negative CMT score were recorded in 731 quarter milk samples (81.1%). A total of 127 infected quarter milk samples from 67 mastitis cows were the most commonly diagnosed form of SM 8.7% from all investigated quarters. At quarter levels, 16 (1.8%), 34 (3.8%) quarters were classified as latent and clinical mastitis, respectively. Numbers and percentages of isolates separated for their severity of mastitis are shown in Table 2. CNS gave the highest percentages (37%) representation on the etiology of mastitis in the monitored herd. SM were represented by up to 61.4% from all mastitis samples. The most common pathogens in CM were *S. aureus*, *S. uberis* and *S. sanguinis*. Other bacteria and *S. intermedius* had very few data and were excluded from analyses.

Table 1 Evaluation of CMT in monitored herd.

	All exanimated quarters*	Healthy quarters	Quarters with positive CMT score*	Infected quarters
n	892	731	161	127
%	100	81.1	18.1	14.2

Evaluation of CMT score				
CMT score	**n**	**%**	**SCC x 10***	**Interpretation***
0 (negative)	731	81.1	0 - 200	Healthy quarters
T (trace)	29	3.3	200 - 400 (±50)	Healthy or LM[1]
1	61	6.8	400 - 650 (±150)	SM[2]
2	40	4.4	850 - 1,200 (±200)	SM or CM[3]
3	23	2.6	1,500 - 5,000 (±300)	CM
4	8	0.9	Over 5,500	CM

Note: n - number of tested quarters, All exanimated quarters* - quarters with milk secretion, 8 quarters were rejected, CMT score* - quarters with positive evaluation of Californian Mastitis Test with score trace, 1, 2, 3 or 4, SCC*- Somatic cell count and interpretation of severity mastitis according to **Jackson and Cockcroft (2002)**.

LM[1] - Latent mastitis are characteristic only with the presence of bacterial pathogens in samples of milk without changing its consistency and SCC. SM[2] - Subclinical mastitis are characteristic with positive CMT score, bacteriological cultivation, increased SCC, reduced milk yield without clinical signs. CM[3] - Clinical mastitsare characteristic with positive CMT score, bacteriological cultivation, high level of SCC, changing the consistency of the milk, reduced or loss of milk production with clinical signs.

Table 2 Isolated microorganisms from infected quarters in monitored herd.

Isolated microorganisms	n	%	Latent		Subclinical		Clinical	
			n	%	n	%	n	%
***Staphylococcus* spp.**								
S. aureus	16	1.8	-	-	7	0.8	9	1.0

Figure 2 Milk malondialdehyde level (MDA) in raw cows' milk. Note: (A) MDA concentration separated by healthy quarters (n = 40), quarters with subclinical mastitis (n = 51) and quarters with clinical mastitis (n = 26); (B) MDA concentrations separated by isolates (n = 51) from quarters with subclinical mastitis. [a-e]Overall MDA values without common superscript differ significantly (p <0.05).

Table 3 MDA concentrations separated by isolates (n = 51) from quarters with subclinical mastitis.

	Groups	Normal	CNS	*S. aureus*	*Str. sanguinis*	*Str. uberis*
		21.40	27.34	29.72	30.85	37.71
1	Normal		**0.000159**	**0.000134**	**0.000134**	**0.000134**
2	CNS	**0.000159**		0.206953	**0.019734**	**0.000134**
3	*S. aureus*	**0.000134**	0.206953		0.838401	**0.000134**
4	*Str. sanguinis*	**0.000134**	**0.019734**	0.838401		**0.000134**
5	*Str. uberis*	**0.000134**	**0.000134**	**0.000134**	**0.000134**	

Note: Tukey HSD test; variable MDA approximate probabilities for Post Hoc Tests Error: Between MS = 5.9733, df = 45.000.

Averages of milk MDA for the selected groups and for the selected pathogens causing SM were shown in Figures 2(A) and (B), respectively. Averages, values of milk MDA in this study from health, subclinical and clinical group were 19.6, 28.8, and 41.3 nmol.mL^{-1}, respectively. From univariate analyses, results show that differences between selected groups and pathogens causing SM were related to MDA concentrations (p <0.001). Milk from SM and CM quarters had highest MDA concentrations and were statistically different (p <0.001) compared to healthy quarters (Figure 2(A)). MDA from milk samples with *S. aureus*, CNS, *Str. sanguinis* and *Str. uberis* was

significantly higher compared to MDA from health milk samples (Figure 2(B)). Results from Post Hoc probabilities showed, that MDA from milk samples infected with *Str. uberis* were statistically higher (p <0.001) compared to other pathogens (Table 3).

Bacteria are the most common cause of mastitis and hence bacteriological culture is routinely used in the laboratory diagnosis. The bacterial pathogens isolated from 127 affected quarters were CNS (41.7%), followed by CPS (16.5%), *Str. sanguinis* (7.0%), *Str. uberis* (6.3%) and other bacteria with mixed infections (8.6%) (Table 2).

The present findings are in accordance with the findings of **Kivaria and Noordhuizen (2007)** isolated *Staphylococcus* spp. followed by *Streptococcus* spp., *E. coli* and *Klebsiella*.

Tenhagen et al. (2006) isolated *Staphylococcus* spp. followed by *E. coli*, streptococci and *Pseudomonas*.

In many countries, CNS have been acknowledged more and more frequently as a cause of intramammary infections in dairy cattle **(Pyörälä and Taponen, 2009; Lange et al., 2015)**.

In the case of CNS, there has been not only an increasing prevalence of such infections but also an expanding list of species reported to be involved in the process. Results of studies from different countries and continents revealed that more than 20 CNS species have been isolated from milk samples of mastitic cows, the most common being *S. chromogenes, S. haemolyticus, S. epidermidis, S. simulans* and S. *xylosus* **(Zadoks et al., 2011; Lange et al., 2015; Khazandia et al., 2018)**.

In our study the most common CNS species such as *S. haemolyticus, S. chromogenes, S. warneri* and *S. xylosus* have been isolated from infected quarter milk samples of cows.

According to **Vasil' et al. (2016)** staphylococci and streptococci are the main etiological agents of ruminant IMI. *Staphylococcus aureus* with CNS are the most frequent isolates from subclinical and clinical cases of IMI.

Monday and Bohach (1999) present in their study that CNS are the most prevalent pathogens causing subclinical mastitis in dairy ruminants. Although less pathogenic than *S. aureus*, CNS can also produce persistent SM as well as producing thermostable enterotoxins. Nevertheless, despite the accepted role of these bacteria as major IMI causing pathogens in dairy ruminants, the pathogenicity of the different CNS species varies widely.

In our study, CNS, *S. aureus* and streptococci were most common isolated from SSM what is generally seen as an increase in the SCC in milk of the infected quarter with positive CMT score.

Increase in SCC during the inflammatory process in mammary glands indicates increased neutrophils in milk which result in oxidation reactions and increase MDA levels. In cows with mastitis, serum lipid peroxidation levels were increased, and the level of blood glutathione peroxidase was decreased compared to the levels in healthy cows **(Atroshi et al., 1996)**.

According to our previous study **Zigo et al. (2014)** infected lactating cows are more sensitive to oxidative stress than cows without IMI. An imbalance between increased production of ROS and the availability of antioxidant defenses needed to reduce ROS accumulation during the infection and may expose cows to increased oxidative stress.

Lipid peroxidation is one of the important consequences of oxidative stress. MDA is generated as a consequence of lipid peroxidation and, as such, is assayed as a biomarker of oxidative stress. The significant higher changes in milk MDA concentration of cows with subclinical and clinical mastitis in the present study (Figure 2(A)) are in accordance with the study **Suriyasathaporn et al. (2012)** that showed a significant increase of milk MDA levels in cows with SM and CM.

According to our expectation, CM quarters had highest MDA concentrations. This might be caused by the higher levels of udder defence mechanism. With the perspective of early diagnosis have shown increased MDA levels in SM quarters. This study showed that MDA level was different among pathogens causing subclinical mastitis (Figure 2(B)). Characteristics of pathogens may be the reason for differences in oxidative environment in udders but MDA from milk samples wit *Str. uberis* were statistically higher compared to other pathogens (Table 3).

CONCLUSION

In the study, we confirmed that the current pathogens mammary gland includes CNS, *S. aureus, S. sanguinis* and *S. uberis*, which were most often isolated from SM and CM. The highest MDA level was observed from clinical cases of mastitis however, elevated levels of MDA were detectable from SM quarters. Bacterial isolates from subclinical quarter milk samples are different levels of MDA. In this study, we found that *S. uberis* was statistically higher compared to other pathogens.

Subclinical mastitis is difficult to detect because of a lack of clinical signs that can be easily identified by visual inspection and palpation of the udder. As can be seen from our study, one of the additional methods for detecting SM can be measurement of MDA level in raw cows' milk.

FRUIT AS A SOURCE OF ANTIOXIDANTS AND TRENDS IN ITS CONSUMPTION

Ján Durec, Dagmar Kozelová, Eva Matejková, Martina Fikselová, Silvia Jakabová

ABSTRACT

The positive effects of fruit on human health are mainly attributed to their antioxidant activity. The aim of this work was to observe public awareness about antioxidants consumed in fruit, to analyze their preferences and the frequency of fruit consumption in selected population groups. Preferences were assessed by questionnaire, which was attended by 220 respondents. Information about the presence of antioxidants in fruit showed 85% of respondents. Temperate zone fruit is prefered by 48% of respondents and 52% of respondents prefer fruit of southern zone. Fresh fruit is consumed by 54% of respondents, 18% of respondents prefer fruit juices, compotes are consumed by 12% of respondents, fruit spreads by 11% of respondents, and 5% favour the dried fruit. Fruit is consumed by 31% of respondents once to three times a week, 26% of respondents consumed fruit once a day, 23% occasionally and 20% of respondents more times a day. In terms of sex, higher fruit consumption was recorded at women who consume fruit mostly once a day, while men only once to three times a week. The relationship between place of residence and the possibility to grow their own fruit as well as preference between home and the consumption of fruit by country of origin was confirmed.

Keywords: consumer behavior; purchase; Chi-Square test of Independence; fruit consumption; research

INTRODUCTION

Consumer behavior regarding the food market is changing and is affected by several factors. Significant part of the consumer's decision to buy fruit takes visual marketing, mainly the shape of fruit and color as well as some other sensory characteristics such as aroma or flavor. Fruit purchase is also affected by dietary habits, which are created mainly during childhood. Consumer decision-making process is affected by own experience, the brand, as well as the reputation of the producer, the country of origin and others. Identifying of customer needs and examining their buying behavior is the basis for developing strategies and advertising campaigns. These activities can increase product sale.

Horská and Berčík (2014) examined the effect of light on the purchasing decisions of consumers and the perception of lighting on the food market. Consumer attitudes to food safety was investigated by **Nagyová et al. (2018), Serenčéš a Rajčániová (2007)**, perception of food safety in Slovakia by **Golian et al. (2018)**, differences in consumer behavior at organic product purchase by **Vietoris et al. (2016)**; **Kádeková et al. (2017)**.

Epidemiologic evidence of a protective role for fruit and vegetables in cancer prevention is substantial. The strength of this scientific base guides US national policymaking in diet and health issues and facilitates community and local programs that address national dietary goals to increase fruit and vegetable consumption **(Duyn, Duyn and Pivonka, 2000)**.

Positive effects of fruit have been attributed to their antioxidant activity, which depend mainly on the content of polyphenols and vitamins in fruit **(Lamien-Meda et al., 2008)**. The most important antioxidants include vitamin C, vitamin A and its precursor beta-carotene, vitamin E, trace elements – zinc, copper, selenium and iron, ascorbic acid, tocopherol, lycopene **(Lenucci et al., 2006)**. The most frequently occurring elements are potassium, sodium, magnesium, calcium, chlorine, sulfur and phosphorus. Fruit contain also a number of important minerals, organic acids, vitamins, tannins, enzymes, flavonoids, aromatic substances. Cohort studies demonstrates that increased consumption of fruit and vegetables from less than 3 to more than 5 servings per day is related to a 17% reduction in coronary heart disease (CHD) risk **(He et al., 2007)**.

A diet rich in fruit and vegetables significantly reduces the risk of lifestyle diseases such as cardiovascular disease, atherosclerosis, cancers, diabetes mellitus **(WHO, 2004)**. Based on several epidemiological studies it was shown that the intake of foods rich in antioxidants, especially fruit and vegetables, cereals and some natural oils increases the concentration of antioxidants in the blood, and is associated

with a decrease in mortality and some chronic diseases such as the obesity **(Bes-Rastrollo et al., 2006)**.

Several healthy foods such as olive oil, fruit, vegetables, nuts, legumes, have been inversely associated with depression risk and even have been postulated to improve depressive symptoms **(Lang et al., 2015)**. Polyphenol content and antioxidant activity in varieties of apple and pear were observed by **Mendelová et al. (2011)**, in bilberry **Habánová et al. (2013**), in cranberries and blackberries **Vollmannová et al. (2014)**. Changes in the composition of orange juice have been examined by **Sádecká et al. (2014**), in a strawberry juice by **Predná et al. (2016)**, in grapefruit juice by **Belajová et al. (2017)**. Degradation of ascorbic acid in orange juice observed **Aguirre et al. (2019)**; **Kopuncová et al. (2018)**; **Aguilar et al. (2017)**; **Lu et al. (2018)**.

The aim of this work was to analyze behavior of consumers at fruit consumption, to search for knowledge awareness/level about antioxidants in foods, to examine which kinds of fruit people prefer and the form(state) of fruit most commonly consumed by Slovak consumers, and if depending on their place of residence.

Scientific hypothesis

We investigated the validity of the following hypotheses as a part of our research:

Hypothesis H1: We suppose that the place of fruit purchase is affected by the economic activity of the consumer.

Hypothesis H2: We expect that consumers who originate from the village will prefer fruit of Slovak origin.

Hypothesis H3: We suppose that fruit of temperate zone will be more preferable by consumers who have the opportunity to grow this kind of fruit themselves.

Hypothesis H4: We suppose that gender, age, economic activity and the origin (village/city) of the consumer affect the frequency of fruit consumption.

MATERIAL AND METHODOLOGY

Preference of fruit and frequency of fruit consumption at Slovak consumers and their awareness of antioxidants importance in human nutrition were monitored by questionnaire technique. The survey was performed from March till May, 2018. The questionnaire consisted of 9 questions and 4 issues classificating age, sex, place of residence and economic activity of respondents.

Questions were as follows:

1. Have you heard about the presence and importance of antioxidants in fruit?
2. Where did you get information on antioxidants?
3. Which of the antioxidants do you know?
4. How often do you eat fruit?
5. What types of fruit do you most frequently eat?
6. In which form do you prefer to eat fruit?
7. Provide the most frequent place to buy fruit.
8. Can you grow your own fruit?
9. When buying a temperate zone fruit, you prefer fruit grown (in Slovakia, abroad)?

Sample group consisted of 220 respondents, women represented 50%, men 50%. Structure of respondents by age was as follows: young people aged 18 – 25 years accounted for 53%, age group 26 – 40 years was represented by 16%, age group 41 – 55 years up 21%, respondents aged over 56 years accounted for 9% of the group. Structure of respondents according to their economic activity: 45% of students, 37% employed, 11% unemployed and 7% retired. The place of residence was at 40% respondents living in the town and 60% in the village.

Statisic analysis

Basic approaches of descriptive statistics was used, as well as methods of association measurement. Results were analyzed by Chi-Square statistic. Statistical significance has been tested based on the *p*-values. Correlations were proved by the Cramer's V coefficient. Statistical analysis was performed in SAS Enterprise 5.1 software.

RESULTS AND DISCUSSION

Antioxidants present in fruit protect the human body against undesirable chemical reactions, increase the resistance of the body, support the immune system, contribute to healthy skin and act against aging of cells. Antioxidants affect nervous system function, particularly the functioning of the brain **(Kindersley, 2001)**. **Jennings et al. (2012)** state that the increased frequency of total flavonoid intake significantly reduces blood pressure and contributes to the overall reduction in the risk of cardiovascular diseases.

We monitored respondent awareness about the importance and presence of antioxidants in fruit. 85% of respondents had information about the presence of antioxidants. For the most used sources of information on antioxidants, respondents identified the internet (29% of respondents) and media (28% respondents) school 18%, magazines 17% (Figure 1). As antioxidants they recognise vitamins (47% of respondents), minerals (29%), 20% of coenzyme Q10, and only 4% of flavonoids and polyphenols. People should consume over 1 g of flavonoids and phenolic acids daily **(Rui, 2003)**. The fruit can be consumed fresh as well as frozen, canned or otherwise modified. We determined that consumers prefer to have fresh fruit (54% of respondents), 18% of respondents prefer fruit juices, compotes 12%, fruit spreads reported 11% of respondents and 5% of respondents prefer dried fruit (Figure 2).

Consumption of fresh fruit and fruit products per capita and year (in terms of fresh fruit) in Slovakia observed **Meravá (2018)**. Consumption of fruit per capita and year reached 60.5 kg in 2017, consumption of fresh fruit reached 42.4 kg per person per year.

The qualitative properties of fresh garden fruit were analyzed by **Hegedüsová et al. (2016)**, **Mezey and Paulen (2003)**, the organoleptic characteristics of fruit and fruit juices during various storage conditions were evaluated by **Ozarda, Demirkoz and Özdemir (2015)**.

Modern trend knowledge in consumption and applying a healthy lifestyle also include consumer decision makers. By linking of current scientific knowledge and practice in the field of new fruit processing technologies, innovative multi-component products are developed, like smoothie.

Consumer preferences at fruit purchase

In terms of place of fruit purchase, respondents prefer supermarkets (48%). Directly from producers is fruit purchased by 19%, (Figure 3) in wholesale/retail stores by

17%. Similarly, 17% of respondents obtained the fruit directly from the small local markets.

We assumed that the purchase of fruit may be affected by economic activity of respondents (Hypothesis H1). Relationship between the place of fruit purchase and economic activity of the respondents is presented in Figure 3. Based on statistical evaluation there was not confirmed any existence of a statistically significant correlation. Place of fruit purchase is therefore influenced by other factors than the economic status of the respondents.

We also analyzed preferences of the respondents in relation to the selection and consumption of fruit according to its origin (Hypothesis H2). At 48% of respondents is prevalent fruit of temperate zone and 52% of respondents prefer fruit of southern zone. In our survey, the most commonly consumed fruit in the first order respondents indicated the pomes (51%), stone fruit (14%), tropical fruit (11%), small fruit (9%), grapes (9%) and nuts (6%).

In consumption of the temperate zone fruit in Slovakia per capita and year dominated apples (11.5 kg), grapes (4.8 kg) and peaches (2.5 kg). The consumption of small fruit per capita per year was 0.5 kg of currants, 1.0 kg of strawberries. Consumption of fresh fruit in fresh state on the Slovak market is increasing **(Meravá, 2018)**.

We also monitored the relationship between place of residence (village, city) and preference by country of origin (domestic versus imported fruit). Based on the *p*-value (*p*-value = 0.007), we can conclude that respondents who live in a village in its shopping behavior prefer fruit grown in Slovakia (Figure 5). Based on the Cramer coefficient (V = 0.18) this is only a weak correlation.

Fiľa and Tóthová (2013) state about the direct sale advantage in promoting the local economy, increasing employment in the region, reduction of transport costs as well as consolidation relations in the region. In relation farmer – consumer, there is a direct relationship between the seller and the buyer. Other benefits for producer are demand, development regarding consumers' needs, supporting social network. Food quality, transparent prices, contact with soil and animals belong to benefits for consumer **(Chreneková, Dirgasová and Fáziková, 2015)**.

Fruit originating from Slovakia is preferred by 86% of the respondents living in the villages and 72% of the respondents from the towns.

Ability to cultivate own fruit indicated 79% of respondents. In relation to the place of residence, it was found that 95% of respondents living in village can cultivate their own fruit. Among the respondents living in the city, the opportunity to cultivate own fruit have 55%. The results are shown in Figure 4.

We examined also the relationship (Hypothesis H3) between the ability to grow their own fruit and fruit preference according to zone, so we assumed that respondents who have the opportunity to grow their own fruit, will prefer more fruit of middle zone (Figure 4) but this relationship was not confirmed (*p*-value = 0.078).

Frequency of fruit consumption

To the question "How often do you eat fruit", 20% of respondents state consumption several times a day, 26% of respondents consume fruit once a day, 31% of respondents consume fruit once to three times per week, 23% of respondents consumed fruit only occasionally. By examining the frequency of fruit consumption (Hypothesis H4) by the age of respondents, we found that in the age category 18 – 24 years dominated consumption of fruit once to three times per week, aged 26 to 40 years consumption several times a day, in the age group 41 – 55 years dominated consumption of one fruit a day and in the age group over 56 years was prevalent once to three times per week. Following gender, we found that higher consumption of fruit is among women who consume fruit most common once a day, while men mostly consumed fruit only once to three times per week. At this point, we assumed the existence of a relationship among the frequency of consumption of fruit and gender, age of respondents, economic activity and provenances (place, residence) of respondents. It is not statistically significant difference in the frequency of fruitconsumption between men and women and it was not confirmed to be the difference in consumption of fruit among the age groups of respondents. Based on the relative frequencies it was shown that respondents who live in a village more often consume fruit, but the statistically significant difference between respondents from the village and the town was not confirmed (Table 1). Frequency of fruit composition was examined by several authors e.g. **Belej et al. (2016)**.

Fatrcová-Šramková, Schwarzová and Juríková (2017) examined the frequency of consumption of fresh as well as processed fruit and vegetables (canned products and vegetable and fruit juices) in adult females under the age of 26 and found that 1 – 2 portions of fresh fruit and 1 portion of vegetables predominated, that does not meet the recommendations. In the recommended doses of food it is stated that the consumption should be 96.7 kg for fresh fruit, of which fresh fruit of temperate zone is 57.7 kg. The World Health Organization **(WHO, 2004)** recommends consuming of five servings of fruit a day.

Eating habits of the population, food choice at purchase, choice of appropriate processing of fruit and its storage and even the popularity of certain foods are derived from the acquired habits from early childhood. Ongoing changes in the diet of consumers are affected by several factors such as globalization of markets, global trends in diet, developing tourism. Preferences of consumers can be affected by acquired eating habits and to a large extent, household income.

CONCLUSION

We can conclude that 85 % of respondents have some information on the presence ofantioxidants in fruit. Almost one-third of respondents eat fruit once to three times per week, 26 % respondents consume fruit once a day, 23% occasionally and 20 %respondents several times a day. Consumers prefer to consume fresh fruit (54% of respondents), 18% of respondents prefer fruit juices, compotes are prefered by 12%, fruit spreads reported 11% of respondents and 5% of respondents prefer dried fruits. Most often is fruit purchased in supermarkets (48%). Directly from producers is fruit obtained by 19%, in wholesale/retail stores 17%. Similarly, 17% of respondents obtain the fruit directly at the small local markets. Respondents living in the village often consume fruit, but statistically significant difference between respondents from village and town was not confirmed. Information obtained suggest that the importance of fresh fruit and juices containing natural antioxidants is quite well known, but their annual consumption is in fluctuating character.

OCCURENCE AND ANTIMICROBIAL RESISTANCE OF COMMON UDDER PATHOGENS ISOLATED FROM SHEEP MILK IN SLOVAKIA

Ivan Holko, Vladimír Tančin, Kristína Tvarožková, Peter Supuka, Anna Supuková, Lucia Mačuhová

ABSTRACT

The aim of this work is to identify the spectrum, frequency and antimicrobial resistance of bacterial pathogens occurring in sheep dairy herds in Slovakia. Of a total of 310 samples of sheep's milk coming from three breeds during two seasons (2017 and 2018), at least one potential pathogen was isolated from 102 samples (32.9%). A total of 131 microbial isolates were isolated. The most represented species were coagulase negative staphylococci CoNS (75.6%), followed by *Streptococcus agalactiae* (10.7%), *Staphylococcus aureus* (6.9%), *Streptococcus dysgalactiae* (4.6%), *Escherichia coli* (1.5%), *Enterococcus faecium* (1.5%), and others (*Streptococcus uberis*, *Streptococcus parauberis*, *Candida* sp., *Klebsiella* sp., moulds) below 1%. A total of 99 isolates of CoNS were tested for antimicrobial resistance. Of these, 63.6% were resistant to at least one antibiotic. A total of 24.2% of the tested isolates were resistant to 3 groups of antimicrobials simultaneously (multi-drug resistance). The highest resistance was observed to lincomycin (57.6%) and neomycin (36.4%), the lowest to sulfamethoxazolum+trimethoprim (0%) and enrofloxacin (3.0%). Based on the results of this work, it is possible to assume a similar spectrum of pathogens and their antimicrobial resistance described in the literature also within the Slovak sheep farms focused on milk production.

Keywords: sheep; milk; mastitis; pathogen; antibiotic

INTRODUCTION

Public health problems associated with consumption of unpasteurized cow's milk and raw-milk products have been well documented **(De Buyser et al., 2001; Harrington et al., 2002)**. There is no evidence that the risk from unpasteurized ewe's milk is any lower **(Allerberger et al., 2001; McIntyre et al., 2002)**. Pathogenic microorganisms can gain access to milk either by faecal contamination or by direct excretion from the udder into the milk.

The importance of subclinical mastitis as a limiting factor in sheep's milk production is well-known. In addition to decreased milk yield, decreased viability of lambs, subclinical mastitis also greatly reduces the hygienic quality of milk as well as its technological properties.

Current knowledge of mastitis in small ruminants has been reviewed by some authors **(Bergonier et al., 1999; Bergonier and Berthelot, 2003; Lafi et al., 1998; Contreras et al., 2007)**. The causative organisms of mastitis are categorized as major or minor pathogens **(Harmon, 1994)**. The most common major pathogens include *Staphylococcus aureus*, *Streptococcus agalactiae*, coliforms and enterococci, while other pathogens such as *Streptococcus* spp., *Pseudomonas aeruginosa*, *Mannheimia hemolytica*, *Corynebacteria*, Coagulase negative staphylococci and fungi, are considered to be minor pathogens which can produce intramammary infection in small ruminants, but occurrence rates are lower **(Contreras et al., 2007)**.

Differences in climatic conditions, production patterns, breeding management and breeding practices influence the different epidemiology and clinical manifestation of sheep milk. The aim of this work is to identify the spectrum, frequency and antimicrobial resistance of bacterial pathogens occurring in sheep dairy herds in Slovakia.

Scientific hypothesis

Staphylococci and streptococci are the most common cause of mastitis in milk sheep and their occurrence in milk is frequent. Antibiotics are not used in sheep as often as in dairy cows, but antimicrobial resistance can occur as the environmental impact to farm animals.

MATERIAL AND METHODOLOGY

Sampling and culture

During two seasons, samples of milk from 3 sheep farms were withdrawn repeatedly in the number 160 (season 2017) and 150 (season 2018). The animals for collection were selected by random selection. The breeding

organization was the following: farm 1 – Slovak Tsigaya, farm 2 – Lacaune, farm 3 – Slovak Walachian/Lacaune. Milk samples of volume 10 mL were collected into sterile tubes from both halves after disinfection and two streaks. After sampling, the samples were cooled to 5 – 10 °C, then frozen and transported to the laboratory. Bacteriological examination was performed within 5 days after collection. Milk samples (10 µL inoculum) were cultured on a selective diagnostic PM test (Lab-Media-Servis, CZ) at 37 °C for 24 hours. Isolated strains of pathogens were subsequently verified by typing with BBL Crystal® (Becton, Dickinson & Co., New Jersey, USA). A milk sample was classified as positive if at least one colony-forming unit (CFU) of *S. aureus* or *Streptococcus* (*Str.*) *agalactiae* was isolated. For other agents, the presence of at least three CFUs was needed for positive classification. Samples were classified as contaminated if three or more bacterial types were isolated from one milk sample and growth of a major udder pathogen was not identified. If growth of a major udder pathogen was found in combination with contaminating species, the sample would be diagnosed as positive for growth of the major udder pathogen.

Susceptibility testing

In vitro susceptibility of the isolates against antimicrobial agents was determined by the standard disk diffusion procedure **(CLSI 2008; 2013)**.

Coagulase-negative staphylococci (n = 99) were tested for susceptibility to 6 antimicrobial agents from the following groups: penicillin (amoxicillin+clavulanic acid 2:1 AMC), tetracyclines (tetracycline TET), aminoglycosides (neomycin NEO), lincosamides (lincomycin LCM), sulphonamides (sulfametoxazolum-trimethoprim SXT), and quinolones (enfofloxacin EFX). The isolates were tested by disc diffusion method according to the CLSI manual **(CLSI 2008; 2013)** using the following antimicrobial discs (Oxoid, Basingstoke, England): AMC (30 µg), NEO (30 µg), TET (30 µg), LCM (2 µg), SXT (25 µg), EFX (5 µg). The diameters of the inhibition zones were evaluated (susceptible, intermediate, resistant) according to CLSI breakpoints. Appropriate quality control tests were performed using reference strains of *E. coli* ATCC 25922, *Staphylococcus aureus* ATCC 29213 and *Enterococcus faecalis* ATCC 29212.

Statistic analysis

Simple descriptive statistics was used. The results of cultivation were processed into a percentage of individual microbial species. The results of antimicrobial resistance were also expressed as the percentage of resistant isolates in each type of antimicrobial.

RESULTS AND DISCUSSION

Of a total of 310 samples of sheep's milk coming from three farms, at least one potential pathogen was isolated from 102 samples (32.9%). The results are shown in the Table 1. The most represented pathogens were coagulase negative staphylococci CoNS, namely *Staphylococcus chromogenes*, *Staphylococcus epidermidis*, *Staphylococcus xylosus* (75.6%), followed by *Streptococcus agalactiae* (10.7%), *Staphylococcus aureus* (6.9%), *Streptococcus dysgalactiae* (4.6%), *Escherichia coli* (1.5%), *Enterococcus faecium* (1.5%) and others (*Streptococcus uberis*, *Streptococcus parauberis*, *Candida* sp., *Klebsiella* sp.). The cause of the sheep's mastitis may be a number of microorganisms, according to the literature, they are mainly representatives of the genus *Staphylococcus* **(Bergonier and Berthelot, 2003; Zigo et al., 2011)**. The results of this work also confirm this bacterial genus as dominant in the farming conditions included in our observation, in both consecutive seasons.

Several authors state that CoNS are most frequent pathogens responsible for subclinical mastitis of dairy sheep **(Fthenakis, 1994; Burriel, 1997; Lafi et al., 1998; Pengov, 2001; Ariznabarreta, Gonzalo and San Primitivo, 2002; Gonzalo et al., 2002)** and *Staphylococcus aureus* is more frequent in meat sheep **(Jones, 1991; Watson et al., 1990; Hariharan et al., 2004; Mork et al., 2007)**. The farms included in this work are focused on the production of sheep's milk and CoNS represent a significant prevalence of all isolated pathogens. *Staphylococcus aureus* represented less than 7% of isolates.

Streptococci are probably the second most common cause of ovine mastitis **(Bergonier et al., 1999)**. The most commonly isolated species are *Streptococcus agalactiae*, *Streptococcus uberis* and *Streptococcus dysgalactiae* **(Las Heras et al., 2002)**. In this work streptococci were mainly represented by *Streptococcus agalactiae*, but only in the first of the monitored seasons. In the second year of follow-up, the occurrence of streptococci in the samples taken decreased significantly. This difference could have been caused by certain breeding measures in the context of milk management and overall hygiene in the farm. The presence of other pathogens in the isolates obtained in this work was negligible.

Antibiotic resistance pattern for staphylococci isolated from subclinical mastitis refers mainly to cattle, and little is known about dairy sheep.

A total of 99 isolates of CoNS were tested for antimicrobial resistance. Of these, 63.6% were resistant to at least one antibiotic. A total of 24.2% of the tested isolates were resistant to 3 antimicrobials simultaneously. The highest resistance was observed to lincomycin (57.6%) and neomycin (36.4%), the lowest to sulfamethoxazolum+trimethoprim (0%) and enrofloxacin (3.0%). The results are shown in Table 2.

The high multidrug resistance rates observed in CoNS are in accordance with previous reports **(Kumar, Yadav and Singh, 2009; Sawant, Gillespie and Oliver, 2009; Vasil' et al., 2018)** and support the hypothesis that CoNS might play an important role as a source of genes resistant to *S. aureus* **(Taponen and Pyörälä, 2009)**. Considering such an assumption, studies about host specificity in *Staphylococcus aureus* and other pathogenic agents could provide useful information about the epidemiological importance of CoNS as reservoirs of genes resistant to pathogenic strains for humans. However, because CoNS are the major mastitis causing agents in small ruminants, the high frequency of resistant genes in such species reported here is worth noting.

Table 1 The numbers of microbial pathogens isolated from three sheep farms during two seasons in 2017 and 2018.

Pathogen	No. of isolates in the season						Total
	2017			2018			
	Farm 1	Farm 2	Farm 3	Farm 1	Farm 2	Farm 3	
Staphylococcus chromogenes	13	6	7	4	2	8	40
Staphylococcus epidermidis	3	4	3	3	4	3	20
Staphylococcus xylosus	8	14	5	4	3	5	39
Staphylococcus aureus	0	4	2	2	1	0	9
Streptococcus agalactiae	9	1	4	0	0	0	14
Streptococcus dysgalactiae	1	1	2	2	0	0	6
Streptococcus uberis	1	0	0	0	0	0	1
Streptococcus parauberis	1	0	0	0	0	0	1
Escherichia coli	0	2	0	0	0	0	2
Klebsiella sp.	0	0	0	0	1	0	1

Candida sp.	0			0	0	0	1
Micromycetes	0	0	1	0	0	0	1

Table 2 The results of antimicrobial resistance testing of coagulase negative staphylococci.

Antimicrobials	Zone diameters (mm) S – I – R	No. of isolates/percentage (n = 99)		
		Sensitive	Intermediate	Resistant
Amoxicillin+clavul.	≥30, 29 – 28, ≤27	81/81.8	3/3.0	15/15.2
Tetracycline	≥19, 18 – 15, ≤14	72/72.7	0/0	27/27.3
Lincomycin	≥20, 19 – 17, ≤16	33/33.3	9/9.1	57/57.6
Enrofloxacin	≥25, 24 – 21, ≤20	81/81.8	15/15.2	3/3.0
Sulphametoxazolum+trimet.	≥19, 18 – 16, ≤15	96/97.0	3/3.0	0/0
Neomycin	≥23, 22 – 20, ≤19	36/36.4	27/27.3	36/36.4

The drugs showing the lowest resistance rates were enrofloxacin and sulphonamides, which are in accordance with other studies on mastitis in several ruminant species **(Kumar et al., 2009)**. **Virdis et al. (2010)** reported high sensitivity to quinolones, but not to aminoglycoside in subclinical mastitis-causing staphylococci.

From the point of view of epizootology, CoNS are frequently found to be a pathogenic especially in the case of subclinical mastitis. They do not represent a major specific pathogen but can potentially cause infections that tend to have a mild clinical manifestation but cause losses in the milk production, in quantity and quality of milk.

CONCLUSION

Based on the results of this work, it is possible to assume a similar spectrum of pathogens and their antimicrobial resistance described in the literature also within the Slovak sheep farms focused on milk production. Coagulase negative staphylococci, as the most common pathogen, poses a risk in the form of a subclinical course of inflammatory changes in the mammary gland that often escape the attention of breeders, but can have a significant impact on the quality of milk production.

APPLICATION OF ELECTRONIC NOSE FOR DETERMINATION OF SLOVAK CHEESE AUTHENTICATION BASED ON AROMA PROFILE

Jana Štefániková, Veronika Nagyová, Matej Hynšt, Vladimír Vietoris, Patrícia Martišová, Ľudmila Nagyová

ABSTRACT

Electronic nose with sensors is used in many industries and for various applications such as quality control, process monitoring, shelf life evaluation, origin or authenticity assessment. The aim of this work was to investigate the electronic nose with FID detectors applicability for characterization of steamed cheese and for the assessment of steamed cheese quality decay during storage. Samples of smoked and unsmoked steamed cheese varieties from 5 Slovak enterprises concerning different regions of Slovakia were analysed. Data from aroma profiles were processed by statistical technique PCA. Compounds like acetaldehyde, 1-propanal, propanoic acid, ethyl hexanoate, furfural, butan-2-one, isovaleric acid, 1-hexanol or α-pinene were determined as significant flavours in fresh steamed cheese samples. In the current study, no significant differences in aroma profiles between fresh and stored cheese samples were confirmed. Thus, differences in main odour substances composition of steamed cheese varieties, obtained from various producers in several geographic regions of Slovakia, were minor.

Keywords: Slovak steamed cheese; aroma profile; e-nose; authentication

INTRODUCTION

Electronic nose (e-nose) is an odour detection device using a sensor array **(Delgado-Rodríguez et al., 2012)**. Many industries use e-nose for diverse applications such as quality control **(Li et al., 2017; Xu et al., 2017; Gancarz et al. 2017; Chen et al., 2018; Buratti et al., 2018)**, process monitoring, durability assessment, origin ranking and originality **(Wilson and Baietto, 2009; Śliwińska et al., 2014; Li et al., 2017)**. Another implementation of e-nose in the food industry involve dairy products classification whether in terms of flavour, variety type, geographical origin, ripening stage (in case of cheese) or its shelf life prediction **(Ampuero and Bosset, 2003)**. E-nose can be used also to monitor volatile compounds that indicate female cattle fertile period, acknowledged by the study of **Manzoli et al. (2019)**.

Working principle of e-nose Heracles II is gas chromatography, detecting aroma compounds of very small concentrations in real-time of a few minutes and identifying them by comparing Kovats retention indices with the NIST library. To obtain vital information from the analysis of samples, multivariate statistics is applied most frequently **(Buratti et al., 2018)**. The use of e-nose analysis is a rapid, easy, reliable, accurate and non-polluting method practice.

Aroma perception occurs by olfaction, when olfactory receptors placed on the nasal cavity roof are stimulated by aroma active compounds. In terms of flavour recognition during food or beverage consumption, the aroma active compounds are perceived retronasally. Different combinations of large variety of compounds including short, medium chain fatty acids, alcohols, aldehydes, ketones, esters or sulphur compounds create a characteristic smell and flavour of each and every cheese product. Multiple cheese types may consist of the same aroma active compounds, yet they differ from each other by altered amount, and therefore the percentage content, of particular component in such product **(Niimi et al., 2014)**. According to **Commission Regulation (EC) No 656/2008**, the protected geographical indication "Slovenská parenica" is an official label of Slovak parenica type steamed cheese if it meets all characteristics and requirements defined within this Regulation (referring to Council Regulation (EC) No 510/2006). Here, Slovak parenica is defined as "a steamed, lightly smoked cheese wound into two rolls 6 – 8 cm in diameter and 5 – 8 cm high, connected in a 'S'- shape having yellow to brown colour on the outside after smoking; white to buttery yellow on the inside. The rolls are bound with cheese string or chain. Prior to being rolled up, the cheese strip is 2 – 3 mm thick, 5 – 8 cm wide and 4 – 6 m long. The ingredients used are fresh raw, unprocessed ewe's milk from grazing ewes of the Wallachian, improved Wallachian, Cigaja and East Friesian breeds or a mixture

of fresh raw, unprocessed ewe's milk and fresh raw, unprocessed cow's milk, containing at least 50% ewe's milk". In Slovakia, the production of parenica type cheese is very widespread, directed either as mechanized production for big dairy factories or as manual operation by small corporations.

In presented study, Slovak steamed cheese samples, produced by small and medium manufacturers from pasteurized raw cows' milk, were analysed. Being processed from cow's milk, they are not referred to as Slovenská parenica. For this work`s purposes, we will refer to the analysed samples as the steamed cheese in the following text. At the beginning of the steamed cheese production, a starter culture is added to the milk for the fermentation process and thereby to reduce the pH of the milk to the desired level. For such aim, mesophilic culture (*Lactococcus lactis* subsp. *lactis, Lactococcus lactis* subsp. *cremoris*) and thermophilic culture (*Streptococcus salivarius* subsp. *thermophilus, Lactobacillus delbrueckii* subsp. *bulgaricus*) are the most commonly used ones **(Onipchenko et al., 2012)**. After the starter culture inoculation, the rennet is added, and the coagulation phase of milk begins. The optimum coagulation temperature is 30 to 35 °C. The created cheese curd is then treated by cutting, stirring and heating to a higher temperature, resulting in separating the whey out and thereby reducing the water content. The raw cheese block is then pressed with gentle pressure to promote the separation of the whey and such a cheese block is then an input raw material for the steaming process. The steaming process runs in two stages. In the first steaming stage, the shredded cheese curd is dosed into a hot water tank (65 – 85 °C). Due to the high temperature, the raw cheese dough gets a stretchable and mouldable consistency. In the second steaming stage, the raw dough is stretched and kneaded. After these phases, the next step in steamed cheese production is forming the cheese into desired shapes. Finally, the steamed cheese is subjected to a salt bath and in case of smoked cheese products the salted cheese undergoes smoking process **(Muliawan and Hatzikiriakos, 2008; Zimanová et al., 2016)**.

Scientific hypothesis

The aim of this study was to determine differences between steamed cheese products and to confirm the ability to evaluate the authentication of these products using the fast method of electronic nose with FID detectors.

MATERIAL AND METHODOLOGY

Sampling

Samples of smoked (S) and unsmoked (U) steamed cheese varieties from 4 Slovak enterprises classified as medium enterprises (samples no. 1, 2, 4, 5) and one small enterprise (sample no. 3) from different regions of Slovakia were collected. Samples were processed from pasteurized cow's milk. Sampling was performed on the day of production, and analysis of fresh samples was carried out on the following day. Subsequently, analyses of samples were performed again after storing the samples for 14 days at 4 – 8 °C. Samples were stored in original packaging bags sealed under protective atmosphere conditions in refrigerator at temperature 4 – 8 °C.

Sample preparation

Steamed cheese samples were sliced into small pieces, and by 4 g weighed into clean 20 mL headspace vials closed by magnetic cap with PTFE/Sil septum. Thus, prepared samples were stirred at 50 °C for 15 minutes on a shaker included as a part of the GC headspace autosampler (Combi Pal, Alpha M.O.S.).

Determination of aroma profiles

E-nose with two FID detectors (Heracles II, Alpha M.O.S.) was used for determination of steamed cheese samples aroma profiles. From the saturated air above the sample level, 5 mL volume was withdrawn using a headspace autosampler syringe and dispensed into the e-nose injector heated to 200 °C. The analysis itself lasted for 110 seconds and the separation of aroma compounds took place in two columns with following temperature program; for the 1st column: isotherm 80 °C, for the 2nd column: initial temperature 50 °C and temperature gradient 3 $°C.s^{-1}$ to 250 °C. Hydrogen was used as the carrier gas. Identification of the compounds was performed by matching the measured peaks with Kovats´retention indices with NIST library (The National Institute of Standards and Technology library) by software Alpha Soft V14 (Alpha M.O.S.).

Statistical analysis

Compounds with a discriminant >0.990 were selected, based on which the semi-qualitative evaluation was performed and PC analysis (Principal Component Analysis) was made by Alpha Soft V 14 (Alpha M.O.S.) software. Descriptors were analysed using single factor analysis of variance and significance was at $p < 0.001$.

RESULTS AND DISCUSSION

Thirteen specified aromatic compounds with a discriminant >0.990 were selected, based on which the semi-qualitative evaluation was performed and PCA analysis was made. Figure 1 displays results processed by PCA technique of the aroma profile of fresh steamed cheese samples. Among smoked and unsmoked fresh steamed cheese from the suppliers no. 1, no. 2 and no. 3 (negative scores), and no. 4 and no. 5 (positive scores) no statistically significant differences ($p < 0.001$) were evident in their aroma profiles (PC1 axis 95.94%). On the contrary, samples of smoked (negative scores) and unsmoked (positive scores) fresh steamed cheese from suppliers no. 2, no. 3, no. 4 and no. 5 were differed in their aroma profiles in the PC2 axis (3.34%). It is assumed that these manufacturers use a different way for cheese smoking in terms of wood used in combustion process.

Cheese types such as Italy mountain cheese, Camembert cheese, Mozzarella cheese, Cheddar cheese etc. are also the subject of number of studies **(Carafa et al., 2019; Batty, Waite-Cusic, Meunier-Goddik, 2019; Kim et al., 2014; Velasco et al., 2019)**, which are of a different cheese type as our investigated samples are, and therefore it is not possible to comapre the results of the Slovak steamed cheese samples with the results of the studies

mentioned above. The aroma profile of unripened steamed cheese produced from cows' milk is not fully investigated and reported, and therefore the results might not correlate with results of the authors of other studies.

Semi-qualitative evaluation was based on comparison of the Kovats` retention indices with the NIST library. Samples were divided into three groups, each consisting of samples with only small differences in their aroma components composition. As significant compound (discriminant >0.990) responsible for the fresh steamed cheese aroma, 1-propanal was detected in samples 1S, 1U, 3U and 2U. Differences causing compounds in aroma profiles of 2S and 3S fresh samples, compared to the other samples, were acetaldehyde, ethyl hexanoate, isovaleric acid, 1-hexanol, furfural, butan-2-one and α-pinene. **Bhandari et al. (2016)** determined the aromatic profile of ripened Italian Parmigiano Reggiano cheese from unpasteurized milk by SPME-GC-MS and detected of furfural, ethyl butanoate, ethyl hexanoate, ethyl octanoate, 2-nonanone, 2-heptanone, 3-methyl butanal, acetic, butanoic, hexanoic, octanoic and decanoic acids and benzeneacetaldehyde as the major compounds. On the contrary, carboxylic acids were the most abundant aroma compounds in the Torta del Casar cheese performing SPME-GC-MS analysis, specifically acetic, butanoic, hexanoic and octanoic acids **(Delgado-Martínez et al., 2019)**.

Smoked and unsmoked fresh steamed cheese samples from suppliers no. 4 and no. 5 differed from other samples by the presence of propanoic acid and 1-propanal in their aroma profiles composition. Identified compounds matched the NIST library with ≥50%. Therefore,

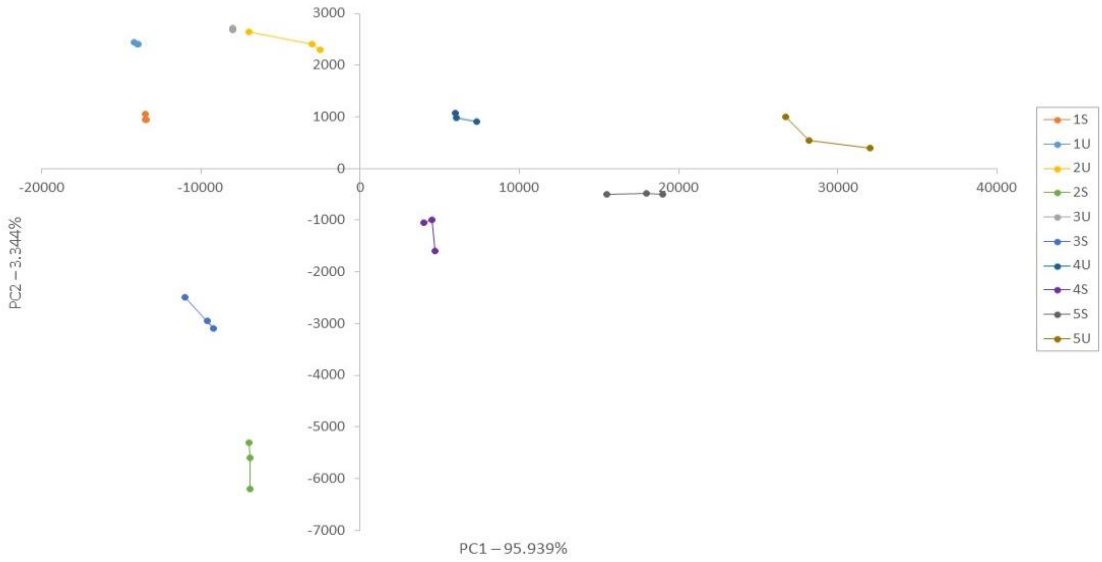

Figure 1 Projection of the samples onto the space defined by the first two principal components (PC1/PC2). Sample groups according to fresh: S (smoked steamed cheese) and U (unsmoked steamed cheese) of five Slovak producers (1 – 5).

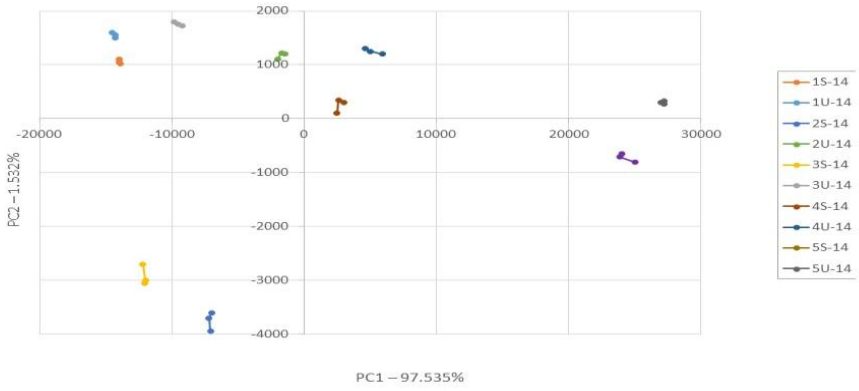

Figure 2 Projection of the samples onto the space defined by the first two principal components (PC1/PC2). Sample groups according to stored: S (smoked steamed cheese) and U (unsmoked steamed cheese) of five Slovak producers (1 – 5).

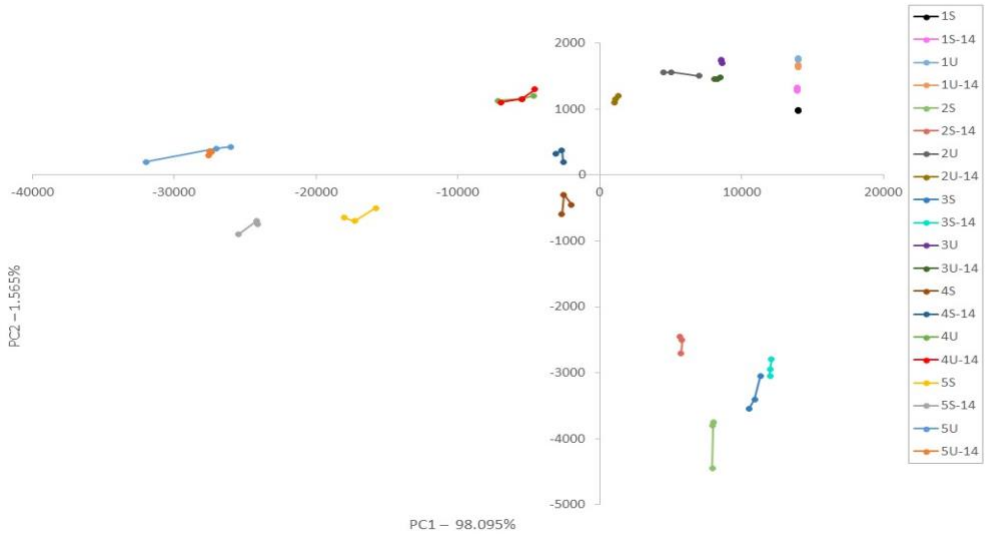

Figure 3 Projection of the samples onto the space defined by the first two principal components (PC1/PC2). Sample groups according to storage conditions: S (smoked steamed cheese) and U (unsmoked steamed cheese) of five Slovak producers (1 – 5).

verification of presented claims for comparison of aroma profiles by GC-MS or GC-FID-O analysis is highly recommended **(Sádecká et al., 2014; Šaková et al., 2015; Sádecká et al., 2016)**.

Samples were stored in the original sealed packages in refrigerator for 14 days, after which their aromatic profiles were determined the similar way as the fresh samples. The stored smoked steamed cheese samples 2S-14, 3S-14 nad 5S-14 were found in the negative scores of PC2 axis, while stored unsmoked samples from the same suppliers (2U-14, 3U-14 and 5U-14) were plotted in the positive PC2 axis 1.53%. There were no differences in the aroma profiles of the samples from the suppliers no. 1 and no.4 (1S-14 and 1U-14, 4S-14 and 4U-14) (PC2).

Evaluation was done by comparing Kovats` retention indices with NIST library (≥50%) and PCA analysis (see Figure 2). In case of stored steamed cheese samples, the number of compounds generating differences in the aromatic profile with discriminant >0.990 increased to 21 as oppose to the fresh ones. In analogy to the fresh samples, similar relationships between samples were observed, with propanal, acetaldehyde, isovaleric acid, 1-hexanol, furfural or α-pinene as predominating compounds. For smoked samples from suppliers no. 2 and no. 3 compounds such as diacetyl, 2-pentanone, 3-heptanone, 2-heptanone, ethyl hexanoate, hexanal and 2-methylpropanal. For stored samples no. 4 and no. 5, except propanoic acid and propanal, 2-methylpropanol was also a significant component of their aroma profiles, yet it was not recorded as significant in the equivalent fresh samples of the same suppliers.

For example, **Majcher et al. (2011)** studied a special type of Polish smoked (1 or 3 days) ewe cheese called Oscypek. Analysed smoked cheese consisted compounds from biochemical reactions (carboxylic acids, alcohols, aldehydes, ketones, esters, sulfur compounds), from smoking (furans/furanones, phenols) and from milk flavour (terpenes). The results of our research, analysing aroma profiles of Slovak steamed cheese by e-nose, confirm the presence of above mentioned compounds (furfural, propanoic acid, diacetyl, ethyl hexanoate, etc.) and compounds alike (2-butanone, propionaldehyde, etc.). **Thomsen et al. (2014)**, examined the aroma profile of seven commercial semi-hard cheese samples by GC-MS and their study is to some extent comparable to the aroma profile (2-propanol, 2-methyl-propanol, 3-methyl butanal, diacetyl, ethyl acetate, ethyl propanoate, ethyl butyrate, propanoic acid) of this work`s steamed cheese samples. **Guarrasi et al. (2017)** examined the effect of starter and non-starter lactic acid bacteria on the aromatic profile of Caciocavallo Palermitano cheese, traditional cheese in Western Sicily. The class of ketones represented a consistent percentage of the volatile compounds, followed by alcohols and esters. 2-butanol, butanoic and hexanoic acids and their esters, diacetyl and 3-hydroxy-2-butanone have been identified as significant compounds of volatile profiles of cheese by lactic acid bacteria. The identified α-pinene from terpenes group is usually introduced to cheese flavour as milk constituents **(Nogueira, Lubachevsky and Rankin, 2005; Majcher et al., 2011)**.

No statistically significant differences (PCA) (p <0.001) in aroma profiles of fresh and stored samples were detected when comparing samples from the same supplier, depicted in Figure 3, except smoked fresh (negative axis PC2) and stored (positive axis PC2) samples from the supplier no. 4.

CONCLUSION

This study for the first time proved possibility of steamed cheese quality evaluation in only a few minutes using e-nose. This simple and rapid method could be implemented also during sensory evaluation by tasters, allowing and granting a fast and inexpensive analysis of the controversial samples.

The results of this research have shown that odours of steamed cheese, obtained from several producers of different geographic Slovak regions, varied only a little in

terms of the main representative aroma substances by means of e-nose detection. Slight differences could be caused due to the use of cows' milk instead of ewe's milk, due to the different geographical area, and also due to the presence of various non-starter and starter dairy bacteria. The 2S and 3S samples had a different aromatic composition compared to other samples, thus opening up the space for evaluation of the cheese smoking effect on the aroma profile of the smoke vapours. For confirmation of submitted conclusions, it is appropriate to measure a larger number of samples and therefore obtain extensive data of the supplied products.

EFFECT OF EUGENOL, NERIDOL AND PIPERINE FEED SUPPLEMENT ON THE THIGH MUSCLE FAT PROFILE OF BROILER CHICKENS

Mária Angelovičová, Michaela Klimentová, Marek Angelovič

ABSTRACT

The purpose of this study was to investigate of the broiler chicken thigh muscle fat profile after feeding a commercial supplement based on eugenol, nerolidol and piperine applied in feeding mixtures. Broiler chickens Ross 308 were reared in a pen equipped with a straw deep litter and placed into 2 groups. One group was designated as control and the second as experimental. Difference between control and experimental groups was in using of feed supplement in experimental feeding mixtures. Experimental supplement is a commercial powder product which was used in an amount of 10 g per 100 kg of feeding mixtures. Chickens of body weight of 1800.0 g were selected from each group, human killed and technologically processed to carcass. Samples were measured according to Fourier Transform Infrared Spectroscopy (FTIR) using the Nicolet 6700 instrument. Infrared area near middle was chosen for determining fat and fatty acids. Mean fat content was found slightly higher value 1.53 g.100g^{-1} in experimental group opposite 1.49 g.100g^{-1} in control group showing no statistically significant difference (p >0.05). Ratio among saturated fatty acids (SFAs), monounsaturated fatty acids (MUFAs) and polyunsaturated fatty acids (PUFAs) was 4.24:5.89:1 in experimental group and 3.75:5.13:1 in control group. Omega-3 PUFAs content was reached 0.54% in experimental group and 0.58% in control group showing no statistically significant (p >0.05). Near-perfect correlation was found between total PUFAs and omega-6 PUFAs as well in the experimental group and control group showing linear, positive and statistically significant relation (p <0.01, p <0.001). Ratio between omega-3 and omega-6 PUFAs was statistically significant (p <0.05) closer in experimental group 1:14.65 opposite ratio 1:16.78 in control group. Conclusion: comparable fat profile in the thigh muscle was achieved, showing no statistically significant difference (p >0.05), in addition to the correlation between total PUFAs and omega-6 PUFAs, which was statistically significant in control (p <0.001) and experimental groups (p <0.01), and statistically significant (p <0.05) closer relation between omega-3 and omega-6 PUFAs in experimental group.

Keywords: feed supplement of eugenol; neridol and piperine; broiler chicken; thigh muscle; fat; fatty acid

INTRODUCTION

We have followed this study for ongoing research at the Slovak University of Agriculture in Nitra, published by **Tkáčová et al. (2015)**, which states, on the basis of the oxidative stability results of chicken meat, that the natural feed component has its justification. This issue requires however, further research. Natural-based products such as, for example, clams, oregano, mint, thyme and cinnamon have been used for many centuries as food preservatives and as medicinal plants, mainly because of their antioxidant and antimicrobial effects. At present, many studies confirm the wide range of properties of these natural resources for public health. Since the ban on the use of feed antibiotics has been the subject of many scientific teams' research. Of these plant products, the aroma of *Syzygium aromaticum* attracted attention mainly because of its strong antioxidant and antimicrobial activity **(Mbaveng and Kuete, 2017)**. **Kardum and Glibetic (2018)** examined natural resources richest on polyphenols. The results show that the spice is a food type with a higher content of polyphenols, followed by fruit, seeds and vegetables. The primacy of the spice is fragrant *Syzygium aromaticum*, which has a higher content of polyphenols and antioxidants. Essential oil of *Syzygium aromaticum* could also be used to influence lipid peroxidation and enzyme activities of catalase, glutathione-S-transferase, peroxidase, polyphenol oxidase and superoxide dismutase **(Afify et al., 2012)**.

Literature review conclusion on Syzygium aromaticum biological effects

On the basis of literary knowledge, *Syzygium aromaticum* is a very interesting plant with enormous potential to use as a food preservative as a rich source of antioxidant compounds. It is proved that its biological effects indicate the development of human and animal drugs and further use in agriculture. This information confirms the use of this plant over the centuries.

Lavender medicine (*Lavandula augustifolia, L. officinalis, L. vera*) contains essential oil, anthocyanins, phytosterols, sugars, minerals, kumaric acid, glycolic acid, valoric acid, ursolic acid, herniarin, coumarin and tallow **(Dănilă et al., 2018)**.

Essential oils from Lavender plants show a wide range of biological activities. The essential oil of *Lavandula dentata* has an inhibitory effect on the growth of bacteria including *Salmonella*, *Enterobacter*, *Klebsiella*, *Escherichia coli*, *Salmonella aureus* and *Listeria monocytogenes*. On the other hand, essential oil of *Syzygium bipinnata* has antibacterial properties against *Escherichia coli*, *Pseudomonas aeruginosa*, *S. aureus* and *Bacillus subtilis* and antifungal properties against *Aspergillus niger*, *Penicillium notatum*, *Candida albicans* at concentrations from 0.5 to 2.0 $\mu g.mL^{-1}$ for bacteria and from 2.0 to 4.0 $\mu g.mL^{-1}$ for fungi **(Hanamanthagouda et al., 2010)**. Essential oils have antioxidant properties, which protect the cells against the harmful effects of free radicals. Lavender medical essential oil has proven antioxidant activity **(Blažeković et al., 2018)**. **Hui et al. (2010)** demonstrated the inhibitory effect of this essential oil on fat oxidation and lipid peroxidation in the linoleic acid model system. **Angelovič et al. (2015)** state that the mechanisms of oxidative degradation can be autoxidation in presence of atmospheric oxygen. **Chia-Wen et al. (2009)** used organic chemical compound 2.2-diphenyl-1-picrylhydrazyl (DPPH) to study the antioxidant properties of lavender essential oil and especially its ability to inactivate free radicals. The value of 15.18 ±0.009% at a concentration of 5 $g.L^{-1}$ indicated properties comparable to essential oils of lime and marjoram. **Viuda-Martos et al. (2011)** reported a significantly lower ability of essential oil to deactivate free radicals at a similar concentration (4.11%). Studies testing the ability of this essential oil to reduce 50% of DPPH residues resulted in different results ranging from 289 $\mu g.mL^{-1}$ to 48.7 $mg.mL^{-1}$. According to **Pereira et al. (2018)** some essential oils such as linalool and terpineol, have an effect on the central nervous system, weaken the physical activity of humans and animals, reduce anxiety, and ease sleep. In a study of brain waves, it turned out that 40 healthy adults had increased *beta* wave activity, and in mathematical tests they were more successful just after inhalation of essential oil lavender medical. On the other hand, it is reported that patients felt relaxed and showed a positive attitude towards life, but was accompanied by drowsiness **(Lee et al., 2017)**.

Literature review conclusion on *Lavandula augustifolia* biological effects

Experiences from scientific and scientific literature suggest that *L. angustifolia* and its secondary metabolites have a very good biological activity with many uses. Research has confirmed that lavender medicine grown in different regional regions is a valuable plant source with chemical and biological properties applicable in many areas of agriculture, medicine, etc. Current modern medicine should pay attention to the synergistic effect of secondary metabolites of plants and synthetic drugs as they can help solve many problems including microbial resistance to synthetic antibiotics.

Piper nigrum L., the genus *Piperaceae*, is one of the most widely used spices in the world, known for its pungent component piperine. Piperine is the major bioactive compound of *Piper nigrum* and *Piper longum*, which are reported to have immunomodulatory, anti-carcinogenic, antiasthmatic, stimulatory, hepatoprotective, anti-inflammatory, anti-viral and antimicrobial effects **(Abdulazeez et al., 2016)**. The method of storing and processing spices is particularly important because piperine is a key active compound and its effectiveness is easily lost due to exposure to heat, for example, in a variety of domestic culinary treatments. Piperine and its isomers pass light-induced isomerisation to isopiperine, chavidine and isochavine. Isomerisation increases with light intensity and exposure time. Chavicin slowly changes to piperine during storage, leading to a loss of pungency. Piperine inhibits many enzyme biotransformation drug responses, which is an important aspect for the metabolic activation of carcinogens and energy production of mitochondria **(Ezawa et al., 2017)**. Further studies confirm that piperine causes specific effects related to its concentration on mitochondrial bioenergy and energy metabolism enzymes **(Gorgani et al., 2017)**. **Mgbeahuruike et al. (2017)** they concluded that piperine significantly increased pancreatic lipase activity and stimulated pancreatic amylase, trypsin and chymotrypsin. Positive effects on pancreatic digestive enzymes developed by piperine consumed in the diet could be a contributing factor to the well-known digestive stimulating effect of black pepper. The bioavailability and bioactivity of many drugs effectively potentiate piperine. Piperine has the ability to inhibit several enzyme-mediated pathways and biotransformation reactions **(Mhaske, Sreedharan and Mahadik, 2018)**.

Literature review conclusion on *Pepper nigrum* L. biological effects

Black pepper is a rich source of many biologically active ingredients, such as monoterpenes, sesquiterphenes and other volatile compounds. Various health benefits of black pepper and black long spice have been confirmed by cell, animal and human tests. It has been found that it has many beneficial therapeutic applications. It is used as an immunomodulator, stimulant, hepato-protective, anti-inflammatory, anti-carcinogenic, contraceptive, fungicidal, antibacterial and anti-asthmatic material. It has also been found to cause increased bioavailability of nutrients from food, drugs, anti-carcinogenic and phytochemical substances, and stimulates the effect on enzymes metabolizing the drug. It accelerates metabolism and lipid peroxidation. Modern science has demonstrated the molecular basis of the pharmacological properties of black pepper and black long spice against human disease, and some clinical studies have demonstrated the safety and efficacy of the spice in humans.

Based on the above-mentioned issue, the aim of our work was experimental investigation of broiler chicken thigh muscle fat profile after feeding a commercial supplement based on eugenol, nerolidol and piperine applied in feeding mixtures.

Scientific hypothesis

Improving the fat profile of broiler chicken thigh muscles after feeding feed mixtures with the supplement of eugenol, nerolidol and piperine.

MATERIAL AND METHODOLOGY

Experiment was carried out at Poultry farm Zámostie, Slovakia. Broilers chickens were reared in a pen equipped with a straw deep litter. Broiler chickens Ross 308 were placed into 2 groups, each in 50 pcs. One group was designated as control and the second as experimental. The chickens in the pen had a permanent access to water, to the feed and enough place to move. They have secured welfare in accordance with **Council Directive 2007/43/EC**. Experimental period was 42 days divided into three stages from 1 to 14 days as a starter, from 15 to 35 days grower and from 36 to 42 days as a finisher. Difference between control and experimental groups was in using of feed supplement in experimental feeding mixtures. Experimental supplement is a commercial powder product based on eugenol, nerolidol and piperine which was used in an amount of 10 g per 100 kg of feeding mixtures.

Chemical analysis of broiler chickens thigh muscle on fat profile

Prepared of based samples for chemical analysis

Thigh samples were prepared for chemical analysis in accordance with **AOAC 983.18**. Chickens were slaughtered at 42 day of age. Chickens were selected from each group of body weight 1800.0 g, human killed and technologically processed to carcass. The left thigh was separated from each carcass. Each thigh was boneless and clear of skin. The thigh muscle was milled with a laboratory homogenizer. A 50.0 g sample was taken for chemical analysis from each homogenized thigh muscle.

Chemical analysis

Fourier Transform Infrared Spectroscopy (FTIR) was used for chemical analysis of broiler chicken thigh samples. Sample measurement was done using the Nicolet 6700 instrument. Infrared area near middle was chosen for determining fat, saturated fatty acids, polyunsaturated fatty acids, omega-3 polyunsaturated fatty acids and omega-6 polyunsaturated fatty acids.

Statistical analysis

All statistical analyses were computed using the ANOVA procedures of SAS software (version 9.3, SAS Institute, USA). Mean values $(\bar{x})$, standard deviation (SD) and variation coefficient (c_v) are reported in tables. Statistical significance was calculated using t-test. Differences between the treatments were considered significant at $p \leq 0.05$. The Pearson correlation coefficient (r_{xy}) was used to test the relation between the two variables.

According to **Cohen (1988)**, the calculated correlation coefficient value (r_{xy}) is interpreted as follows: r_{xy} over 0.5 is strong dependence, from 0.3 to 0.5 is middle dependence, and from 0.1 to 0.3 is weak dependence, less than 0.1 is trivial (simple) dependence. Correlation, relation between two variables, as near-perfect, is reached in the range of values from 0.9 to 1.0. A very strong correlation is characterized by values ranging from 0.7 to 0.9. The strength of correlation between two variables was statistically tested at a significance level $p \leq 0.05$, $p \leq 0.01$ and $p \leq 0.001$.

RESULTS AND DISCUSSION

Fat content in broiler chicken thigh muscle

Mean values and statistical analysis for fat content in broiler chicken thigh muscle shows Table 1. Mean fat content in broiler chicken thigh muscle was found slightly higher value 1.53 g.100g^{-1} in experimental group with supplement of eugenol, nerolidol and piperine opposite 1.49 g.100g^{-1} in control group. The difference in fat content in broiler chicken thigh muscle was not statistically significant between groups ($p > 0.05$). Based on the statistical evaluation of the results by standard deviation and coefficient of variation it was found that the measured values of the fat content in the broiler thigh muscle was more even in the control group compared to the measured fat content in the broiler chicken thigh muscle after feeding of the feeding mixtures with a supplement of eugenol, piperine and nerolidol ($SD = 0.33$, $c_v = 21.57\%$ opposite $SD = 0.37$, $c_v = 24.83\%$). Investigation and control of the total fat intake in the ingested food has its own justification. Total fat intake recommendations are based on evidence that indicates consumption outside of these ranges is associated with a greater intake of energy and saturated fatty acids (fat intake >35%) or greater intake in carbohydrate (fat intake <20%); higher intake of carbohydrate leads to increases in plasma triglyceride and reductions in high-density lipoprotein cholesterol levels **(Vannice and Rasmussen, 2014)**. The structure of each fatty acid differs. Individual fatty acids may have unique and specific impacts on health. The impact of specific fatty acids on disease incidence is difficult to elucidate. Chronic disease develops over many months to several years and is the culmination of many genetic and lifestyle factors. This complexity makes randomized controlled trials of dietary interventions largely impractical. Experimental trials, coupled with observational, epidemiological, and mechanistic studies, provide valuable evidence of the human health effects of dietary fat and specific fatty acids **(Mozaffarian, 2008)**.

Ratio among saturated, monounsaturated and polyunsaturated fatty acids in fat of broiler chicken thigh muscle

Mean values for ratio among saturated, monounsaturated and polyunsaturated fatty acids in fat of broiler chicken thigh muscle shows Table 2. Ratio among saturated fatty acids, monounsaturated fatty acids and polyunsaturated fatty acids in fat of broiler chicken thigh muscle was 4.24:5.89:1 in experimental group with supplement of eugenol, nerolidol and piperine and 3.75:5.13:1 in control group. Fatty acid composition is a very important component of meat quality and has received considerable interest in view of its implications for human health **(De Smet, Raes and Demeyer, 2004)**.

It is well known that the higher intake of saturated fatty acids in the human diet increases the risk of the development of coronary heart disease, atherosclerosis and cancer **(Mensink and Katan, 1992)**, whereas monounsaturated fatty acid and polyunsaturated fatty acid, especially omega-3, have a number of associated health benefits **(Siriwardhana et al., 2012)**.

Table 1 Mean values and statistical analysis for fat content in broiler chicken thigh muscle.

Group	n	$\bar{x}$, g.100g^{-1}	*SD*	c_v, %	t-test
Control	6	1.49	0.33	21.57	
Experimental with supplement of eugenol, nerolidol and piperine	6	1.53	0.37	24.83	p >0.05

Note: n – multiplicity, $\bar{x}$ – mean, *SD* – standard deviation, c_v – coefficient *of* variation, p >0.05: no statistically significant difference between control and experimental group with supplement of eugenol, nerolidol and piperine.

Table 2 Mean values for ratio among saturated, monounsaturated and polyunsaturated fatty acids in fat of broiler chicken thigh muscle.

	Ratio		
	Saturated fatty acids	Monounsaturated fatty acids	Polyunsaturated fatty acids
Group	n = 6	n = 6	n = 6
Control	3.75	5.13	1
Experimental with supplement of eugenol, nerolidol and piperine	4.24	5.89	1

Note: n – multiciplity, ratio values are calculated from the average values of the fatty acid content.

Table 3 Mean values and statistical analysis for share of omega-3 and omega-6 polyunsaturated fatty acids from total fatty acids in fat of broiler chicken thigh muscle.

Group	n	$\bar{x}$, %	*SD*	c_v, %	t-test
Omega-3 polyunsaturated fatty acids					
Control	6	0.58	0.07	12.07	
Experimental with supplement of eugenol, nerolidol and piperine	6	0.54	0.03	5.55	p >0.05
Omega-6 polyunsaturated fatty acids					
Control	6	9.73	2.28	23.43	
Experimental with supplement eugenol, nerolidol and piperine	6	7.91	1.98	25.03	p >0.05

Note: n – multiplicity, $\bar{x}$ – mean, *SD* – standard deviation, c_v – coefficient *of* variation, p >0.05: no statistically significant difference between control and experimental group with supplement of eugenol, nerolidol and piperine.

Table 4 Correlation relation between polyunsaturated, omega-3 and omega-6 polyunsaturated fatty acids in fat of broiler chicken thigh muscle and statistically significant between two variables in control group.

Indicator	Omega-3 polyunsaturated fatty acids	Omega-6 polyunsaturated fatty acids
Polyunsaturated fatty acids	0.82, p >0.05	1.00, p <0.001
Omega-3 polyunsaturated fatty acids		0.73, p >0.05

Note: Numeric value – correlation coefficient (r_{xy}) between variables, p >0.05: no statistically significant difference between two variables, p <0.001: statistically significant difference between two variables

Table 5 Correlation relation between polyunsaturated, omega-3 a omega-6 polyunsaturated fatty acids in fat of broiler chicken thigh muscle and statistically significant between two variables in experimental group with supplement of eugenol, nerolidol and piperine.

Indicator	Omega-3 polyunsaturated fatty acids	Omega-6 polyunsaturated fatty acids
Polyunsaturated fatty acids	0.29, p >0.05	0.98, p <0.01
Omega-3 polyunsaturated fatty acids		0.28, p >0.05

Note: Numeric value – correlation coefficient (r_{xy}) between variables, p >0.05: no statistically significant difference between two variables, p <0.001: statistically significant difference between two variables.

Table 6 Mean values for ratio between omega-3 and omega-6 polyunsaturated fatty acids in fat of broiler chicken thigh muscle.

Group	Ratio		*SD*	c_v, %	t-test
	Omega-3 polyunsaturated fatty acids, n = 6	omega-6 polyunsaturated fatty acids, n = 6			
Control	1	16.78	2.91	17.34	p <0.05
Experimental with supplement of eugenol, nerolidol and piperine	1	14.65	3.72	25.39	

Note: n – multiplicity.

Share of omega-3 and omega-6 polyunsaturated fatty acids from total fatty acids in fat of broiler chicken thigh muscle

Mean values and statistical analysis for share of omega-3 and omega-6 polyunsaturated fatty acids from total fatty acids in fat of broiler chicken thigh muscle shows Table 3. Omega-3 polyunsaturated fatty acids content was reached 0.54% from total fatty acids in fat of broiler chicken thigh muscle in experimental group with supplement of eugenol, nerolidol and piperine and 0.58% in control group. These values are comparable without statistically significant (p >0.05). A slightly larger difference was found in the omega-6 polyunsaturated fatty acid content between the control group and the experimental group with the supplement of eugenol, nerolidol and piperine, which was not statistically significant (p >0.05). In recent years, there has been interest in the role of poultry meat as a dietary source of long chain omega-3 polyunsaturated fatty acids, including alpha-linolenic acid (ALA, 18:3), eicosapentaenoic acid (EPA, 20:3) and docosahexaenoic acid (DHA, 22:6) **(Dalziel, Kliem and Givens, 2015)**. Observational studies randomized clinical trials, and *in vivo* experimental studies have established the likely magnitude and dose-response of benefits e.g. of fish and fish oil consumption as prevention of coronary heart disease and Sudden cardiac death as well as the effects of omega-3 fatty acids on a wide range of cardiovascular risk factors. The molecular mechanisms underlying these benefits are not well established, and continued experimental investigation is needed to clarify the effects of omega-3 fatty acids on different tissues on ion channels, other transmembrane protein receptors and lipid rafts, endoplasmic reticulum and mitochondrial function, and cytosolic nuclear receptors **(Mozaffarian, 2008)**.

Correlation relation between polyunsaturated, omega-3 and omega-6 polyunsaturated fatty acids in fat of broiler chicken thigh muscle

Correlation relation between polyunsaturated, omega-3 and omega-6 polyunsaturated fatty acids in fat of broiler chicken thigh muscle and its statistically significant between two variables in control group shows Table 4 and experimental group with supplement of eugenol, nerolidol and piperine shows Table 5. Near-perfect correlation relation was found between total polyunsaturated and omega-6 polyunsaturated fatty acids as well in the experimental group with supplement of eugenol, nerolidol and piperine, and control group. This correlation was linear, positive and statistically significant (p <0.01, p <0.001).

Ratio between omega-3 and omega-6 polyunsaturated fatty acids in fat of broiler chicken thigh muscle

Mean values of ratio between omega-3 and omega-6 polyunsaturated fatty acids in fat of broiler chicken thigh muscle shows Table 6. Ratio between omega-3 and omega-6 polyunsaturated fatty acids was statistically significant (p <0.05) closer in experimental group with supplement of eugenol, nerolidol and piperine 1:14.65 opposite ratio 1:16.78 between omega-3 and omega-6 polyunsaturated fatty acids in control group. Adequate intake of omega-3 polyunsaturated fatty acids, a balanced ratio between omega-3 polyunsaturated fatty acids and omega-6 polyunsaturated fatty acids, even a proper ratio between polyunsaturated fatty acids and saturated fatty acids, may reduce the risk of life-style diseases such as coronary artery disease, hypertension, diabetes, and inflammatory and immune disorders **(Zhou et al., 2012)**. There is evidence suggesting that saturated fatty acids have negative consequences on human health whereas polyunsaturated fatty acids have beneficial effects **(Gibbs, Rymer and Givens, 2013)**; polyunsaturated fatty acids should constitute 7% of total energy consumed **(Soriano-Santos, 2010)**.

CONCLUSION

Based on the statistical evaluation of our experimental results with the Ross 308 broiler chickens, we can conclude that by the effect of the biologically active substances of eugenol, nerolidol and piperine as a supplement in feed mixtures, compared to the control group, was achieved:

a) comparable fat profile in the thigh muscle, showing no statistically significant difference (p >0.05),in addition to the correlation between polyunsaturated and omega-6 polyunsaturated fatty acids, which was statistically significant in control (p <0.001) and experimental groups with eugenol, nerolidol, piperine (p <0.01),

b) statistically significant (p <0.05) and closer relationship between omega-3 and omega-6 polyunsaturated fatty acids.

EFFECT OF WEANING SYSTEM AND TYPE OF MILK FLOW ON MILK PRODUCTION OF CROSSBRED EWES IMPROVED VALACHIAN AND TSIGAI WITH LACAUNE

Lucia Mačuhová, Vladimír Tančin, Juliana Mačuhová, Michal Uhrinčať, Milan Margetín

ABSTRACT

Improved Valachian (IV x LC; n = 41) and Tsigai (TS x LC; n = 44) crossbred ewes with Lacaune were used to study the effects of three weaning systems on milk production. Prior to parturition, ewes were assigned to one of the following three treatments for the first 53 day of lactation: 1) ewes weaned from their lambs at 24 h postpartum and afterwards machine milked twice daily (MTD), 2) ewes, beginning 24 h postpartum, kept during the daytime with their lambs and allowed them to suckle for 12 h, nights separated from their lambs for 12 h and machine milked once daily in the morning (MIX), and 3) ewes exclusively suckled by their lambs (ES). After the treatment period, lambs were weaned from MIX and ES ewes, and all three groups were machine milked twice daily. Furthermore, ewes were evaluated according to number of live-born and weaned lambs (with one (n = 35) or with two lambs (n = 50)). The measurements of milk yield and milk flow were performed on 110 ±5 day of lactation by the equipment for graduated electronic recording of the milk level in a jar in one-second intervals. No significant differences were observed in the measured values (total milk yield, machine milk yield, latency time, milking time, machine stripping, milk flow rate, and machine milk yield in 30 and 60 s) among weaning treatments and between ewes with one or two lambs and evaluated breeds too. The highest occurrence of one peak milk flow (milk flow without milk ejection) was found out in MTD ewes (50%) compared to MIX (19%) and ES (17%). In conclusion, the different systems of weaning did not influence the milk yield and milk flow parameters in the mid-lactation.

Keywords: ewe; weaning system; milk flow curve

INTRODUCTION

The mammary glands serve to nourish the new-born young in all mammalian species. However, in dairy animals such as the cows, the sheep, and goats, through genetic selection and breeding advances in milking technology, the mammary glands yield far more milk than a new-born young requirement for normal growth and far greater quantities than the original organ was designed to accommodate **(Marnet and Negrao, 2000; Nickerson, 2011)**. Approximately 25% of the total milk yield of a dairy ewe is produced during the first 30 day of lactation **(Folman, Volcani and Eyal, 1966)**; it is the period when lambs are typically allowed to suckle their dams. There are several lambs' weaning systems applied on dairy sheep farms. A mixed-management weaning system of suckling and milking (MIX, allowing suckling only during the day hours and performing once daily machine milking at mornings) is an option for the farmers to obtain milk, which lamb does not need for normal grow **(McKusick, Thomas and Berger, 2001; Dikmen et al., 2007)**. The main disadvantage of the MIX system is low milk fat content **(McKusick, Thomas and Berger, 2001)**. **McKusick et al. (2002)** observed the inhibition of milk ejection during machine milking (i.e. only cisternal milk was obtained) in ewes with MIX system. Moreover, also the inhibition of transfer milk fat was found out, whereas the transfer of milk protein from alveoli to cistern during the separation of MIX ewes from their lambs **(McKusick et al., 2002)**. Another system of weaning are exclusively milking (MTD; (where lambs are weaned at 24 h postpartum and the ewes are machine milked twice daily) and exclusively suckling (ES; during the first 30 to 60 d ewes are only suckled and no milking is performed) **(Marnet and Negrao, 2000; McKusick, Thomas and Berger, 2001; McKusick, 2002; Dikmen et al., 2007; Thomas et al., 2014)**. In Slovakia, the lambs are traditionally suckled until the weaning age of 40 to 60 days without any milking during this period. Due to intense crossing Tsigai and Improved Valachian with Lacaune, the milk production is growing **(Mačuhová et al., 2008; Tančin et al., 2011; Margetín et al., 2013)**. Therefore, it is necessary to optimize the weaning systems of lamb so that the market milk production is as high as possible while maintaining good milk quality. Whether the milk

ejection reflex during milking occurred can be found out by invasive detection of oxytocin release **(Bruckmaier et al., 1997; Marnet, Negrao and Labussière, 1998; Marnet and Negrao, 2000)** or by non-invasive method of recording milk flow during machine milking **(Bruckmaier et al., 1997; Marnet, Negrao and Labussière, 1998; Mačuhová et al., 2012)**. Milk flow kinetic could be a good indicator of stress load under different milking conditions **(Bruckmaier et al. 1997; Tančin et al. 2015)**.

The aim of the trial was to study the effect of three weaning systems on the milkability of ewes. Possible effect of number of lambs, mil flow type and breed was evaluated too.

Scientific hypothesis

In this study, we hypothesized that ewes, which were not suckled by lamb during the first 53 days of lactation, would have a higher milk production at the middle stage of lactation. The second hypothesis was that ewes with two lambs would have a higher production of milk at the middle stage of lactation than ewes with one lamb. The third hypothesis was that breed did not affect the production parameters. The milk flow type affects the production parameters was the fourth hypothesis.

MATERIAL AND METHODOLOGY

The experiment was conducted at the research farm of NPPC- Research Institute for Animal Production Nitra in Trenčianska Teplá. 85 animals of crossbreds Tsigai (50% TS x LC; n = 40) and Improved Valachian (50% IV x LC, n = 45) with Lacaune were included in the experiment. Prior to parturition, ewes were assigned to one of the following three weaning systems for the first day of lactation: 1) ewes weaned from their lambs at 24 h postpartum and afterwards machine milked twice daily (MTD), 2) ewes, beginning 24 h postpartum, kept during the daytime with their lambs and allowed them to suckle for 12 h, nights separated from their lambs for 12 h and machine milked once daily in the morning (MIX), or 3) ewes exclusively suckled by their lambs (ES). After the treatment period of 38 days, lambs were weaned from MIX and ES ewes, and all three groups were machine milked twice daily. Furthermore, the ewes were evaluated according to live - born and weaned lambs (with one (n = 35) or with two lambs (n = 50)). The measurements of milk yield and milk flow were performed on 110 ±5 day of lactation. The ewes were milked in one-platform milking parlour with 24 stalls. The milking machine was set to provide 160 pulsations per minute in a 50:50 ratio with vacuum level of 39 kPa. During each milking, ewes received 0.1 kg concentrate per head in the parlour. Ewes were milked routinely twice daily at 7:00 and 19:00 without any udder preparation. At the end of milking, machine stripping was performed (machine stripping started when milk flow rate declined to 0 $L.min^{-1}$, but not earlier than 70 s from the beginning of milking).

Milk flow recording and samples analysis

Milk flow kinetic was recorded using an electronic jar. Within the jar, there was a 2-wire compact magnetostrictive level transmitter (NIVO-TRACK, NIVELKO Ipari Elektronika Rt, Budapest Hungary) connected to a computer. The milk level was continuously measured by a transmitter that recorded the position of the float in the jar on a computer once per second. The milk flow patterns were drawn by using a formula by **Mačuhová et al. (2008)**. Milk flow rate ($L.min^{-1}$) = (L_n-L_{n-4}) x 15 (where L = recorded milk yield in L, n = time in s, 15 = coefficient to correct milk yield increase in 4 s to milk flow in $L.min^{-1}$). The following milking characteristics were evaluated: total milk yield (L), machine milk yield (L), machine stripping yield (L), milking time (i.e. time from attaching of clusters until the milk flow ceased before stripping; s), milk flow latency (i.e. time from attaching of cluster until start of milk flow 0.006 $L.min^{-1}$; s), peak flow rate ($L.min^{-1}$), machine milk yield in 30 s (l), and machine milk yield in 60 s (L). Milk flow curves were evaluated according to **Marnet, Negrao and Labussière, (1998)** and **Mačuhová et al. (2008)** into 4 milk flow types: one peak (no significant milk flow after 40 s of milking; 1P), 2 peaks (bimodal; 2P), plateau (represents milk flow by ewes with longer duration of steady phase and peak flow rate >0.4 $L.min^{-1}$ without clear differences between peaks 1 and 2; PLI), and plateau low (represents also milk flow curves with steady milk flow during milking but at peak flow rate ≤0.4 $L.min^{-1}$; PLII). In 6 animals, the curve of milk flow was not evaluated due to zero machine milk yield.

Statistic analysis

Data from evening milkings were available for statistical evaluation. The data set consisted of 85 measurements belonging to 85 ewes. Mixed model (Mixed procedure; SAS/STAT 9.1, 2002-2003) was applied to study the influence of the sources of variation in studied traits (milk production and milk emission parameters). The experimental measurements were performed during two years. Therefore, factor YEAR included 2 groups of ewes in model: data obtained during 2012 (n = 52) and 2013 (n = 33). Other factors included: FLOW represented 4 groups of ewes divided according to milk flow type (1P, n = 21 ewes; 2P n = 30 ewes; PLI n = 21 ewes; PLII n = 7 ewes), system of WEANING (only milking n = 22 ewes (MTD); milking/suckling n = 38 ewes (MIX); only suckling n = 25 ewes (ES)), number of LAMBs (single n = 35 ewes, twins = 50 ewes), BREED (Tsigai x Lacaune, (CxLC) n = 40 ewes, Improved Valachian x Lacaune, (IVxLC) n = 45 ewes).

$$y_{ijklm} = \mu + YEAR_i + LAMB_j + WEANING_k + FLOW_l + BREED_m + e_{ijklm}$$

where: y_{ijklm} – individual observations of studied parameters: total milk yield (L), machine milk yield (L), machine stripping (L), machine milking time (s), latency time (s), peak flow rate ($L.min^{-1}$), proportion of machine stripping from total milk yield (%), machine milk yield in 30 s and 60 s.

y_{ijklm} = the measurements of the studied parameters, μ = overall mean, $YEAR_i$ = the fixed effects of year (i = 2012, 2013), $LAMB_j$ = fixed effect of lambs (j = 1 to 2), $WEANING_k$ = fixed effect of weaning systems (k = 1 to 3), $FLOW_l$ = fixed effect of milk flow type (l = 1 to 4), $BREED_m$ = fixed effect of breed (m = 1 to 2.), e_{ijklm} = random error, assuming $e_{ijklm} \sim N(0, I\,\sigma_e^2)$.

Fixed effects of the model were estimated using the LSM (Least Squares Means) method. Statistical significance at the 5% level was tested by Fischer's F-test and differences between the estimated levels of effects were tested by Scheffe's multiple range tests.

RESULTS AND DISCUSSION

In Table 1, there are presented a basic statistics of studied traits. The year of measurement did not affect the evaluated parameters (Table 2, Table 3). The factor breeds did not influence the evaluated parameters except of the machine milk yield. The machine milk yield was significantly higher in IV x LC than TS x LC (0.217 ±0.015 and 0.170 ±0.016 l, resp.; p <0.0260). However, in previous studies **(Mačuhová et al., 2008, 2017)**, there were not found out any significant differences in the machine milk yield. Moreover, high proportion of the machine stripping from total milk yield was recorded in tested crossbreds IV x LC and TS x LC (50 ±3%; and 47 ±3%; resp.). 33% of the animals had a higher proportion machine striping yield from total milk yield than 50% (from 100 to 75% – 11% of animals; from 74.99 to 50% – 22% of animals; from 49.99 to 25% – 43.5% of animals; from 24.99 to 0% – 23.5% of animals).

Table 5 Frequency of milk flow types according to weaning system.

Weaning system		Type of milk flow				Total
		Bimodal	One peak	Plateau	Plateau low	
MTD	count	4	10	5	1	20
	% within group	20	50	25	5	
MIX	count	15	7	9	5	36
	% within group	41.67	19.44	25	13.89	
ES	count	11	4	7	1	23
	% within group	47.83	17.39	30.43	4.35	
Total	count	30	21	21	7	79
	%	37.97	26.58	26.58	8.86	

So high values of proportion of the machine stripping from total milk yield have not been detected in these crossbreds so far **(Mačuhová et al., 2008, 2017; Margetín et al., 2013)**. High machine stripping could be due to improper teat position of ewes **(Marnet et al., 1998)**, but this parameter was not evaluated in this study. The impact of the weaning system and the number of lambs on the performance parameters observed is shown in the Table 3. Unlike previous studies **(Dikmen et al., 2007; Thomas et al., 2014)**, it was not found any significant differences in the machine milk yield between different weaning systems. No machine milk yield was observed in 6 animals. Therefore, only 79 milk flow curves were evaluated. All four types of milk flow curves could be observed in the present study as in previous studies testing these crossbreds **(Mačuhová et al., 2012; Mačuhová et al., 2017; Tančin et al., 2011)**. The number and the frequency of occurrence of particular milk flow types are shown in Table 4. The highest occurrence of one peak milk flow was found out in MTD ewes (50%) compared to MIX (19%) and ES (17%). One peak milk flow curves are supposed to represent milk flow without alveolar milk ejection when only cisternal milk fraction is removed in response to machine milking **(Mayer et al., 1989; Bruckmaier et al., 1997)**. On the other side, the proportion of bimodal milk flow in MTD ewes was lower than in ewes of other systems. The milk flow curves with two peaks (bimodal) show alveolar milk ejection after the cisternal milk is removed. In consequence of the genetic selection for higher milk production or decreased average milk flow rate, the occurrence of bimodal milk flow curve has become rarer **(Marnet et al., 1998)** and a third type of milk flow with a plateau phase can be observed. Thus, the second peak is masked because at the time of milk ejection, the cistern fraction has not yet been completely removed from the udder when alveolar fraction descends into cistern for removal **(Marnet et al., 1998)**. Even the second peak is not observed, it is supposed that milk ejection occurs in ewes with this milk flow **(Marnet et al., 1998; Mačuhová et al., 2012; Tančin et al., 2011)**.

The proportion of this milk flow type was quiet similar in all weaning system. Ewes with bimodal and plateau milk flows had the highest machine milk yield (0.266 ±0.019, 0.271 ±0.021, 0.172 ±0.021, 0.064 ±0.052 L in bimodal, plateau, one peak, plateau low; p <0.0001; Table 5). According to **Labussiere (1988)** when ewes are not exclusively machine milked immediately post-partum, the longer they remain in contact with their lambs during the suckling period, the more difficult it is for them to adapt to exclusive machine milking following weaning. And whereas ewes with bimodal and plateau milk flow belong to well-adapted to machine milking **(Marnet et al. 2001)**, it is surprising that, ES ewes had the highest incidence of bimodal and plateau milk flows (Table 5). On the other hand, the release of oxytocin takes longer time during suckling compared to milking **(Marnet and Negrao, 2000)** what can support milk production, and probably the weaning took place at a time when there was no such great the mother-young bond. So, ewes were very well prepared for machine milking. When the milking machine parameters are optimized, and the ewes had time to adapt to the milking routine, oxytocin release patterns are similar during milking as during suckling **(Marnet and Negrao, 2000)**. The fourth, but least occurring milk flow type, was plateau low (9%). This type of milk flow was associated with the longest milking time (94 ± 5 in plateu low, 39 ±4 in one peak, 65 ±4 in plateau and 72 ±4 s in bimodal; p <0.0001, Table 5). According to **Bruckmaier et al. (1997)** this type of milk flow was obviously associated with extremely weak or totally absent oxytocin release during milking. This shape of milk flow in our study was probably due to uneven milk flow distribution in two udder halves, and it cannot be excluded that the milk ejection occurred also in ewes with this type of milk flow.

CONCLUSION

In conclusion, the application of different weaning systems (MTD, MIX, and ES) and the number of lambs had not effect on total milk yield, machine milk yield, machine stripping, and milking time in the middle of lactation. The relatively high ocurrence of bimodal and plateau milk flow curves was observed in ES system. Both milk flow types characterize better-adapted animals to machine milking, because it is assumed that the ewes with these milk flow types achieve milk ejection during milking.

INVASIVE *SOLIDAGO CANADENSIS* L. AS A RESOURCE OF VALUABLE BIOLOGICAL COMPOUNDS

Olga Shelepova, Yulia Vinogradova, Olena Vergun, Olga Grygorieva, Jan Brindza

ABSTRACT

The phytochemical characteristics of alien species have not yet been fully studied. Meanwhile, the reserves of their raw materials in the secondary distribution range are very large and can be used as new sources of functional ingredients for food, nutraceuticals, cosmeceuticals, and medicines. Particular attention is attracted by species which have closely related native plants that are included in the official pharmacopeia. *Solidago canadensis* L. in Slovakia has already formed powerful thickets, and a similar species *Solidago virgaurea* L. is used as a medicinal plant. The goal of our study is to examine biologically active compounds from leaves and inflorescences of *Solidago canadensis* collected in some invasive populations along the Nitra river and Gron river. Leaves and inflorescences of 3 populations have been taken for analysis. In addition, we tested herbal tea was made by a traditional procedure using 2 types of fermentation. The following parameters have been understudying: total dry matter, ash and protein content, total lipid, saccharides, vitamin C content, total carotenoid content, amino acids content, elemental analysis, and antioxidant activity. Mean values and variations of these parameters are given in the article. The results demonstrated that *S. canadensis* can be a valuable raw material resource for many sectors of the economy with the possibility of its wider application in the future.

Keywords: *Solidago canadensis*; goldenrod; phytochemical analyses; economic value

INTRODUCTION

Valuable phytochemicals with antioxidant, antimicrobial and other health benefits are synthesized by plants in the process of secondary metabolism. Therefore, medicinal and aromatic plants have been used in health care, food, and cosmetics since ancient times. The importance of herbal medicines in the XXI century increases significantly due to the rapid development of functional foods and nutraceuticals, which became the main trend in food science and technology, as well as in nutrition and disease prevention **(Nitrayová et al., 2014; Kraujaliene, Pukalskas and Venskutonis, 2017)**. Many plant species have not been sufficiently studied from the phytochemical point of view. This suggestion applies specially to alien plant species, the phytochemistry of which in the secondary distribution range may differ significantly, due to a change in the soil and climatic conditions during the expansion the secondary distribution range. Evaluation of widespread invasive species will, perhaps, reveal new sources of functional ingredients for food, nutraceuticals, cosmeceuticals, medicines, and other applications. Invasive species can be a valid resource and instead of eliminating them, there could be a great benefit obtained.

Canadian goldenrod (*Solidago canadensis* L.) is a highly aggressive alien plant native to North America. Once established, it can reduce biodiversity or locally out-compete all native plants. It is considered as the worst invasive alien weed in Europe **(Lambdon, 2008; Vinogradova et al., 2010)**. Nowadays it is widely spread in China, Russia (from Kaliningrad to the Far East), Japan, Taiwan, Europe and Australia **(Walck et al., 1999; Weber, 2000; Vinogradova, Mayorov and Choroon, 2010)**. Complex *Solidago canadensis* is a highly variable and its taxonomic status is not clear and difficult to assess **(Semple and Cook, 2006; Melville and Morton, 2011; Vinogradova, Ryabchenko and Mayorov, 2013; Semple et al., 2013; Semple et al., 2015; Vinogradova et al., 2017)**. Invasive *S. canadensis* may acquire spreading advantage in non-native habitat by using "novel weapons" to inhibit not only local plants but also soilborne pathogens **(Zhang et al., 2009)**. Thus, invasion success of *Solidago canadensis* is depended on allelopathic compounds which plant can release **(Abilasha et al., 2008)**. It has been found that acetone extracts of *S. canadensis* showed allelopathic effects on the growth of other weeds **(Solymosi, 1994)**.

Numerous organic compounds were reported for the genus *Solidago*, for example, flavonoids, phenolic acids and glucosides, polysaccharides, diterpenes, triterpenoid saponosides, tannins, and essential oils. These results highlighted the potential of using *S. canadensis* extracts as

a natural antimicrobial and antioxidant substances for food applications **(Deng et al., 2015)**. The flowers were used in traditional medicine as an analgesic, burns and ulcers treatment, febrifuge, gastrointestinal and liver aids **(Vinogradova and Kuklina, 2012; Zihare and Blumberga, 2017)**. This species has been used in traditional medicine as a urological and antiphlogistic medicament **(Apati et al., 2003)**. Many herbal preparations exploited in traditional medicine contain a significant number of polysaccharides or their glycoconjugates. It has been found that polyphenolic–polysaccharide–protein complexes isolated from medicinal plants of *Asteraceae* and *Rosaceae* families showed anticoagulant activity **(Pawlaczyk et al., 2009)**. Special medicals "Goldenrod" with antispasmodic, diuretic and anti-inflammatory effects is produced in Ukraine and Russia. Available for sale "Prostanorm" – for the treatment of prostate diseases, "Marelin" and "Fitolizin" – from urolithiasis **(Vinogradova and Kuklina, 2018)**.

In terms of bioeconomics, large populations of *S. canadensis* are important for honey production **(Botta-Dukat and Dancza, 2008)**. Our earlier data confirm the availability of *Solidago canadensis*: its aerial part containe from 0.1 to 0.7% of essential oil in the leaves and from 0.1 to 0.4% of essential oil in the inflorescens. A-pinene (1.3 – 61.2%), limonene (0.5 – 22.5%), bornyl acetat (3.4 – 29.8%) and germacrene D (1.8 – 39.2%) were the major compounds detected in oil samples of *S. canadensis*. Samples from inflorescences contained the maximal percentage of monoterpene hydrocarbons, while the leaves' samples showed the maximal cumulative percentage of sesquiterpene and monoterpene hydrocarbons **(Shelepova et al., 2018)**. The threats and benefits to food production from *S. canadensis* in the Nitra river basin are described in detail **(Fehér et al., 2016)**.

The aim of this article was to investigate the composition and structural features of the complex isolated from leaves and inflorescence of *S. canadensis*, growing in Slovakia for to assess the possibility of using this species for bioeconomics in the future.

Scientific hypothesis

Worldwide, works are being carried out the estimation of the content and accumulation of compounds during the growth of *Solidago*. The main research is done in the field of extracts. Essential oil is the next largest researches object. The scientific hypothesis of this study was to examine the leaves and inflorescences of *Solidago canadensis* due to its biologically active compounds. They may serve as potential sources of phytochemical compounds in foods and health promoting ingredients for humans.

MATERIAL AND METHODOLOGY

Biological material

Three populations from different regions of Slovakia have been observed: 1) nearby Nitra (N48.3355, E18.0468), 2) along the Gron river nearby Hronovce (N47.9915, E 18.6620) 3) along the Gron river nearby Zvolen (N48.5637, E19.1159). Populations of *Solidago* are very dense and occupy large areas (Figure 1). Thus, there is no shortage of this plant as a biological resource. Material has been dried in the shade, temperature

Figure 1 Thicket of *Solidago canadensis* L. in the Zvolen.

20 – 30 °C. Because of our earlier studies proved the minimal concentration of functional ingredients in stems **(Vinogradova and Kolesnikov, 2007; Akimova, Kolesnikov and Vinogradova, 2008)**, only leaves and inflorescences have been taken for analysis.

Preparation of herbal tea from S. canadensis leaves

The tested herbal tea was made by a traditional procedure. Herbal tea infusions were obtained by air-dried and freeze-drying leaves and activation using 2 types of fermentation – fermentation of leaves after deep freezing and fermentation of fresh leaves.

Chemicals

All the chemicals used were of analytical grade and were purchased from Sigma-Aldrich (Steinheim, Germany), Merck (Darmstadt, Germany) and CentralChem (Slovakia).

Phytochemical analyses

Total dry matter, ash and protein content were determined according to EN method **(ČSN EN 12145, 1997)**. Total lipid content was determined according to methods specified in ISO method **(ISO 659:1998)**.

For determination of saccharides, 1 g of sample was extracted with 10 mL of extraction solution (ultrapure water and ethanol mixed in ration 4:1) in a 50 mL centrifugation tube placed on vertical shake table (GFL, Germany). After 1 h of extraction, samples were centrifuged for 4 min at 6000 rpm in a centrifuge (EBA 21, Hettich, Germany); the supernatant was filtered using a filter with 0.45 μm pore size (Labicom, Czech Republic) and filled up to 50 mL in a volumetric flask with ultrapure water. An Agilent Infinity 1260 liquid chromatograph (Agilent Technologies, USA) equipped with ELSD detector was used for determination of saccharides. A Prevail Carbohydrates ES column (250/4.6 mm) was used

as a stationary phase and acetonitrile (VWR) mixed with water in 75:25 volume ratio was used as the mobile phase.

Total carotenoid content expressed as beta-carotene was analysed at a wavelength of 445 nm spectrophotometrically (VIS spectrophotometer UV Jenway Model 6405 UV/VIS). Sample (1 g) was disrupted with sea sand and extracted with acetone until complete discoloration. Petroleum-ether was added and then water, in purpose to the separation of phases. After the separation, the petroleum ether-carotenoid phase was obtained, and the absorbance was measured **(ČSN 560053, 1986)**. HPLC method of L-ascorbic acid (vitamin C) content estimation **(Stan, Soran and Marutoiu, 2014)** was used by the help of Shimadzu HPLC model LC2010 with PDA detector, for separation was used RP C18 column, mobile phase was methanol: water (5:95, v/v), PDA detector was adjusted to 243 nm.

Sample for elemental analysis was prepared using wet ashing method in a microwave oven (Milestone 1200, Milestone, Italy). Total of 0.25 g sample matrix was decomposed in a mixture of nitric acid (6 mL) (Analytika Praha spol. s.r.o., Czech Republic) and hydrochloric acid (2 mL) (Analytika Praha spol. s.r.o., Czech Republic). After the decomposition sample was filtered using a filter with 0.45 μm pore size and filled up to 25 mL in a volumetric flask with ultrapure water. Elemental analysis was performed using ICP-OES (Ultima 2, Horiba Scientific, France) according to the procedure described by **Divis et al. (2015)**.

Amino acids were determined by ion-exchange liquid chromatography (Model AAA-400 amino acid analyser, Ingos, Czech Republic) using post-column derivatization with ninhydrin and a VIS detector. A glass column (inner diameter 3.7 mm, length 350 mm) was filled manually with a strong cation exchanger in the LG ANB sodium cycle (Laboratory of Spolchemie) with average particles size 12 μM and 8% porosity. The column was tempered within the range 35 to 95 °C. Elution of the studied amino acids took place at a column temperature set to 74 °C. A double-channel VIS detector with the inner cell volume of 5 μL was set to two wavelengths: 440 and 570 nm. A solution of ninhydrin (Ingos, Czech Republic) was prepared in 75% v/v methyl cellosolve (Ingos, Czech Republic) and in 2% v/v 4 M acetic buffer (pH 5.5). Tin chloride ($SnCl_2$) was used as a reducing agent. The prepared solution of ninhydrin was stored in an inert atmosphere (N_2) in darkness at 4 °C. The flow rate was 0.25 mL.min^{-1}. and the reactor temperature was 120 °C.

Antiradical activity

Biochemical analyse of antioxidant activity detection was conducted according to **Brand-Williams, Cuvelier and Berset (1995)**. Plant extracts were prepared in following solvents: methanol, ethanol and distilled water. 1 g of dry powder of plant sample was mixed with 25 mL of each solvent. Extraction was carried out during 12 hours at continuous stirring. Preparing of the radical solution was following: 25 mg of DPPH-radical (2,2-diphenyl-2-picrylhydrazyl) was solved in methanol (in 100 mL volumetric flask) and used for following dilution (1:10). 0.1 mL of investigated plant extract was added to 3.9 mL of a radical solution. The optical density of the radical solution was measured immediately and after 10 min of incubation in the dark after adding a sample. The measurement was conducted at 515 nm on the spectrophotometer (Genesis 20, Germany). Obtained data calculated using a formula:

$$\% \; Inh = \frac{A_0 - A_1}{A_0} x \; 100$$

Statistic analysis

Student *t*-test was used for the statistical analysis of the obtained results. Data are presented as mean ±standard error of the mean (SEM). $p < 0.05$ was considered statistically significant. Significance of $p < 0.05$ and $p < 0.01$ is shown by one and two asterisks, respectively.

RESULTS AND DISCUSSION

Phytochemicals possess various bioactivities and may serve as potential sources of antioxidants in foods and health promoting ingredients in humans. Chemical analyses of *Solidago canadensis* leaves and inflorescences revealed the presence of protein (12.2 wt/wt%), carbohydrates (4 wt/wt%)), lipids (5.1 wt/w %) and inorganic material (6.7 wt/wt%)) (Table 1a and 1b). Monosaccharide analysis of neutral carbohydrate part showed the presence of one main sugar – fructose (8.8 g.kg^{-1}), while other saccharides as maltose, sucrose, and lactose were found in low amounts only (<0.5 g.kg^{-1}). However, this may not always be the case. So, according to **Šutovska et al. (2013)**, *S. canadensis* complex (hot alkaline extraction of flowers) revealed the presence of rhamnose (~23 wt/wt%), arabinose (~20 wt/wt%), galactose (~17 wt/wt%) and glucose (~14 wt/wt%). In our study, we did not detect these monosaccharides.

S. canadensis contains vitamin C (L-ascorbic acid (1.53 μmol.g^{-1})) and beta carotene (93.9 mg.kg^{-1}) (Table 1a and 1b). The vitamin E family includes four tocopherols, α-tocopherol being the most potent member of this family **(Shahidi and Ambigaipalan, 2015)**. The major quantitative tocopherol in *S. canadensis* leaves and inflorescences was α-tocopherol (48.8 ±3.2 mg.kg^{-1} DWP). It is in agreement with **Kraujaliene, Pukalskas and Venskutonis (2017)**. Vitamin E is known as a reducing agent and may contribute to antioxidant activity by reducing the oxidized state of the phenolic antioxidant compounds. Thus, these compounds may be regenerated, allowing their antioxidant capacity to increase. Carotenoids have been reported to show chain-breaking antioxidant activity. These compounds are also effective singlet oxygen quenchers **(Demir, 2009)**.

Lipids are another important group of *S. canadensis* phytochemicals. The oil contents were 5.1% dry weight plant material (Table 1a and 1b). It is reasonable because the majority of botanical materials (leaves and inflorescences) contain low amounts of lipids. The fatty acids composition was comprised of saturated fatty, monounsaturated and polyunsaturated fatty acids (34.0; 14.3 and 44.8 g.100g^{-1} oil, respectively). The lipophilic fraction contains of 20 fatty acids; four acids (linoleic acid, C-18:2; oleic acid, C-18:1; palmitic acid, C-16, linolenic acid, C-18:3) is dominated. Of these acids, the first two, the unsaturated C-18 acids, amounted to 57.2% of the total (Figure 2).

Table 1a The contents of some phytochemical compounds in leaves and inflorescences of *Solidago canadensis* L.

Components	*mean ±SD*	Components	*mean ±SD*
Total dry matter (%)	91.07 ±1.14	**Saturated fatty acids (g.100g^{-1} oil)**	34.0 ±1.0
Total content of protein (%)	12.15 ±0.74	**Monounsaturated fatty acids (g.100g-1 oil)**	14.3 ±0.80
Total content of ash (%)	6.68 ±0.18	**Polyunsaturated fatty acids (g.100g^{-1} oil)**	44.8 ±2.10
Total content of lipids (%)	5.11 ±0.11	**Fructose (g.kg^{-1})**	8.8 ±0.50
Beta carotene (mg.kg^{-1})	93.9 ±5.30	**Maltose (g.kg^{-1})**	<0.50

Note: mean – arithmetic mean; SD – standard error of the mean.

Table 1b The contents of some phytochemical compounds in leaves and inflorescences of *Solidago canadensis* L.

Components	*mean ±SD*
Sucrose (g.kg^{-1})	<0.50
Lactose (g.kg^{-1})	<0.50
Vitamin A (retinyl acetate) (mg.kg^{-1})	<0.10
Vitamin E (α-tocopherol) (mg.kg^{-1})	48.8 ±3.20
L-ascorbic acid (vitamin C) (μmol.g^{-1})	1.53 ±0.01

Table 2 Mineral composition of air-dry leaves and inflorescences *Solidago canadensis* L. (mg.kg^{-1}).

Components	*mean ±SD*	Components	*mean ±SD*	Components	*mean ±SD*
P	4112 ±327	**Mg**	1387 ±71	**Se**	<0.2
K	21573 ±210	**Na**	8.0 ±0.4	**As**	<0.3
Ca	6665 ±78	**Al**	5.6 ±0.2	**Cd**	0.038 ±0.007
S	1585 ±61	**Cr**	<0.2	**Ni**	0.29 ±0.03
Fe	20.0 ±0.9	**Cu**	9.0 ±0.3	**Hg**	0.006 ±0.001
Mn	21.0 ±1.1	**Zn**	28.0 ±1.1	**Pb**	0.15 ±0.03

Note: *mean* – arithmetic mean; *SD* – standard error of the mean.

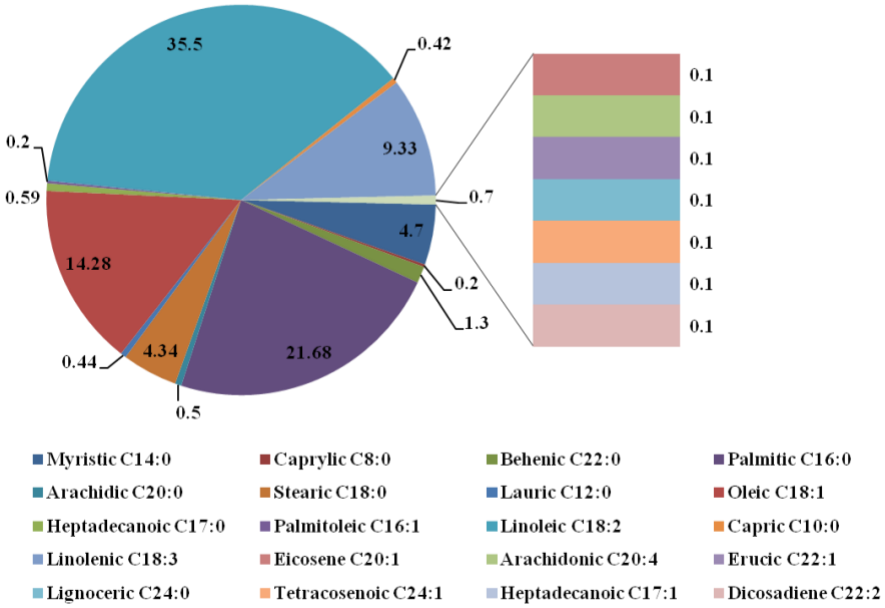

Figure 2 Fatty acid composition from leaves and inflorescences of *Solidago canadensis* L. (g.100g^{-1} oil). Note: Minor components (<0.1): Eicosene C20:1, Arachidonic C20:4, Erucic C22:1, Lignoceric C24:0, Tetracosenoic C24:1, Heptadecanoic C17:1 and Dicosadiene C22:2 are in the right column, their total amount is 0.7 g.100g^{-1} oil.

Table 3 Antioxidant activity of experimental herbal tea from *Solidago canadensis* L. leaves by DPPH method.

Specimen	Methanol extracts, %	Ethanol extracts, %	Water extracts, %
Freeze-drying leaves	54.66 ±1.09	35.67 ±0.48	34.92 ±1.04
Air-dried leaves	83.17 ±0.52	83.78 ±0.62	18.59 ±0.84
Fermentation of fresh leaves	76.32 ±1.15	55.55 ±1.25	66.91 ±2.52
Fermentation of leaves after deep freezing	74.78 ±2.83	56.80 ±0.65	58.20 ±1.05

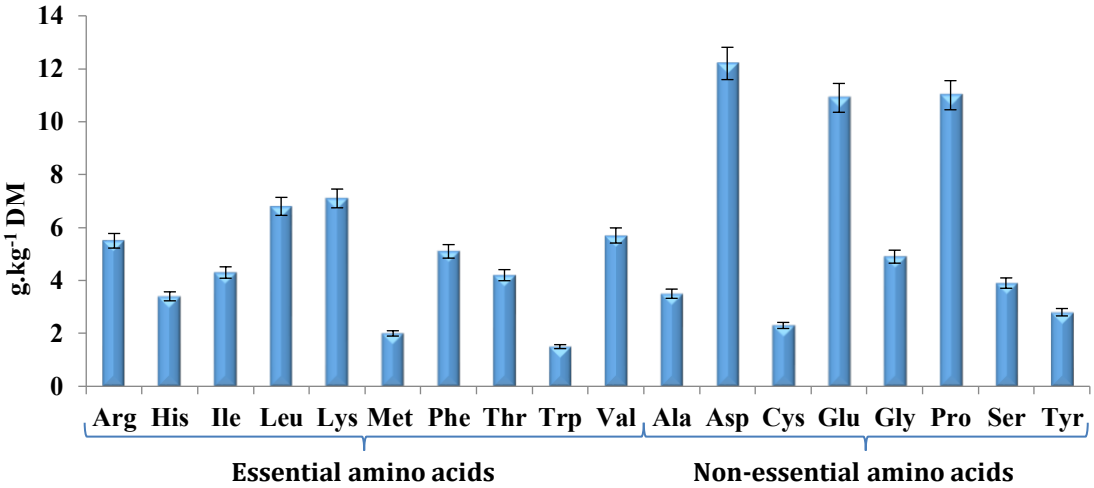

Figure 3 Amino acid composition from leaves and inflorescences of *Solidago canadensis* L. (g.kg^{-1} DM).

S. canadensis fatty acid profiles showed the presence of high amounts of linoleic acid (35.5%) (Figure 2). From linoleic acid is synthesized γ-linolenic acid and is the first intermediate in the conversion of linoleic acid to arachidonic acid. γ-linolenic acid prevents or alleviates a wide variety of human diseases, and it is important as a dietary and cosmetic component. Palmitic acid is the second quantitatively major compound (21.7 %).

Amino acid analysis has shown that the studied *S. canadensis* leaves and inflorescences contained 18 amino acids (10 essential and 8 non-essential) (Figure 3). Aspartic acid was found to be the dominant free amino acid (12.2 g.kg^{-1}) followed by a proline (11.0 g.kg^{-1}) and glutamic acid (10.9 g/kg), respectively. Proline content of *S. canadensis* inflorescences could be one of the parameters in the determination of *S. canadensis* honey authenticity and could be a good indicator of the botanical origin of honey. Amino acids found in high levels were: lysine, leucine, valine, arginine, phenylalanine – average content in from 7.1 to over 5.1 g.kg^{-1}. Lower but also important amounts of glycine, isoleucine, threonine, serine, alanine, histidine, tyrosine, cystine, methionine, and tryptophan (ranging from 1.5 to 4.9 g.kg^{-1}) were detected in the study. The total number of amino acids was 97.10 g.kg^{-1} DM, including total essential amino acids (45.60 g.kg^{-1} DM) and percentage of total essential amino acids (46.96%).

The results of the elemental analysis of *S. canadensis* leaves and inflorescences are summarized in Table 2; these values are averages of three independent measurements having ±SD. Concentration of various elements decreases in the order: K>Ca>P>S>Mg>Zn>Mn>Fe>Cu> Na>Al>Ni>As>Cr>Se>Pb>Cd>Hg.

Among the various elements As, Cr, Se, Pb, Cd, Hg are found to be present at the trace level. Zn, Mn, Fe, Cu, Na, Al, and Ni are at the minor level and K, Ca, P, S and Mg are at the major levels. This result is supported by the results of **Pytlakowska et al. (2012)**.

We note here that our focus is not to compare but rather to explore the mineral composition in the selected plants and to discuss their importance in human health. Due to a deficiency of these minerals in the human diet, most of these minerals are often taken as supplements **(Agarwal et al., 2011)** for their important role in human health.

In fact, the chemical constituents present in plants are responsible for their medicinal as well as toxic properties which include vegetable bases comprising of alkaloids and amines, glycosides, essential oils responsible for their characteristic odour, toxic substances known as toxalbumin, resins, and antibiotics. Whereby the trace elements play a very important role in the formation of these compounds.

One important factor for the formation of active constituents in plants are the trace elements because they are known to play an important role in plant metabolism and active constituents of medicinal plants are metabolic products of plant cells. Among the various elements estimated, the potassium and sodium ions play an important role in the diseases related to renal disorder. Potassium and sodium salts are partially responsible for the diuretic action of some drugs. Potassium is readily excreted by the kidneys both by glomerular filtration and by tubular excretion. Potassium salts act as osmotic diuretics and deficiency of potassium causes diabetic acidosis. Calcium ion concentration also plays an important role in the urinary tract system. Hypercalcemia causes renal failure and calcium stones in the urinary tract. Iron deficiency is common in uremic patients, it causes substantial blood losses. Iron may bind to the dialyzer membrane. Some reports indicate that dysgeusia, poor food intake, and impaired sexual function, which are common problems of uremic patients, may be improved by zinc supplements **(Rajurkar and Damame, 1998)**. Magnesium is reported to have a curative effect in more than 300 health disorders, including headache and fatigue **(Daur, 2015)**. Mn ameliorates some of the symptoms of diabetes and plays a role in the function of connective tissue, bones, and blood clotting factors Similarly Cr, Mn, Fe, Co, Cu, and Zn have been reported as essential or beneficial to human health **(Kozlowska et al., 2015)**.

The total antioxidant activity of extracts from freeze-drying leaves of *S. canadensis* was not high and amounted to 34.9% (aqueous extracts), 35.7% (ethanol extracts) and 54.7% (methanol extracts) (Table 3). While the total antioxidant activity of extracts from air-dry leaves was significantly higher for methanol and ethanol extracts and amounted to 83.2 and 85.8%, respectively. But it was lower for the water extract – 18.6%. The total antioxidant activity of the herbal tea samples from the 2 types of fermentation was generally similar and significantly higher than the

native samples for aqueous extracts (66.9 – 58.2 %). The indices of alcoholic extracts of herbal tea were lower than those for dry leaves but higher than those of native samples (55.6 – 56.8% (ethanol extract) and 74.8 – 76.6% (methanol extract)). **Deng et al. (2015)** determined antioxidant activity from leaves and bark of *S. canadensis* using DPPH radical. The capacity ranged from 25.3 – 37.2% (ultrasound-assisted extraction) to 18.8 – 21.1% (ethanol extraction) by DPPH method. **Demir et al. (2009)** reported results antioxidant capacity of young shoots with leaves for *S. virgaurea* using DPPH method. The antioxidant capacity ranged from 30.7% (aqueous extracts) to 64.3% (methanol extract) of DPPH inhibition.

CONCLUSION

The results demonstrated that *S. canadensis* can be a valuable raw material resource for many sectors of the economy. Many high added value products can be obtained from this species. This proves the value of *S. canadensis* for the bioeconomy and the possibility of its wider application in the future.

TOTAL PHENOLIC CONTENT AND ANTIOXIDANT ACTIVITY OF METHANOLIC EXTRACT OF SELECTED WILD LEAFY VEGETABLES GROWN IN BANGLADESH: A CHEAPEST SOURCE OF ANTIOXIDANTS

Mohammad Khairul Alam, Ziaul Hasan Rana, Sheikh Nazrul Islam, Mohammad Akhtaruzzaman

ABSTRACT

Nowadays, more attention has been paid on wild plants as new source of natural antioxidants. Therefore, methanolic extracts of 10 traditionally consumed wild leafy vegetables of Bangladesh were analyzed for their total phenolic content (TPC) and free radical scavenging activity. Folin–Ciocalteu method followed by spectrophotometric measurement was used to quantify the TPC of the selected wild leafy vegetables. Free radical scavenging activity was examined utilizing 1,1-diphenyl-2-picryl-hydrazyl (DPPH) assay. Different concentrations of the plant extract were applied to ascertain the dose response relationship in inhibiting DPPH free radical. The results revealed that the TPC ranged from 102.20 to 710.42 mg GAE.100g^{-1} dry weight (DW). The highest TPC was observed in *Bauhinia acuminata* (Shetokanchan) while *Leucas aspera* (Shetodhron) exhibited the lowest TPC among the undertaken vegetables. The studied samples proportionately inhibited DPPH with increasing concentrations. At high concentration (500 µg.mL^{-1}), the percentage inhibition of DPPH radical by plant extract ranged from 68.1 ±2.65% to 93.1 ±1.23%. The highest DPPH radical inhibition was observed in *Bauhinia acuminata* (Shetokanchan) (93.10 ±1.23%), followed by *Commelina benghalensis* (Bat baittashak) (91.97 ±1.31%), *Hydrocotyle sibthorpiodes L.* (Sakumubakla) (91.83 ±2.13%). The lowest DPPH radical inhibition among the studied samples was observed in *Leucas aspera* (Shetodhron) (68.1 ±2.65%). IC_{50} values measured by DPPH assay in this study ranged from 11.64 to 313.79 µg.mL^{-1}. The study findings indicated that the samples under study possesses strong activity against DPPH, and thus could be used as natural antioxidants in the food and/or pharmaceutical industry.

Keywords: antioxidants; Bangladesh; DPPH; wild vegetables; total phenolic content

INTRODUCTION

Antioxidant is termed as a compound whose major function is to inhibit the oxidation of biological molecules (lipids, proteins or other molecules) and hence provides a defensive effect against ROS (Reactive oxygen species) such as hydrogen peroxide (H_2O_2), superoxide ($O_2^{\bullet-}$), hydroxyl radical ($OH^{\bullet}$), peroxyl radical ($ROO^{\bullet}$), and singlet oxygen ($_1O^2$) **(Moyo et al., 2013; Brindza et al., 2019)**. These ROS are produced in the body either as a by-product of normal cellular aerobic respiration or exposure to environmental factors such as pollution, radiation, cigarette smoke and herbicides **(Thomas et al., 2010)**.

The production of ROS in a healthy individuals is governed by the antioxidant defense mechanism **(Anahita, Asmah and Fauziah, 2015)**. Overproduction of ROS disrupts the antioxidant defense mechanism in the body and generates oxidative stress as a result of damaging effects on nucleic acids, proteins, enzymes and other biological molecules containing a lipid component of polyunsaturated fatty acids through oxidation **(Alam, Rana and Akhtaruzzaman, 2017a; Alam, Rana and Akhtaruzzaman 2017b; Škrovánková et al., 2018)**. Dietary antioxidant nutrients, which include phenolic acids, polyphenols, flavonoids vitamin E, vitamin C, and carotenoids are believed to scavenge free radicals and thus inhibit the oxidative mechanisms which are responsible for many disorders and diseases in humans such as infections, diabetes, arthritis, cardiovascular diseases, cancer, Alzheimer's diseases, AIDS etc. **(Mendoza-Wilson et al., 2016; Bystrická et al., 2017; Lenková et al., 2017)**.

Antioxidants are generally classified into two categories, synthetic and natural **(Gülçin, 2012)**. However, toxic effects of synthetic antioxidants (fx. butylated hydroxyanisole (BHA), butylated hydroxytoluene (BHT)) has led to search for an alternative natural antioxidants which have no toxic effects **(Gülçin, 2012; Baba and Malik, 2015; Mendoza-Wilson et al., 2016)**. Wild/traditional plants as a source of natural antioxidants

Figure 1 Photograph of selected wild leafy vegetables of Bangladesh.

are recently received much attention from the researchers **(Gülçin, 2012; Baba and Malik, 2015; Mendoza-Wilson et al., 2016)**. These plants contain significant amounts of antioxidants, such as polyphenols, flavonoids, terpenoids, vitamin C, vitamin E, selenium, β-carotene, other carotenoids, which play an important role neutralizing free radicals **(Gülçin, 2012; Mendoza-Wilson et al., 2016)**. Several studies have indicated the inverse relationship between intake of traditional plants and chronic diseases **(Wang et al., 2011; Baba and Malik, 2015)**. Thus, increasing intake of these antioxidant rich plants can lower and/or prevent the generation of free radicals associated health problems **(Wang et al., 2011; Gülçin, 2012; Baba and Malik, 2015; Mendoza-Wilson et al., 2016)**.

Bangladesh is blessed with a rich biodiversity of plant foods. Indigenous people residing in different areas of the country rely on local plant and plant products to meet their daily requirements for micro and macro nutrients **(Shajib et al., 2013)**. Despite widespread use of wild plants as staple and medicines in Bangladesh, little is known about the antioxidant potential of these plants. Therefore, in this study an effort has been made to study and report the total phenolic content **(**TPC**)** and antioxidant activity of some wild leafy vegetables of Bangladesh consumed by the indigenous community. The preliminary data from these vegetables could be incorporated into food composition database to enrich it and used for increasing awareness to preserve these and maintain biodiversity.

Scientific hypothesis

The content of total polyphenols and antioxidant activity were evaluated in different types of leafy vegetables consumed by specific community of Bangladesh. We presumed that there exist a significant difference with respect to total polyphenol content and antioxidant activity, measured by DPPH method, in different indigenous leafy vegetable species.

MATERIAL AND METHODOLOGY

Reagents

Folin-Ciocaltu reagent and gallic acid were obtained from Sigma–Aldrich Co. **(**St. Louis, MO, USA**)**. The analytical grade acetone, petroleum ether, and methanol were purchased from Merck **(**Darmstadt, Germany**)**.

Sample plan

Muli-region sampling plan was employed for the vegetable sampling. In order to conform the representative sample principle – "what the mass people consume' and from where they collect it"? **(Greenfield and Southgate, 2003)**, the vegetables were collected from the retail markets located at wholesale markets where the vegetables

are arrived from different geographical regions of the country and also from cultivation fields. It was, thus, ensured the representative sample.

Identification of vegetable sample

A taxonomist who also accompanied the collection team, confirmed the sample identity. The identified samples undertaken in this study were *Cajanus cajan, Stereospermum suaveolens, Calamus tenuis, Commelina benghalensis, Enhydra fluctuans, Albizia procera, Tamarindus indica, Hydrocotyle sibthorpiodes, Leucas aspera,* and *Bauhinia acuminate*. Photographs of the studied vegetables are also of given in the Figure 1.

Sample processing

The samples were collected fresh, packed into autoseal poly bags with little water spray and brought to the laboratory for processing and analysis. Two to three samples (250 – 500 g) were collected for each of the items from every market and growing fields, which were then mixed to make three analytes or composite test samples. Samples were first gently washed with tap water to remove sand and other extraneous material before being washed with distilled water. Surface water was removed with tissue paper, air dried, cut into small pieces. The sample was freeze-dried at -48 °C (il Shin lab.Co. Ltd., Korea) and stored in refrigerator for phenolics analysis.

Extraction of phenolics

Approximately two grams of freeze-dried powdered sample was taken into a 250 mL conical flask and 42.5 mL methanol and 7.5 mL 1N hydrochloric acid were added. It was soaked for 24 hours at room temperature with intermittent shaking. Extracts were filtered through No. 1 Whitman filter paper and the filtrate was concentrated using a rotary evaporator at low temperature under reduced pressure. Methanol was added to make a final concentration of 1 $mg.mL^{-1}$ to be used as stock solution.

Analysis of phenolic content

The total phenolics content was estimated by Folin-Ciocalteu colorimetric **(Alam, Rana and Islam, 2016)**. In brief,

150 µL diluted sample extract was added to 225 µL of x2 diluted Folin-Ciocalteu reagent and was kept for 5 minutes at room temperature. Then 1.125 mL of 2% Na_2CO_3 solution was added, mixed well and kept for 15 minutes at room temperature and finally, the absorbance was measured at 750 nm by UV-VIS Spectrophotometer (UV-1800, Shimadzu, Japan). Total phenol content was calculated using a standard curve made by standard gallic acid. Results were expressed as mg gallic acid equivalent (GAE) per 100 g dry weight (DW).

DPPH free radical scavenging assay

The antioxidant activity of the plant extracts was evaluated by utilizing 1,1-diphenyl-2-pycrylhydrazyl (DPPH) free radical according to **Piang-Siong et al. (2017)** with slight modification. Briefly, DPPH stock solution was prepared by dissolving 6.5 mg of DPPH in 5 mL of 100% methanol and protected from light. 100 µL of varying concentrations (100 – 500 $\mu g.mL^{-1}$) of the plant sample extracts were taken and the volume was made up to 200 µL using methanol. Each of the samples was then further diluted with methanol up to 4 mL and to each 200 µL of DPPH stock solution was added. The mixture was then shaken vigorously and allowed to stand at room temperature for 30 min in the dark. After 30 min, the mixture was measured spectrophotometrically at 520 nm (UV-1800, Shimadzu, Kyoto, Japan). Absorbance of the control (200 µL DPPH in 4 mL methanol) and blank (methanol without DPPH) were also measured. The DPPH free radical inhibition capacity was calculated according to the following equation:

$$\% \text{ DPPH inhibition} = ((1 - ((Abs_{sample} - Abs_{blank})/(Abs_{control} - Abs_{blank}))) \times 100$$

where, Abs_{blank} is the absorbance of the blank (containing only methanol), $Abs_{control}$ is the absorbance of the control reaction (containing all reagents minus plant extracts), and Abs_{sample} is the absorbance of the plant extracts. The plant extracts concentration required for 50% inhibition of DPPH free radical (IC_{50}) was estimated from the dose-response graph plotted with percentage inhibition and concentrations of plant extract.

Statistic analysis

Descriptive statistics were performed and values were expressed as mean ± standard deviation. One-way analysis of variance (ANOVA) was employed to evaluate the differences among varieties for total polyphenol content and antioxidant activity and was declared significant when $p < 0.05$ at 5% level of significance. SPSS (version 20.0 SPSS Inc, IL, USA) was used to analyze the data.

RESULTS AND DISCUSSION

Total phenolic contents of selected wild vegetables

The TPC of selected wild vegetables was analyzed using the Folin–Ciocalteu method, and also presented in Table 1. Generally, these vegetables had high TPC. *Bauhinia acuminata* had the highest phenolic content (710.42 ±4.32 mg $GAE.100g^{-1}$ DW), followed by *Commelina benghalensis* L. (701.33 ±5.01 mg $GAE.100g^{-1}$ DW), *Hydrocotyle sibthorpiodes* L. (633.45 ±3.73 mg $GAE.100g^{-1}$ DW), *Albizia procera* (550.89 ±1.58 mg $GAE.100g^{-1}$ DW), *Cajanus cajan* Millsp. (491.51 ±2.71 mg $GAE.100g^{-1}$ DW). The lowest TPC was found in *Leucas aspera* (102.20 ±1.10 mg $GAE.100g^{-1}$ DW). The TPC in the wild leafy vegetables of the present study ranged from 102.20 to 710.42 mg $GAE.100g^{-1}$ DW. Previous study reported that the TPC of some common Indian leafy vegetables was in the range of 5 – 69.5 mg of tannic $acid.g^{-1}$ of extract **(Shyamala et al., 2005)**. Compared to other studies, the wild vegetables under investigation had higher TPC than some frequently consumed leafy and non-leafy vegetables **(Uusiku et al., 2010; Kaur and Kapoor, 2002; Gupta et al., 2005; Salvatore et al., 2005; Gupta and Prakash, 2009; Mohankumar, Uthira and Maheswari, 2018)**.

Table 1 Total phenolic content of the selected wild leafy vegetables.

Local Name	English Name	Scientific Name	Total phenolic content (mg GAE.100g^{-1} DW)
Orohorpata	Pigeon pea	*Cajanus cajan* Millsp.	491.51 ±2.71^{e}
Parul	Rose flower fragrant	*Stereospermum suaveolens*	405.64 ±2.97^{g}

Note: different superscript letters in each column indicates the significant differences in the mean at p <0.05.

Secondary plant metabolites, such as aromatic phenolic compounds, are widely distributed throughout the plant kingdom and related with colour, sensory qualities and nutritional and antioxidant attributes of food. The antioxidant activity of phenolic compounds is mainly due to redox properties, which allow them to act as reducing agents, hydrogen donors, singlet oxygen quenchers, heavy metal chelators and hydroxy radical quenchers **(Kaur and Kapoor, 2002)**. Phenolic compounds such as flavonoids, phenolic acid and tannins exerts varied biological activities such as anti-inflammatory, anti-carcinogenic and anti-atherosclerotic activities and these effects could be attributed to their antioxidant activity **(Podsędek, 2007; Mertz et al., 2009)**.

However, it has been reported that the TPC of vegetables varies widely depending on the variety of vegetable, climatic conditions, stage of maturation, soil features, extraction methods, especially the extraction solvent, time and pH **(Kamffer, Bindon and Oberholster, 2010)** and thus makes it difficult for effective comparison, as different standard compounds have been used for their analysis.

Several studies have reported an inverse relation between flavonoid intake and risk of lung cancer, cardiovascular diseases **(Wang et al., 2011; Bystrická et al., 2017; Lenková et al., 2017; Brindza et al., 2019)** and biomarkers of inflammation **(Shaik et al., 2006)**. Hence, the consumption of such wild vegetables, rich in phenolic compound, could ameliorate or prevent the generation of chronic diseases.

DPPH free radical scavenging activity of selected wild vegetables

The DPPH free radical assay is an easy, reliable and quick way to evaluate antioxidant potential of various extracts **(Piang-Siong et al., 2017)**. This method is simple and do not call for a special reaction and device. In this method, the antioxidant activity is assessed on the basis of the ability of the antioxidant to donate hydrogen or electron to $DPPH^{\cdot}$ to produce a stable DPPH-H (diphenylhydrazine) molecule. Changes in the color occur as DPPH radicals in the environment decreases and this **(Piang-Siong et al., 2017)**. Hence the more potent antioxidant, more decrease in absorbance is seen and accordingly the IC_{50} value will be minimum.

$$DPPH^{\cdot} + A\text{-}H = DPPH\text{-}H + A^{\cdot}$$

In this study, the extracts of the undertaken vegetable samples were assessed for the antioxidant potential by utilizing the above principle of DPPH radical scavenging method. Table 2 represents the $DPPH^{\cdot}$ radical scavenging abilities of the wild vegetables used in this study. At 500 µg.mL^{-1}, *Bauhinia acuminata* (Shetokanchan) showed the highest DPPH inhibition (93.10 ±1.23%), followed by *Commelina benghalensis* (Bat baittashak) (91.97 ±1.31%), *Hydrocotyle sibthorpiodes L.* (Sakumubakla) (91.83 ±2.13%), *Albizia procera* (Shada Koroi) (91.21 ±4.90%), *Cajanus cajan* (Orohorpata) (90.79 ±5.81%). The lowest DPPH radical inhibition among the studied samples was observed in *Leucas aspera* (Shetodhron) (68.1 ±2.65%) compared to other samples studied. In this study, all extracts prepared from the vegetable leaves contain varying degrees of DPPH scavenging activity. At a higher concentration, these extracts exhibit more significant DPPH free radical scavenging activity. From Table 2, we can also observe that there is a dose response relationship in inhibiting $DPPH^{\cdot}$ free radical.

Fabaceae species are one of the several indigenous vegetables that have been reported to be rich in antioxidant compounds **(Gođevac et al., 2008)**. As stated, this was the first study to evaluate the antioxidant capacities of the undertaken wild vegetables, no reference data was available to compare. Thus, only few studies could be found examining the other members of the same species. In a study by **Gođevac et al., (2008)** using nine different Fabaceae species, they found that the Fabaceae species possess good antiradical activity. Similar results was also reported by **Srinivasan et al. (2016)**. Similar to our study, few other studies have also reported that the *Tamarindus indica*, *Commelina nudiflora* L., *Bauhinia variegata*, *Leucas aspera* exhibited potent DPPH free radical scavengers **(Rajani and Ashok, 2009; Das et al., 2011; Chew et al., 2012; Kuppusamy et al., 2015; Mbaye et al., 2017)**. It is speculated that the antioxidant activity of the extract is attributed to the presence of phenolic components **(Rajani and Ashok, 2009; Das et al., 2011; Chew, Jessica and Sasidharan, 2012; Kuppusamy et al., 2015; Mbaye et al., 2017)**.

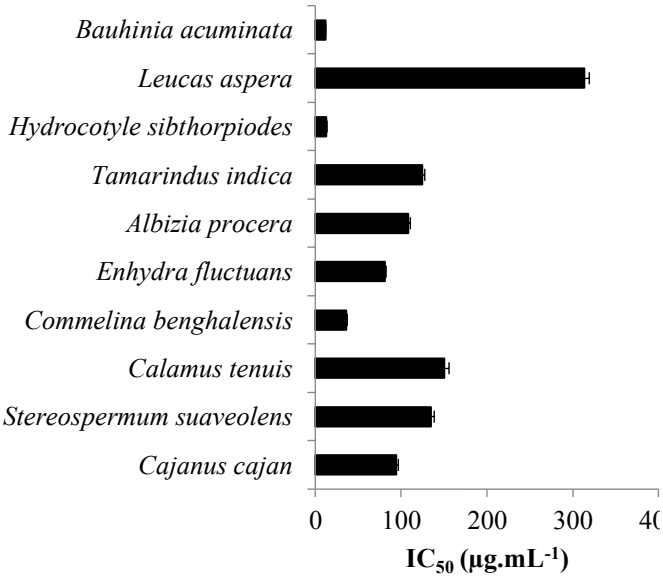

Figure 2 IC_{50} values of selected wild leafy vegetables of Bangladesh.

The DPPH radical scavenging activity was further expressed as the effective concentration (IC_{50}) at which antioxidant activity was 50% (Figure 2). The lowest IC_{50} values for the vegetables were recorded of *Bauhinia acuminata* (11.64 µg.mL^{-1}), *Hydrocotyle sibthorpiodes* L. (12.78 µg.mL^{-1}), *Enhydra fluctuans* (81.19 µg.mL^{-1}), *Cajanus cajan* (94.28 µg.mL^{-1}), whereas *Leucas aspera* (313.79 µg.mL^{-1}) exhibited the highest IC_{50} value in all the studied samples.

The IC_{50} values observed in this study were varying from other reports **(Gođevac et al., 2008; Rajani and Ashok, 2009; Das et al., 2011; Chew, Jessica and Sasidharan, 2012; Kuppusamy et al., 2015; Srinivasan et al., 2016; Mbaye et al., 2017)**. Ethanolic extract of *L. aspera* root exhibited a significant DPPH radical scavenging activity having an IC_{50} value of 7.5 µg.mL^{-1} **(Rahman, Sadhu and Hasan, 2007)** whereas we found 313.79 µg.mL^{-1} in methanolic extract of the leaves. Moreover, the ethanolic extract of whole *L. aspera* plant showed an IC_{50} value of 176.46 mg.mL^{-1} **(Das et al., 2011)**. This difference in scavenging activity could be due to the different solvent extract system, growing conditions, fractions of the plant and some other variables **(Rahman Sadhu and Hasan, 2007; Chew, Jessica and Sasidharan, 2012)**.

CONCLUSION

The selected wild plant extracts investigated in this study showed potent antioxidant activity and varying degree of phenolic content. Among the studied samples, *Bauhinia acuminata* (Shetokanchan) exhibited the highest phenolic content (710.42 mg GAE.100g^{-1}) and free radical scavenging activity (up to 93.1 ±1.23% inhibition). As the plant extracts are quite safe and the use of synthetic

antioxidant has been limited because of their toxicity, therefore, these wild vegetables could be employed as antioxidant additives or as nutritional supplements. However, further studies are required to isolate and characterize the individual components from these plants which are actually responsible for their antioxidant activities and develop their applications for food and pharmaceutical industries.

GENETIC DIVERSITY IN TUNISIAN CASTOR GENOTYPES (*RICINUS COMMUNIS* L.) DETECTED USING RAPD MARKERS

Martin Vivodík, Ezzeddine Saadaoui, Želmíra Balážová, Zdenka Gálová and Lenka Petrovičová

ABSTRACT

Castor (*Ricinus communis* L.) is a plant that is commercially very important to the world. It is produced in about 30 countries lying in the tropical belt of the world. It is an important plant for production of industrial oil. Assessment of genetic diversity of a crop species is a prerequisite to its improvement; hence it is important to identify the genetic diversity of castor genetic resources for development of improved cultivars. The present study is focused on estimation of genetic distance between 56 Tunisian castor genotypes, based on 18 RAPD markers. Seeds of castor were obtained from the University of Carthage, National Institute of Research in Rural Engineering, Waters and Forests (INRGREF), Regional Station of Gabès, Tunisia. The ricin genotypes were obtained from 12 regions of Tunisia. The efficacy of the RAPD technique in this study is further supported by the obtained PIC values of the primers used in the analysis. PCR amplification of DNA using 18 primers for RAPD analysis produced 145 DNA fragments that could be scored in all 56 genotypes of Tunisian castor. The number of amplified fragments varied from 3 (OPE-07) to 13 (SIGMA-D-01), and the amplicon size ranged from 100 to 1500 bp. Of the 145 amplified bands, 145 were polymorphic, with an average of 8.11 polymorphic bands per primer. The lowest values of polymorphic information content were recorded for RLZ 9 (0.618) and the the highest PIC values were detected for OPD-08 (0.846) with an average of 0.761. A dendrogram was constructed from a genetic distance matrix based on profiles of the 18 RAPD primers using the unweighted pair-group method with the arithmetic average (UPGMA). According to analysis, the collection of 56 Tunisian castor genotypes were clustered into five main clusters. Genetically the closest were four genotypes from cluster 1 (BT-1 – S-5 and K-1 – N-3). Knowledge of the genetic diversity of castor can be used in future breeding programs for increased oil production to meet the ever increasing demand of castor oil for industrial uses as well as for biodiesel production.

Keywords: castor; DNA; dendrogram; PCR; PIC

INTRODUCTION

Castor bean (syn. castorbean, castor, castor-oil-plant), *Ricinus communis* L. (2n = 20, X = 10), is a species of flowering plant in the spurge family, *Euphorbiaceae*. It is an oilseed crop cultivated mainly in India, Mozambique, Brazil, and China **(FAOSTAT, 2014)**.

Genetic diversity in a germplasm is the fundamental requirement for crop improvement programs. There are several genetic markers available for assessment of genetic diversity among the genotypes and accessions **(Kole and Rabinowicz, 2018)**. Though castor bean is a monotypic, it exhibits wide phenotypic diversity. In castor bean, genetic markers such as agro-morphological characters, biochemical and cytological markers were widely used in characterization of genetic variation in the germplasm **(Kole and Rabinowicz, 2018).**

Since 1990, random amplified polymorphic DNA (RAPD) markers have been successfully applied for identification of DNA polymorphism in various plant species **(Williams et al., 1990)**. They are often used for screening of a wide range of genetic stocks in order to find linkage with traits of agronomic significance **(Masojć, Myśków and Milczarski, 2001)**. Genetic diversity in castor bean was assessed by using both dominant and codominant molecular markers (random amplified polymorphic DNA, RAPD) **(Reddy, Nadigatla and Mulpuri, 2015; Vivodík et al., 2015a)**, inter-simple sequence repeats (ISSR) **(Wang et al., 2013; Vasconcelos et al., 2016)**, start codon targeted (SCoT)

(Kallamadi et al., 2015; Reddy, Nadigatla and Mulpuri, 2015), amplified fragment length polymorphism (AFLP) **(Allan et al., 2008; Quintero et al., 2013)**, simple sequence repeat (SSR) **(Gálová et al., 2015; Rukhsar et al., 2017)**, expressed sequence tag-simple sequence repeats (EST-SSR) **(Kanti et al., 2015; Wang et al., 2017)**, and random microsatellite amplified polymorphic DNA (RMAPD) **(Dong et al. 2012)**, and also advanced molecular markers, such as single nucleotide polymorphism (SNP) **(Foster et al. 2010)**, sequencerelated amplification polymorphism (SRAP) **(Lu et al., 2010)**, target region amplification polymorphism (TRAP) **(Simões et al., 2017a)**, and methylation-sensitive amplification polymorphism (MSAP) **(He et al., 2017)**. The polymerase chain reaction (PCR) has been used by many authors, such as **Žiarovská et. al., (2015)**; **Vyhnánek et. al., (2015)**; **Bošeľová and Žiarovská (2016)**; **Ražná et. al., (2016)**; **Žiarovská et. al., (2017)**; **Simões et. al., (2017b); Žiarovská et. al., (2018)**; **Ansari et al., (2018); Balážová et al., (2018); El-Fiki and Adly, (2019).**

Scientific hypothesis

The present study is focused on estimation of genetic distance between 56 Tunisian castor genotypes, based on 18 RAPD markers.

MATERIAL AND METHODOLOGY

Fifty-six castor (*Ricinus communis* L.) genotypes were used in the present study. Seeds of castor were obtained from the University of Carthage, National Institute of Research in Rural Engineering, Waters and Forests (INRGREF), Regional Station of Gabès, Tunisia. The ricin genotypes were obtained from 12 regions of Tunisia: S- Souassi (5 genotypes), BT- Bouthay (4 genotypes), GH- Ghomrassen (5 genotypes), BA- Sidi bou ali (5 genotypes), MT- Matmata (4 genotypes), AG- Mateur (5 genotypes), N- Nefza (4 genotypes), MD- Mednine (5 genotypes), M- Mornag (5 genotypes), G- Gabes (4 genotypes), K- Kebili (5 genotypes), KJ- Ksar jedid (5 genotypes). Genomic DNA of castor cultivars was extracted from leaves of 14-day old plantlets with GeneJET Plant Genomic DNA Purification Mini Kit according to the manufacturer's instructions. DNA concentrations were estimated by UV-Vis spectrophotometer Q5000, Quawell.

Figure 1 Photo of *Ricinus communis* L. (Spanishalex, Dreamstime.com)

Amplification of RAPD fragments was performed according to **Gajeraa et al. (2010)** using decamer arbitrary primers (Table 1). Amplifications were performed in a 25 μL reaction volume containing 100 ng of DNA, 12.5 μL of Master Mix (Genei, Bangalore, India) and 10 pmol of primer. Amplification was performed in a programmed thermocycler (Biometra, Germany) with initial denaturation at 94 °C for 5 min, 42 cycles of denaturation at 94 °C for 1 min, primer annealing at 38 °C for 1 min, extension at 72 °C for 1 min, and final extension at 72 °C for 5 min. Amplified products were electrophoresed in 1.5% agarose in 1× TBE buffer. The gels were stained with ethidium bromide and documented using gel documentation system.

Statisic analysis

A dendrogram based on hierarchical cluster analysis using the unweighted pair group method with arithmetic average (UPGMA) with the SPSS professional statistics version 17 software package was constructed. For the assessment of the polymorphism between genotypes ricin and usability RAPD markers in their differentiation we used polymorphic information content (PIC) **(Weber, 1990)**.

RESULTS AND DISCUSSION

In the present study, the representatives of the genus *Ricinus communis* collected from 12 different parts of Tunisia were differentiated by the DNA fingerprinting patterns using 18 RAPD primers. The efficacy of the RAPD technique in this study is further supported by the obtained PIC values of the primers used in the analysis. PCR amplification of DNA using 18 primers (Table 1) for RAPD analysis produced 145 DNA fragments that could be scored in all 56 genotypes of Tunisian castor (Figure 2). The number of amplified fragments varied from 3 (OPE-07) to 13 (SIGMA-D-01), and the amplicon size ranged from 100 to 1500 bp. Of the 145 amplified bands, 145 were polymorphic, with an average of 8.11 polymorphic bands per primer. Results indicated the presence of wide genetic variability among different genotypes of Tunisian castor. To determine the level of polymorphism in the analysed group of Tunisian castor genotypes polymorphic information content (PIC) was calculated. The lowest values of polymorphic information content were recorded for RLZ 9 (0.618) and the the highest PIC values were detected for OPD-08 (0.846) with an average of 0.761.

A dendrogram was constructed from a genetic distance matrix based on profiles of the 18 RAPD primers using the unweighted pair-group method with the arithmetic average (UPGMA). According to analysis, the collection of 56 Tunisian castor genotypes were clustered into five main clusters (Figure 3). Cluster 1 contained 10 genotypes of castor from different regions of Tunisia and cluster 2 contained 10 genotypes of castor from different regions of Tunisia. Cluster 3 contained 6 genotypes of Tunisian castor and cluster 4 contained 17 genotypes of Tunisian castor and cluster 5 contained 13 genotypes of tunisian castor. Genetically the closest

were four genotypes from cluster 1 (BT-1 – S-5 and K-1 – N-3) (Figure 2).

Dhingani et al. (2012) used 25 RAPD primers in this study. Amplification of genomic DNA of 8 genotypes, using RAPD analysis, yielded 92 fragments, of which 72 were polymorphic, with an average PIC value of 0.29. Number of amplified fragments with RAPD primers ranged from 4 to 13, with the size of amplicons ranging from 100 to 2650 bp in size. The polymorphism ranged from 54.54 to 100.0, with an average of 79.54 percent. The objective of work **Machado et al. (2013)** was to identify genetically different cultivars of castor bean (*Ricinus communis*) using RAPD markers. A total of 58 RAPD primers were used to genotype 15 cultivars. The genetic dissimilarity between cultivars was calculated by Jaccard's index, using the unweighted pair-group method with arithmetic mean (UPGMA). Five hundred and fifty-two fragments were identified, of which 311 were polymorphic (56.3%). The cultivars were clustered in five groups, evidence that there is genetic difference among them. RAPD markers are efficient in the study of genetic dissimilarity in castor bean. The aim of the present study of **Lakhani et al. (2015)** was to study the molecular diversity for varietal identification and phylogenetic relationships among thirteen castor genotypes and identify those with distinct DNA profiles. Twenty-seven RAPDs primers were used, out of which 16 polymorphic primers revealed 100% polymorphism among the castor genotypes. Dendrogram was constructed using UPGMA method which revealed distinct clusters. Values of the polymorphic information content (PIC) value ranged from 0.423 to 0.883 with an average of 0.705. This work of **Tomar Rukam et al. (2014)** investigated the fingerprinting and phenotyping of 25 castor genotypes available in Gujarat and other States of India. An integrated approach based on the exploitation of morphological traits and molecular markers, such as RAPD and ISSR fingerprints was employed. Morphological trait analysis and statistical analysis of markers were useful for reconstructing a castor varietal dendrogram. The results of the morphological and molecular analyses allowed us to confirm a remarkable differentiation among castor genotypes. The UPGMA dendrogram obtained using morphological characters clearly separated the 25 genotypes of castor into three groups.

The aim of study **Vivodík et al. (2015a)** was to assess genetic diversity within the set of 111 ricin genotypes using 13 RAPD primers. For differentiation of 111 ricin genotypes 13 RAPD primers were used. Amplification of genomic DNA of 111 genotypes using RAPD analysis yielded 102 fragments, with an average of 7.85 polymorphic fragments per primer. Number of amplified fragments with RAPD primers ranged from 3 to 13, with the size of amplicons ranging from 100 to 1500 bp. The polymorphism information content (PIC) value ranged from 0.491 to 0.898 with an average of 0.764 and diversity index (DI) value ranged from 0.576 to 0.900 with an average of 0.776. The dendrogram based on hierarchical cluster analysis using UPGMA algorithm was prepared. In dendrogram separated unique genotype RM-32 from other 110 genotypes which were further grouped into 3 subclusters (1, 2, 3). Only four genotypes were not distinguished. The aim of work **Vivodík et al. (2015b)** was to detect genetic variability among the set of 32 castor genotypes using five random amplified polymorphic DNA (RAPD) markers. Amplification of genomic DNA of 32 genotypes, using RAPD analysis, yielded 41 fragments, with an average of 8.20 polymorphic fragments per primer. Number of amplified fragments ranged from 5 to 11, with the size of amplicons varied from 100 to 1200 bp. The polymorphic information content value ranged from 0.598 (RLZ 9) to 0.811 (RLZ 6) with an average of 0.746 and diversity index value ranged from 0.557 (RLZ 9) to 0.889 (RLZ 7) with an average of 0.784. The dendrogram based on hierarchical cluster analysis using unweighted pair group method with arithmetic average algorithm was prepared. The aim of work **Balážová, Vivodík and Gálová (2016)** was to detect genetic variability among the set of 30 castor genotypes using 6 RAPD markers. Amplification of genomic DNA of 30 genotypes using RAPD analysis yielded 50 polymorphic fragments with an average of 8.33 fragments per primer. Number of amplified fragments varied from 5 (RLZ7) to 11 (RLZ8) and the amplicon size ranged from 330 to 1200 bp. All 50 amplified bands were polymorphic. The polymorphic information content (PIC) values ranged from 0.774 (RLZ7) to 0.870 (RLZ8) with an average of 0.825 and index diversity (DI) value ranged from 0.786 (RLZ7) to 0.872 (RLZ8) with an average of 0.831. The dendrogram based on hierarchical cluster analysis using UPGMA algorithm was prepared. Dendrogram separated ricin genotypes into three main clusters. Two genotypes (RM-72 and RM-73) were genetically the closest. Knowledge on the genetic diversity of castor can be used for future breeding programs for increased oil production to meet the ever increasing demand of castor oil for industrial uses as well as for biodiesel production. **Vivodík et al. (2015c)** analyzed seventeen castor genotypes for genetic variability using Random Amplified Polymorphic DNA (RAPD) markers. Thirteen polymorphic RAPD primers amplified 102 DNA fragments, with an average of 7.85 fragments per primer. Number of amplified fragments ranged from 3 (OPE-07) to 13 (SIGMA-D-01), with the size of amplicons ranging from 100 to 1200 bp. The polymorphic information content (PIC) value ranged from 0.450 (OPE-07) to 0.892 (SIGMA-D-01) with an average of 0.771 and diversity index (DI) value ranged from 0.551 (OPE-07) to 0.894 (SIGMA-D-01) with an average of 0.787. The dendrogram based on hierarchical cluster analysis using UPGMA algorithm was prepared and analyzed genotypes were grouped into two main clusters and only two genotypes (RM-5 and RM-23) could not be distinguished.

Table 1 Statistical characteristics of the RAPD markers used in Tunisian castor genotypes.

CONCLUSION

Genetic diversity in a germplasm is the fundamental requirement for crop improvement programs. PCR amplification of DNA using 18 primers for RAPD analysis produced 145 DNA fragments that could be scored in all 56 genotypes of Tunisian castor (Figure 1). The number of amplified fragments varied from 3 (OPE-07) to 13 (SIGMA-D-01), and the amplicon size ranged from 100 to 1500 bp. Of the 145 amplified bands, 145 were polymorphic, with an average of 8.11 polymorphic bands per primer. A dendrogram was constructed from a genetic distance matrix based on profiles of the 18 RAPD primers using the unweighted pair-group method with the arithmetic average (UPGMA). According to analysis, the collection of 56 Tunisian castor genotypes were clustered into five main clusters. Polymorphism revealed by RAPD technique was abundant and could be used for molecular genetics study of the castor accessions, providing high-valued information for the management of germplasm, improvement of the current breeding strategies, construction of linkage maps, conservation of the genetic resources of oat species and QTL mapping.

RISK ASSOCIATED WITH FOREIGN BODIES IN FOOD IN THE CZECH REPUBLIC

Pavla Svrčinová, Hana Tomášková, Vladimír Janout

ABSTRACT
The food safety is the main concern of the politicians and inhabitants in whole Europe. According the currently valid legislation the food should be save. The food should be safe from all aspects: chemical, microbiological, physical and radiological. Physical hazard/foreign body in food is perceived by public as something to be very simply solved by food business operators. However, foreign body is the biggest single source of customer complaints received by food business operators, retailers and enforcement authorities. In even the best-managed processes, the accidental presence of unwanted items could occasionally occur. Foreign body in food is believed to be a matter of concern to all food business operators. However, the level of inclusion of physical hazards by Czech food business operators in the hazard analysis is still low. Consumers experience with foreign bodies in food or even health problems caused by foreign bodies is continuing high level. Consumer complaints regarding foreign bodies reported from food products should be an important question for the food industry that should implement corrective actions to prevent such unwanted events.

Keywords: physical hazards; foreign bodies; hazard analysis; health risk; HACCP

INTRODUCTION
People expect, that food they eat is hygienically and health safe. Mass consumption of food is the cause of a high risk to human health, but only in the case of harmful food. Protection of human, animal and plant health is one of the main economic priorities of each country. The political objective of the European Union is therefore to ensure that European Union citizens have access to safe and nutritious foods, so it must meet strict safety standards. In ensuring food safety, it is necessary to consider all aspects of the food production chain, because each subject can have a potential impact on food safety **(Nagyová et al., 2019)**. The issue of food safety and quality is very important in view of the growing globalization of economy, whose mission is to encourage food businesses to improve the production process and competitiveness **(Nagyová et al., 2018)**.

The aim of this study is to present results of a survey on the experience of the food business operators in the Czech Republic and consumers with the physical hazards/foreign bodies in food. According currently valid legislation namely **Regulation (EC) No 852/2004** on food hygiene Food business operators shall put in place, implement and maintain a permanent procedure or procedures based on the hazard analysis and critical control points (HACCP) principles. The HACCP principles include identifying any hazards that must be prevented, eliminated or reduced to acceptable levels. The HACCP requirements should take account of the principles contained in the *Codex Alimentarius* **(Regulation (EC) No 852/2004)**.

According the ***Codex Alimentarius*** **(1969)** Code of practice CAC/RCP1-1969 – General principles of food hygiene the HACCP should list all the hazards that may be reasonably expected to occur at each step according to the scope from primary production, processing, manufacture, and distribution until the point of consumption. In conducting the hazard analysis, wherever possible the following should be included: the likely occurrence of hazards and severity of their adverse health effects; the qualitative and/or quantitative evaluation of the presence of hazards; survival or multiplication of micro-organisms of concern and production or persistence in foods of toxins, chemicals or physical agents. However foreign bodies are in the Czech Republic still present in food on the market: RASFF annual report 2016 reported 106 notifications due the presence of foreign bodies. In 2017 there were 131 notifications **(European Union 2017; European Union 2018)**.

In the report prepared by Food and veterinary office is stated: "Better HACCP implementation/Final overview report the state of implementation of HACCP in the EU and areas for improvement "**(European Union, 2015)** identified as a major problem hazard analysis. There is a widespread lack of understanding of how to undertake a hazard analysis correctly and this process creates difficulties particularly for

small FBOs due to lack of available expertise. In many cases, the assessment of the likely occurrence of any hazard and the severity of their adverse health effects was not properly undertaken. In general, operators were better equipped to address microbiological hazards. Analysis of physical contaminants that is foreign bodies representing a food safety hazard, has not been so far reported. Gap analysis showed that for EU a comprehensive analysis of incidents of physical hazards is missing and that this information is available may provide clues on actual risks and possible contingency measures that can be related to type of physical hazards, type of food and regional specificities **(Djekic, Jankovic and Rajkovic, 2017)**.

This cross-sectional study tried to evaluate situation in the Czech Republic (CZ), three years later after publication of above-mentioned EU publication. Since then EU created on webpages platform for HACCP implementation wit aim to help small and medium size FBOs, however, no significant progress in CZ was not noted by our study. Quarter of the FBOs did not consider physical hazards/foreign bodies as a problem. To verify existence of this problem we carried out study among CZ population on their experience with foreign bodies in food and 67.91% of them had in past five year at least one experience with foreign bodies and four of them had health problem caused by foreign body in food. The results showed, that there is still gap in the hazard analysis carried out by the food business operators concerning physical hazards/foreign bodies and consumers still experience foreign bodies in food.

Scientific hypothesis

Hypothesis 1: We assume, that all CZ food business operators included in their hazard analysis risks associated with foreign bodies/physical hazards. During development their permanent procedure or procedures based on the HACCP principles .

Hypothesis 2: We assume, that all CZ food business operators correctly implemented during establishment of their permanent procedure or procedures based on the HACCP principles all steps as described in **Regulation (EC) No 852/2004** for physical hazards.

Hypothesis 3: We assume, that the average CZ citizen has no experience with foreign bodies in food.

MATERIAL AND METHODOLOGY

The cross-sectional study aimed at the experience of the food business operators (FBO) and consumers with foreign bodies/ physical hazards in food. The questionnaire for producers focused on hazard analysis done by FBOs and establishment of critical control points (CCPs) and critical limits (CL). The questionnaire was distributed by e-mail, or by post to 100 FBOs within whole CZ. The FBO were randomly selected from list of food producers registered in trade register. The second part of study was questionnaire for consumers. We distributed 200 questionnaires to randomly selected visitors of food festival, which took place in Moravia-Silesian region. Questionnaire focused on their experience with foreign bodies in food and adverse health effect of consumption of such food.

Statistic analysis

Chi-squar test was used to determine whether there is a significant difference between the the observed frequencies in two or more categories between men and women experience with foreign bodies. The level of statistical significance was set at 0.05. Statistical processing was performed using Stata v. 13 (StataCorp).

RESULTS AND DISCUSSION

The questionnaire to FBOs returned fully filled in 54%. Out of 54 questionnaires only 40 FBOs (75%) evaluated in their hazard analysis foreign bodies/ physical risks. Out of these FBOs, that included in their hazard analysis also physical hazards, assessed the most frequently these materials of foreign bodies: glass 31x (77%), hair, nails 28x (70%), metal, plastic, small bugs 22x (55%), stones and personal belongings 16x (40%). See also Table 1. Out of 40 FBO, who included in hazard analysis physical hazards, only 14 (35%) of them based on the hazard analysis identified critical production steps (CPS) in relation to physical hazards.

The identified CPSs were preparation 10x, reception of raw material nine times, expedition/delivery eight times, storage six times, personal hygiene twice, and cleaning one times. Some FBOs identified as critical more production steps. 14 (35%) FBOs identified CPSs in connection with physical hazards.

Out of them 10 (46%) only identified CPS, two (9%) established in these steps CCP but without CL. The last two (9%) established CPS with CCP and CL. Four (18%) FBO established CCP without CPS and CL, two (9%) defined CCPS with CL but without CPS. The same number of FBOs (2, 9%) established CL without CPS and CCP. See Table 2. For some materials as metal, glass, plastics, organic parts, small bugs, stones, wood or inner undesirable parts there were cases, when CCP was established without their assessment during hazard analysis. See Table 3.

In total 12 FBOs established CCP to manage/control physical hazards in their production, 10 of them carried out hazard analysis, two did not carried out hazard analysis for physical hazards at all. In one such case the CCP was established based on internal procedure and in the other case the CCP was established by supplier of the HACCP plan. The most frequently were CCPs established for hair, nails (12x), and glass (10x) metal (eight times). The only material for which any FBO decided to establish CCP was rubber. To prevent or eliminate a hazard or to reduce it to acceptable levels, the FBOs decided for stones (44%) hair, nails (43%) and inner undesirable parts 40% establish the CCP. For other materials it was lower percentage. See Table 4.

Only six FBO replied, that they do have established critical limits for CCPs in connection with physical hazards. In all cases they choose limit not present. Two of them established critical limit without establishing CPS, and two without defining CPS or CCP. The next question verified how the critical limit was validated and in total 25 FBOs replied, that they had their CL validated. 19 of them did not answered previous question “what is your critical limit“. Out of them 20 had CL established by supplier of the HACCP plan, three times it was done by FBO based on previous experience, in one case limit was based on internal procedure, ones it was chosen based on external cooperation.

In total 60 complaints concerning foreign bodies in food were received by FBOs during 2016. The highest number of complaints received by one producer was 20 and the lowest was one. The out of 54 participants on the study only 10 FBOs received consumers' complaint. Three of them had not included physical hazards in their hazard analysis. The FBO, that received highest number of complaints (20), did not evaluate physical hazard during hazard analysis and as corrective action this FBO choose the training of the staff. The most frequently compliant was due the presence hair or nails in food (nine times) or bugs (three times). Corrective action implemented all FBOs after compliant. In majority it included stricter control by supervisor during production (13x) or on reception of raw materials (seven times), providing personal with protective cloths (seven times), change of equipment (four times), stricter sanitation (four times) or installation of the x- ray (one times) into the production line. Three FBOs decide to provide staff with further training. The only one produces carried out reassessment of CCP established in the HACCP plan.

The fully filled in questionnaire returned 134 persons, out of them 85 females (63, 43%) and 49 men (36, 56%). The age of participants was mainly between 15 – 65 years – 123 participants, the rest were older people. The majority were with university degree 48% and high school 37%, the rest of participants had lower level of education, and the only person had no education. Out of 134 participants 91 (67, 91%) had experience with foreign body in food during the last five years. The females met foreign body in 58 cases, men in 33. Females met foreign body statistically more frequently than men (tested by ch^2 test on the level of 5%, $p \leq 0.0001$). Out of these 91 participants the majority – 40 persons (43%) discovered foreign body in food 2 – 5 times in the last 5 years, 37 (40%) persons only once and 13 people experienced foreign bodies more than 5 times. The results did not show the statistical difference between females and men concerning the frequency of foreign body discovery in food (tested by ch^2 test on the level of 5%, $p \leq 0.0001$).

Concerning material, the most frequently were notified stones 38x (28.3%), inner undesirable parts 37x (27%) organic parts 36x (26.8%), pests, hair and nails, each by 35 (26.11%) participants. The results show Figure 3.

The questionnaire included also questions on the solution of the discovery of the foreign body in food. Only nine persons solved the problem making complaint, out of them eight made complaint to food business operator and the only person to competent authority controlling food safety.

In the next step the comparison was made between experiences of consumers with foreign bodies founded in food with FBOs assessment done within their hazard analysis. The most frequently assessed material was glass- 31 FBOs and 10 (32%) decided to establish CCP to manage this hazard. The glass was notified only by 4 persons. For plastic 22 FBOs carried out hazard analysis and 6 (27.2%) of them established for this hazard CCP. This material was notified by 23 consumers. Small bugs were assessed by 22 FBOs, 7 (31.8%) managed that hazard by establishment of CCP. Small bugs were notified by 35 persons.

Out of 134 participants four (2, 9%) had adverse health Out of 134 participants four (2, 9%) had adverse health effect after consumption food with foreign body in it. One person had even two cases of health problem. Four times it was broken tooth and in one case it was wooden chip stacked in throat. All cases of health problem needed health care treatment.

For organic parts of food and inner undesirable parts of food only 9, respectively 10 FBOs carried out hazard analysis and 3 (33.3%) respectively 4 (40%) of them established CCP to manage this hazard. These two types of foreign bodies were frequently notified by consumers 36x, 37x. The most frequently notified foreign bodies were stones, while only 7 FBOs decided to manage this hazard by establishment of CCP, while 16 carried out hazard analysis. The hair and nail were assessed by 28 FBOs, 12 managed that hazard by CCP (42.85%).

Table 1 Number of FBOs in relation to material assessed in hazard analysis.

Personal belongings	16	3	18.75
Other	7	1	14.28

Hair or nail were notified by 35 persons. The results did not show the statistical difference between FBO and consumers concerning the frequency of foreign body material assessment in hazard analysis and discovery in food (tested by ch^2 test on the level of 5%, $p \leq 0.0001$). Further details are presented in Figure 4.

A foreign body may be defined as something that the consumer perceives as being alien to the food. The perception of the consumer is important, since not all foreign bodies are in fact alien to the food, though all have the potential to give rise to a consumer complaint. Hence foreign bodies can range from items that are demonstrably alien to the food, such as pieces of glass, metal or plastic through items that are related to the food, such as fragments of bone in meat products to part of the food itself, such as crystals of sugar or salt that are mistaken for glass.

Foreign bodies may get into food at any stage from initial harvesting to final processing or even preparation and consumption by the consumer. Food processing should include procedures to remove foreign bodies incorporated during harvesting of the crop, but it can also give rise to foreign bodies itself, any foreign bodies can be traced back to pieces of food processing machinery **(Edwards M., 2014)**.

In the HACCP Annex, Hazard Analysis and the decision tree for determining CCPs focuses too much on microbiological hazards, while chemical and physical hazards are given less importance. This reflects the historic focus of HACCP when the initial guidelines were being developed, but chemical and physical hazards need to be addressed to cover issues such as, for example, the effective management of allergens with respect to food safety. In revising the GPFH text and the HACCP Annex, consideration should be given to how to incorporate additional guidance on chemical and physical hazards **(*Codex Alimentarius*, 2014)**.

Foreign matter is the biggest single source of customer complaints received by many food manufacturers, retailers and enforcement authorities. In even the best-managed processes, the accidental inclusion of unwanted items may sometimes occur. Foreign matter in foods is therefore quite rightly a matter of concern to all food manufacturers and retailers. Consumer complaints regarding foreign material reported from food products will continue to be a significant issue for the food industry. However, careful study of data from a wide range of foreign matter investigations demonstrates that in many cases the occurrence of foreign matter is far from random **(Edwards and Stringer, 2007)**. 16,878 foreign bodies injuries occurred in children aged 0 – 14 years have been recorded in the SUSY Safe databases. FB type was specified in 10,564 cases, among them 2,744 (26%) were due to a food item **(Van As et al., 2012)**.

Contrary to microbial and chemical hazards, physical contaminants are the most obvious evidence of contamination of product. Regarding types of foreign bodies notified the top three material were pest (54.6%), glass (17.4%) and metal (11.5%) **(Djekic at al., 2017)**. Consumer complaints about foreign bodies are a continuing problem for the food industry. Recent years have seen an increasing emphasis on consumer rights, with frequent encouragement in the media for consumers to complain to food companies about incidents that would in the past have been viewed as trivial **(Edwards, 2014)**.

The foreign bodies statistically were found more by women than men. This is due women are the main chefs at Czech homes. The results of study shoved, that the most frequently met foreign bodies by consumers were stones followed by organic foreign bodies (both inner and outer), followed by hair and small bugs. The difference could be caused by type of foreign bodies, when hair or inner organic parts are not seen by consumers as a problem. Therefore, these materials are not notified by them. The problems with foreign body in food were reported to FBOs only in minority of cases, even in the case of health problem caused by foreign body complaints was not made. This could be caused by no adverse health effect and by consumer's historical experience with their complaint's solution.

Food factory operatives are a major source of foreign bodies, from stray hairs not contained by hairnets or beard snoods to studs or sleepers from earrings. Personnel are a major potential source of foreign bodies in food premises of all kinds **(Edwards, 2014)**. The one of the most frequently founded foreign body by consumers involved in study was hair and nail. That is sign that staff is still one of the major sources of contamination. The root of this could be the staff itself, when the staff turnover in food industry is very high and staff has no specific background in food safety.

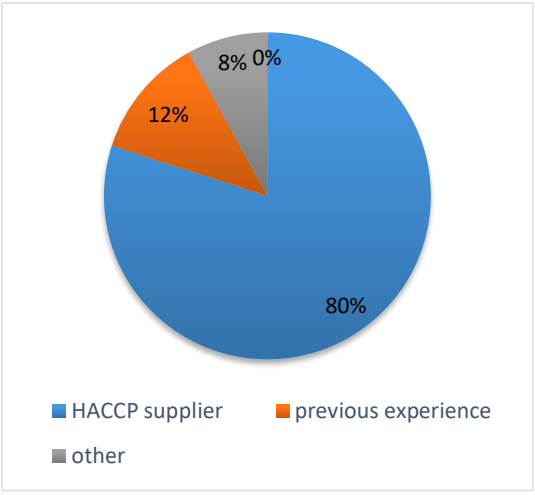

Figure 1 Validation of CL.

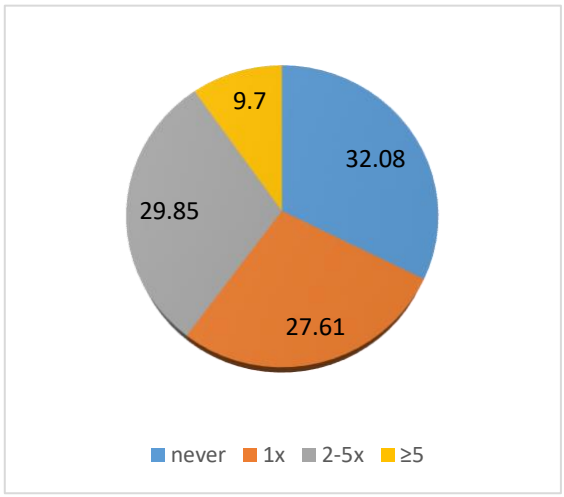

Figure 2 Frequency of foreign bodies founded in food.

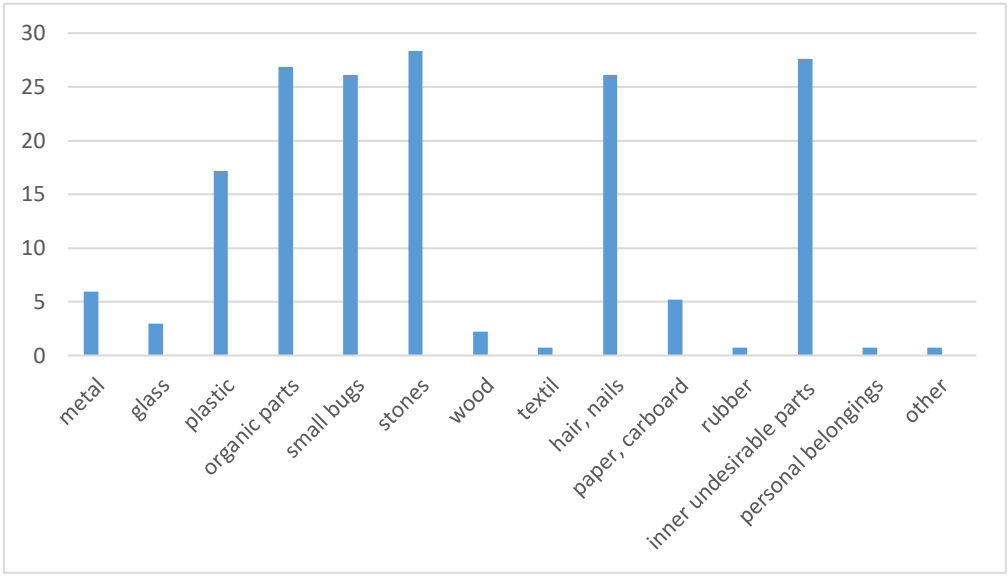

Figure 3 Foreign bodies discovered in food by material in %.

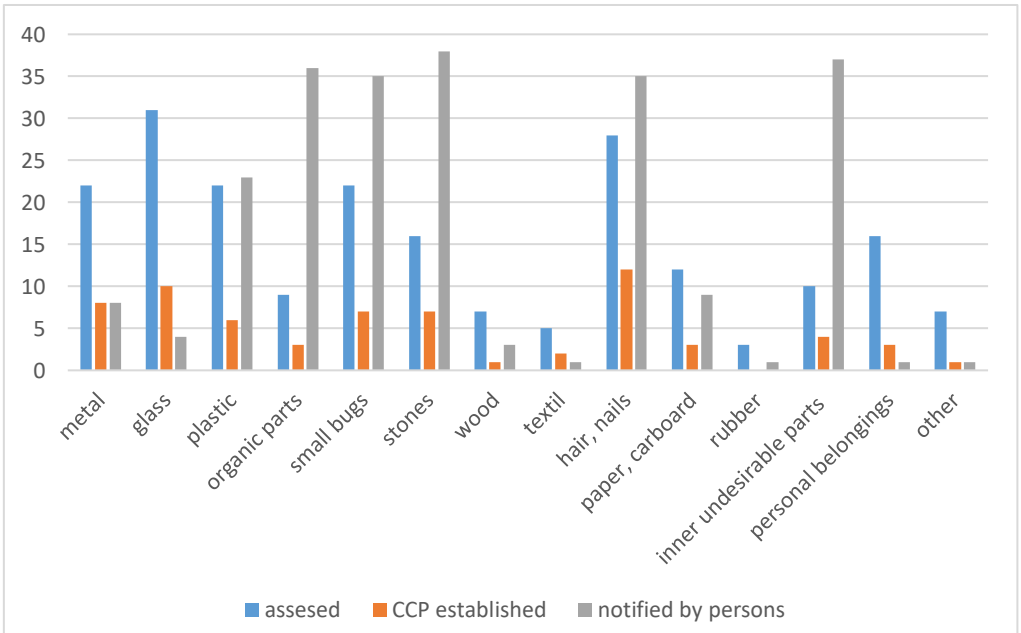

Figure 4 Comparison assessment carried out by FBOs, CCP establishment and consumers experience (total number).

Although, the FBOs provided staff by training as corrective measure in case of non-compliance, the training did not sufficiently prevent occurrence of hail or nail in food. Staff training should go together with thorough control by hierarchy directly on production site.

A good quality management system is vital to the effective prevention and control of foreign bogies in food manufacture. A structured preventive approach is likely to be the most reliable basis for such a system. The traditional approach of sole reliance on finished product analysis and factory inspection is nowadays unlikely to give acceptable assurance and consumer confidence that the process is under control on continuous basis. Hazard analysis is the approach which all companies, whatever their size, should use to identify the points in their manufacturing operations which critically affect product safety. Foreign body hazard analysis of a food product process starts with the identification of the sequential stages in the process from raw materials and packaging materials through to the dispatch, distribution and end use of the food product **(Edwards, 2014)**. Substantial part of the FBOs did not include in their hazard analysis physical hazards at all. The FBOs do not understand importance of hazard analysis, when CCPs or critical limits were in many cases established without carrying out hazard analysis. Some critical limits were established without having chosen critical control points. That is due the not understanding importance of hazard analysis for establishment of CCPs and CLs within the procedures based on HACCP principles.

The investigation of a foreign body incident involves a number of clear stages. The first essential step is to determine all the known facts in the case. It is important that precise details of the circumstances under which the foreign body was discovered are recorded. In particular, it is essential to know whether the foreign body was found when the pack was opened, during food preparation or whilst eating the product, and whether or not the foreign body could have been heated during preparation or mixed with other food products **(Edwards, 2014)**. In case of non-compliance caused by foreign body all FBOs implemented corrective action. However, only few of them applied further training for the staff, although large part of the complaints concerned hair or nail.

While the available technology may not eliminate all foreign bodies from food, the correct application of technology will assist in removing many of them **(Edwards, 2014)**. The critical point in the detection of physical contaminants is nearly always the large variability that it is observed in the distribution of impurities between the repeated determinations carried out on the same sample. This variability is due to the fact this kind of the contaminants do not have a uniform distribution within the sample, thus resulting in the need to transform the data into values that can express a normal distribution; alternatively, it may be necessary to increase the number of determinations in order to ensure a significant result **(Schiavo et al., 2015)**. There are many ways food processors can prevent physical hazards in food products **(CVO/Food Safety Knowledge, 2018)**. The presence of foreign bodies in food is of major concern to the producer. Mechanical separation techniques have been used for many years for foreign bodies in powdered and owing products based on size and weight. Optical inspection techniques extend the range of detectable foreign objects regarding shape and color in free materials. Metal detectors enable metallic particles inside the body of a product to be found. With advances in sensor technologies and computing power more advanced detection systems are becoming available **(Graves, Smith and Batchelor, 1998)**.

Our study has proven that there is still space for improvement from side of the FBOs; some of them do not implement all possible preventive measures in their establishments. There was one FBO did not including in hazard analysis physical hazards, although received 20 consumers complaints. It seems, that preventive measures applied by FBOs are not effective enough and do not prevent occurrence of some foreign bodies such as plastic, small bugs, stones, hair and nail. Organic parts and inner undesirable parts of food are not in focus of FBOs, while they are founded frequently by consumers.

Flour beetles are among the most common pest insects found in stored grain and milled products. Beetles have defensive glands which secret quinones such as 2-methyl-p-benzoquinone, 2-ethyl-p-benzoquionone, hydroquinone commonly referred to as benzoquinones. Benzoquinones have a carcinogenic effect, they are inhibitors of growth of various microorganisms, and they produce a self-defense mechanism in threat situations and affect population aggregation **(Lis et al., 2011)**. Stored product pest may be source of indirect contamination of stored commodities, by pesticide residues of chemical treatment by protectants. Some species of *Acarina, Blattodea, Coleptera, Lepidoptera* and *Psocoptera* may cause allergic reactions in humans exposed to remnants of their bodies. No critical levels are available for contamination of food agrocommodities by allergens of arthropods **(Mattos et al., 2016)**. The presence of pests in food was quite frequent among consumers, although quite substantial number of FBOs assessed hazard associated with them. There should be more focus on presence of pests in food as there is severe chemical risk associated with them.

1,309 complaints reported from 2000 to September 2002, 331 were related to foreign materials (25%), about 6% of those cases resulted in injury. The most common materials were identified as metal, glass and plastic **(Mattos et al., 2016)**. In our study the percentage of injuries was lower, the difference could be caused by the population under investigation. Our study included general population while above mentioned study investigated only cases, when foreign body was notified to the competent authority. However, the health effect of foreign body in food was severe and needed to be solved by health service providers.

CONCLUSION

All of our hypothesis were not proven to be truth. There is high number of FBOs not including physical hazards in hazard analysis or not following correctly all necessary steps in implementation of their procedures based on HACCP principles. As the result there is quite high number of consumers experiencing foreign bodies in food. The problem is also the quality of guidelines for hazard analysis, that do not include physical hazards and especially small FBOs do not have all necessary knowledge to carry out thorough hazard analysis. There should be more focus on physical hazards from competent authorities and producers

associations to develop guides to cover physical hazards in a future.

ASSESSMENT OF ANTIMICROBIAL POTENTIAL OF SUBSTANCES ISOLATED FROM SOME WASTES OF MEAT PROCESSING INDUSTRY

Elena Kotenkova, Ekaterina Polishchuk

ABSTRACT

The slaughter of farm animals generates a large number of by-products. Meat waste management includes various methods, but cost-effective technologies are still in priority. This manuscript reports the results of the study of antimicrobial activity of substances isolated from such wastes of meat processing industry as bovine and pork mucous membranes and epithelial tissues. Proteomic study included two-dimensional electrophoresis with following mass spectrometric identification. Antimicrobial activity against *L. monocytogenes*, *P. aeruginosa* and *S. aureus* of neutralized native extracts and after enzymatic treatment as well as its ultrafiltrates was determined by flow cytometry with EvaGreen and PI dyes. It was shown that a large number of histones were found in bovine mucous membranes as well as several tissue-specific proteins, which would be a precursor of bioactive peptides. Bovine mucous membranes of the tongue and nasal cavity possessed the greatest activity in relation to *P. aeruginosa*, the rate of surviving cells decreased to 22.0%. Bovine mucous membranes of the rectum and the oral cavity, submandibular lymph nodes, pig mucous membranes of the larynx, tongue, lips, and rectum increased dead cells count up to 40% of all cells. Bovine nasal mucosa and pork mucous of labial cavity possessed the greatest activity against *S. aureus*, the rate of surviving cells did not exceed 10.0%. Determination of antimicrobial action against *L. monocytogenes* of native samples and treated with trypsin showed that bovine mucous membranes of the rectum and oral cavity, pork mucosa of the lips and submandibular glands were the most active. Treatment with trypsin or ultrafiltration demonstrated different effects on activity of samples. It was shown the perspectivity of recycling of such type of by-products into effective and demanded substances which can be used, for example, in the food industry as an alternative to chemical preservatives.

Keywords: AMP; antimicrobial activity; slaughter wastes; flow cytometry; mucous membranes

INTRODUCTION

The slaughter of farm animals generates a large number of by-products. The amount of such kind of wastes averages approximately about 10% to 15% of the value of the live animal in developed countries, in other countries this rate can reach for about two-third of the animal after slaughter **(Alao et al., 2017)**. The yield of animal by-products is high and ranges between 50-60% of the live weight **(Irshad and Sharma, 2015)**, including carcasses, hides, hoofs, and heads, offal, viscera, bones, fat and meat trimmings, blood **(Helkar, Sahoo and Patil, 2016)**. Non-carcass parts of animal (by-products) are divided into edible or inedible parts **(Barbut, 2015; Alao et al., 2017)**. Some internal organs, e. g. liver, kidney, hearts, tongue etc. could be used for humans food but it depends on traditions and religion **(Jayathilakan et al., 2012)**, as well as legacy regulations **(Jędrejek et al., 2016)**. Therefore, effective by-product utilization is a quite sharp problem.

Meat waste management included such methods as composting, aerobic and anaerobic digestion **(Banks and Wang, 2004; Arvanitoyannis and Ladas, 2008)**. Usage of by-products for animal feed and pet food and biofuel or solid fuel production is also widely developed **(Virmond et al., 2011; Jędrejek et al., 2016; Hamawand et al., 2017; Adhikari et al., 2018)**. On the other hand, for a safety reasons most produced feed materials are in severe restrictions in their use for feed farm animals, because slaughterhouse wastes are potentially contaminated by several pathogens **(Arvanitoyannis and Ladas, 2008; Jędrejek et al., 2016; Adhikari, Chae and Bressler, 2018)**.

Nevertheless, animal by-products are a good source of nutrients and bioactive substances, therefore its widely used in food industry, e.g. as functional ingredients, for technological applications and biopeptides production as well as for medical and pharmaceutical applications **(Toldrá, Mora and Reig, 2016; Alao et al., 2017; Chernukha et al., 2018)**. Some kind of by-products also recycled for fertilizer and chemical applications **(Irshad and Sharma, 2015; Toldrá Mora and Reig, 2016; Helkar Sahoo and Patil, 2016)**.

Concerning meat waste management, cost-effective technologies are in priority, therefore the developing progressive technologies, which can be based on by-

products as a source of certain bioactive substances is in demand.

This manuscript reports the results of the study of antimicrobial activity of substances isolated from some wastes of meat processing industry.

Scientific hypothesis

Most of the studied mammalian antimicrobial peptides (AMP) and proteins were isolated from neutrophils, but some such compounds were found in the small intestine, tongue, myeloid and epithelial cells **(Wang, Li and Wang, 2016)**. Therefore, not only the granular apparatus can be considered as a source of AMP, but also mucous membranes and epithelial tissues. These tissues due to its border position are constantly in contact with a wide range of pathogenic and opportunistic microorganisms and viruses, fungi, and therefore can potentially contain a set of substances with antimicrobial action.

MATERIAL AND METHODOLOGY

Pork mucous membranes of the larynx, tongue, labial and nasal cavities, rectum, and submandibular glands, bovine mucous membranes of the tongue, larynx, nasal and oral cavities, rectum and submandibular and lymphatic glands were selected as objects of study.

Proteomic study

Two-dimensional electrophoresis (2DE) was performed according to the method of O'Farrell with isoelectric focusing in ampholine pH gradient (IEF-PAGE). The subsequent detection of the proteins was carried out by staining with Coomassie R-250 (Applichem, USA) and silver nitrate (PanReac, Spain) as described previously **(Kovalyov et al., 2006)**. The resulting digital images were edited in a graphic editor and the quantitative protein content was calculated using ImageMaster 2D Platinum version 7 (GE Healthcare, Switzerland).

Protein fractions were excised from the gel, grinded and undergone trypsinolysis (Sigma, Germany) **(Zvereva et al., 2015)**. Obtained peptides were investigated by MALDI-TOF MS and MS/MS mass spectrometry on Ultraflex MALDI-TOF mass spectrometer (Bruker, Germany) with UV laser(336 nm) in the positive ion mode in molecular weight range of 500 – 8000 Da with calibration according to known peaks of trypsin autolysis.

Bioinformatics analysis

Analysis of obtained tryptic peptides mass spectra was performed using Peptide Fingerprint option in Mascot software (Matrix Science, USA) with MH+ mass determination accuracy of 0.01%; search was performed in databases of the National Center for Biotechnology Information, USA (NCBI). Comparative analysis of obtained proteomic profiles was carried out with use of information module "Proteins of skeletal muscle of cows (Bos Taurus)" of the Database "Proteomics of muscle organs" (http://mp.inbi.ras.ru).

Preparing testing samples

Grinded mucous membranes were extracted with 10% acetic acid solution at ratio 1:5, stirring speed of 400 rpm, for 5 hours at 4 – 5 °C at Laboratory dispersing equipment (Labotex, Russia). Then extracts were centrifuged (Sigma 3K30, Germany) at 15,000 rpm and 4.0 °C for 5 min. The supernatant was neutralized to pH = 6 with a 4N sodium hydroxide solution. Neutralized extracts were subjected to trypsinolysis (PanReac, activity 328 USP $U.mg^{-1}$). Ultrafiltrates were obtained by centrifugation on centrifuge ultrafilters Amicon Ultra-4 (50kDA, Millipore). Native extracts and extracts after enzymatic treatment were subjected to a sterilizing filtration on syringe filters with a pore size of 0.22 μm (Nylon L. E., Teknokroma).

Antimicrobial activity study

The activity of antimicrobial substances contained in native extracts after neutralization and after enzymatic treatment, and ultrafiltrates were studied by flow cytometry. *L. monocytogenes* ATCC 13932, *P. aeruginosa* ATCC 27853 and *S. aureus* ATCC 25923 strains were obtained from the State Research Center for Applied Biotechnology and Microbiology (Obolensk, Moscow region, Russia). Suspensions with an approximate concentration of 1 × 106 $cells.mL^{-1}$ were used as positive controls. To obtain negative control of *L. monocytogenes* ATCC 13932, the resulting suspensions were heated at 100 °C for 10 min.

Neutralized native samples and ultrafiltrates analysis protocol

A total of 10 μL of tested sample was mixed with 90 μL *P. aeruginosa* ATCC 27853 or *S. aureus* ATCC 25923 (an approximate concentration of 1×10^6 $cells.mL^{-1}$) and incubated overnight in thermostat at 37ºC. A total of 20 μL overnight incubated mixture of tested sample and bacterial cells was mixed with 5 μL of EvaGreen (Synthol, Russia), 365 μL of deionized water, and 10 μL of DMSO (Biolot, Russia); then, samples were incubated in the dark for 15 min and green fluorescence signals corresponding to live cells were measured on a Guava EasyCyte flow cytometer (Merck Millipore, Germany) up to 5000 events. A total of 20 μL overnight incubated mixture of tested sample and bacterial cells was mixed with 3 μL of PI (Logos Biosystems, Republic of Korea), 377 μL of 0.9% sodium chloride solution; then, samples were incubated in the dark for 15 min and red fluorescence signals corresponding to dead cells were measured on a Guava EasyCyte flow cytometer (Merck Millipore, Germany) up to 5000 events. Survived cells were calculated in relation to control and expressed in percentage, dead cells were calculated in relation to the survived cells and expressed in percentage.

Native extracts and after enzymatic treatment analysis protocol

A total of 50 μL of tested sample was mixed with 50 μL *L. monocytogenes* ATCC 13932 (an approximate concentration of 1×10^6 $cells.mL^{-1}$) and incubated overnight in thermostat at 37 ºC. A total of 20 μL overnight incubated mixture of tested sample and bacterial cells was mixed with 5 μL of EvaGreen (Synthol, Russia), 365 μL of deionized water, and 10 μL of DMSO (Biolot, Russia); then, samples were incubated in the dark for 15 min and green and red fluorescence signals were measured on a Guava EasyCyte flow cytometer (Merck Millipore, Germany) up to 5000 events **(Kotenkova et al., 2019)**.

All cells corresponded to survive were taken as 100 percent, live and dead cells were calculated in percentage of survived cells.

RESULTS AND DISCUSSION

In previous study it was shown that a large number of histones were found in bovine mucous membranes as well as several tissue-specific proteins, which would be a precursor of bioactive peptides **(Kotenkova et al., 2019)**.

The proteomic study of porcine tissues was also carried out. A large number of histones were found too, such as H2B type 1-like, HIST1H2BB, H2B ½ and H2B type 1-N as well as proteins S100-A12 and AGR2, which were previously identified in bovine mucous membranes. Lysozyme C was identified in the mucous membranes of the tongue and rectum.

Bovine mucous membranes of the tongue and nasal cavity were the most active against *P. aeruginosa*, the proportion of survived cells decreased to 22.0%. In some cases, there was noticed an increase in the number of cells by almost 2 times when extracts of bovine lymphatic glands, mucous membranes of oral cavite and rectum, porcine mucous membranes of the larynx, tongue, labial cavity and rectum were added to the cell culture. However, a large amount of dead cells was noticed in these samples, the ratio of dead cells reached 40.0% of all cells. Presumably, this observation could be explained by the fact that AMP is "packed" into a protein molecule, which can be used by microorganisms initially as a substrate, and only after release demonstrate an antimicrobial effect **(Abaturov, 2011; Pasupuleti, Schmidtchen and Malmsten, 2012; Wang, 2014)**. The noted observation was confirmed by the fact that no such effect was observed while ultrafiltrates addition. In addition, addition of some ultrafiltrates with removed high molecular weight substances led to increase of antimicrobial activity. Native extracts of bovine mucous membrane of the larynx and submandibular glands salivary glands, pork mucous membrane of the nasal cavity did not have a significant antimicrobial effect against *P. aeruginosa*. Ultrafiltration of extracts of bovine mucous membranes of the larynx, oral cavity and rectum, pork mucous membranes of the larynx, tongue, nasal cavity, rectum and submandibular glands led to increasing of antimicrobial activity, in the case of bovine lymphatic glands and pork mucous membrane of labial cavity – did not affect on the activity, and in relation to bovine mucous membrane of the tongue and submandibular glands – on the contrary, reduced. Figure 1A shows the type of cytogram using Eva Green and PI dyes when antimicrobial activity was determined against *P. aeruginosa.*

Almost all native extracts were active against *S. aureus*. The greatest antimicrobial effect was observed when extracts of bovine mucous membrane of the nasal cavity and pork mucous membrane of the labial cavity were added to cell culture, the proportion of surviving cells did not exceed 10.0%. An increase of survived cells by more than 1.5 times was observed when pork rectum mucosa extract was added to cell culture. However, this sample showed a similar observation as in case *P. aeruginosa*: the proportion of dead cells reached 46.5% of all cells. It should be noted that the proportion of dead cells in all samples was significantly higher than in the experiment with *P. aeruginosa*. This observation indicated a higher activity of samples against gram-positive bacteria. Ultrafiltration of extracts in most cases did not lead to an increase in activity, except pork mucous membranes of the larynx, tongue and rectum – on the contrary, there was an increase in activity. Figure 1B shows the type of cytogram using Eva Green and PI dyes when antimicrobial activity was determined against *S. aureus.*

It was observed that EvaGreen dye, which is commonly used in PCR analysis, stained live cells of *L. monocytogenes* ATCC 13932 and fluoresced in green and red spectra; the dye also stained dead cells and only demonstrated red fluorescence **(Kotenkova et al., 2019)**. Bovine mucous membranes of the rectum and oral cavity, porcine mucous membranes of labial cavity and submandibular glands demonstrated the highest activity against *L. monocytogenes*, the proportion of living cells decreased to 2.7%. Enzymatic treatment with trypsin of extracts of bovine mucous membranes of the tongue, and submandibular and lymphatic glands, pork mucous membranes of the larynx, labial and nasal cavities, rectum resulted in increased activity, in the case of bovine mucous membranes of the larynx, nasal cavity and rectum, pork mucous membranes of the larynx, tongue and submandibular – did not effect on activity, and in relation to bovine mucous membrane of the oral cavity - on the contrary, reduced. Figure 2 shows the type of cytogram using Eva Green dye when antimicrobial activity was determined against *L. monocytogenes*.

In mammals, AMPs are most frequently found in blood, less often - in the saliva, mucous membrane of gingivae, tongue, cheeks and lips, submandibular gland and small labial glands, neutrophils, Paneth cells, tissues of small intestine, epithelial cells of nose and bronchi, and tracheae **(Kokryakov, 1995; Shamova, 1995; Jarczak et al., 2013; Shamova, 2013; Bosch-Marcé et al., 2014; Wang, 2014; Zhao and Lu, 2014; Wang et al., 2015; Zharkova, 2016)**. According to an analysis of the International UniProt Protein Database and Antimicrobial Peptide Database, porcine and bovine tissues have the high content of both AMPs and other substances with antimicrobial and antiviral action. Protegrins are determined in pigs; bovine tissues are characterized by cathelicidins and defensins. Different isoforms of lysozyme present in both animal species.

Nevertheless, in our pilot study we confirmed that mucous membranes and epithelial tissues of farm animals could be also a good source of such substances.

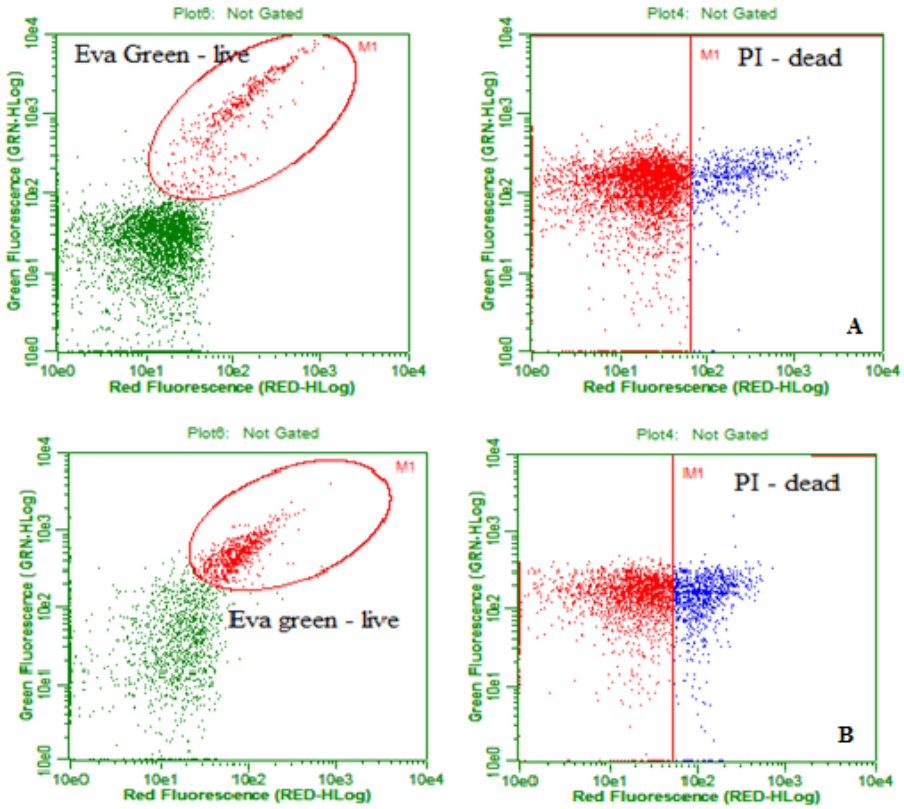

Figure 1 The type of cytogram using Eva Green and PI dyes when antimicrobial activity against *P. aeruginosa* (A) and *S. aureus* (B) of pork rectum was determined.

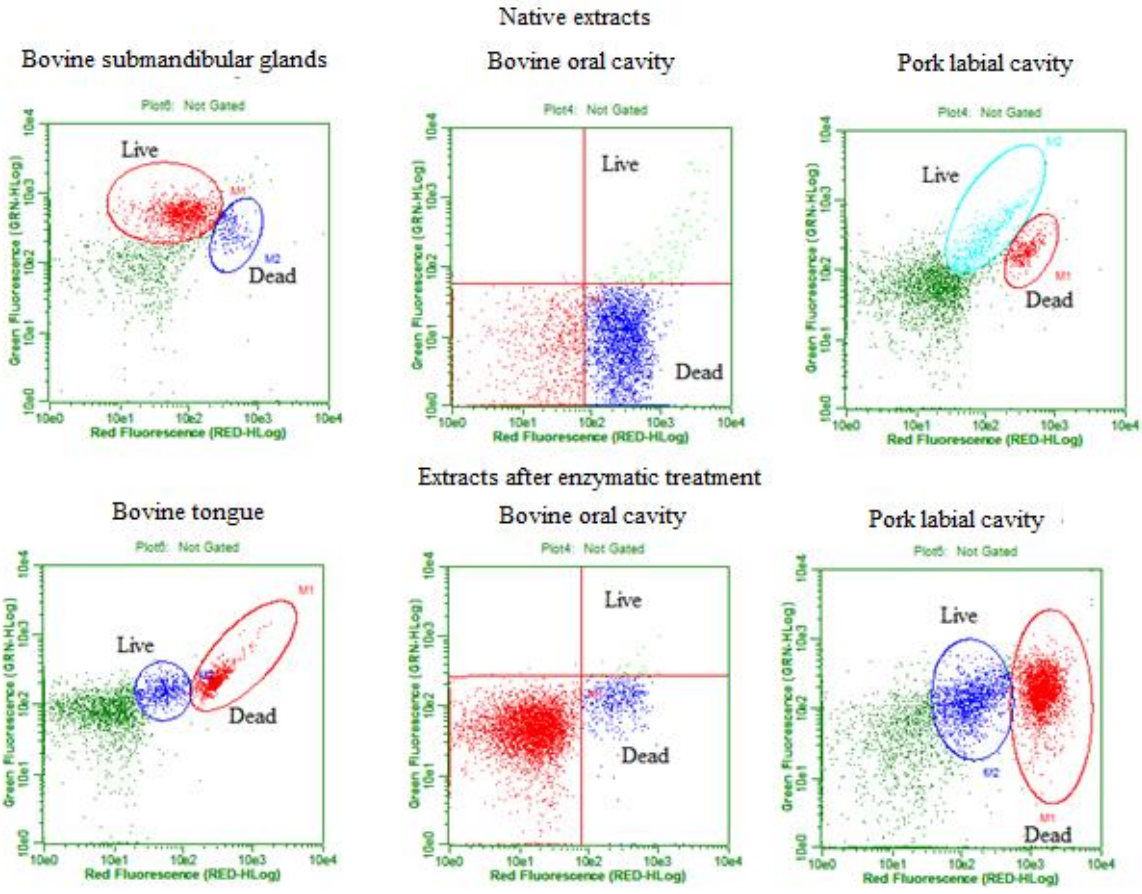

Figure 2 The type of cytogram using Eva Green dye when antimicrobial activity against *L. monocytogenes* of native extracts and after enzymatic treatment were determined.

CONCLUSION

Results of pilot study confirmed bovine mucous membranes of the tongue and nasal cavity, pork mucous membrane of labial cavity as a most promising source of antimicrobial compounds. The samples were the most active against gram-positive bacteria. It was also interesting observations found in respect of bovine submandibular lymph nodes and pork mucosa of the rectum. In connection with the revealed observation of "unpacking" of AMP from a high molecular weight protein molecule by a culture or trypsin, it is planned to consider in more detail the expediency of removal of high molecular weight substances from extracts, as well as the effects of enzyme treatment.

Moreover, it was shown the perspectivity of recycling of such type of by-products into effective and demanded substances which can be used, for example, in the food industry as an alternative to chemical preservatives.

PROTEOMIC STUDY OF PIG'S SPLEEN

Ekaterina Romanovna Vasilevskaya, Anastasiya Gennadievna Akhremko

ABSTRACT

This work is devoted to pig spleen proteome study. Spleens were taken from Duroc pigs (females, 145 – 160 days old) and typical two-dimensional electrophoregrams were obtained. On proteomic maps after visualization and image analysis there were detected 600 fractions, including organ-specific proteins – 3 62 fractions. Among the identified constitutive fractions, the highest expression was observed (Vol spots more than 3.0E + 07) four protein spots S1, S9, S12 and S21, which are supposedly Annexin A1 (MW 38.76 kDa), Ectonucleoside triphosphate diphosphohydrolase 1 (MW 57.75 kDa) Pro-cathepsin H CD59 (MW 37.45 kDa) and glycoprotein (MW 13.79 kDa), respectively. Obtained electrophoregrams analysis using information resources made it possible to identify different active compounds in spleen with various functions, mainly immunoregulatory – glycoprotein CD59 (Mm 13.79 kDa) and ATP-dependent RNA helicase (Mm 107.58 kDa); the intensely expressed LIM-domain of the actin-binding protein (Mm 83.99 kDa). The results obtained are a prospect for immunomodulating biologic development based on animal raw materials for farm animals.

Keywords: spleen; two-dimensional electrophoresis; pork; proteomic

INTRODUCTION

Farm animals' organs and tissues are an inexhaustible resource of compounds involved in various regulatory and compensatory oraganism reactions **(Chernukha et al., 2016; Kotenkova, Lukinova and Fedulova, 2017)**. Modern researches are aimed to identifying, studying and isolating proteins that are potentially capable of exhibiting biological activity.

Today, one of the most effective ways to study active compounds derived from animal raw materials is complex tissue-specific proteins analysis at molecular level, which is commonly called the "proteomic approach". The main proteomics method, still relevant today, is two-dimensional electrophoresis, used to study protein changes and identify functional species and tissue-specific compounds **(Chernukha et al., 2017)**. Two-dimensional electrophoresis technology allows us to separate thousands of proteins with high resolution, and characterize the isolated protein fractions using mass spectrometric methods. Obvious advantage proteomic approach over others lies in its ability to detect alternative proteins forms that are the result of co-and/ or post-translational modifications.

Currently, animal tissue researches are aimed at studying biological processes in order to identify product quality and safety markers (for example, species, autolysis, quality defects) **(Mora, Gallego and Toldrá, 2018)**. However, scientific projects devoted to productive animals individual organs proteomic analysis for active protein components isolation and biologics creation based on them have great potential.

This work is devoted to protein composition comparative study of pigs spleen and resulting two-dimensional electrophoregrams analysis in order to identify potential constitutive proteins to create biological preparations of immunomodulatory action.

Scientific hypothesis

Productive animals' organs and tissues are bioactive protein compounds source. Spleen as an immune organ may contain physiologically active proteins with a pronounced immune orientation.

MATERIAL AND METHODOLOGY

Duroc pigs spleen was selected as study object. In order to level the geographic population characteristics, animals were selected from healthy females of 145 – 160 days old on three farms: Lipetsk region (C1); Voronezh region (C2); Tyumen region (C3).

Two dimensional gel electrophoresis (2-DE)

The samples described above were subjected to 2-DE. Proteins were separated by IEF in the first dimension and SDS-PAGE in the second dimension essentially as described by Hirano **(Hirano, 1982)** with slight modifications **(Kimura et al., 2003)**. IEF in the first dimension was performed at 3650 $V.h^{-1}$. The anodic and cathodic electrode solutions used for IEF were 0.02 M H3PO4 and 0.02 M NaOH, respectively, in

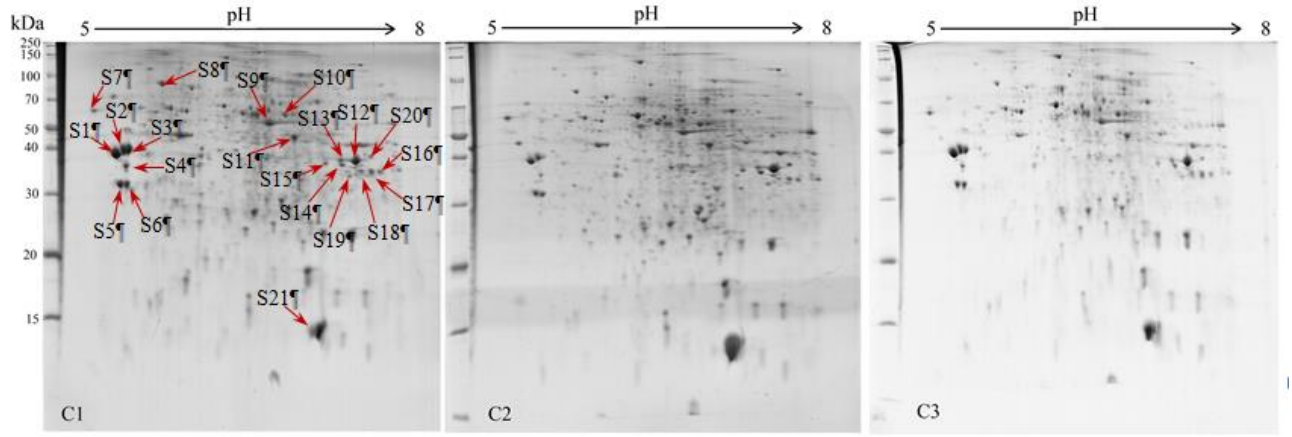

Figure 1 2D PAGE of pig's spleen.
Note: C1 – AgroEko, C2 – SGC, C3 – Tumen. Spots showing differential expression were marked excised.

2.4 mm × 160 mm tube gels. After IEF, the extruded tube gels were incubated for 10 min, in 2.5 mL of equilibration buffer I (6 M urea, 20% w/v glycerol, 2% w/v SDS and 1% w/v DTT in 50 mM Tris-HCl buffer, pH 8.8) followed by equilibration buffer II (6 M urea, 30% w/v glycerol, 2% w/v SDS and 4% w/v iodoacetamide in 375 mM Tris/HCl buffer, pH 8.8). For SDS-PAGE, the equilibrated tube gels were transferred to a 12.5% polyacrylamide gel (170 mm × 180 mm × 1.5 mm). Electrophoresis was carried out with a gel running buffer containing 25 mM Tris-HCl, 192 mM glycine, and 0.1% w/v SDS at 30 mA per gel until the bromophenol blue front had reached the bottom ofthe gel.

Protein visualization and image analysis

Protein spots were visualized by staining with Coomassie Brilliant Blue G-250. For computerized densitometry, two-dimensional electrophoregrams were used, which were in a wet state. Their full digital images and/or images of individual fragments were obtained using a Bio-5000 plus scanner (Serva, Germany). Scanned images were analyzed with ImageMaster™ 2D Platinum software powered by Melanie 8.0 (GE Healthcare and Genebio, Switzerland). Spots were detected and quantified automatically. The relative optical density (OD) and relative volume were computed to correct for differences in gel staining. These measures take into account variations due to protein loading and staining, by considering the total OD or volume over all the spots in the gel. The digitized 2DE images of cortex were then compared by the matching method.

Protein spots interpretation on spleen two-dimensional electrophoregrams was carried out in accordance with the **Swiss-Prot database (2002)**.

Statisic analysis

The experimental data between three organs were analyzed using student's t-test, and data among several groups were analyzed by one-way ANOVA by ImageMaster™ 2D Platinum software powered by Melanie 8.0 (GE Healthcare and Genebio, Switzerland). A p value <0.05 was considered significantly different. All results are presented as mean ±SD from at least three independent experiments.

RESULTS AND DISCUSSION

As a result of spleens 2-DE gels quantitative proteomic study images from pigs at three different farms (Figure 1) using ImageMaster ™ 2D Platinum software, it was found that, on average, there are about 597 spots on each gel. At the same time, the most pronounced protein expression was detected in samples C2 – 624 fractions, the least pronounced protein expression was observed in samples C3 – 570 fractions. Two-dimensional electrophoregrams comparative analysis in all samples revealed 362 major (constitutively present) fractions.

Among identified constitutive fractions (Figure 2), there were noted high expression protein spots S1, S9, S12, and S21, presumably Annexin A1 (MW 38.76 kDa), Ectonucleoside triphosphate diphosphohydrolase 1 (NTPDase 1, MW 57.75 kDa), Pro-cathepsin H CD59 (MW 37.45 kDa) and glycoprotein (MW 13.79 kDa), respectively. The biology of protein Annexin A1 functions, as revealed by studies **D'acquisto, Perretti and Flower (2008)** using transgenic animals, peptide mimetics and neutralizing antibodies, speaks to its role as a key modulator of both innate and adaptive immune systems. **Lemmens et al. (2000)** found that NTPDase 1 possesses both immunological identity and functional characteristics of vascular ATPDase. It is also known that Prokatepsin H regulates the signaling pathway of immune response **(Gladue et al., 2014)**, and Glycoprotein is a strong inhibitor of membrane attack complex and nonspecific immune response **(Maher et al., 1998)**.

In accordance with the information databases resources, the following functional compounds were found in spleen samples: the leptin receptor (Mm 132.52 kDa), which acts as factor regulating appetite, causing decrease in food intake and an increase in energy consumption, also regulates bone mass and secretion of hypothalamic-adrenal pituitary hormones **(Ruiz-Cortés et al., 2000)**; in small quantities, the transmembrane glycoprotein 3-hydroxy-3-methylglutaryl-coenzyme A reductase (Mm 97.15 kDa), which limits the rate of cholesterol biosynthesis and participates in the biosynthesis of isoprenoids necessary for the normal functioning of cells **(Chen et al., 2012)**.

Fractions, involved to innate immune response mechanisms, were identified, such as glycoprotein CD59 (Mm 13.79 kDa) and ATP-dependent RNA helicase (Mm 107.58 kDa) **(Zhang et al., 2000)**; the intensely expressed LIM-domain of the actin-binding protein (Mm 83.99 kDa),

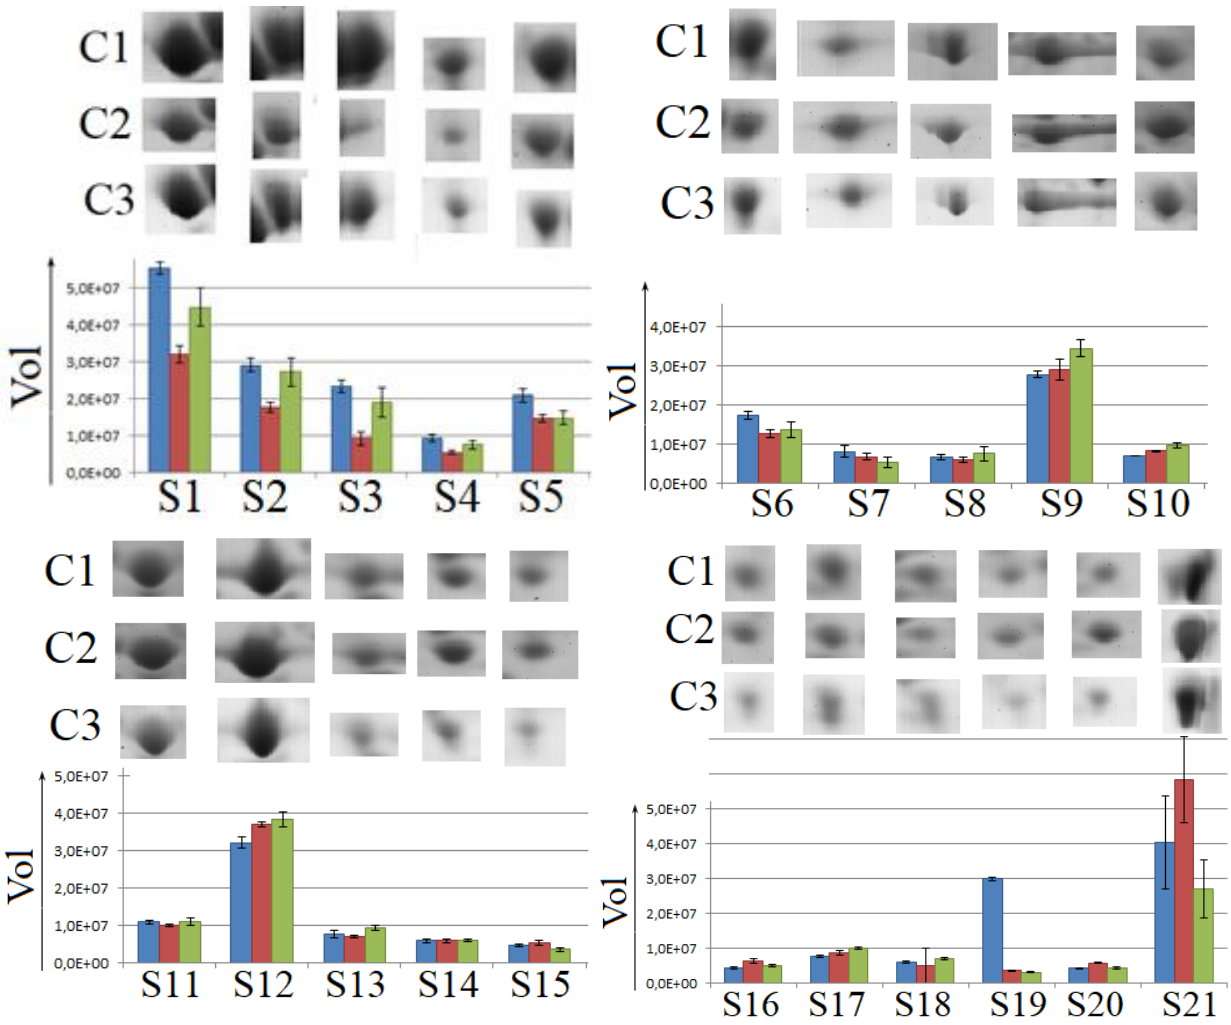

Figure 2 Relative vol change in differentially expressed proteins in spleens (blue – C1, red – C2, green – C3).
Note: Spot intensities were normalized by total valid spot intensities and mean of values from duplicate analytical gels from three replicates. Data represented are means ±SD of three independent experiments.

which is involved in the regulation of the cytoskeleton of actin, which increases the number and size of actin stress fibers, as well as inhibits the depolymerization of actin filaments **(Wang et al., 2007)**.

Also on two-dimensional electrophoregrams, a proteins group was identified that is characteristic of all analyzed spleens and plays an important role in innate immune response and inflammatory processes regulation: interferon stimulator protein (Mm 41.8 kDa), chemokine-like receptor 1 (Mm 41.38 kDa), platelet activating receptor (Mm 39.43 kDa); TYRO tyrosine kinase binding protein (Mm 11.61 kDa), activating macrophages and neutrophils, directly involved in immune response **(Xie et al., 2010; Huang et al., 2010;. Yang, Diehl and Roudebush, 2003; Yang et al., 2003; Yim et al., 2000).**

CONCLUSION

Studies of pigs spleens two-dimensional maps made it possible to establish proteins wide range presence — up to 600 fractions, of which 362 fractions are structural.

Detected fractions on the obtained maps are predominantly physiologically active, wherein their activity consists mainly in participation in various immunoregulatory reactions. Thus, in spleen samples there are found both compounds with immunoregulatory function (glycoprotein CD59, ATP-dependent RNA-helicase, LIM-domain of actin-binding protein), and factors involved in metabolism regulation (leptin receptor, transmembrane glycoprotein 3-hydroxy- 3-methylglutaryl-coenzyme A-reductase). It can be explaned by spleen biological role in organism and, as a result, a special structure – the division into red and white pulp and marginal zone, which produce compounds of various specificities.

This work is the first step to development of immunomodulating biologic based on animal raw materials for farm animals.

FOOD ALLERGY AND FOOD INTOLERANCE KNOWLEDGE OF FOODSERVICE WORKERS IN HUNGARIAN SCHOOLS

Anna Dunay, Anikó Kovács, Csaba Bálint Illés, András Tóth, András Bittsánszky

ABSTRACT

To provide food for children with food allergy or food intolerances represents an increasingly important role in school catering services. The number of children with food intolerances is growing continuously; therefore, it is necessary to improve the knowledge of foodservice workers, who are responsible for food provision in school catering units in relation with food intolerances, food allergies. The main goal of our research is to assess and analyze the knowledge of food service workers and food handlers on food intolerances and to determine those factors, which may influence their knowledge. Our research was conducted by using paper and pencil questionnaires. The mean of test results was 89.16% while deviation was 12.26%. There were no correlations between the test results and respondents' education level, age group and the number of years working in food catering sector, and only partial correlation was detected with the job of the respondents. Based on the answers the food handling techniques of diet foods represented the poorest results. Our findings proved that the knowledge and food handling practice of food handlers regarding food intolerances and the preparation of diet meals should be improved.

Keywords: food hypersensitivity; food allergy; food intolerances; food handler; school catering; knowledge test

INTRODUCTION

Food allergies and food intolerances are among the most frequent reasons of bad or unfavorable reactions on certain food or meals. Food intolerances are those side effects, which are resulted by any ingredients, components or additives of meals or food products, and are not derived from immune system problems, but it is a caused by any other problems when the human body is not able to digest, to absorb or to metabolize certain food or food components. The most frequent food intolerances are lactose and fructose intolerances **(Mahan and Swift, 2017)**.

Food intolerances generally produce undesirable symptoms in the digestive system, such as abdominal distension, pains, diarrhea and vomiting. The symptoms and impacts of food allergies can be more dangerous **(Caballero, 2013)**.

Food allergies are the abnormal reactions of the immune system on specific components of food (mostly proteins) which are recognized by the allergen-specific immune cells, generating specific immune responses which will result specific symptoms **(L'Hocine, Achouri and Pitre, 2018)**. The reactions on a given allergenic substance may be different in different individuals, from the less intensive to the dangerous forms, which may be even life threatening reaction. Some allergenic substances will cause abdominal discomfort, skin rashes, vomiting or diarrhea, but others may cause difficulties in breathing, drowning or anaphylaxis as well **(Bird, Jones and Burks, 2019)**.

In Europe, based on the information from parents, one from 20 children has any type of health problems because of food allergies **(Nwaru et al., 2014)**. In Hungary, in 72% of the schools there is at least one pupil or student who claimed for dietary menus. The most frequent food allergies and intolerances are caused by milk, eggs and gluten. As a consequence, in 2017, the most frequently required dietary meals were lactose-free, milk protein-free, gluten-free and egg-free dietary menus **(Bakacs et al., 2017)**.

The manifested cases of food allergies and food intolerances show an increasing tendency, so it is among the most important health and food safety questions of our time, which will bring more and more challenges for the food industry and catering industry. The only treatment for allergies and intolerances is the absence of the harmful substances, so these substances should be deleted from the everyday life, everyday food of the hypersensitive persons **(NIAID-Sponsored Expert Panel, 2010)**.

The answer for the question of how to avoid these problems, how to avoid these harmful ingredients in order to keep health, will depend not only on the knowledge of

the patients and their families, but also on the knowledge of their environment, such as school, workplace, food industry, governmental bodies and the authorities.

In public catering, special food and meals shall be provided for those children, who confirm their disease with the certification of specialists. The meals for them may be prepared on the spot, or food may be provided by special delivery service, and the prepared meals shall contain all those nutrients and food types which are given for the relevant age group of healthy children as it is given in an official decree **(No. 37/2014 decree of Hungarian Ministry of Human Capabilities)**.

To avoid the contamination with allergenic components and to keep food safety requirements a high level of knowledge is required **(Sicherer and Sampson, 2018)**. In order to meet these strict requirements, and to prepare the appropriate food and meals for hypersensitive consumers, catering services shall comply with three main requirements.

Firstly, the caterer shall know which are those food types or ingredients which shall be avoided by the hypersensitive person in the given diet, and caterers shall provide the relevant information for these customers.

Secondly, the caterers shall provide information for the consumers about the dietary food or meals **(Hattersley and King, 2014)** as well as the nutritional point of view in order to allow consumers to make healthy food choices **(Šedík et al., 2018)**. Each catering services (school kitchens, fast food or street food caterers, restaurants) shall give the appropriate information for the consumer about the food itself, the meals displayed at the menu card, the ingredients, the appearance of different allergenic components, the food preparing technology and storage matters, as not only the absence of allergenic components is necessary, but also the storage and the avoidance of cross contamination **(Abbot, Byrd-Bredbenner and Grasso, 2007)**.

This procedure is highlighted by the **decree of the European Parliament and Commission (1169/2011/EU)** which outlines the compulsory information, which shall be given by the caterers at each stages of the food supply chain. The minimum requirement is to indicate the 14 main allergenic materials, namely cereals containing gluten, crustaceans, eggs, fish, peanuts, soybeans, milk, nuts, celery, mustard, sesame seed, sulphur dioxide and sulphites, lupin and molluscs. Ingredients containing these allergens shall be indicated on menu cards and food labels.

Thirdly – and this requirement has a critically high importance – caterers shall provide appropriate training and education for the kitchen staff, to inform them about the importance of allergies and food intolerances. Information shall also be given about the special steps of food handling in the preparation of dietary food and meals. The knowledge of the food handlers is one of the most important influencing factors in the course of health protection of hypersensitive consumers (i.e. patients with food allergies or food intolerances).

The main objective of our research is to evaluate the knowledge of the kitchen workers in relation with food allergies or food intolerances.

Scientific hypothesis

Based on the previous research results and own experiences two scientific hypotheses were formulated.

Hypothesis H1: We assume that the knowledge level of the food handlers in school catering services in relation with food intolerances is rather low, as these workers do not have such education or training.

Hypothesis H2: We assume that the job type, the age, the time spent in catering sector (work experiences) and the education level are correlated with the knowledge about food intolerances.

MATERIAL AND METHODOLOGY

Structure of the questionnaire

The goal of the survey was to evaluate the general knowledge of food handlers on food allergies and food intolerances, by conducting a questionnaire survey. The questionnaire was prepared by the help of food experts, and the suggestions of literature sources dealing with this topic were also taken into consideration. **(Ajala et al., 2010; Dzwolak, 2017; Lee and Sozen, 2018)**. The first version of the questionnaire was filled in after preliminary discussions by 24 kitchen workers, and based on the experiences and suggestions, some modifications were conducted. The final version of the questionnaire contained 12 questions, from which the 4^{th} question included 9 sub-questions. Three questions were related to the knowledge of food and meals which may cause food intolerances, 5 questions were related to the main characteristics of food intolerances and 4 questions were related to the appropriate preparation and handling techniques of dietary meals.

Besides the questions related to the knowledge of food handlers, additional demographic questions were also given to help in the deeper analysis of the results, namely age, job/profile, work experiences in the catering sector, educational level and skills. Each proper answer represented one point and in case of question 4, partial points were also given. The maximum result was 12 points. The results are shown in the percentage of the maximum points.

Study samples

The survey was conducted in June of 2018. The questionnaires were filled in during special training days organized for the food handlers, it means that workers should not work in their shifts at that day. All food workers were employees of different school catering units (kindergartens, primary and secondary schools), some of them worked at cooking kitchens and the other part worked in institutions with serving kitchens. 215 workers filled in the questionnaire, 180 of them worked as kitchen maid, 24 as cook and 11 workers as storage manager.

The kitchen workers of the sample previously took part regularly at compulsory trainings in food hygiene topics, but they did not have specific knowledge about food allergies and food intolerances before filling in the questionnaire. They could rely on only their general knowledge and experiences while responding the questions.

Statistical analysis

Data processing and statistical analyses were performed by using the IBM SPSS Statistics 22.0 for Windows. On one hand, in order to compare means between two groups, we used the independent two-sample t tests. On the other hand, when comparing more than two groups, we used one-way variance analysis (one-way ANOVA). The equality of group variances was tested by Levene-test. Significant differences were detected by using the Duncan's multiple range test in the case of equal variances; while in case of different variances, we used the Tamhane-test.

RESULTS AND DISCUSSION

Sample

The average age of the respondents at the time of the survey was 49 years, the youngest food worker was 22 years old, and the oldest was 75 years old. 35% of the respondents were in the age group of older than 55 years, 48% of the respondents were between 40 – 54 years old and 15% was younger than 39 years old. Five respondents did not indicate their age group, so their answers were not taken into consideration in calculations related to age. The majority (92%) of the respondents was female. The general distribution of educational level showed a relatively balanced image: 28% of respondents indicated that their highest educational level is elementary school, 36% of them finished basic professional level of education (semi-skilled) and 34% of them had secondary or higher education level. Three respondents did not answer for the question related to the educational level. 118 kitchen maids worked at serving kitchens, the others worked at cooking kitchens, from this 62 worked as kitchen maids. Nearly half of the respondents (102 food handlers) indicated that they have more than 10 years of experience in the catering sector (Table 1).

Test results

The average result of the tests was 89.16%, standard deviation was 12.26%. The worst result was 22.92%, the best result was 100%.

According to the job (position), there were significant differences between kitchen maids and cooks. Although the average result the storage managers was better than the results of kitchen maids, significant differences were not detected (Table 1). According to the statistical analyses, there were no correlations between the educational levels, age of respondents, work experience, and there were no differences in the knowledge level of kitchen staff working in cooking and serving kitchens (Table 1).

Results on questionnaire questions

The distribution of the answers of the 215 respondents is shown in Table 2. The questions were separated into three groups:

- food knowledge related to meals which may have impact on hypersensitive individuals (i.e. allergenic food) were represented by questions No. 1., 2. and 4.,
- knowledge on the symptoms of food allergies and intolerances (i.e. allergenic reactions) were represented by questions No. 3., 5., 6., 7. and 8.,
- knowledge of the special handling techniques of the dietary foods and meals (diet food handling) were represented by questions No. 9., 10., 11 and 12.

Food knowledge

The knowledge of the respondents about those food components and meals, which may cause problems for hypersensitive individuals was answered successfully with 91% ±13% result, there were no differences according to the age and job of the food handlers.

Nevertheless, the result of workers with professional education showed significantly better results, compared to workers with elementary education. Other correlations were detected according to the working experience and the knowledge of food that may cause harmful reactions for hypersensitive consumers. Those workers, who had less than one year of working experience, reached worse results than those who had more than 5 years of working experience. The workers of cooking kitchens also reached better results in total, but in case of kitchen maids, their group did not show such differences according to their kitchen type (i.e. cooking or serving kitchens).

Table 1 Descriptive data of food handlers' knowledge scores.

		N	% ±StDev
Total		215	89.16 ±12.27
Position	Kitchen maid	180	87.87 ±12.74[a]
	Storage manager	11	94.88 ±7.02[a,b]
	Cook	24	97.73 ±4.11[b]
Educational level	Elementary	60	87.33 ±15.69[a]
	Semi-skilled	78	90.09 ±8.9[a]
	Skilled	74	89.84 ±11.98[a]
Age	Age range: 55 and above	74	88.82 ±12.47[a]
	Age range: 40 – 54	101	89.6 ±12.86[a]
	Age range: below 39	35	87.38 ±10.5[a]
Work experience	less than 1 year	35	86.61 ±13.59[a]
	1 – 4.99 years	43	87.84 ±13.25[a]
	5 – 9.99 years	35	87.8 ±11.6[a]
	10+ years	102	91.05 ±11.44[a]
Cooking/serving kitchen*	Cooking	62	90.29 ±11.54[a]
	Serving	118	86.6 ±13.19[a]

Note: *Kitchen maids only. [a, b] Results indicated by different letters are statistically different (p <0.05 Student's t-test and ANOVA with Duncan's multiple range test).

Table 2 Food intolerance questionnaire and correct answers in %.

Question	Question type	Kitchen maid (n = 180)	Cook (n = 24)	Storage manager (n = 11)	Total (n = 215)
1. Which of the following items contains gluten? (Apple, Pork stew, **Spaghetti,** Potato with parsley)	Allergenic food	92	100	100	93
2. Which of the following items are risky for guests who have food allergies? (**Pasta with walnut**, Fresh salad, Cooked rice, Fried leg of chicken)	Allergenic food	97	100	100	98
3. What is lactose intolerance? (Intolerance against cereals, **Intolerance against sugar of milk**, Intolerance against nuts, Intolerance against egg)	Allergic reactions	96	100	100	96
4. Check the food items that are considered as major food allergen [b,c]	Allergenic food				
a) **Milk**		91	88	100	91
b) Chocolate		63	42	27	59
c) **Egg**		79	83	91	80
d) **Peanut**		88	92	100	89
e) Strawberry		51	50	55	51
f) Carrot		97	100	100	97
g) Tomato		94	100	82	94
h) Orange		94	100	100	95
i) **Almond**		73	75	73	73
5. Individuals with food allergies can safely consume the foods that cause the allergies if only a small amount is consumed. (True, **False**)[a]	Allergic reactions	86	100	91	87
6. Can high temperature (deep-frying, cooking) destroy food allergens? (Yes, **No**)[a,c]	Allergic reactions	89	100	100	91
7. If someone has an allergic reaction, is it correct to offer water in order to ‘‘dilute” the allergen and stop the reaction. (True, **False**)[a]	Allergic reactions	97	100	100	98
8. If you remove allergenic food items (such as walnuts) from a finished dish, will it prevent the client from having an allergic reaction? (Yes, **No**)[a,c]	Allergic reactions	91	92	100	92
9. Gluten-free meal can be handled together with regular utensils. (True, **False**)	Diet food handling	80	88	100	82
10. The utensils used for handling gluten-free food can be stored with other utensils. (True, **False**)	Diet food handling	71	92	100	75
11. Gluten-free meal can be transported only in airtight container. (**True**, False)	Diet food handling	85	96	91	87
12. Gluten free meal must be handled separately. (**True**, False)	Diet food handling	87	88	100	88

Note: [a] These questions are from **Ajala et al. (2010)**; [b] Similar question has been published by **Ajala et al. (2010)**; [c] Similar question has been published by **Lee and Sozen (2018)**. Correct answers are indicated by **bold** letters.

Knowledge of food allergies and intolerances

The respondents of the survey reached the best results in these field, the average result and deviation was 92% ±15%. There were no differences according to job, age and working experience, moreover the type of kitchen also did not influence the results. The results of respondents with elementary educational level were worse than the responses of skilled and semi-skilled kitchen workers.

Handling of dietary food and meals

This part of the survey brought the worst results, the average result and deviation was 83% ±22%. The storage managers reached better results than the kitchen maids, but the cooks did not differ from the other groups. The results of kitchen maids working in cooking kitchens were better than of those who worked in serving kitchens. This part of the results was not influenced by the age, educational level and working experience.

Discussion

Nowadays, the importance of the existence of food intolerances is increasing in the school catering sector, and one of the most important players of this process is the group of food handlers, who works at the end of the food chain. Food handlers serve the consumers directly, i.e. food handlers will make the final decision about the food (meal): is it safe or not? In this situation, the responsibility of the food handlers is very high, and the knowledge of these workers will determine the final objective, i.e. to serve the appropriate meal for each customers. As the number of children with food allergies and intolerances showed a growing tendency in the past decades, so it is necessary to improve the knowledge level of food workers in this specific topic. The primary goal of our research was to explore and evaluate the knowledge of kitchen workers of the school catering sector in relation with this topic, and to determine those factors, which may influence the knowledge on food hypersensitivity issues.

Our survey was conducted by a paper-and-pencil questionnaire, which was elaborated based on the findings of different literature sources. Based on the feedbacks, we could detect some problems. For example, the 4th question of our questionnaire was not appropriate for measuring the knowledge properly. In this question, chocolate and strawberry was indicated by almost 50% of the respondents as major allergens. Of course, chocolate and strawberry allergy is existing, but they are not so frequent and dangerous, so the term “major allergen” is not clear in this aspect. This problem was also highlighted by previous researchers as well, such type of questions cannot be understood clearly, so the answers might be very diverse **(Ajala et al., 2010**; **Lee and Sozen, 2018)**.

The respondents of the survey have not passed previously any specific training in the topic of food hypersensitivity; they have finished only general training courses in food hygiene topics. Thus, according to our first hypothesis, they do not have high level of knowledge, or they have different knowledge levels related to topics in food allergy and food intolerances. In our research, the average score of 215 food handlers was 89.16% with a deviation of 12.27%, which was higher than the preliminary expectations. The scores on the different questions showed a wide range between 75 – 98%, excluding the results of question 4, which was not considered in the final evaluation. The findings of other literature sources showed lower scores for such questions: according to the findings of **Lee and Sozen (2018)**, the results of the food handlers were between 41.5 – 89.5%, and the results of **Ayala et al. (2010)** were between 69 – 84%.

Based on the abovementioned facts, we rejected our first hypotheses (H1), because the knowledge level of Hungarian food handlers, who did not have previous specific knowledge on food hypersensitivity, cannot be considered as low, even in international comparison.

According to our results, there were some correlations between the knowledge of the food handlers and their job (position). For the position of kitchen maid, no educational requirements are needed, therefore, it was assumed, that their knowledge will be lower than the knowledge of the skilled worker cooks and storage managers. This assumption was verified only in case of the comparison with cooks. The results of other previous researches on the knowledge of food hygiene issues **(Illés et al., 2018)** also showed that there is no correlation between the knowledge and working position of the food workers working in positions like kitchen maids, cooks and storage managers. There were no correlations at all between the test results and the educational level, working experiences and age, in addition, the type of the working place (i.e. cooking or serving kitchens) have not shown any correlations with the knowledge of food handlers. As cooks and storage managers work only in cooking kitchens, an additional analysis was conducted only for the evaluation of kitchen maids, who work in both kitchen types (Table 1).

Based on the abovementioned results, H2 hypotheses was rejected, because the age, the working experience in the catering sector and the educational level did not show correlations with the knowledge level, while the job profile (position) was just partly influenced by the knowledge on food hypersensitivity.

During the analysis of the different fields, it was an alarming observation that the worst results were achieved in the questions related to handling of dietary food. These questions were connected to the everyday working processes and practices of food handlers. Based on these results it is clearly concluded that there is need for specific education and trainings in this topic. Another important observation was related to the knowledge of allergens. Respondents, who have only elementary education level, reached lower scores in general knowledge on the reasons of food intolerances and allergies. To provide safe dietary food for the consumers at cooking or serving kitchens is the responsibility of the food catering service. Therefore, food caterers and food services shall ensure the traceability of allergenic components, which shall be built into their monitoring system based on the principles of HACCS and GHP, and this traceability process is to be monitored by the authorities **(Fontcuberta-Famadas et al., 2018)**. In the course of preparing dietary meals, the general principle is that preparation of dietary food should be separated in time and place. The cleanness of the devices and utensils should be ensured, because the surfaces of the equipment may be a primary source of cross-contaminations **(Ortiz et al., 2018)**. The production and supply of allergen-free food may have several hidden dangers, for which the food

producer or food provider shall take the responsibility. Besides other previous researches **(Ahuja and Sicherer, 2007)**, our survey results also highlighted that the sources of such dangers frequently arise from the non-appropriate knowledge of food handlers.

CONCLUSION

A contemporary challenge of food providers, particularly for school catering services is to prepare and serve food for children with food intolerances or food allergies. In managing this process, and in the prevention of diseases, harmful reactions and diet mistakes, the food handlers – as players who work at the end of the food chain – play an important and active role.

Our research findings highlighted that the general principles of preparing dietary food and meals are not clear enough for the food handlers. In order to manage the process properly, and to prepare and serve healthy food for hypersensitive consumers in a safe and appropriate way, the knowledge of the kitchen workers shall be improved not only in general, but also this special field.

INFLUENCE OF TEMPERATURE, HUMIDITY, AND DILUENT TYPE ON SURVIVAL OF *SALMONELLA* SPP. ON THE SURFACE OF RAW TOMATOES

Oleksandr Tokarskyy, Keith Schneider

ABSTRACT

Tomatoes are an important commodity, placing fourth among most popular vegetables in the U.S. However, fresh tomatoes lack a final pathogen elimination step and have been implicated in *Salmonella*-related outbreaks. The purpose of the study was to evaluate survival of *Salmonella* post-drying in three diluents on the surface of green mature tomatoes at 12 °C or 25 °C. Additionally, low and high air relative humidity influence was evaluated at 25 °C on pathogen survival. A five *Salmonella* rifampin-resistant strain cocktail was double-washed in buffered peptone water (BPW) and resuspended in 0.1% peptone, BPW, or fresh tomato serum. Inoculum (0.1 mL) was allowed to dry on the surface of tomatoes. For study I, tomatoes were placed in 12 °C and 25 °C incubators with no humidity control and sampled on days 0, 1, 3, and 5. For study II, tomatoes were sampled on days 0, 1 (biosafety hood storage) and on day 5 after storage in two 25 °C incubators (low and high relative humidity). *Salmonella* was recovered from tomatoes (20 mL BPW) and plated (TSA-rif80, 37 °C, 48 hours). Post-drying *Salmonella* counts (ca. 4.5 – 5.0 $\log_{10}$ CFU.mL^{-1}) remained at 4.03 and 4.40 $\log_{10}$ CFU.mL^{-1} in serum after 5 days of storage at 12 °C and 25 °C, respectively. Conversely, corresponding counts in BPW and peptone were lower at ca. 1.4 to 1.8 and 2.2 to 2.8 log units at 12 °C and 25 °C, respectively. At low humidity, post-drying *Salmonella* counts showed highest decline for peptone (final 1.98 $\log_{10}$ CFU.mL^{-1}) compared to BPW (3.79 $\log_{10}$ CFU.mL^{-1}) and tomato serum (4.75 $\log_{10}$ CFU.mL^{-1}) on day 5. Counts declined rapidly to 0.03, 0.56, and 0.44 $\log_{10}$ CFU.mL^{-1} for peptone, BPW, and tomato serum, respectively, at high humidity on day 5. To summarize, it was shown that increased solutes have protective effect on *Salmonella* in desiccated conditions, while high humidity storage causes accelerated death of stationary culture within five days storage period.

Keywords: tomatoes; *Salmonella*; humidity; refrigeration; survival

INTRODUCTION

Tomatoes are an important commodity, placing fourth among most popular vegetables in the U.S. According to **FAOSTAT (2017)**, top ten tomato producing countries in the world were China, India, Turkey, USA, Egypt, Iran, Italy, Spain, Mexico, and Brazil, with Slovakia present in the top twenty and producing as much as 21,964 tonnes in 2017 alone. Enteric pathogens, such as *Escherichia coli* O157:H7 and *Salmonella*, may be present on fresh produce as contamination from environment and may persist on the surfaces **(Sreedharan et al., 2015; Tokarskyy et al., 2018)**. *Salmonella*-associated tomato outbreaks were recorded in the United States on numerous occasions **(CDC, 2002; Croby et al., 2005)**. It is generally believed that pathogen will grow in the tomato flesh at ambient temperature if introduced through stem scars, wounds, and abrasions **(Wei, 1995; Zhuang, Beuchat and Angulo, 1995; Shi et al., 2007; Beuchat and Mann, 2008)**. As for the fate of the pathogen on the healthy tomato surface, most studies agree that *Salmonella* populations decline over time, depending on bacterial strain, humidity, and tomato storage temperature **(Yuk, Warren and Schneider, 2007; Tokarskyy et al., 2018)**. Conversely, a study by **Iturriaga, Tamplin and Escartín (2007)** showed the potential for *Salmonella* Montevideo to colonize and grow on the surface of healthy undamaged tomatoes, but those results could have been due to the presence of micro abrasions on the surface where pathogen could have been introduced, or possibility of the pathogen introduction onto the stem part during wash-off step **(Wei et al. 1995)**. Therefore, *Salmonella* will likely to die on the surface of healthy tomatoes, and its behaviour might mimic survival rate on non-biological inanimate objects.

A systematic review by **Kramer, Schwebke and Kampf (2006)** suggested that nosocomial bacterial pathogens, including *Salmonella* and *Escherichia coli*, persist on inanimate objects longer at higher inocula, higher solute concentration, higher humidity, and lower temperature. Early studies on bacterial desiccation/drying on glass have shown that solutes overall protect bacteria in desiccated

state. For example, **Hirai (1991)** showed, using Rodac plate technique, that *Salmonella* counts in sterile distilled water dried on glass surface decreased to non-detectable level after 7 hours; however, *Salmonella* was detectable for over 5 days if suspended in 2% bovine serum albumen before glass inoculation.

Conversely, humidity effects might be more complicated as **Møretrø et al. (2010)** showed that shigatoxin-producing *Escherichia coli* dried on plastic or steel had highest inactivation rate at 85% relative air humidity, while survived the best at 98%. It can be argued that microorganisms in dried inoculum survive better at low humidity (low metabolic activity) compared to high humidity, where stationary culture, still metabolically active, slowly dies off. However, at low inoculation levels and high organic matter and high humidity might stimulate growth.

It is generally believed that *Salmonella* survives desiccation very well and may persist in dry and low water activity foods. Several *Salmonella* foodborne outbreaks involving dry/low water activity foods, such as peanut butter, were recorded. **Li, Megalis and Tortorello (2010)** has shown that dried (a_W = 0.21) *Salmonella* Typhimurium LT2 culture had 5-log reduction in numbers at 97% relative air humidity, while only 2 log reduction was observed at 33% relative humidity, with similar trend observed for *Salmonella* Tennessee. However, only desiccation-injured pathogens (drying to a_W = 0.21) were impacted by high humidity, while cells dried to higher water activity (a_W = 0.55) survived high relative humidity better.

Stine et al (2005) came to an overall conclusion that lower relative humidity stimulates survival of bacterial pathogens and indicators, such as *Escherichia coli*, *Salmonella enterica*, and *Shigella sonnei* on the surface of lettuce, and bell pepper. However, controversial data exist for *Salmonella* survival on tomatoes, which might be attributed to the phenotypic strain variations. For example, **Rathinasabapathi (2004)** showed that *Salmonella* Montevideo spiked on the surface of pericarp discs cut from green mature tomato can survive with little reduction for at least 6 days at 100% relative humidity. However, **Wei at al. (1995)** have shown that *Salmonella* Montevideo introduced on the surface of unbroken skin at 4 $\log_{10}$ CFU per site survived for at least 48 hours but could not be consistently detected after 5 days. **Lang, Harris and Beuchat (2004)** showed that *Salmonella* counts in 5% horse serum on the spot-inoculated tomatoes decreased 0.8 log after 1 hour drying and 2.2 $\log_{10}$ 24 hours post-drying from initial 7.22 $\log_{10}$ CFU per tomato. However, **Guo et al. (2002)** found that a cocktail of five *Salmonella* strains diluted in sterile tap water and inoculated on the surface of green tomato at 7.72 $\log_{10}$ CFU per tomato experienced only 1 $\log_{10}$ CFU per tomato reduction on day 1 and 3 log reduction on day 7 at 20 °C and 70% relative air humidity. Similarly, **Allen et al. (2005)** showed persistence of *Salmonella* in phosphate buffered saline dried on the surface of tomatoes for at least 14 days at 30 °C/80% RH, 20 °C/60% RH, and 20 °C/90% RH.

Other studies have used deionized water, tryptic soy broth, 5% sterile horse blood, tomato serum, soil, 0.1% peptone water, buffered peptone water, phosphate buffered saline, among others, to dilute *Salmonella* culture before placing on the surface of tomatoes. As noted by **Wei et al. (1995)**, TSB as a diluent supported better bacterial survival on tomato surface and provided protection against chlorine treatment. According to the researchers, *Salmonella* Montevideo grew in TSB, but died rapidly in Butterfield's buffer or tomato serum, while death rate in deionized water was slower. **Guo et al. (2002)** showed that *Salmonella* on tomato in contact with soil was capable to grow up to day 4 and persisted thereafter up to day 10.

Many of the *Salmonella* spot-inoculation studies were done with high level of inoculum (~10^7 CFU per tomato). Low level of inoculation resulted in quick bacterial die-off. It can be argued that such high inoculum might mimic high solute diluent, where solutes from bacteria themselves might protect them in bulk. For example, **Wei et al. (1995)** showed that *Salmonella* Montevideo die-off at <5.12 $\log_{10}$ CFU.mL^{-1} was significantly faster in Butterfield's buffer, tomato serum, and deionized water, compared to 8.15 $\log_{10}$ CFU.mL^{-1} culture. When bacteria were inoculated at 2.85 – 3.86 $\log_{10}$ CFU per tomato in deionized water, the bacterial die off occurred overnight, while survival for 3 days was observed at 9.48 $\log_{10}$ CFU per tomato level. According to **Kusumaningrum et al. (2003)**, *Salmonella* Enteritidis was recovered from inoculated steel squares after drying for at least 4 days at high contamination level (10^5 CFU.cm^{-2}), while at moderate level (10^3 CFU.cm^{-2}) and low level (10 CFU.cm^{-2}) inoculation counts went below detection limit within 24 hours and 1 hour, respectively. In addition, milk residue and chicken fillet suspension improved survivability compared to 0.1% peptone +0.89% saline solution **(Kusumaningrum et al., 2003)**.

Scientific hypothesis

It is hypothesized that high organic solute concentration in inoculation diluent (buffered peptone water and natural tomato serum), as well as low humidity and low temperature, may improve survival of *Salmonella* on the surface of undamaged tomatoes. It is expected that stationary phase *Salmonella* culture on spot inoculated tomatoes stored in high humidity will experience rapid die-off as compared to tomatoes held at low humidity.

MATERIALS AND METHODOLOGY

Rifampin preparation and microbiological media supplementation

Rifampin stock solution (10,000 ppm) was prepared by dissolving 0.4 g of rifampin (Fisher Scientific, BP26795, Pittsburgh, PA) in 40 mL HPLC grade methanol (Fisher Scientific), filter-sterilized (0.2 µm nylon filter), and stored in the dark at 2 °C for no longer than 1 month. Tryptic Soy Broth (TSB) with rifampin at 100 ppm was prepared by aseptic addition of 0.1 mL of rifampin stock solution to 9.9 mL of sterile TSB (Becton, Dickinson and Company, Franklin Lakes, NJ, USA).

Tryptic Soy Agar (TSA) with rifampin 80 ppm was prepared by aseptically addition of 8 mL of rifampin stock solution to 1 L of sterilized and cooled to 45 °C TSA (Becton, Dickinson and Company, Franklin Lakes, NJ, USA). TSA-rif80 was used either for pour plate method (1 mL of analyte with 15 – 18 of liquid TSA-rif80) or spiral plating on pre-poured TSA-rif80 plates (WASP2

spiral plater, Don Whitley Scientific Limited, West Yorkshire England).

Tomatoes and tomato serum preparation

Green mature unwashed and unwaxed round tomatoes (variety Florida 47) for inoculation studies were acquired from local packinghouses. Eight tomatoes were ripened, washed, trimmed, chopped, and 945 grams were homogenized into slurry (1-minute, Waring blender, Waring Products Inc., Torrington, CT, USA). Approximately 100 mL of slurry was centrifuged (10 minutes, 5,000 rpm, SG-3 rotor, Sorvall RC-5B, DuPont Instruments, Corp, Parkersburg, WV, USA) and the supernatant was filter sterilized (0.2 µm nylon filter), stored at 2 °C, and used as a "tomato serum" diluent for *Salmonella* within 24 hours of preparation. Absence of rif resistant microflora in the serum was confirmed on day 0 and day 5 (25 °C) using pour plating using TSA-rif80.

Bacterial strains and inoculation

Salmonella rif-resistant strains (derivatives of Typhimurium ATCC 13311, Braenderup ATCC BAA-664, Enteritidis ATCC 4931, Newport ATCC 6962, and Javiana ATCC BAA-1593, American Type Culture Collection, Manassas, VA, USA), grown in three consecutive TBS-rif100ppm (37 °C, for 12 hours, 1st broth; 12 hours , 2nd broth; and 18 hours, final transfer), were combined 2 mL each, double-washed in BPW (4,000 g, 10 minutes), and finally resuspended in 10 mL of 0.1% Bacto™ peptone **(**Becton, Dickinson and Company, Franklin Lakes, NJ, USA), buffered peptone water (BPW, Becton, Dickinson and Company, Franklin Lakes, NJ, USA), or tomato serum. Total solids and pH of the uninoculated diluents were measured (Brix, refractometer; pH meter). The resulting cocktails were diluted 1:10 in corresponding diluent and 0.1 mL of inoculum was spotted as ten 10 µL drops around blossom end of each green tomato. Inoculated spots were allowed to completely dry on tomatoes for 90 minutes in a biosafety hood.

Tomato storage

For study I, inoculated green tomatoes were placed in 12 °C and 25 °C incubators for 5 days after initial inoculum pre-drying in biosafety hood for 90 minutes, with no humidity control or monitoring.

For study II, green tomatoes were placed in two 25 °C incubators after initial inoculum pre-drying in biosafety hood for 24 hours. First incubator was maintained with low air relative humidity (LH) (~20 – 30% RH), and the atmosphere of the second one was humidified with a shallow pan filled with deionized water and soaked paper towels (HH) (~70 – 90% RH). Humidity and temperature were recorded at 10-minutes intervals (Hobo U12 dataloggers, Onset Computer Corporation, Bourne, MA, USA; software Hoboware Lite v. 3.1.0) throughout the study.

Salmonella enumeration

For study I three inoculated tomatoes and one negative control tomato were randomly pulled on day 0 (90 minutes dry) and afterwards from each incubator (12 and 25 °C) on days 1, 3, and 5.

For study II same set of tomatoes was analysed immediately after inoculation, after 90 minutes pre-drying in biosafety hood, on day 1 (24 hours dry in biosafety hood), and day 5 (25 °C, LH incubator and HH incubator). Each tomato was transferred to 20 mL BPW in sterile stomacher bag and pathogen was recovered by 20 seconds shake, followed by 20 seconds rub, and 20 seconds shake. The rinsate was either plated directly or serially diluted (BPW) and spiral plated (WASP2 spiral plater) or pour plated (TSA-rif80ppm, 37 °C, 24 to 48 hours).

Data and statistical analysis

Each experiment (Study I and Study II) was repeated three times on three different days. Statistical analysis was performed using commercially available software Statistica ver. 10.0 (StatSoft, Inc., Tulsa, OK, USA).

Study I. A multi-factorial design was utilized to determine the influence of diluent type (BPW, 0.1% peptone, and tomato serum), storage temperature (12 and 25 °C), and storage day (day 0, 1, 3, and 5), as well as their interactions, on *Salmonella* counts on tomato surface. Fisher's Least Significant Difference (LSD) test was utilized to separate treatment means when differences (p <0.05) occurred among factors.

Study II. A two-factorial design was used to test the effects of treatment-storage factor (immediately, 90 minutes dry, 24 hours dry, day 5 LH, day 5 HH) and diluent type (BPW, 0.1% peptone, and tomato serum), as well as their interaction, on *Salmonella* counts on tomato surface. Fisher's Least Significant Difference (LSD) test was utilized to separate treatment means when differences (p <0.05) occurred among factors.

Total solids of the uninoculated diluents (BPW, 0.1% peptone, and tomato serum) were evaluated three times, once for each replication, indirectly using handheld refractometer and expressed as average value of degree Brix with standard deviation among three measurements.

Similarly, pH value of the uninoculated diluents (BPW, 0.1% peptone, and tomato serum) were evaluated three times, once for each replication, and expressed as average pH value with standard deviation among three measurements.

Temperature and humidity measurements for each incubator for each replication (Study II) were averaged for all 10-minutes intervals and expressed as average value ±standard deviation.

RESULTS AND DISCUSSION

The measured solids in the diluents, indirectly expressed as ^{o}Brix, were 0.20 ±0.00, 2.50 ±0.00, and 4.93 ±0.15, for 0.1% peptone, buffered peptone water, and tomato serum, respectively. The corresponding pH values were 6.99 ±0.23 (0.1% peptone), 7.16 ±0.04 (BPW), and 4.29 ±0.10 (tomato serum).

Peptone diluent used at concentration 1 g.L^{-1} contained enzymatic digest of protein with no salt. Conversely, BPW used at recommended 20 g.L^{-1} concentration contained enzymatic digest of protein (peptone) 10 g.L^{-1}, sodium chloride 5 g.L^{-1}, disodium phosphate 3.5 g.L^{-1}, monopotassium phosphate 1.5 g.L^{-1} with claimed pH value as 7.2 ±0.2 by manufacturer. The composition of tomato serum remained unknown.

Table 1 Temperature and humidity variations in LH and HH incubators at 25 °C during 5 days tomato storage.

	LH incubator		HH incubator	
	Temp (ºC ±*SD*)	Humidity (% ±*SD*)	Temperature (ºC ±*SD*)	Humidity (% ±*SD*)
Replication 1	25.1 ±0.2	19.3 ±3.7	24.6 ±0.7	71.8 ±2.2
Replication 2	24.8 ±0.3	30.0 ±12.3	25.9 ±0.4	88.1 ±5.9
Replication 3	24.9 ±0.0	19.5 ±3.0	24.7 ±0.3	92.9 ±3.0

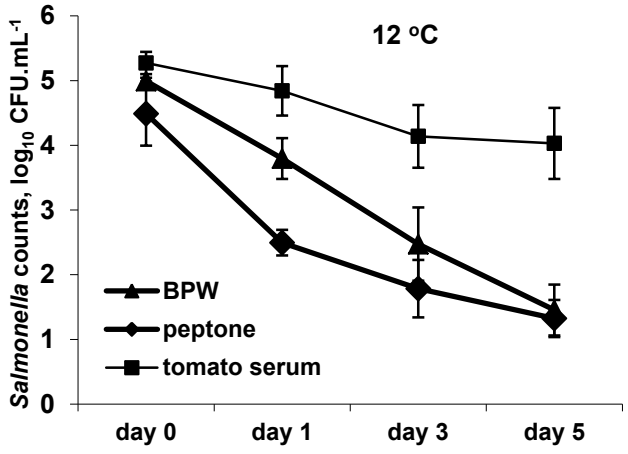

Figure 1 Survival of *Salmonella* on the surface of raw green tomatoes in BPW, 0.1% peptone and tomato serum for 5 days at 12 °C. Counts expressed as $\log_{10}$ CFU.mL^{-1} in 20 mL BPW rinsate. Error bars reflect standard deviation.

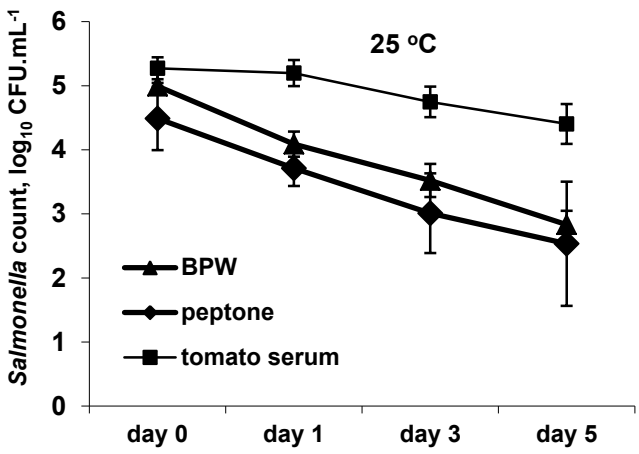

Figure 2 Survival of *Salmonella* on the surface of raw green tomatoes in BPW, 0.1 % peptone and tomato serum for 5 days at 25 °C. Counts expressed as log10 CFU.mL-1 in 20 mL BPW rinsate. Error bars reflect standard deviation.

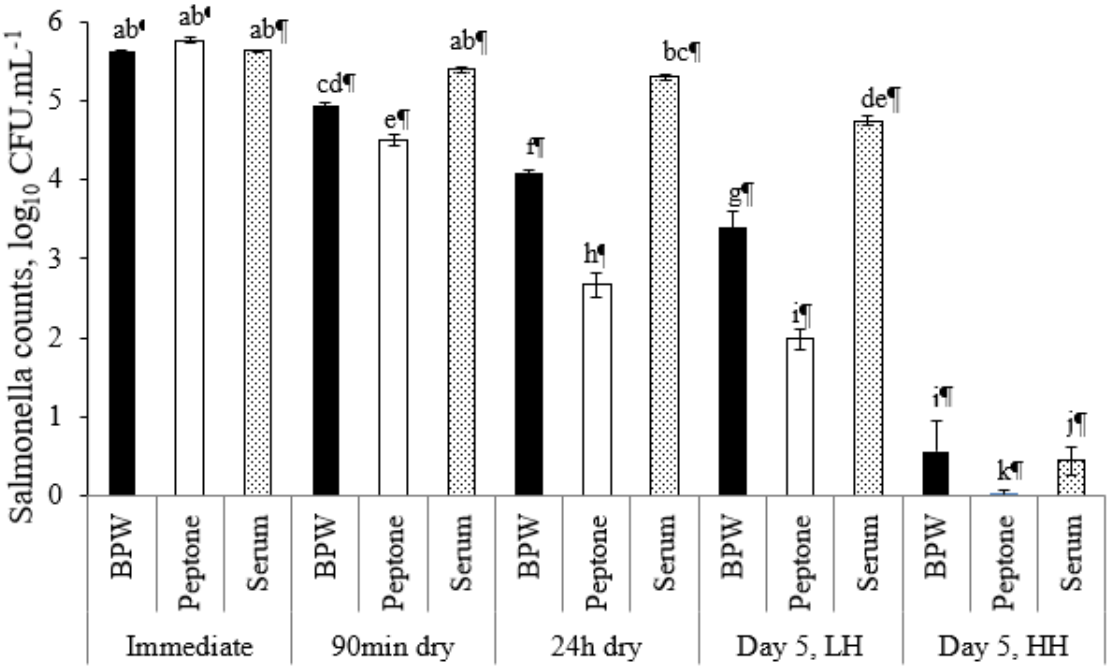

Figure 3 Survival of *Salmonella* on the surface of raw green tomatoes immediately after inoculation, 90 minutes postdrying and 24 hours postdrying in biosafety hood, and after 5 days in low humidity incubator and high humidity incubator at 25 ºC. *Salmonella* counts are expressed as mean values of $\log_{10}$ CFU.mL^{-1} in 20 mL BPW rinsate of three replications. Error bars reflect standard error of mean. Means with the same letters are not significantly different (p >0.05)

Study I. All three factors (diluent type, storage temperature, and storage day) had significant influence on *Salmonella* recovery in rinsate diluent (p <0.05).

Estimated inoculation level was ca. 5.6 $\log_{10}$ CFU.mL^{-1} per tomato as expressed by counts in BPW rinsate. *Salmonella* counts upon storage at two different temperatures is shown in Figures 1 and 2. Upon 90 minutes drying, *Salmonella* counts declined significantly the most in low-solute 0.1% peptone (4.49 $\log_{10}$ CFU.mL^{-1}, p <0.05), comparing to BPW (4.99 $\log_{10}$ CFU.mL^{-1}) and tomato serum (5.27 $\log_{10}$ CFU.mL^{-1}), which were not significantly different between each other (p >0.05). *Salmonella* counts remained at 4.03 $\log_{10}$ and 4.40 $\log_{10}$ CFU.mL^{-1} in tomato serum after 5 days of storage at 12 °C and 25 °C, respectively, with no significant difference between two values (p <0.05). *Salmonella* counts in BPW were significantly lower (p >0.05) comparing to tomato serum on day 5 at both storage temperatures, 1.45 $\log_{10}$ and 2.83 $\log_{10}$ for 12 °C and 25 °C, respectively. Moreover, there was a significant difference between two storage temperatures for BPW diluent on day 5 (p >0.05). Similarly, *Salmonella* counts in peptone were significantly lower (p >0.05) comparing to tomato serum, but not to BPW, on day 5 at both storage temperatures, 1.32 $\log_{10}$ and 2.53 $\log_{10}$ for 12 °C and 25 °C, respectively. The difference for *Salmonella* counts between 12 °C and 25 °C for peptone diluent on day 5 was significant as well (p >0.05).

Similarly, **Wei et al. (1995)** showed that *Salmonella* Montevideo dried on tomato surface in water at ca. 5.8 $\log_{10}$ CFU per area died after four days, while pathogen dried in TSB persisted and increased in numbers at 25 °C and 72% RH. Conversely, *Salmonella* died in tomato juice upon storage, which might be attributed to autoclaving **(Wei et al., 1995)**, as tomato pulp is suitable for *Salmonella* growth. **Guo et al. (2002)** showed *Salmonella* growth on tomato surface in contact with soil up to four days and persistence until day 10 thereafter, while *Salmonella* in water diluent declined by 3 $\log_{10}$ units on day 7. Similarly, **Hirai (1991)** showed that solutes overall protect *Salmonella* in desiccated state on inert glass surface. As expected, death in the presence of high solutes was slower. However, the lack of preservation effect of low temperature on *Salmonella* can be explained by rapid humidification of air in the incubator during sampling and inoculated spots temporary liquefaction, causing stress to bacteria.

Study II visual observations of inoculated tomatoes stored at high humidity suggested hygroscopic nature of diluent solids, as BPW and tomato serum inoculated spots, but not peptone water spots, liquefied. Average temperature and humidity values, both in LH and HH incubator, are shown in Table 1. *Salmonella* counts obtained during Study II experiments are shown in Figure 3. Both factors, namely, treatment-storage and diluent type, as well as their interaction, had significant influence on *Salmonella* counts (Figure 3, p >0.05). *Salmonella* counts post-drying in biosafety hood (24 hours) declined to 5.3 $\log_{10}$ CFU.mL^{-1} in tomato serum, comparing to 4.08 and 2.67 $\log_{10}$ in BPW and peptone, respectively. At this time frame, only *Salmonella* counts in tomato serum were not significantly different comparing to initial counts upon inoculation and 90 minutes post drying (Figure 3, p <0.05). At 5 days low humidity storage at 25 °C, *Salmonella* counts in tomatoes remained as high as 4.75 $\log_{10}$ comparing to decline in BPW (final 3.40 $\log_{10}$ CFU.mL^{-1}) and peptone (1.98 $\log_{10}$ CFU.mL^{-1}). Interestingly, 5 days high humidity storage at 25 °C accelerated *Salmonella* populations decline to close to below detection limit at 0.44, 0.56, and 0.03 $\log_{10}$ CFU.mL^{-1} for tomato serum, BPW, and peptone diluent, respectively. Those data further solidified the concept of solute protective effect in desiccated state. **Li, Megalis and Tortorello (2010)** has shown that day one dried (a_W = 0.21) *Salmonella* Typhimurium LT2 culture had 5-log reduction in numbers at 97% RH, while only 2-log reduction was observed at 33% RH. It has been shown that microorganisms in dried inoculum survive better at low humidity compared to high humidity. However, at a low inoculation level along with high organic matter, high humidity may stimulate growth **(Wei et al., 1995; Guo et al., 2002)**. As noted by **Wei at al. (1995)**, TSB as a diluent not only supported better bacterial survival on tomato surface, but also caused protection against chlorine treatment. According to the researchers, *Salmonella* Montevideo grew in TSB, but died rapidly in Butterfield's buffer or tomato serum.

These data can be compared to the temperature/humidity fluctuations during tomato growing season in major US tomato growing states, such as Florida and California, as well in European countries. According to the results, lower temperature storage was not more beneficial regarding rate of *Salmonella* die-off. A recommendation of high average relative humidity (>72%) within first three days of storage, might result in higher bacterial die-offs. Potentially more significant in terms of public health is that tomato surface cleanness may play an important role regarding *Salmonella* survival.

CONCLUSION

It has been shown that high solute diluent for inoculum preparation, mimicking naturally soiled tomato surface, improves survival of *Salmonella* on the surface of undamaged tomatoes at low humidity storage. Additionally, stationary phase culture on spot inoculated tomatoes stored in high humidity experiences rapid die-off. Cleanness is one of the key factors to keep tomato surface unsuitable for pathogen survival, as solutes can contribute to survival and growth.

INFLUENCE OF TECHNOLOGICAL PROCESSING ON LIPID-LOWERING ACTIVITY OF SUBSTANCES CONTAINING IN PORCINE HEARTS AND AORTAS

Elena Kotenkova, Irina Chernukha

ABSTRACT
Edible by-products are a good source of nutrients and bioactive substances and could be used as functional ingredients or for biopeptides production natively contained in raw materials. A wide range of peptides are also formed during the enzymatic hydrolysis or food processing. The comparative results of the effectiveness of isolated certain protein and peptide fractions by ultrafiltration with the same natively presented in raw tissues, as well as the influence of heat treatment on biological activity of origin active substances are presented. The model of rat alimentary hyperlipidemia was developed by adding cholesterol and fat to the standard diet and vitamin D_2 injection *per os*. Serum lipid profile was determined on automatic analyzer BioChem FC-360. Dynamic of changes in serum lipid profile was assessed as corresponding control group medium results in ratio to certain rat data. Two-dimensional electrophoresis (2DE) was performed according to the method of O'Farrell with isoelectric focusing in ampholine pH gradient (IEF-PAGE) with following identification by MALDI-TOF MS and MS/MS mass spectrometry. Consumption of native pig aorta and pig heart during 14th days led to normalization of lipid profile in serum of hyperlipidemic rats, while low molecular weight (LMUF, MW <5 kDa) and medium molecular weight (MMUF, MW = 5 – 30 kDa) ultrafiltrates of pig aorta extract did not strongly influenced on level of triglicerides and, on contrary, elevated high density cholesterol. Consumption of developed product by hyperlipidemic rats during 28th days did not lead to significant changes in serum lipid profile, while on 42nd day all ratios reached ones in group, which were treated with native raw material or isolated active fractions. The stability of developed product was confirmed by proteomic studies. Obtained results open prospects to modernization the technology, presumably use as a matrix dietary meat (e.g. poultry) with incorporated active identified components.

Keywords: by-products; heart; aorta; lipid-lowering activity; functional additives and product

INTRODUCTION
A large number of by-products are left after farm animal's slaughter; edible ones such as internal organs are a good source of nutrients and bioactive substances and could be used as functional ingredients or for biopeptides production **(Toldrá, Mora and Reig, 2016; Alao et al., 2017)**.

Natively contained in raw materials peptides or formed during the enzymatic hydrolysis or food processing demonstrated hypotensive, antioxidant, opioid, immunomodulatory, prebiotic, mineral-binding, cholesterol-lowering and antimicrobial activity **(Bauchart et al., 2006; Mine and Shahidi, 2006; Ahhmed and Muguruma, 2010; Toldrá et al., 2012; Udenigwe and Howard, 2013; Lafarga and Hayes, 2014)** and could be used as a functional ingredient in food processing for specialized purposes. Collagen, hemoglobin and casein are mostly studied, a lot of peptides were isolated, identified and their functions were determined **(Toldrá et al., 2011; Wang et al., 2013; Lafarga et al., 2016; Mohanty et al., 2016; Arrutia et al., 2017; Bamdad et al., 2017; Hongdong and Bo, 2017)**.

Technological processing, especially enzymatic treatment is a good tool for bioactive peptide generation. Nevertheless, it's known that every tissue is characterized uniqe proteome and peptidome, which are involved in maitance of its own normal physiological condition **(Fagerberg et al., 2014)**. Moreover, it was found that besides peptides with defined functions, tissues of living organisms contain powerful peptide background, which mainly consists of fragments of larger molecules or functional proteins **(Chugunov, 2010)**.

In previous studies we confirm lipid-lowering action of raw material (porcine heart and aorta), different protein fractions isolated from aorta, and functional meat product produced from porcine heart and aorta in certain ratio on hyperlipidemic rats **(Chernukha, Fedulova and Kotenkova, 2015; Chernukha, Fedulova and Kotenkova, 2018; Chernukha et al., 2018a, Chernukha et al., 2018b)**.

This paper reports the analytical results of influence of the type of technological treatment on hypolipidemic activity substances naturally presenting in porcine heart and aorta.

Scientific hypothesis

Different technological treatment could influence on biological effectiveness of substances presenting in corresponding tissue. It's known that an enzymatic treatment lead to release different active peptides from some wastes of farm animal's slaughter. On the other hand, specific by-products are already enriched with unique substances with certain biological function and involved in maitance of its own normal physiological condition. In this case we decided to compare the effectiveness of isolated certain protein and peptide fractions by ultrafiltration with the same natively presented in raw tissues. Also we studied the influence of heat treatment on biological activity of origin active substances. All these analytical results could propose final recommendation for further raw material processing to produce functional meat product.

MATERIAL AND METHODOLOGY

Native porcine heart and aorta, low molecular weight (LMUF, MW <5 kDa) and medium molecular weight (MMUF, MW = 5 – 30 kDa) ultrafiltrates of pig aorta extract, meat product containing porcine heart and aorta in ratio 3:1 were objects of study.

Ultrafiltrates production

Aorta tissues were homogenized in a grinder KENWOOD (UK) with a stainless steel plate (3 – 5 mm hole), re-frozed and then homogenized in a cutter KG Wetter 258/1336 (Germany) with the addition of distilled water in the ratio (4:1) and knife shaft speed 2000 rpm. Then homogenate were reconstituted in 0.9% NaCl solution, and extracted during 24 hours with stirrer speed 500 rpm. Extract separation was carried out by centrifugation for 7 – 10 minutes at 3,000 – 3,500 rpm on centrifuge CM-6M (ELMI, Latvia). Supernatant was collected and ultrafiltrated on PES membrane (MWCO 5 and 30 kDa) by tangential filtrationon VivaFlow 200 system (Sartorius, Germany). Low molecular weight (LMUF, MW <5 kDa) and medium molecular weight (MMUF, MW = 5 – 30 kDa) ultrafiltrates were lyophilized in INEY-4 (IPB RAN, Russia) to protein concentration 0.9 $g.L^{-1}$.

Meat product manufacture

Meat functional product was produced on ZAO "Yoshkar-OlinskiyMyasokombinat". Porcine hearts were chopped with a particle size of 2 – 3 mm and salted for 12 h. Porcine aortas were chopped with a particle size of 2 – 3 mm and homogenized in cutter at 3000 rpm for 2 – 3 min. Minced hearts with the juice were quantitatively transferred in the cutter and mixture was then homogenized at 3000 rpm for 6 – 8 min (ratio of aorta to hearts 1:3). Obtained mince was packed in cans and sterilized at 115 °C, a pressure of 0.23 MPa for 40 min. Meat product contained 17.53 ±0.95% protein, 3.82 ±0.13% fat, 0.305 ±0.015% sodium chloride, and 2.35 ±0.25% starch.

Animal experiments

Male Wistar rats (380 ±20 g) aged approximately 12 months were kept under standard conditions (temperature 20 ±3 °C, humidity 48 ±2%, day/night (from 06.00 to 18.00 hours/from 18.00 to 06.00 hours), no more than six rats per plastic cage), and water and feed were available ad libitum. Rats were obtained from Andreevka (Moscow region, Russia), acclimatized for 5 days, and grew up to 12 months of age before use in this study. The model of alimentary hyperlipidemia was developed by adding cholesterol and fat to the standard diet (standard chow (Labkorm, Russia)) and vitamin D_2 injection *per os* **(Chernukha et al., 2018b)**.

Native porcine heart and aorta testing protocol

After modeling the rats were randomly divided into three groups: control (n = 10) animals were administered standard chow, group A (n = 10) - pig heart tissue, group B (n = 10) - pig aorta tissues. All samples were mixed with standard chow in quantity 10 g per kg body weight for 14 days. According to physic-chemical protocol of raw material testing and electrophoretic study results, porcine aorta contained 21.40% protein, including approximately 10% proteins lower 30 kDa and 30% polypeptydes in all nitrogen, therefore experimental animals consumed 10 x 0.214 x 0.4 = 0.86 g target fraction per kg body weight. Porcine heart contained 13.23% protein, including approximately 14% proteins lower 30 kDa and 51% polypeptydes in all nitrogen, therefore experimental animals consumed 10 x 0.1323 x 0.65 = 0.86 g target fraction per kg body weight.

Ultrafiltratesand meat product testing protocol

At the end of modeling animals were randomly divided into four groups: control (n = 10) rats were administered 0.9% solution of sodium chloride, group C (n=10) – LMUF, group D (n=10) – MMUF. All samples were administered *per os* in dose 0.3 mg protein per kg body weight for 14 days. The dose was determined according to the recommended dose of commercial analogue - food bioactive additive containing a mixture of peptides isolated from the vessels of farm animals (Scientific and Production center of Revitalization and Health (SPRH), Russia).

Meat product testing protocol

After modeling, rats in control group were fed with standard chow, in group E – meat product ($8g.kg^{-1}$ b.w.) in mixture with standard chow during 28 and 42 days. The dose was reduced to $8g.kg^{-1}$ b.w. because in raw material experiment animals during all study left about 30 – 40% of standart chow mixrure with testes samples. During meat product testing there was no such observation.

Biochemical analysis

After the experiment, the animals were euthanized (VETtech, UK), blood samples for biochemical studies and were taken. Biochemical investigations were carried out on automatic analyzer BioChem FC-360 (HTI, USA) according to instructions applied to measurement kits

(HTI, USA). Total cholesterol (TCL), triglyceride (TG), cholesterol low-density lipoproteins (CL LDL) and cholesterol high-density lipoproteins (CL HDL) levels were measured in rat serum. Atherogenic index (AI) = (TCL - CL HDL)/ CL HDL. Dynamic of changes in serum lipid profile was assessed as corresponding control group medium results in ratio to certain rat data. Therefore ratio <1 means that experimental group value was higher control mean, ratio >1 – lower.

Proteomic study

Two-dimensional electrophoresis (2DE) was performed according to the method of O'Farrell with isoelectric focusing in ampholine pH gradient (IEF-PAGE). Following reagents were used: urea, acrylamide, methylene bisacrylamide, agarose, Tris, glycine, sodium dodecyl sulfate, ammonium persulfate, Triton X-100, 2-mercaptoetanol, bull serum albumine, ampholines pH 3 – 10, 5 – 8 (Sigma, United States), amberlite IRN-150L (Amersham Biosciences, Sweden). The subsequent detection of the proteins was carried out by staining with silver nitrate (Panreac, Spain) as described previously **(Kovalyov et al., 2006)**. The resulting digital images were edited in a graphic editor and the quantitative protein content was calculated using ImageMaster 2D Platinum version 7 ("GE Healthcare", Switzerland).

Protein fractions were excised from the gel, grinded and undergone trypsinolysis (Sigma, Germany) **(Zvereva et al., 2015)**. Obtained peptides were investigated by MALDI-TOF MS and MS/MS mass spectrometry on Ultraflex MALDI-TOF mass spectrometer (Bruker, Germany) with UV laser (336 nm) in the positive ion mode in molecular weight range of 500 – 8000 Da with calibration according to known peaks of trypsin autolysis.

Bioinformatics analysis

Analysis of obtained tryptic peptides mass spectra was performed using Peptide Fingerprint option in Mascot software (MatrixScience, USA) with MH+ mass determination accuracy of 0.01%; search was performed in databases of the National Center for Biotechnology Information, USA (NCBI).

Statistic analysis

STATISTICA 10.0 software was used in this study for the statistical analyses. The results were calculated as "middle value ± standard error" (M ± SE). Significant differences were tested by one-way ANOVA, followed by the Tukey test. Differences with *p*-values less than 0.05 were considered as statistically significant.

RESULTS AND DISCUSSION

The analytical results of dynamic of changes in serum lipid profile are presented in Table 1. Maximum elevation of total CL ratio was noticed in group B (native pig aorta) and was higher value in group A (native pig heart) by 27.5%, while TG ratio was lower by 42.4%. CL LDL ratio, on contrary, in serum of rats group B (native pig aorta) was higher group A (native pig heart) value by 19.3%, as well as CL HDL ratio was higher by 24.3%. Observed changes compensated each other; therefore the AI ratio was the same and showed no statistical difference.

There were no significant changes in total CL, CL LDL, CL HDL and TG ratios between group C (LMWU) and D (MMWU). It was also noticed, that CL HDL and TG elevated control values, because ratios did not exceed 1, while CL LDL was also higer control – corresponding ratios were higher 1. Nevertheless, the AI ratios corresponded with group A (native pig heart) and B (native pig aorta) and was lower control group approximately by 2 fold. This observation was explained previously by phenomenon of CL non-LDL and non-HDL reduction in rat serum, which is also associated with atherogenic lipoprotein fractions, as well as elevation of CL HDL **(Chernukha et al., 2018)**.

Consumption of developed product by hyperlipidemic rats during 28 days did not lead to significant changes in serum lipid profile. Total CL and CL ratio did not differ from control; corresponding ratios did not exceed 1, CL HDL ratio was lower 1. There was a slight increase in TG ratio, as well as in AI ratio. On 42nd day of developed product consumption all ratios reached ones in group A – D, which were treated with native raw material or isolated active fractions. Total CL, CL LDL, CL HDL, TG and AI ratios elevated by 50.5% (p <0.05), 39.0%, 29.8%, 11.4% and 37.0%, respectively.

Summarising, we observed that in group C (LMWU) and D (LMWU) there was not such effect as in group B (native pig aorta), the ratio of TG was lower 1 and therefore higher control value. It could be explained both significantly lower concentration of ultrafiltrates dosage as well as separation of active fraction into two-lower 5 kDa and 5 – 30 kDa. Nevertheless, the ratio of AI in both group

Table 1 Lipid profile in the serum of hyperlipidemic rat model.

Groups	Cholesterols (medium control value in ratioto certain rat data)			Triglycerides	Atherogenic index
	Total	LDL	HDL	(medium control value in ratio to certain rat data)	
Group A	1.31 ±0.10	1.09 ±0.07	1.07 ±0.11	3.09 ±0.92^{a}	1.88 ±0.31
Group B	1.67 ±0.16^{b}	1.30 ±0.05	1.33 ±0.13^{a}	1.78 ±0.33	1.91 ±0.06
Group C	1.30 ±0.09	1.13 ±0.09	0.85 ±0.06^{b}	0.92 ±0.15^{b}	1.90 ±0.09
Group D	1.46 ±0.11^{b}	1.12 ±0.09	0.95 ±0.07^{b}	0.90 ±0.13^{b}	1.98 ±0.19
Group E (28 days)	1.01 ±0.04^{a}	1.05 ±0.04	0.84 ±0.07^{b}	1.32 ±0.18^{b}	1.35 ±0.09
Group E(42 days)	1.52 ±0.15^{b}	1.46 ±0.30	1.09 ±0.03	1.47 ±0.18^{b}	1.85 ±0.25

Note: $^{a-b}$ -significant differences between the experimental groups (p <0.05).

Table 2 The results of mass spectrometric identification (MALDI-TOF MS и MS/MS) of protein fractions.

№	Protein name; (Gene symbol)	S/M/C *	Мм/pI (exp.)**	Мм/pI (calc.)**
1	heart fatty acid-binding protein (H-FABP) (+ Acetyl (Protein N-term)*****(1)	283/13/68	14.8/5.11	14.8/6.11
2	Mixture of heart fatty acid-binding protein (*H-FABP*)***(1) + Deamidated (96Q,99N), cytochrome c oxidase subunit 5A, mitoch (*LOC100156967*)***(1) + Acetyl (Protein N-term)	122/9/56 38/17/73	15.0/5.25	14,8/6,11 16.7/6.42
3	Mixture of heart fatty acid-binding protein (*H-FABP*)***(1) + Acetyl (Protein N-term) and NADH dehydrogenase [ubiquinone] 1 alpha subcomplex subunit 5 isoform X1 (*NDUFA5*)***(1)	120/4/36 113/2/36	15.0/5.60	14.8/6.11 13.3/7.79

Note: * S/M/C: Score – indicator of conformity or «scorecard»; Match peptides – the number of matched peptides; Coverage – % coverage of the entire amino acid sequence of the protein by identified peptides.
**mM/pI (experiment) – scores obtained as a result of electrophoretic mobility on the DE and mM/pI (calculation) – estimates made based on amino acid sequence data with consideration of signal peptide removal, but with no consideration of other post-synthetic modifications using the ExPASy Compute pI/Mw tool software.
***msms – indication of identification by tandem mass spectrometry, the number of sequenced tryptic peptides in parentheses.

C (LMWU) and D (LMWU) was approximately equal to group B (native pig aorta) and A (native pig heart).

In contrast to group C (LMWU) and D (LMWU) in group E there was another dynamic: on 28th day the ratio of TG was higer 1, while the ratio of AI was not so high despite of elevation CL HDL (ratio was lower 1). On 42nd day the ratio of CL HDL was higer 1, the ratio of AI was approximately equal to groups A (native pig heart), B (native pig aorta), C (LMWU) and D (LMWU).

In previous studies, several tissue-specific proteins were identified in porcine heart and aorta, as well as peptides. Mostly observed substances were decomposed during heat treatment of meat product, except fatty acid binding protein and several peptides **(Chernukha et al., 2016)**. However, it was proposed that tissue-specific proteins could be decomposed into active peptides with similar biological action or retained residual activity. In this study analytical study we revealed that meat product characterized by milder hypolipidemic action compare with native raw material or isolated active fractions; a significant effect was observed only after 42 days of consumption. Obtained results confirm our hypothesis.

There are different opinions about the relationship between the content of cholesterol or its atherogenic fractions and the risk of heart attack or stroke. While some scientists argue that there is no established relationship, others link worsening of a person after stroke or heart attack with elevated concentrations of cholesterol in blood, in particular, low-density cholesterol **(Demarin et al., 2010; Nelson, 2013; Ference et al., 2017; Hindy et al., 2018; Matthews, 2018)**. Developed product pronounced as a component of diet. Revealed long-term effect of product meets the requirements for patients receiving traditional medical treatment.

The creation of food products aimed at their constant use and positively affecting on the lipid profile can be considered as an important component of rehabilitation

therapy as accommodating diet therapy in particular for people with risk of stroke or heart attack.

The developed product was processed twice with two year interval. The 2D proteomic maps presented in Figure 1, results of fatty acid binding protein identification presented in Table 2. It was shown that there were no significant changes in major proteins, which indirectly confirm reproducibility of production technology and long shelf life. Moreover, fatty acid binding protein retained during 2-year storage.

Obtained results confirm that developed product contain peptides with residual hypolipidemic activity. On the other hand, native raw material or isolated active fractions demonstrated higher hypolipidemic effect, therefore it would be perspective to modernize the technology, presumably use as a matrix dietary meat (e.g. poultry) with incorporated active identified components.

CONCLUSION

Despite on the decomposition of target proteins and peptides after product processing, a pronounced lipid-lowering effect was noted, but less active than in case of native raw material or isolated active fractions. It was also found, that such technology treatment as ultrafiltration did not affect on activity of target compounds.

The obtained results open wide horizons for modification of the existing technology both in respect of variation of production modes and in respect of matrix changes and dosing of active proteins and peptides.

Antioxidant effect of oregano essential oil during various storage meat time of hybrid combination ross 308

Michaela Klimentová, Mária Angelovičová

ABSTRACT

This study was conducted to evaluate the effect of *Origanum vulgare* L. *Hirtum* essential oil on the oxidation stability of raw chicken meat. Oregano essential oil was applied in a different way, on the one hand in a feed for broiler chickens (E1) and on the other hand on a surface of chicken thighs (E2). Broiler chickens were fed during the experimental period in the all groups with commercial feed mixtures except the experimental group of E1 (with the addition of 0.05% oregano essential oil, 50 g EO per 100 g of the feed mixture). In E2 was application of oregano essential oil (0.5%) on surface of thighs 1 mL per 60 g of meat realized. The oxidative stability of the chicken meat was investigated in the same way, 8th days after vacuum-packed and stored at temperature 4 °C and 6, 9 and 12 months after vacuum-packed and storage at -18 °C. The samples of the E1 consisted of breast and thigh muscles with skin (150 g) and of the E2 thigh muscle with skin (60 g). The impact of oregano essential oil was measured by content of fat and peroxide value (PV). Fat content in both experiments was not affected by storage time and EO addition. Content of chicken meat fat in E1 in control group ranged between M = 9.64 – 12.95 g.100 g^{-1} and in experimental group contained similar amount of fat mean from M = 9.94 – 12.24 g.100 g^{-1}; E2: in control group M = 7.01 – 7.73 g.100 g^{-1} and in experimental group M = 6.15 – 8.03 g.100 g^{-1}. Measured peroxide values confirm that oregano essential oil has effect on broiler chicken meat oxidative stability, if applied to feed, manifested statistically significant differences between control and experimental group. The mean of peroxide value in control group of E1 was M = 0.58 –3.60 µmol O_2.kg^{-1} and in experimental group was M = 1.06 – 2.11 µmol O_2.kg^{-1}. We found not statistically significant difference in peroxide values, if applied oregano essential oil to raw chicken meat. The results impact of oregano essential oil on chicken meat comparable to control group, but a tendency to improve oxidative stability was indicated.

Keywords: oregano essential oil; antioxidant; chicken meat storage; oxidative stability; peroxide value

INTRODUCTION

The relationship between the consumption of meat and health is multifaceted, and it needs to be analyzed in detail, with specific attention to the relevant differences that characterize the effects of the different meat types. A variable but moderate energy content, highly digestible proteins of good nutritional quality, unsaturated lipids, B-group vitamins and minerals make poultry meat a valuable food. Epidemiological studies performed across the world, in highly diverse populations with different food preferences and nutritional habits, provide solid information on the association between poultry consumption, within a balanced diet, and good health **(Marangoni et al., 2015)**.

Meat and meat products are important sources of high-quality protein. Their acceptance of consumers depends mainly on the proportion of fat, that is responsible for its taste properties and structure **(Lorenzo a Franco, 2012)**. However, despite this benefit, fat is the cause of deterioration in the nutritional and sensory quality of the meat due to its greater susceptibility to oxidative damage **(Qi et al., 2015)**.

Angelovič et al. (2015) constate that the mechanisms of oxidative degradation can be autoxidation in presence of atmospheric oxygen.

The intake of lipids from chicken meat is variable dependent on the cut considered by consumers. Fats are mainly found in the skin and can, therefore, be easily removed during processing or consumption of meat. The lipid content varies from 1% in poor parts such as breasts to 17% in chicken wings with skin. The inclusion of skin can increase these values **(Marangoni et al., 2015)**.

Muscular lipids are highly susceptible to oxidation due to a high degree of unsaturation. Oxidation leads to a deterioration in the taste, color, structure and nutritional value of the meat. Of great importance in the oxidation of

chicken meat are some ingredients (iron content, antioxidants) as well as external factors (feeding with fodder feed, stress, killing process, temperature, processing procedures, storage conditions, etc.) **(Estévez et al., 2014)**.

The main factor influencing lipid oxidation in meat is oxygen, which reacts with unsaturated lipids to form lipid peroxides. The resulting lipid peroxides lead to the formation of various chemical compounds such as alcohols, aldehydes and ketones **(Domínguez et al., 2014)**, which are responsible for the unpleasant taste and odor and thus also for the reduction of the sensory and nutritional quality of the meat.

Lipid oxidation is possible to prevent through adding synthetic and natural antioxidants to animal feed or to processes meat and meat products. Synthetic antioxidants have been confirmed for their toxicological and carcinogenic effects. Natural antioxidants may be found in any plant part and most natural antioxidants are phenolic compounds, and the most important are the tocopherols, flavonoids, and phenolic acids **(Kumar et al., 2015)**.

The genus *Origanum* belongs to the family of *Labiatae* and includes many species that are commonly found as wild plants in the Mediterranean areas. Thirty-eight (38) *Origanum* species are recognized in the world. Due to the variability in chemical and aroma characteristics is used *Origanum* in cosmetic industries, as a culinary herb, flavoring substances of food products, alcoholic beverages and perfumery for their spicy fragrance **(Pirigharnaei et al., 2011)**.

Essential oils (EO) are volatile, natural compounds formed by aromatic plants as secondary metabolites, known for their antiseptic, bactericidal, viricidal and fungicidal, and medicinal properties and their fragrance, they are used in preservation of foods and as antimicrobial, analgesic, sedative, anti-inflammatory, spasmolytic and locally anesthetic remedies **(Bakkali et al., 2008)**.

Dominant components of oregano EO are composed of carvacrol and thymol, followed by γ-terpinene, pcymene, linalool, terpinen-4-ol and sabinene hydrate. *O. vulgare* ssp. *hirtum*, contained a high amount of EO. The content of EO as high as 8% with carvacrol as dominant component (95%) was reported for this subspecies **(Pirigharnaei et al., 2011)**.

Freezing is one of the several methods of preserving meat and protecting its quality until it reaches the consumer **(Xia et al., 2012)**.

The main objectives of this preservation method are to inhibit microbial growth, delay metabolic activities and oxidative damages. It allows maintaining almost all product characteristics of products and to stock them for long periods **(He et al., 2013)**. Despite being one of the least aggressive preservation methods, freezing still produces modifications in foods.

Bennett et al. (2014) report that oxidation can be initiated by the formation of lipid peroxides, which can be detected by measuring the peroxide value, that quantifies the levels of peroxides and hydroperoxides formed in the initial phase of lipid oxidation. The determination of the fat peroxide value is used to determine the degree of fat loss. The low peroxide fat value usually indicates that the fat has not become rancid and will have good stability.

Fresh fats have a peroxide value of 1 – 2, whereas rancid fats have a peroxide value of 15 – 20. Rancidity is caused by oxidation and hydrolysis **(Sharma, Giriprasad and Goswani, 2013)**.

Scientific hypothesis

The aim of this paper is to study the effect of oregano essential oil supplementation on chicken meat quality and lipid oxidation stability during various storage time of meat.

MATERIAL AND METHODOLOGY

Biological material

Two experiments were carried out. The difference between the 1st (E1) and 2nd (E2) experiment was in the way of application of oregano essential oil (EO). The application of oregano essential oil was performed in the E1 in the feed and in the E2 on the surface of the chicken thighs. The oxidative stability of the chicken meat was investigated in the same way in both experiments, after vacuum-packed 8 days after vacuum-packed and storage at 4 °C and 6, 9 and 12 months after vacuum-packed and storage at -18 °C.

The E1 was conducted in poultry farm, in conditions of the welfare principles application whit deep litter breeding system. The conditions responded protection requirements for broilers chickens **Council Directive 2007/43/EC**. Microclimatic conditions (light, temperature, humidity and air exchange) were uniform for both groups in accordance with recommendations for the meat broiler chickens ROSS 308. Broiler chickens (40 one-day-old broiler chickens) were divided in the E1 into 2 groups, control (CG) and experimental – EG (n = 20). Broiler chickens were fed during the experimental period in the control group with commercial feed mixtures without oregano essential oil (EO) and in the experimental group with similar diets as in the control group but with the addition of 0.05% EO, in amount of 50 g of EO per 100 g of the feed mixture. Broiler chickens consumed of feed mixtures *ad libitum*. The experimental period lasted 38 days and tree feed mixtures were used: starter feed mixture, for chickens to 18 days of age (feed from plate feeders and water from the hat drinkers located on the floor); grower mixture, from 19 to 31 day of age (feed from the tube feeders and drank water from bucket drinkers till end of the experiment) and finisher mixture, from 32 to 38 day of age. Broiler chickens were transported to the chemical laboratory of Department of Food Hygiene and Safety, Faculty of Biotechnology and Food Sciences, Slovak University of Agriculture Nitra and killed after ending experiment. The breast and thigh muscles with skin were deboned and used for analyses (8th days after slaughter and storage at 4 °C and after 6, 9 and 12 months of storage at -18 °C of chicken meat).

In the E2 were broilers chickens killed on slaughterhouse and selected thighs randomly, after slaughtering. Chicken thighs were obtained from broiler chickens that were farmed and fed with commercial feed mixtures. Chicken thighs were deboned and used for analyses in the 8th day (measurement 30 minutes after application 0.5% of EO on the surface of thighs) and after 6, 9 and 12 months. In both measurements were thighs divided to two groups: control group (samples without treatment), experimental group (samples with application of EO on surface of thigh). Each

Table 1 Experiment scheme.

Experiment	Sample n	Storage time and temperature	Chemical analysis
E1			
Control group	20	8 days at 4 °C 6, 9 and 12 months at -18 °C	of chicken meat achieved from broiler chickens fed with commercial feed mixtures without EO
Experimental group	20		of chicken meat achieved from broiler chickens fed with 0.05% EO in the feed mixtures
E2			
Control group	6	8 days at 4 °C 6, 9 and 12 months at -18 °C	chicken thighs without application of EO
Experimental group	6		chicken thighs with application of 0.5% EO

Note: E1 – 1st experiment with EO in feed mixtures, E2 - 2nd experiment with application EO on raw thigh muscle.

group contained 6 samples which were used for oxidative stability measurements. Scheme of experiment is given in Table 1.

Laboratory testing

Sample preparation

The samples consisted of: E1: chicken muscles (breast and thigh) and skin; E2: thigh muscle and skin. Samples were deboned and collected on the day of slaughter vacuum-packed and stored at 4 °C for 8 days and at -18 °C for further analysis after 6, 9 and 12 months of storage. In the E2 were samples of experimental group with EO treated (1 ml of oregano essential oil applied on surface of thigh muscle 60 g). Time of EO treat was 30 minutes, amount 1 ml per 60 g of meat. Chemical analysis (fat content, peroxide value) of the meat samples were carried out after homogenization (according to the method AOAC 983.18), drying of the samples under the prescribed conditions at 105 °C to constant weight. The dried samples were then milled into powder using Grindomix GM 200 grinder and used to obtain fat by extraction (non-polar solvent) in a Soxhlet extractor and expressed as g per 100 g of fresh tissue.

Chemicals analyses

Oregano essential oil (*Origanum vulgare* sup. *Hirtum*) was purchased from Calendula a.s., Nová Ľubovňa, Slovensko with a total antioxidant activity of EO 93.85% and carvacrol content 57%.

Determination of fat content: was used an official method to determine fat AOAC 991.36. Crude fat content is determined by extracting the fat from sample using a chemical solvent (petroleum) under the extraction method. Lipid extraction was carried out using a device Det-gras N, model 4002842.

Fat content calculation (g.100 g^{-1}):

$$Crude\ fat = \frac{\mathrm{w2} - w0}{w1} \times 100$$

w2 – is weight of the extraction thimble with extracted fat
w0 – is weight of the empty extraction thimble
w1 - is weight of the sample

Determination of peroxide value (PV): was used an official method to determine peroxide value **IFRA (2011)** with minor modifications. Peroxide value test measures amount of iodine released from potassium iodide next estimated using a standard sodium-thiosulfate solution. Peroxide value is stated by millimoles of active oxygen per kilogram of lipids mmol $O_2.kg^{-1}$. Peroxide value was carried out using a chemical: chloroform, acetic acid, potassium iodide (freshly prepared saturated solution dark stored), sodium thiosulphate (0.01 $mol.L^{-1}$), starch.

Peroxide value calculation (mmol $O_2.kg^{-1}$):

$$PV = \frac{(V1 - V0) * \mathrm{c} * 1000 * \mathrm{T}}{w}$$

V1 – consumption of 0.01 $mol.L^{-1}$ sodium thiosulphate solution in the main test
V0 – consumption of 0.01 $mol.L^{-1}$ sodium thiosulphate solution in the blank test
c – molar concentration of the sodium thiosulphate solution
T – titre of the sodium thiosulphate solution
w – weighed portion of fat in grams

Statistic analysis

The statistical analysis was performed by the program SAS, version 9.1. The results of measurements were analysed using ANOVA for the repeated measure and Student t test for independent samples if the normality was met. If the normality wasn't met, Friedman test and Mann-Whitney test were used. Significance was established at $p < 0.05$.

RESULTS AND DISCUSSION

Fat content

The fat content of chicken meat after the application of EO to the feed and measured in raw chicken muscle homogenates depending on its storage, is reported in Table 2. In E1 mean content of chicken meat fat in control group ranged between M = 9.64 g.100 g^{-1} in 9th month and M = 12.95 g.100 g^{-1} in 12th months. The time has not a statistically significant effect on content of chicken meat fat in control group ($F(1.94, 36.864) = 2.075$, $p > 0.05$).

Table 2 Fat content of chicken meat during storage, g.100 g^{-1}.

Group	Storage period							
	8 days		6 months		9 months		12 months	
	1st experiment with EO in feed mixtures							
	M ±*SD*	c_v (%)	*M* ±*SD*	c_v (%)	*M* ±*SD*	c_v (%)	*M* ±*SD*	c_v (%)
CG	11.17 ±6.97	62.39	10.95 ±2.46	22.47	9.64 ±4.40	45.64	12.95 ±2.09	16.14
EG	10.84 ±2.41	22.23	9.94 ±2.76	27.77	11.07 ±4.35	39.30	12.24 ±3.74	30.56
	2nd experiment with application EO on raw thigh muscle							
CG	7.44 ±0.98	13.17	7.01 ±1.74	24.28	7.12 ±2.11	29.63	7.73 ±2.05	26.52
EG	8.03 ±2.11	26.28	6.15 ±1.70	27.64	7.14 ±1.49	20.87	7.00 ±1.79	25.57

Note: CG – control group without oregano essential oil, EG – experimental group whit oregano essential oil, *M* - mean, *SD* – standard deviation, c_v – coefficient of variation.

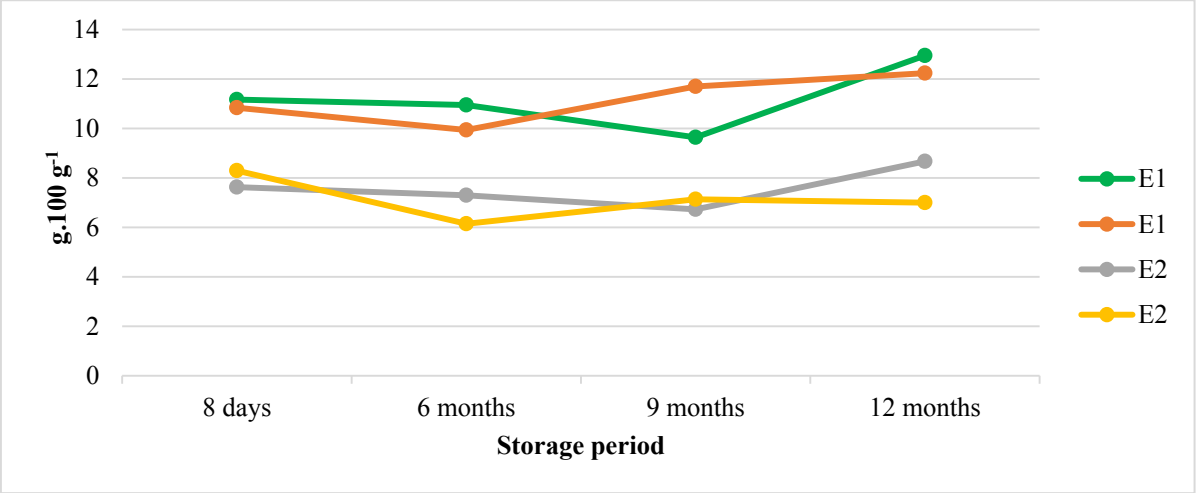

Figure 1 Fat content of chicken meat during storage, g.100 g^{-1}.

Chicken meat from experimental group contained similar amount of fat mean from $M = 9.94$ g.100 g^{-1} in 6th month to $M = 12.24$ in 12th months. We found out in experimental group too, that the time has not a statistically significant effect on content of chicken meat fat ($F(3, 57) = 1.749$, $p > 0.05$).

The difference between control group and experimental group of oregano essential oil feeding broiler chickens was not significant in measurements of fat content of chicken meat (8 days ($t(38) = 0.2$, $p > 0.05$), 6 months ($t(38) = 1.23$, $p > 0.05$), 9 months ($t(38) = -1.036$, $p > 0.05$), 12 months ($t(38) = 0.735$, $p > 0.05$)).

In E2 the fat content has been balanced during whole storage period (Figure 1). In control group was mean from $M = 7.01$ g.100 g^{-1} to mean $M = 7.73$ g.100 g^{-1}. There was not a statistically significant effect of time on fat content in control group ($F(3, 33) = 0.41$, $p > 0.05$). Fat content of chicken tight in experimental group ranged between mean $M = 6.15$ g.100 g^{-1} in 6th month and $M = 8.03$ g.100 g^{-1} at 8th day storage period. In experimental control group was not found a statistically significant effect of time on fat content ($F(3, 33) = 2.228$, $p > 0.05$).

In comparison of control group and experimental group we didn't found a statistically significant difference in individual measurements (8 days ($t(22) = -0.877$, $p > 0.05$), 6 months ($t(22) = 1.219$, $p > 0.05$), 9 months ($t(22) = -0.032$, $p > 0.05$), 12 months ($t(22) = 0.924$, $p > 0.05$)).

These results correspond to the results of **Liptaiová et al. (2010)**, which reported average fat content of chicken meat of broilers chickens fytoadditives feeding with concentration 0.1% 9.9 g.100 g^{-1}, 0.05% 9.5 g.100 g^{-1}, 0.025% 10.45 g.100 g^{-1}. The fat content of the chicken meat in the control group (without fytoadditives), was 9.8 g.100 g^{-1}. Differences in the fat content of chicken meat between the groups were not statistically significant ($p > 0.05$).

Giannenas et al. (2016) in a 42-day-long fattening experiment with 5% oregano essential oil in feed mixtures (300 g.ton^{-1}) of broiler chickens Ross 308 hybrid combination and 5% oregano essential oil and 0.5% virgin oil in feed mixtures (500 g.ton^{-1}) indicated fat content in chicken breasts without skin of 5.4 g.100 g^{-1} in both groups compared to the control group of 5.5 g.100 g^{-1}. Fat content in chicken thighs without skin 8.2 g.100 g^{-1} in both experimental groups and 8.4 g.100 g^{-1} in the control group without a statistically significant difference between the groups ($p > 0.05$).

Comparable fat content introduced in their study by broiler chickens Ross 308 hybrid combination **Čuboň et al. (2013)**, where measured in thigh muscle with skin 12.2 – 13.2 g.100 g^{-1}, **Milićević et al. (2014)** measured in thigh muscle with skin 5.19 – 9.85 g.100 g^{-1}.

Table 3 Fat peroxide value during storage, mmol $O_2.kg^{-1}$.

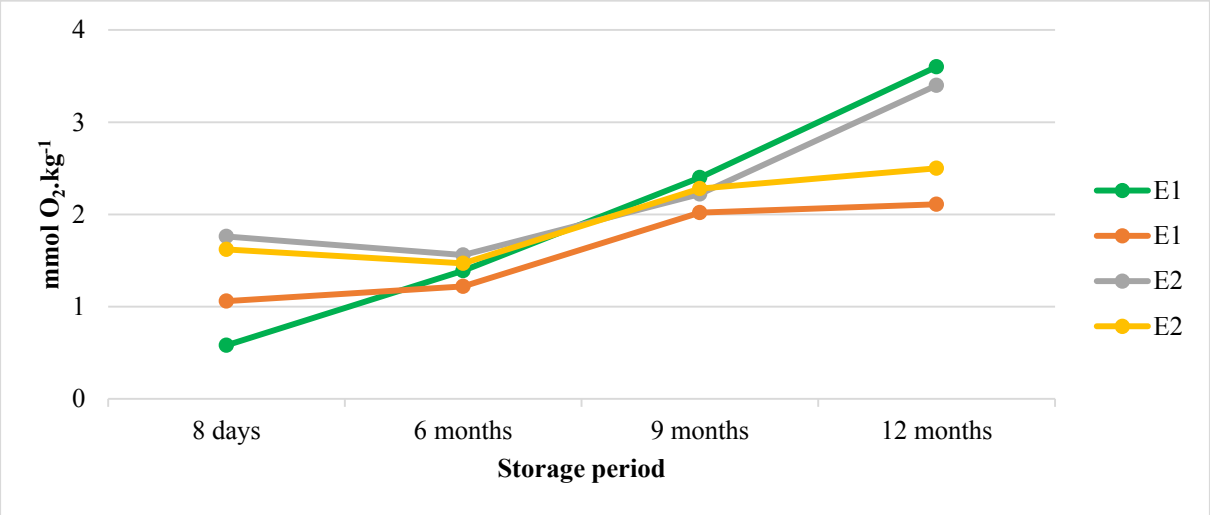

Figure 2 Fat peroxide value during storage, mmol $O_2.kg^{-1}$.

Peroxide value

The oxidative stability parameter of the peroxide value after the application of EO to the feed and measured in raw chicken muscle homogenates depending on its storage is reported in Table 3.

The mean of peroxide value in control group of E1 was M = 0.58 µmol $O_2.kg^{-1}$ at 8th day of storage time and increased during whole storage period up to M = 3.60 µmol $O_2.kg^{-1}$ in 12th months (Figure 2). There is a statistically significant effect of time on content of peroxide value in control group (F(1.823, 34.634) = 19.357, p <0.05).

Peroxide value in experimental group with EO was M = 1.06 µmol $O_2.kg^{-1}$ at 8th day of storage time and after 12th months M = 2.11 µmol $O_2.kg^{-1}$. There is a statistically significant difference between peroxide values in experimental group measured in various period (χ^2(3) = 21.211, p <0.05).

The difference between control group and experimental group with oregano essential oil feeding broiler chickens was statistically significant in first and last measurements (8 days (U = 101, p <0.05), 12 months (U = 90.5, p <0.05)). In first measurement was peroxide value significantly higher in experimental group (*Mdn* = 0.85) than in control group (*Mdn* = 0.57). In the last measurement it was inside out. Peroxide value was significantly higher in control group (*Mdn* = 3.66) than in experimental group (*Mdn* = 1.98).

Peroxide value of the samples in E2 evaluated in the control group ranged between M = 1.56 µmol $O_2.kg^{-1}$ and M = 3.40 µmol $O_2.kg^{-1}$. We didn't found a statistically significant difference between peroxide values measured in various time (χ^2(3) = 1.4, p >0.05) in control group. In experimental group we observed increased peroxide value too and there was not found a statistically significant difference between peroxide values measured in various time (χ^2(3) = 5.034, p >0.05).

In comparison between control group and experimental group with EO, we found not a statistically significant difference in individual measurements (8 days (U = 17.5, p >0.05), 6 months (U = 14.5, p >0.05), 9 months (U = 12.5, p >0.05), 12 months (U = 12.5, p >0.05)).

Sing et al. (2014) noticed significantly higher peroxide value in control group without fytoadditives during storage at 4 °C after 7 and 9 days in raw chicken meat unlike our study, where was peroxide value of E2 after 8th days similar in both groups. In our experiments, the peroxide value was comparable to 8th day and after 6th months of storage, indicated oxidative damage to chicken meat, well below the peroxide limit reported **Min and Ellefson (2010)**, which indicates, that a low peroxide value can represent either the beginning or advanced oxidation and can be distinguished based on the PV over time or by

measuring secondary oxidation products. A high quality, fresh fat has a PV of zero, on the other hand very poor-quality fats resulting in a PV ≥20 mmol.kg^{-1}. Peroxide value of chicken meat increased during the whole period of storage, but its value was not so high as to cause that meat to be damaged. In 12 months were in both experiments' numbers of peroxide value higher in control group. The increase could be caused due to the faster rate of formation of new hydroperoxides than reduction of hydroperoxides into secondary oxidation products that signify effect of supplementation oregano essential oil in experimental groups.

Results of **Dashti et al. (2015)** showed that thyme essential oil was effective in preventing oxidative spoilage. No difference of peroxide value was observed between the treated samples and control during the first month of chicken nuggets storage but differences among samples can be observed from 2nd month to the 6th month of the storage time. Control samples showed higher oxidation rate than treated samples containing different concentrations of essential oil (0.1%, 0.2%, 0.05%) throughout the storage. In 6th months, peroxide value for all three concentrations was significantly different from samples without thyme essential oil. His research demonstrated the strongest effect of 0.2% essential oil that is lower concentration like in our experiment without significant difference in peroxide value of chicken thighs.

Dzomba et al. (2014) confirmed in their study with different parts of the chosen plants improves meat oxidative stability and provides better protection as synthetic antioxidant. The profile of the untreated meat was above all other profiles. Treating meat by mixing with 50 mg of *Cleome gynandra* leaf extract gave more promising results with a peroxide value that was below 50 mmol O_2.kg^{-1} even after 26 days. It depicted the slowest rate of formation of peroxides as compared to synthetic antioxidant BHT.

Our results do not consist with authors, who reported that the peroxide value of mechanically deboned chicken meat treated with a polyphenol extract increases and thereafter decreases with storage time. They represented, that decomposition of hydroperoxides into secondary products increases at a higher rate as lipid oxidation progresses, as compared with the formation of new hydroperoxides, resulting in decreased peroxide value **(Teets and Were, 2008, Soyer et al., 2010, Hwang et al., 2013)**.

CONCLUSION

Results of our experiments indicate that the oregano essential oil and storage time not influenced the fat content in chicken meat but manifested an impact on the oxidative stability of chicken meat its application to feed. This effect was statistically significant compared with control group. We found not statistically significant difference in peroxide values, if applied oregano essential oil to raw chicken meat. The results impact of oregano essential oil on chicken meat comparable to control group, but a tendency to improve oxidative stability was indicated. We recommend the use of 0.05% oregano essential oil for broiler chickens due to its antioxidant properties in amount 50 g of oregano essential oil per 100 g of the feed mixture. Oregano essential oil appears to be alternative to synthetic additives in broiler nutrition.

THE EFFECT OF COFFEE BEANS ROASTING ON ITS CHEMICAL COMPOSITION

Pavel Diviš, Jaromír Pořízka, Jakub Křikala

ABSTRACT

Drinking coffee has become part of our everyday culture. Coffee cultivation is devoted to over 50 countries in the world, located between latitudes 25 degrees North and 30 degrees South. Almost all of the world's coffee production is provided by two varieties, called 'Arabica' and 'Robusta' whereas the share of Arabica is 70% of the world's coffee harvest. Green (raw) coffee can not be used to prepare coffee beverages, coffee beans must first be roasted. Roasting coffee and reaching a certain degree of coffee roasting determine its flavor and aroma characteristics. In the present study the fate of sucrose, chlorogenic acid, acetic acid, formic acid, lactic acid, caffeic acid, total phenolic compounds and 5-hydroxymethylfurfural was studied in coffee (Brazil Cerrado Dulce, 100% Arabica) roasted in two ways (Medium roast and Full city roast). It has been found that almost all sucrose has been degraded (96 – 98%) in both roasting ways. During Medium roast 65% of chlorogenic acid contained in green coffee was degraded while during Full city roast it was 85%. During both Medium and Full city roasting, the formation of acetic acid but especially formic and lactic acid was recorded. The highest concentration of organic acids was recorded at Full City roasting at medium roasting times (3.3 $mg.g^{-1}$ d.w. acetic acid, 1.79 $mg.g^{-1}$ d.w. formic acid, 0.65 $mg.g^{-1}$d.w. lactic acid). The amount of phenolic substances also increased during roasting up to 16.7 $mg.g^{-1}$ d.w. of gallic acid equivalent. Highest concentrations of 5-hydroxymethylfurfural were measured at medium roasting times at both Medium (0.357 $mg.g^{-1}$ d.w.) and French city (0.597 $mg.g^{-1}$ d.w.) roasting temperatures. At the end of roasting, the 5-hydroxymethylfurfural concentration in coffee were 0.237 $mg.g^{-1}$ d.w. (Medium roast) and 0.095 $mg.g^{-1}$ d.w. (Full city roast).

Keywords: coffee; roasting; hydroxymethylfurfural; sucrose; organic acids

INTRODUCTION

Coffee is made up of modified seed of the fruit of various tropical to subtropical trees or coffee shrubs. Coffee has a large number of varieties, only a few of them have economic significance. Almost all of the world's coffee production is provided by two varieties, called 'Arabica' and 'Robusta' **(Butt and Tauseef Sultan, 2011)**. Arabica (*Coffea arabica*), is the most important botanical species, especially for the high quality of its fruits. It comes from about 70% of the world's green coffee production. Robusta (*Coffea canephora*), is the second most important variety of coffee, and its share of world production is steadily growing mainly due to its greater adaptability to habitats and disease resistance. Other reasons to increase demand of Robusta coffee in the market are the growing demand for instant coffee, which is preferentially made from Robusta coffee and last but not least, lower price of Robusta coffee compared to Arabica coffee **(Kemsley et al., 1995)**. World coffee production in 2017 was about 9.5 million tonnes, which makes coffee the second most important commodity of world trade **(FAOSTAT, 2018)**.

After processing the coffee beans by wet or dry drying technologies **(Arya and Jagan Mohan Rao, 2007; Guimar, Berbert and Silva, 1998),** coffee beans are roasted. During coffee roasting, coffee beans get brown colour and their characteristic flavour and aroma **(Yeretzian et al., 2002)**. In different countries, different roasting styles have been created according to population preferences. These roasting styles differ from each other at the roasting temperature used and the total coffee roasting time **(Moon, Yoo and Shibamoto, 2009; Dórea and DaCosta, 2005)**.

Due to the popularity of coffee in the world many researchers were involved in coffee research in the last quarter of a century. Most studies on coffee are health-related studies **(Ciaramelli, Palmioli and Airoldi, 2019; Poole et al., 2017; Ludwig et al., 2014; Butt and Tauseef Sultan, 2011; Dórea et al., 2005)**. Other studies are focused on the role of roasting conditions of the coffee in the level of selected compounds. Information on what is happening in roasted coffee beans is quite sufficient in the available literature, but there are only few studies that deal with the complex monitoring of changes in the chemical composition of coffee beans during roasting **(Wei et al., 2012)**.

In the present study the fate of sucrose, chlorogenic acid, acetic acid, formic acid, lactic acid, caffeic acid, total phenolic compounds and 5-hydroxymethylfurfural was studied in coffee roasted in two ways (Medium roast and Full city roast).

Scientific hypothesis

Higher temperature and higher time of coffee beans roasting cause higher amounts of 5-hydroxymethylfurfural, organic acids and phenolic compounds while reducing the carbohydrate content in the coffee beans.

MATERIAL AND METHODOLOGY

Chemicals and reagents

All water used in this study was ultrapure water (Elga pure lab classic, Veolia water systems, UK). All chemicals used in this study were analytical grade chemicals purchased from Sigma-Aldrich (Germany) company except of Karl-Fisher titration reagent and water standard which have been purchased from Labicom (Czech Republic).

Sample preparation

The 100% Arabica coffee (Brazil Cerrado Dulce, 4coffee, Czech Republic) was used in this study. Total amount of 25g of green coffee beans was roasted in a home coffee roaster (Gene café CBR101, 4coffee, Czech Republic). Coffee was roasted with two roasting degrees as Medium roast and Full city roast. Roasting on Medium roast degree was done at 210 °C and the total roasting time was 14 min. Roasting on Full city roast degree was done at 225 °C and the total roasting time was 19 min. Extraction of organic acids, sucrose, 5-hydroxymethylfurfural and total phenolic compounds was performed in 25 mL Erlenmeyer flasks. One gram of sample weighted on analytical balancer and 10 mL of solvent (80 °C water mixed with ethanol in 60:40 volume ratio) were used for extraction. Extraction was carried out on a magnetic stirrer for 30 minutes. After the extraction, the samples were centrifuged at 5000 rpm in centrifuge and the supernatant was filtered using nylon syringe filters (0.45 μm, Labicom, Czech Republic) and used for analysis. All samples were prepared in two replicates.

Chemical analysis

Acetic, formic and lactic acid were determined using ion chromatography (Metroohm 850 professional IC, Metroohm, Switzerland) with conductivity detector. An Agilent Infinity 1260 liquid chromatograph (Agilent Technologies, USA) equipped with ELSD detector was used for determination of sucrose. Both methods are described in detail at work published by **Diviš et al. (2018)**. Total phenolic compounds were determined using Helios gamma spectrophotometer (Spectronic Unicam, Great Britain) through the Folin-Ciocalteus method **(Singleton et al. 1999)** and expressed as gallic acid equivalent. Concentration of 5-hydroxymethylfurfural was determined on Agilent Infinity 1260 liquid chromatograph with DAD detector using Kinetex EVO-C18 column and acetonitrile mixed with water in 15:85 volume ratio. Chlorogenic and caffeic acid were determined on Agilent Infinity 1260 liquid chromatograph with DAD detector using Kinetex EVO-C18 column and mixture of 2.5% formic acid and acetonitrile in 90:10 volume ratio as mobile phase. Water content in all samples was determined by Karl-Fisher titration **(Verhoef and Barendrecht, 1977)** using KF Titrino 701 titrator (Metroohm, Switzerland)**.** The pH value was measured using pH meter with combined electrodes (WTW, Germany). All parameters for a single sample were measured in three replicates. All measured concentrations were recalculated to dry weight of coffee.

Statistic analysis

All experimental data were statistically processed using software XLstat (Addinsoft, USA). Obtained data were pre-treated by using Analysis of Variance (ANOVA) to find statistical significant differences between groups. Tukey's comparative test on the significance level 0.05 has been performed for individual parameters observed during coffee roasting. The pre-treated data were used as input parameters in Principal Component Analysis (PCA) to find correlation between the chemical composition changes during the roasting process.

RESULTS AND DISCUSSION

Coffee beans contain, in addition to water and minerals, a large number of organic substances. The main component of coffee beans are carbohydrates. The coffee beans contain various hemicelluloses, starch, oligosaccharides and mainly sucrose. The amount of monosaccharides is relatively small. Other substances contained in coffee are proteins, non-protein nitrogenous substances, phenolic substances, non-volatile organic acids, volatile substances and oils **(Arya and Jagan Mohan Rao, 2007; Farah and Marino Donagelo, 2006; Redgwell and Fisher, 2006)**.

Concentration of sucrose in green coffee beans and in roasted coffee beans is presented in Table 1 and Table 2. The results show that sucrose degradation occurs during the roasting process. Sucrose degradation is explained by sucrose hydrolysis to glucose and fructose, which may be further fragmented to form aliphatic acids, or which may participate in Maillard reactions with proteins or amino acids **(Ginz et al. 2000)**. The sucrose concentration decreased in the middle of the roasting process by 47% in the case of Medium roast and by 59% in the case of Full city roast. At the end of the roasting process, almost all sucrose has already been degraded (96 – 98%).

Another substance that has been observed to reduce the concentration during the roasting process was chlorogenic acid. Concentration of chlorogenic acid in green coffee beans and in roasted coffee beans is presented in Table 3 and Table 4. Chlorogenic acid concentration decreased in the middle of the roasting process by 45% in the case of Medium roast and by 42% in the case of Full city roast. At the end of the roasting process, 67% of chlorogenic acid contained in green coffee was degraded during Medium roast and 85% during Full city roast. Chlorogenic acid is involved in colour, flavour and aroma formation of coffee **Farah and Marino Donagelo, 2006; Farah et al., 2005)**. Major degradation products of chlorogenic acid are melanoids and low molecular weight compounds.

Strong significant correlation was found between sucrose concentration and concentration of organic acid during coffee roasting (r >0.9).

Concentration of organic acid in coffee during the roasting process is shown in Table 3 and Table 4. While the sucrose concentration in coffee decreases during roasting, the concentration of organic acids significantly increases. The most significant change was found in the lactic and formic acid content. The content of these acids in coffee beans rose almost 100 times after coffee roasting. Trend of changes in the concentration of organic acids was similar for Medium roasting and French roasting, however in the case of French roasting decrease in organic acid content was observed in the later stage of roasting. **Ginz et al. (2000)** lists the content of organic acids in Robusta coffee after roasting to be approximately 2 $mg.g^{-1}$ in the case of formic acid and acetic acid and 0.2 $mg.g^{-1}$ in the case of lactic acid. Formation of organic acids in coffee is described by Lobry-deBruyn-vanEckenstein rearrangement reaction in which fructose or glucose produced by sucrose hydrolysis is involved, and by formation of 1,2-endiole or 2,3-endiole as acid precursors **(Ginz et al., 2000)**. Formation of organic acids in coffee during roasting process did not significantly affect the pH of the coffee (Table 1 and Table 2.). This finding can be caused due to highly complex buffering effects and the wide distributions of salts and acids present in coffee. **Jeszka- Jeszka-Skowron et al. (2016)** measured pH value

of water treated Brazil Arabica green coffee to be 4.92. **Ginz et al. 2000** monitored pH changes in Robusta coffee during the roasting process and recorded pH change from 6.1 to 5.7 similar to this study (Table 1 and Table 2).

Another strong correlation was found between chlorogenic acid concentration and caffeic acid concentration in the case of Medium roast (r = 0.8025). However, in the case of Full city roast, this correlation was not significant and week (r = 0.2403). Chlorogenic acid is an ester of quinic acid and phenolic acid, mostly caffeic, ferulic or 3-hydroxycinnamic acid **(Farah and Marino Donagelo, 2006)**. During shorter roasting at lower temperatures chlorogenic acid can be hydrolysed and concentration of caffeic acid in coffee beans may temporarily increase. On the other side, with longer roasting times and higher temperatures, caffeic acid released from chlorogenic acid can be further degraded. From the results summarized in Table 4 it can be seen a significant increase of caffeic acid concentration in roasted coffee beans and subsequent reduction of caffeic acid concentration over longer periods of roasting. The formation of phenolic substances during roasting of coffee is also evident from the total concentration of phenolic compounds presented in Table 1 and Table 2. Measured concentrations of chlorogenic acid, caffeic acid or total phenolic compounds in this study are comparable with data published in literature. Chlorogenic acid concentration in green coffee beans is reported within the

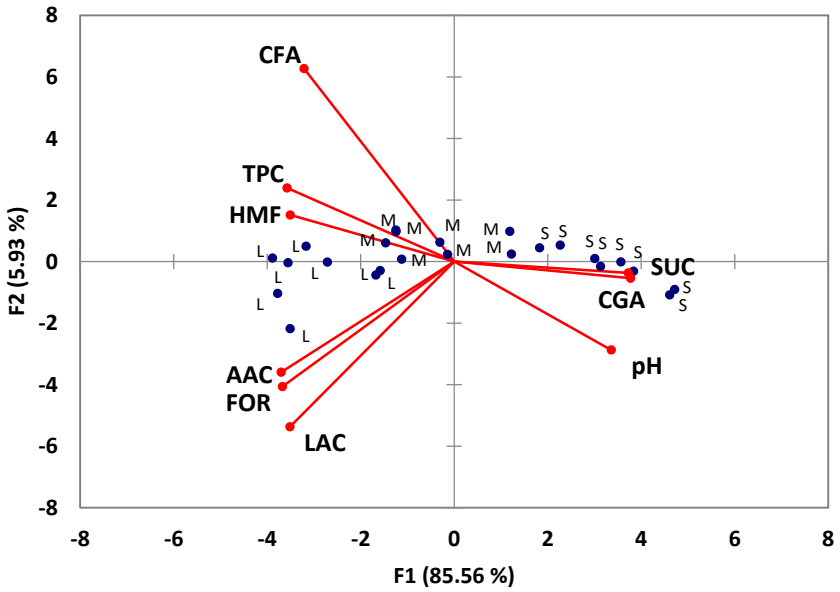

Figure 1 PCA score of the monitored analytes in coffee beans roasted on Medium roast degree. Note: S = short time of roasting (0 – 6 min), M = medium time of roasting (7 – 10 min), L=long time of roasting (8 – 14min). CGA = chlorogenic acid, SUC = sucrose, LAC = lactic acid, FOR = formic acid, AAC = acetic acid, HMF = hydroxymethylfurfural,
TPC = total phenolic compounds, CFA = caffeic acid.

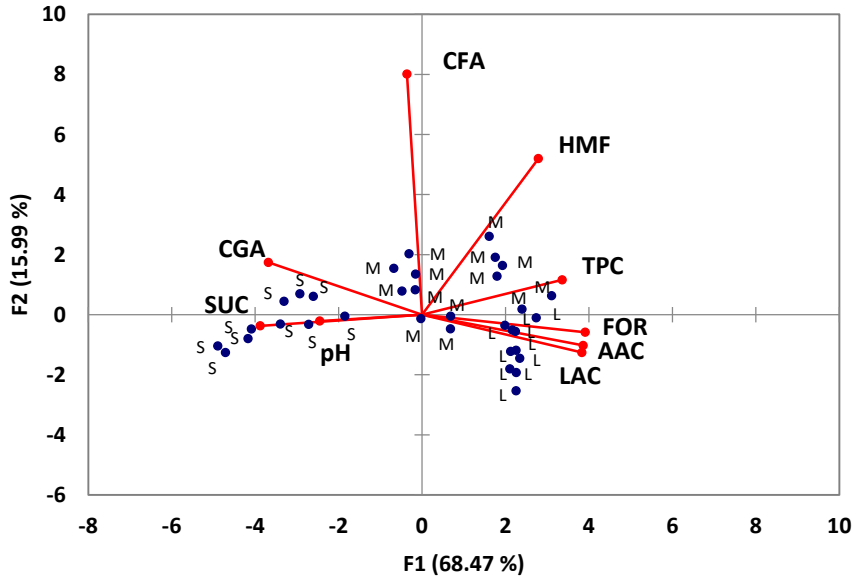

Figure 2 PCA score of the monitored analytes in coffee beans roasted on Full city roast degree. Note: S = short time of roasting (0 – 7 min), M = medium time of roasting (8 – 14 min), L = long time of roasting (15 – 19 min). CGA = chlorogenic acid, SUC = sucrose, LAC = lactic acid, FOR = formic acid, AAC = acetic acid, HMF = hydroxymethylfurfural, TPC = total phenolic compounds, CFA = caffeic acid.

range of 34 – 57 mg.g^{-1} while in roasted coffee beans in the range of 2 – 19 mg.g^{-1} **(Ludwig et al., 2014; Narita and Inouye, 2015; Farah and Marino Donagelo, 2006; Moon, Yoo and Shibamoto, 2009)**.
Total phenolic compounds content in coffee is reported to be 14 – 30 mg.g^{-1} (gallic acid equivalent) while caffeic acid content in coffee is reported to be 1.4 – 3 mg.g^{-1} **(Bauer et al., 2018; Hall, Yuen and Grant, 2018)**.

Almost all foods that are heat-treated are monitored for content of 5-hydroxymethylfurfural. This compound is generated in food by the Maillard reaction **(Antal et al., 1990)**. Increased interest in 5-hydroxymethylfurfural stems from a partially verified suspicion that this compound is a health hazard compound that may be mutagenic, carcinogenic and cytotoxic **(Abraham et al., 2011)**. The content of 5-hydroxymethylfurfural in roasted coffee is reported to be 0.3 – 1.9 mg.g^{-1} **(Murkovic and Pichler, 2006)**. In this study, maximum concentration of 5-hydroxymethylfurfural was measured to be 0.549 mg.g^{-1} in coffee during Full city roast. During Medium roast

maximum content of 5-hydroxymethylfurfural was found to be 0.346 mg.g^{-1}. Relatively interesting is the course of 5-hydroxymethylfurfural concentration during roasting. During both Medium and Full city roast two sharp maxima in 5-hydroxymethylfurfural concentration were recorded, which could correspond to the first and second crack in coffee beans. After reaching the second maximum, concentration of 5-hydroxymethylfurfural in coffee decreases, because of its degradation to organic acids **(Murkovic and Bornik, 2007)**.

To investigate the overall composition changes during the roasting process, PCA was performed on the data for all coffee bean extracts at different time of roast. The roasting process was divided into three categories according to the total roasting time (short, medium and long time). The results are shown in Figure 1 and Figure 2. The PCA plots confirmed that sucrose and chlorogenic acid degraded during the roasting process and also that with longer roasting times the content of organic acids in coffee increases. Both Figures 1 and Figures 2 also show that content of 5-hydroxymethylfurfural is the highest in medium roasting times.

CONCLUSION

This study proved that coffee roasting is a complex chemical process. The basic processes detectable during coffee roasting are the decomposition of sucrose and chlorogenic acid. Almost all sucrose is degraded during roasting independently of the roasting method. Degradation of chlorogenic acid is higher with longer roasting at higher temperatures. During the Full city roast (225 °C, 19 min) up to 85% of chlorogenic acid was degraded. Degradation products of sucrose and chlorogenic acid are low molecular organic acids and phenolic acids. Formic or lactic acid concentrations in coffee beans increased up to 100-fold during roasting. The increase in the concentration of phenolic compounds was not so steep, but it was observable. From the measured results, it cannot be clearly stated that with higher temperature and with higher roasting time concentration of 5-hydroxymethylfurfural is increasing. Highest concentrations of 5-hydroxymethylfurfural were measured at medium roasting times at both Medium and French city roasting temperatures. Conversely, at shorter roasting time and lower temperature higher concentrations of 5-hydroxymethylfurfural were found at the end of roasting.

INCREASING OF SELENIUM CONTENT AND QUALITATIVE PARAMETERS IN TOMATO (*LYCOPERSICON ESCULENTUM* MILL.) AFTER ITS FOLIAR APPLICATION

Alena Andrejiová, Alžbeta Hegedűsová, Samuel Adamec, Ondrej Hegedűs, Ivana Mezeyová

ABSTRACT

The effect of genotype and selenium foliar biofortification in the form of an aqueous solution of sodium selenate on the content of total carotenoids, vitamin C, total polyphenols and selenium content in the tomato fruits was studied. Field experiment was held in the Botanical garden of the Slovak University of Agriculture in 2016. Seven determinant varieties of tomato in the two variants were observed. The results of experiments show that treatment of plants with the dose of Se concentration (150 g Se.ha^{-1}) at the flowering stage significantly increased the total Se content in the in tomato fruits. Foliar application of selenium had a positive effect on the increase of total polyphenol. The influence of Se biofortification on the content of vitamin C and carotenoids was not detected. Selenium foliar fertilization in dosage 150 g.ha^{-1} is suitable way of tomato fruits enriching in polyphenols, without negative effect on other antioxidants content.

Keywords: tomato; selenium; biologically active substances; biofortification

INTRODUCTION

The tomato (*Lycopersicon esculentum* Mill.) is ranked first in terms of world vegetable production. Over the last 20-year horizon, its production (more than 170 million tons per year) has doubled, while in Asian countries as China and India was recorded the most significant increase in production. The states of European Union together produce 16.9 million tonnes, while the greatest producers are Italy and Spain **(FAOSTAT, 2014)**. Within Slovakia, in 2017 were tomatoes cultivated on production area of 597 ha with a total production of 21,963 t **(Meravá, 2017)**.

Latest research highlights the relationship between consuming tomato and its products with reduced risk of various maladies like obesity, hyperglycemic and hypercholesterolemic attributes, cardiovascular disorders, and cancer insurgences. Moreover, tomato and its bioactive components hold potential to become effective modules in diet-based regimens **(Perveen et al., 2015)**. They are consumed like a functional food all over the world because of health promoting compounds in its fruit. The main reason is due to the presence of different antioxidant molecules such as carotenoids, ascorbic acid, vitamin E and polyphenol compounds such as flavanones, flavonols **(Vallverdú-Queralt, 2012)**, flavonoids **(Frusciante et al., 2007)** and other.

According to various authors, the total carotenoids content as well as lycopene in fresh tomato fruits depends mainly on genotypes, as well as on the maturity degree, growing conditions and agricultural technologies **(Carli et al., 2011; Mendelová, Fikselová and Mendel, 2013; Mendelová et al., 2015; Andrejiová et al., 2015)**. The content of carotenoids and in particular lycopene in the fruits of red tomatoes varieties is increased 10 to 14 times during vegetation **(Thompson, 2015)**.

Ascorbic acid (AA) also named vitamin C is an essential micronutrient soluble in water. It is occurring in almost all living organisms. The people, as well as a number of other animals cannot synthesize the vitamin C in their bodies and therefore it can be taken only through the diet. Following **Pinela et al. (2012)** ascorbic acid was the most abundant antioxidant in all tomato samples (following vitamins, carotenoids and phenolics).

Polyphenols are secondary metabolites of plants and are generally involved in defence against ultraviolet radiation or aggression by pathogens. In the last decade, there has been much interest in the potential health benefits of dietary plant polyphenols as antioxidant **(Pandey and Rizvi, 2009)**. The free radical scavenging, in which the polyphenols can break the free radical chain reaction, as well as suppression of the free radical formation by regulation of enzyme activity or chelating metal ions involved in free radical production are reported to be the most important mechanisms of their antioxidant activity **(Vladimir-Knežević et al., 2012)**. The content of polyphenols was more dependent on year and cultivar than on cultivation conditions **(Anton et al., 2014)**.

Table 4 Agrochemical characteristics of the soil before the foundation of the experiment in 2016.

Humus, %	pH/KCl	Nutrients content in $mg.kg^{-1}$ of the soil					
		Nan	P	K	S	Ca	Mg
4.17	7.14	13.0 M	198.8 VH	487.5 VH	26.25 M	610 H	816 VH

Note: Nutrient content: M – medium content. H – high content. VH – very high content.

Tomatoes contain minerals such as calcium, magnesium, iron and potassium, as well as microelements such a copper, zinc and manganese. Moreover, the tomatoes are ranged in to the vegetables with the highest concentration of selenium (0.034 $mg.kg^{-1}$). Selenium (Se) is ultramikroelement, essential trace mineral and antioxidant. It is essential for the growth of animals and humans. That's the reason of its repeated using in biofortification programs. In the soil Se is rapidly reduced to insoluble forms and usually less than 10% of the applied Se was taken up by the crop. Another method of transferring Se to plants is foliar application of Se, either as sodium selenate or sodium selenite **(Haug et al., 2007)**. In recent years, selenium research attracts great interest because its activity plays an important role in protection against oxidative stress, initiated by redundant reactive oxygen forms (ROS) and reactive nitrogen forms (NOS). The increased risk of diseases such as cancer and heart disease, and also civilization diseases are associated with low income of selenium **(Tinggi, 2008)**.

Plants receive selenium from the growing medium in the form of inorganic compounds and they subsequently incorporate it thanks to selenocysteine in to its proteins **(Hegedűs, 2005)**. Foliar application was significantly several times more effective than the application of fertilizers **(Aspila, 2005)**. At foliar application the selenium ions diffuse from the surface of leaves to epidermal cells. There is strong correlation between solution concentration on the leaf surface and ions absorption rate, anyway, too high concentration can damage the leaf surface **(Wójcik, 2004)**. Absorption rate is limited with damage of ectodesmata **(Ježek et al., 2012)**.

The aim of the work was to monitor the effect of genotype and selenium foliar biofortification in the form of an aqueous solution of sodium selenate on the content of total carotenoids, vitamin C, total polyphenols and selenium in the tomato fruits.

Scientific hypothesis

Foliar application of selenium, in the form of sodium selenate, had a significant effect on the increase of the Se content in tomato fruits. Other antioxidants such a vitamin C and carotenoids will not be negatively affected. The concentration of total carotenoids and polyphenols is variety dependant.

MATERIAL AND METHODOLOGY

The trial establishment

An experiment was founded in 2016 in Botanical Garden of Slovak University of Agriculture (below BG SUA) in field conditions. Area is situated in very warm agro-climatic region, very dry sub-region. The mean annual temperature was 10 °C. Meteorological measurements were carried out by the help of meteorological station in the area of botanical garden, SUA in Nitra. The mean monthly air temperature and average rainfall for the year 2016 were evaluated by the climate normal 1961 – 1990 (Table 1 and Table 2). Sowing was carried out on March 14th, 2016 in a heated greenhouse BZ SUA. There were included 7 tomato determinate varieties (Table 3). According to the techniques of tomato cultivation it was done preparing of the land. According to agrochemical analysis of the soil (Table 4) in case of all three variants there was applied nitrogen fertilizer DASA®26/13 – Ammonium nitrate with sulfur (26% N and 13% of S) in dosage 254 kg.ha^{-1} (60% of recommended normative).

The field experiment was established by block method in three replications, plants were planted in uniform plant spacing 0.7 x 0.3 m. Planting of pre-growing planting was carried out on May 15th, 2016. According to necessity the supplementary irrigation was applied, as well as loosening and weeding of the crop. The application of selenium was done on June 26th, 2016 at the growth stage of fruits creation on the first inflorescences and second inflorescence establishment. Selenium was foliar applied in solution Na_2SeO_4. During the growing season the crop is in the process of setting up third-fourth inflorescence fertilization with nitrogen fertilizers DASA®26/13 (169 kg.ha^{-1}, it means 40% of the recommended normative). In the second half of vegetation protection of the plants against fungal diseases was carried out. Collection was realized in August 17th, 26th and in September 9h, 14th 2016 in full botanical ripeness of the fruits. In the small plot experiment there were observed the following options:

1st variant (K) – without applying of selenium (control),

2nd variant (Se) – selenium was applied in dosage of 150 g.ha^{-1}.

Laboratory analysis

For laboratory analysis were used only fresh fruits in full botanical maturity of all observed varieties of tomato after first harvesting of the fruits. Both control as well as the variant fortified with sodium selenite were used. An average sample of 2000 g was prepared from the harvested fruit yield. We homogenized the opposite two quarters of each sliced fruit within average sample and used it for the determination of total carotenoids and vitamin C content. Fresh fruit analysis was performed within 24 hours after harvest.

Qualitative characteristics

The qualitative characteristics were estimated in laboratory of Department of vegetable growing, SUA, in Nitra involving:

Total carotenoids estimation – Carotenoids were estimated by spectrophotometric measurement of substances absorbance in petroleum ether extract on spectrophotometer PHARO 100 Spectroquant® at 450 nm wavelengths.

Ascorbic acid estimation (AA) – HPLC method of vitamin C content estimation **Stan, Soran and Marutoiu (2014**) was used by the help of liquid chromatograph with UV detector, for separation was used RP C18 column, mobile phase was methanol:water (5:95, v/v), UV detection was adjusted to 258 nm (HPLC fy. VARIAN).

Total polyphenols content estimation (TPC) – total polyphenols were determined by the method of **Lachman (2011)** and expressed as mg of gallic acid equivalent per kg fresh mater. Gallic acid is usually used as a standard unit for phenolic content determination because a wide spectrum of phenolic compounds. The total polyphenol content was estimated using Folin-Ciocalteau assay.

Selenium content – mineralization of the plant material took place in the microwave mineralizer type CEM Mars X–press (microwave digestion oven). Quantitative determination of Se was done by using of ET-AAS method with Zeeman background correction. Atomic absorption spectrometer SpectrAA240FS (Varian, Mulgrave Virginia, Australia) was used to measure the total selenium content **(Hegedűs et al., 2008)**. Conditions for selenium measurement were set in the equipment according to the recommendations of the manufacturer **(Rothery, 1988)** for ET-AAS technique. In the research, chemicals with analytical purity were used.

Statistic analysis

The analysis of variance (ANOVA), the multifactor analysis of variance and the multiple Range test were done using the Statgraphic Centurion XVII (StatPoint, USA).

RESULTS AND DISCUSSION

Total carotenoids content

The total carotenoid content in the fresh fruits of our observed hybridized tomato varieties ranged from 8.17 to 10.28 mg.100g^{-1} of fresh matter for control variant and from 8.03 to 11.45 mg.100g^{-1} after selenium application (Table 5). The highest carotenoid content obtained UG-Red F1 variety. The average values in our tested varieties were comparable to those of **Mendelová et al. (2012)** showing an average content of total carotenoids in tomato varieties (Báb, Žiara PK, Champion, Roti) ranging from 4.8 to 7.0 mg.100g^{-1}.

Due to the foliar application of selenium, we observed a slight decrease in total carotenoid content in three hybrid varieties: Townsville F1, Triple Red F1 and Brixol F1. For other varieties of tomatoes, foliar application of selenium has resulted in increased carotenoid content.

Based on statistical evaluation of the data obtained by the multifactor analysis of variance, we can state that the variety had a proven impact on the total carotenoids content in fresh fruits and tomato juice. The effect of the variant on the total carotenoid content in fruits wasn´t statistically significant (Figure 1).

Table 5 Carotenoids content in estimated varieties (mg.100g^{-1} FM). Nitra 2016.

Variety/variant	K	Se
Townsville F1	9.23 ±0.20ab	8.03 ±0.20a
Uno Rosso F1	8.17 ±0.14ab	8.68 ±0.40a
Torquay F1	9.82 ±0.44bc	9.80 ±1.27ab
Durpeel F1	9.84 ±0.69bc	10.05 ±1.01ab
Brixol F1	9.91 ±1.27bc	8.06 ±0.52a
Triple Red F1	10.15 ±0.14c	8.21 ±0.37a
UG-Red F1	10.28 ±0.18c	11.45 ±0.51b

Note: Average ±standard deviation. The different letters listed with the mean values in the columns represent statistically significant differences between the observed varieties (p <0.05).

Table 6 Total polyphenols content (TPC) in lyophilized tomato fruits (mg GAE.kg^{-1}) depending on the observed tomato varieties and variants.

Variety/variant	K	Se
Durpeel F1	3588.30 ±73.86a	3603.40 ±45.47a
UG-Red F1	3975.00 ±73.32b	3989.00 ±51.21b
Triple Red F1	4233.55 ±56.36c	4605.28 ±49.30c
Brixol F1	4600.20 ±47.83d	4842.15 ±65.55d
Townsville F1	4752.07 ±32.17e	5223.75 ±74.36e
Uno Rosso F1	4870.83 ±43.13f	3938.53 ±75.81b
Torquay F1	4944.78 ±73.77f	5350.70 ±65.75f

Note: Average ±standard deviation, K – control (0 g.ha^{-1} Se), Se – selenium (150 g.ha^{-1} Se). The different letters listed with the mean values in the columns represent statistically significant differences between the observed varieties (p <0.001).

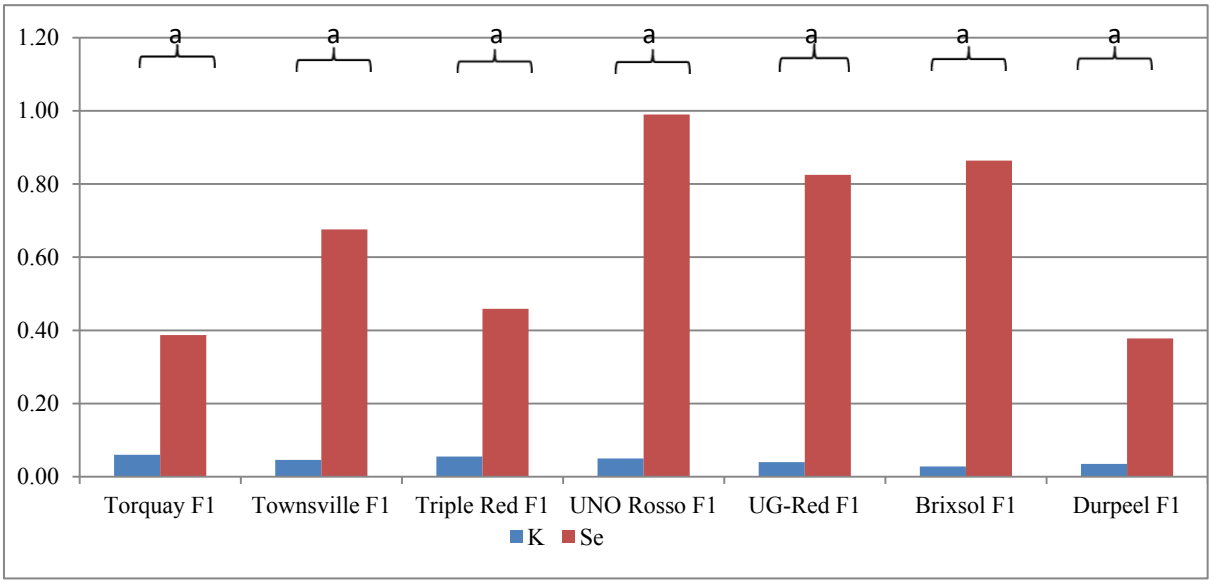

Figure 6 Selenium content (mg.kg^{-1} of dry matter) in fruits depending on the observed tomato varieties and variants (K – 0 g.ha^{-1} Se; Se – 150 g.ha^{-1} Se) Note: Statistically insignificant differences between varieties are indicated by the same letters (p >0.05).

Vitamin C content

Vitamin C (ascorbic acid) is one of the most important antioxidants in tomato. The content of antioxidants in tomato fruits depends on a number of factors such as ripeness, cultivation conditions and the variety itself **(Hart and Scott, 1995; Kotíková et al., 2011),** while the skin of fruits contains more vitamin C than the flesh **(George et al., 2004).**

Carli et al. (2011) tested 7 parental lines and 8 tomato hybrids and found that the vitamin C content in the fruits ranged from 9.1 to 16.1 mg.100g^{-1} of fresh matter. Our results show that similar levels of vitamin C content have also been found in our experiment. The vitamin C content

measured in fresh fruits of 7 hybrid tomato varieties was ranging from 11.90 to 19.44 mg.100 g^{-1} for control variant and from 11.46 to 20.14 mg.100g^{-1} of fresh mass for variant with foliar application of selenium (Figure 3).
The highest vitamin C content was in the Triple Red F1 variety in both experimental variants. Foliar application of selenium has a positive effect on the vitamin C increase only in Troquay F1, Townsville F1 and Triple Red F1 and Brixol F1 varieties.

By statistical analysis of the obtained data based on vitamin C content we can conclude, that the effect of the variety on the vitamin C content in the fruits of evaluated *Lycopersicon esculentum* varieties has been proven (Figure 3). Among the observed variants, we didn´t find any significant differences in the vitamin C content in fresh tomato fruits (Figure 2).

Total polyphenols content

During the evaluation of total polyphenol content in tomato fruit, we found that within the selenium control variant, polyphenols content ranged from 3588.30 mg GAE.kg^{-1} of dry matter in Durpeel F1 variety to 4944.78 mg GAE.kg^{-1} dry matter in Torquay F1 variety. Similar results are also reported by **Luthria, Mukhopadhyay and Krizek (2006)**, who determined the total polyphenols in tomatoes ranging from 3400 to 4400 mg GAE.kg^{-1}.

By foliar application of selenium at a dose of 150 g.ha^{-1}, all of the tomato varieties, except the Brixol F1 variety, increased the content of polyphenols in its fruits. For this variant, the content of total polyphenols ranged from 3603.40 mg GAE.kg^{-1} to 5350.70 mg GAE.kg^{-1} of dry matter (Table 6).

Kavalcová et al. (2014), based on the onion field experiments reported that the sodium selenate applied in different doses didn´t have a significant effect on the total polyphenols content in the consuming parts of evaluated onion varieties.

On the contrary, authors **Hegedűsová et al. (2017)**, on the basis of two-year field experiment, confirmed the significant influence of foliar application of selenium on increasing the polyphenols content in peas within two varieties of *Pisum sativum*.

By statistical evaluation of our results, we can conclude that the effect of the variety on the total polyphenols in the fruits was statistically significant. Although the effect of foliar application of selenium had a slight increase in the total polyphenols in the fruits, the effect of the variant on the total polyphenols content wasn´t confirmed (Figure 4).

Selenium content

To ensure the necessary income of selenium by human population, different ways of supplementing are used in the world. One of them is the addition of selenium into fertilizer preparations, which according to the authors **Ducsay, Ložek and Varga (2007)** can be considered as the most effective method of selenium intake, whereby selenium gets into individual food chain links. During the evaluation of the effect of selenium foliar application on selenium content in tomato fruit we found, that in experimental year 2016 selenium content in the fruits of studied varieties ranged in the control variant from 0.028 mg.kg^{-1} to 0.060 mg.kg^{-1} of dry matter. Foliar application of selenium caused an increase in selenium content in the fruits of observed tomato varieties and its content was in the range of 0.378 mg.kg^{-1} in a variety Durpeel F1 to 0.990 mg.kg^{-1} dry matter in a variety Uno Rosso F1 (Figure 6). **Hegedűsová et al. (2017)** also wrote about the positive effect of foliar application of selenium in the form of sodium selenate in the blooming phase of the pea,on the increase of selenium content in immature seeds (varieties: Ambrosador and Premium). They point to the fact that the total content of selenium in the consuming part is affected not only by the dose of applied selenium but also by the climatic conditions of the given growing year.

Using the statistical analysis of variance, we didn´t detect the difference in selenium content between the evaluated varieties. We recorded a statistically significant effect of the variant on the selenium content in tomato fruits (Figure 5).

CONCLUSION

Foliar application of selenium, in the form of sodium selenate, had a significant effect on the increase of the Se content, but did not affect the content of total carotenoids, and vitamin C in the fruits of tomato. The 150 g.ha^{-1} selenium dose slightly increased the total polyphenols content in the fruits. This way it is possible to enrich the tomatoes in selenium and polyphenols, which are antioxidants and to enhance healthy effects of the fruits. Based on our results, we can conclude that a shortage of daily selenium could be supplemented by consuming 250 g of fresh tomatoes foliar selenized with an average selenium content of 42 µg.kg^{-1} of fresh matter.

HYGIENIC QUALITY AND COMPOSITION OF RAW SHEEP'S BULK MILK SAMPLES ON SELECTED SLOVAK FARMS DURING YEAR 2018

Martina Vršková, Vladimír Tančin, Michal Uhrinčať, Lucia Mačuhová, Kristína Tvarožková

ABSTRACT

At the control of raw ewe's milk (REM) quality is a major microbiological criterion to the total bacterial count (TBC). The aim of our work was to determine the incidence of technologically important species of microorganisms in REM in Slovak Republic. At the monitored 28 ewe´s farms, we took bulk milk samples from evening or morning milking in spring, summer and autumn during year 2018. We analyzed nutrients (fat, protein, lactose and urea) and somatic cell count (SCC). We established technologically important microorganisms (MO) of psychotrophic MO, coliform MO, thermoresistant MO, spore-forming anaerobic MO. We have found a gradual increase in milk components, except for lactose, which is apparently related to the increasing cont of somatic cells during the milking period. We found that the TBC in raw sheep's milk complied an average of 132 x 10^3 CFU.mL^{-1} per spring (min 34 x 10^3 CFU.mL^{-1}, max 501 x 10^3 CFU.mL^{-1}), 300 x 10^3 CFU.mL^{-1} in summer (min. 31 x 10^3 CFU.mL-1, max 640 x 10^3 CFU.mL^{-1}) and in autumn with an average value of 147 x 10^3 CFU.mL^{-1} (min 52 x 10^3 CFU.mL^{-1}, max 276 x 10^3 CFU.mL$^{-1)}$. The enormous occurrence of psychrotrophic bacteria was found in one farm in northern Slovakia during spring and summer, in the summer we increased our number to 3 farms, in the autumn of 2 farms. At the other farms we evaluated the average value of 12 x 10^3 CFU.mL^{-1} per spring and 28 x 10^3 CFU.mL^{-1} in summer, 130.5 x 10^3 CFU.mL^{-1} in the autumn. The count of thermoresistent MO achieved 57 CFU.mL^{-1} per spring, 15 CFU.mL^{-1} in summer and 33 CFU.mL^{-1} in the autumn. The presence of spore-forming anaerobic MO in raw ewe´s milk was found during spring at six farms out of 15, but in the summer at just one in 9, in the autumn two farms.

Keywords: SCC; TBC; microbiological quality raw ewe´s milk; milk composition

INTRODUCTION

In Slovakia sheep farming is focused on milk production. The increase in dairy yield was ensured by imports of specialized milk breeds, lacaune or East Friesian sheep and their subsequent crossing with our sheep breeds (Tsigai, Improved Valachian) **(Tančin et al., 2013)**. Ewe's milk was much more concentrated with about twice as much fat and 40% more protein that cow and goat milk. That also found that sheep milk responded differently in the cheese make procedure. It was more sensitive to rennet, coagulated faster, produced a firmer curd and yielded more cheese per unit of milk than cow milk **(Wendorff and Haenlein, 2017)**.

The quality of milk includes, in broad terms, the chemical composition, physical and technological properties, biochemical, microbiological and health indicators. In the narrower sense, we can only talk about hygienic (microbiological) aspects. Each of these features includes a number of quality features that determine the resulting quality of milk but also the quality of the dairy products. The quality of raw milk is regularly checked, because milk is the ideal environment for developing microorganisms because of its high water and nutrient content. All unwanted bacteria may not be pathogenic to humans. There are species that cause technological problems by producing thermostable lipolytic and proteolytic extracellular enzymes that pass through pasteurization in the active form. In order to avoid risks, and to ensure hygiene-sanitary quality and raw cows', sheep's and goats' milk safety, in its **Regulations (EC) Nos. 852/2004** and **853/2004 European legislation** lays down general food hygiene rules and specific ones for food of animal origin. It also sets out aspects relating to mandatory controls (EC) No. 853/2004 on raw milk production on farms, and in dairy centres and laboratories. Raw milk has to be tested for not only its physico-chemical composition, but also for its hygienic characteristics, such as microbiology, somatic cell count (SCC) **(Martínez et al., 2018)**. According to which the total bacterial count (TBC) in 1 mL of raw sheep's milk (at 30 °C) must not exceed 1 500 000 CFU and for raw milk for further processing not subjected to heat treatment, this number is reduced to 500 000 CFU. The TBC in the raw sheep's milk delivered indicates the overall level of breeding hygiene and technology of harvesting (machine

and hand milking) and milk storage. TBC reflects the hygiene of breeding conditions in milk production and is in the hands of the breeder itself. Bacterial contamination comes from a variety of sources, such as flora and pathogens present in hives, milking facilities, during storage and transport, feeding, rinsing water, udder or mastitis milk. Some of these bacteria are resistant to pasteurization or are able to grow at refrigeration temperature or to indicate fecal contamination, mastitis, or they can ferment lactic acid to butter, CO_2 and H_2, which cause late flushing of the cheese **(Gonzalo, 2017)**.

Scientific hypothesis

The occurrence of individual species of technologically significant microorganisms is influenced by the hygiene of obtaining milk in the milking process.

MATERIAL AND METHODOLOGY

At the monitored 28 ewe´s farms, we took bulk milk samples from evening or morning milking in March, April and May (spring), in June, July and August (summer) and September, October, November (autumn) during year 2018. Nutrients (fat, protein and lactose) were analyzed using the MilkoScan FT 120 (Foss Electric, Hillerød, Denmark). Somatic cell count (SCC) were set on the Somacount 150 (Bentley Instruments, Chaska, MN, USA). Urea was determined by polarimetry method. We analyzed the total bacterial count (TBC, mandatory indicator according to EC Regulation No. 1662/2006) according to **STN ISO 4833:1997**. We established technologically important microorganisms (MO) of psychotrophic MO according to **STN ISO 6730:2000** and coliform MO according to **STN ISO 4832:1997**. The presence of thermosensitive MO was detected in the Plate-Count-Agar and the presence of spore-forming anaerobic MO by liquid paraffin irrigation.

Statistic analysis

The values were evaluated through mean and standard deviation by Microsoft Excel 2013.

RESULTS AND DISCUSSION

It is known that the fat and protein content of milk is dependent on nutrition, and indirectly, nutrition will also affect the solids-non-fat (SNF) of milk. In Table 1 are presented the basic composition of milk and non-fat dry matter during the milking period. We have found a gradual increase in milk components, except for lactose, which is apparently related to the increasing number of somatic cells during the milking period and consequently the health of the milk udders.

Both fat and protein tend to increase throughout the lactation as well as **Kuchtík et al. (2017)**. This would typically result in higher cheese yields in late lactation milk **(Wendorff and Haenlein, 2017)**. As the SCC increases in the milk supply, the composition of milk also changes. As SCC increased, milkfat and the Casein/Total Protein ratio decreased. Protein recovery rate was lower in the high SCC milk while cheese yield was not significantly different.

Bocquier and Caja (2004) are reported that a high level of nutrition will reduce the level of milkfat but increase milk protein and casein. Conversely, a negative energy balance will decrease milk protein and increase milkfat. Milk protein will increase with an increased level of dietary protein. When feeding higher levels of concentrate in the diet, milkfat will be decreased and milk protein will be increased. The degree of impact from nutrition of the ewe will obviously be limited by the potential milk production capacity of the animal dictated by genetics. These trends are consistent with our results. Urea content depended on feed intensity, feeding system and pasture quality.

In Table 2, we presented the species of the most important technological types of bacteria. We found that the TBC in raw sheep's milk complied with the requirements of **Commission Regulation No. 1662/2006** with an average of 132 x 10^3 CFU.mL^{-1} per spring (min 34 x 10^3 CFU.mL^{-1} and max 501 x 10^3 CFU.mL^{-1}),

Table 1 Milk composition during the milking period.

Season	SNF		Milk composition (%)						Urea	
			fat		protein		lactose		%	
	mean	St.deviation	mean	St.deviation	mean	St.deviation	mean	St.deviation	mean	St.deviation
spring	11.26	0.59	7.50	1.61	5.56	0.58	4.84	0.45	42.39	12.44
summer	11.65	0.32	7.91	0.85	5.95	0.32	4.81	0.15	61.82	7.75
autumn	11.74	0.53	8.69	0.29	6.52	0.30	4.29	0.54	55.87	7.62

Note: SNF – solids non-fat.

Table 2 Hygienic quality of raw sheep's milk.

Microbiological characteristics (x 10^3 CFU.mL^{-1})	spring (n = 15)		summer (n = 9)		autumn (n = 4)	
	mean	St.deviation	mean	St.deviation	mean	St.deviation
TBC	132.13	87.71	300.00	217.01	147.00	124.78
Psychrotrophs MO	12.33	40.87	33.86	3.87	13.05	4.50
Coliforms MO	0.40	-	3.61	-	0.30	-
Termorezistant MO v 1 mL	57.69	29.31	13.33	11.15	40.50	33.27
SCC (x 10^3.mL^{-1})	1229.93	818.40	1411.08	770.25	2468.25	1147.14

Note: TBC – total bacteria count, SCC – somatic cell count.

300 x 10^3 CFU.mL^{-1} in summer (min. 31 x 10^3 CFU.mL^{-1} and max 640 x 10^3 CFU.mL^{-1}) and in autumn with an average value of 147 x 10^3 CFU.mL^{-1} (min 52 x 10^3 CFU.mL^{-1} and max 276 x 10^3 CFU.mL^{-1}). **Gonzalo (2017)** found similar TBC to our spring, **Martínez et al. (2018)** significantly lower values (49 x 10^3 CFU.mL^{-1}). **Vršková et al. (2017)** reported in the summer 2016 TBC range of 187 to 964 x 10^3 CFU.mL^{-1}. **Skapetas et al. (2017)** found a higher TBC of 494 x 10^3 CFU.mL^{-1} by SCC 313 x 10^3 cells in 1 mL. **Kondyli et al. (2012)** found lower TBC values in summer of 170 x 10^3 CFU.mL^{-1} than in the spring of 600 x 10^3 CFU.mL^{-1}. The microbiological quality of sheep's milk according to **Gamčíková and Hanzelyová (2009)** in the primary production is mainly affected by unmasked mastitis of ewes. **Carloni et al. (2016)** found a range between the farms at TBC of 2 to 865 x 10^3 CFU.mL^{-1} and SCC from 151 to 3384 x 10^3 cells in 1 mL. **Kološta and Dončovský (2006)** found an arithmetic mean TBC of 21.921 x 10^3 CFU.mL^{-1} of raw sheep's milk. **Ducková and Čanigová (2004)** determined the TBC from 57 x 103 to 3,400 x 103 CFU.mL^{-1} at an average of 580 x 103 CFU.mL^{-1}.

The somatic cells count (SCC) is not yet a mandatory indicator as it is for dairy cows. In the spring, 7 farms of 15 had SCC above 1000 x 10^3 cells in 1 mL. The remaining farms ranged from 131 to 825 x 10^3 cells in 1 mL. In the summer, SCC was in 5 farms over 1000 x 10^3 cells in 1 mL. The remaining four farms ranged from 60 to 965 x 10^3 cells in 1 mL. In the autumn there were 2 farms out of 4. The remaining two farms reached SCC 958 x 10^3 cells per 1 mL. **Martínez et al. (2018), Kuchtík et al. (2017)** and **Gonzalo (2017)** reported lower SCC than our results.

Season was an important effect associated with the variation of bulk tank milk prevalence for specific bacterial groups and pathogens. Psychrotrophic and coliform bacterial groups were highest in connection with more dirty beds and udders due to the wetter weather (ambient combinantion) and with beginning of milking season **(Gonzalo, 2017)**. Raw milk is stored in the primary production at 8 °C and can result in the growth of psychrotrophic microflora. Its proven relationship with a high incidence of lipolytic and proteolytic activities on milk and cheese components.

The enormous occurrence of psychrotrophic bacteria was found in one farm in northern Slovakia during spring and summer, in the summer we increased our number to 3 farms, in the autumn of 2 farms. We did not, therefore, enter statistical evaluation. We explain this by contaminating the milk in insufficiently disinfected and cooled collecting containers in accordance with statement **Ducková and Čanigová (2004)**. The remaining farms have a milking parlor and beside the dairy tank with cooling. At the other farms we are evaluated the average value of 12 x 10^3 CFU.mL^{-1} per spring and 28 x 10^3 CFU.mL^{-1} in summer, 130.5 x 10^3 CFU.mL^{-1} in the autumn. **Ducková and Čanigová (2004)** found up to 240 x 10^3 CFU.mL^{-1} psychrotrophic MO.

Thermodurics are a contaminant group of milk that contains thermophilic spore-forming bacteria which can survive pasteurization during dairy-product processing causing dairy-product spoilage in the post-processing **(Gonzalo, 2017)**. The count of thermoresistent MO achieved 57 CFU.mL^{-1} per spring, 15 CFU.mL^{-1} in summer and 33 CFU.mL^{-1} in the autumn. **Gonzalo (2017)** found a high incidence of thermoresistent MO (930 CFU in 1 mL) by the ewes.

Several studies in ewe bulk tank milk showed that the main on-farm management risk factors associated to an increase of spore counts were farm-made total mixed ration, the silages and wet brewer's grains used for feeding, and the presence of dust in the milking parlour **(Arias et al., 2013)**. The presence of spore-forming anaerobic MO in raw ewe´s milk was found during spring at six farms out of 15, but in the summer at just one in 9, in the autumn the count rose to two farms.

CONCLUSION

The amount of microorganisms in milk gives us an overall picture of the level of hygiene in the primary production. The degree of contamination of raw cows' milk with mesophilic and psychrotrophic microorganisms affects the dairy health and hygiene of dairy ewes, the hygiene of the milkers and the environment in which the ewes are farmed and milked, the methods used for the preparation of the udder and the milking technique, the methods used for cleaning and sanitizing milking equipment and bulk tank milk. Depending on the species of microorganisms found in milk, we can identify the source of contamination and then use the correct methods to eliminate them. For small ruminants, milk hygiene is important for serious economic and sanitary consequences for farmers, the processing industry and consumers due to the interrelationship between loss of production, yield in cheese production, excreted milk (and its safe disposal) and consequently the safety of dairy foods for the consumer. Consumers' demands on "natural" food, heat untreated, added preservatives or increased salt concentration are increasing. Such foods also include raw milk.

ANTIMICROBIAL ACTIVITY OF RESVERATROL AND GRAPE POMACE EXTRACT

Simona Kunová, Soňa Felšöciová, Eva Tvrdá, Eva Ivanišová, Attila Kántor, Jana Žiarovská, Margarita Terentjeva, Miroslava Kačániová

ABSTRACT

Resveratrol is commonly found in food and drinks, including red wine and grapes. Grape extracts have a potent antimicrobial activity *in vitro*. The antimicrobial activity of plant extracts is the base of their potential application in food preservation agents, pharmaceuticals, cosmetics, alternative drugs and natural therapies. The aim of our study was to evaluate the antimicrobial activity of resveratrol and Blue Frankish pomace extract against Grampositive and Gramnegative bacteria as well as yeasts from the genus *Candida*. Six bacterial strains (three Grampositive bacteria *Staphylococcus aureus* CCM 2461, *Enterococcus faecalis* CCM 4224 and *Listeria monocytogenes* CCM 4699; three Gramnegative bacteria *Escherichia coli* CCM 3988, *Pseudomonas aeruginosa CCM* 1959 and *Salmonella enteritidis subsp. enteritidis* CCM 4420) and three yeast strains (*Candida albicans* CCM 8186, *Candida krusei* CCM 8271 and *Candida tropicalis* CCM 8223) were evaluated using the antimicrobial assay. Pure resveratrol and grape pomace extracts of red variety Blue Frankish were used. Our results show that resveratrol and red grape pomace extract have a very good antimicrobial activity against Grampositive bacteria when compared with Gramnegative bacteria and yeasts.

Keywords: grape pomace extract; resveratrol; pathogenic bacteria and yeasts; antimicrobial activity

INTRODUCTION

Winemaking is currently one of the most relevant agro-industrial activities in the world. Undoubtedly, grapes are an abundant fruit crop worldwide, with *Vitis vinifera* being the species most frequently cultivated for wine production **(Pareja et al., 2015; Barba et al., 2016)**.

Resveratrol (3,5,4′-trihydroxystilbene) is a naturally occurring stilbenoid which has been gaining considerable attention in the medical field due to its diverse biological activities – it has been reported to exhibit antioxidant, cardioprotective, anti-diabetic, anticancer, and antiaging properties. Given that resveratrol is a phytoalexin, exhibiting an increased synthesis in response to infection by phytopathogens, there has been interest in exploring its antimicrobial activity **(Chan, 2002)**.

Although there is still very limited work on the antibacterial activity of resveratrol, it has been shown that resveratrol exhibits antibacterial activity against several Gram-positive and Gram-negative foodborne bacteria **(Chan, 2002; Tegos et al., 2002; Paulo et al., 2010; Paolillo, Carratelli and Rizzo, 2011; Alvarez, Moreira and Ponce, 2012; Alvarez, Ponce and Moreira, 2013; Kumar et al., 2012; Plumed-Ferrer et al., 2013; Augustine et al., 2014; Ferreira et al., 2014; Morán et al., 2014; Promgool, Pancharoen and Deachathai, 2014; Subramanian, Soundar and Mangoli, 2016; Duarte et al., 2015; Kim et al., 2014; Makwana et al., 2015; Ferreira and Domingues, 2016; Liu et al., 2016; Seukep et al., 2016; Silva et al., 2016; Surendran Nair et al., 2016; Klancnik et al., 2016; Lai, Chiu and Chiou, 2017; Lee and Lee, 2017; Oliveira, Domingues and Ferreira, 2017)**.

Based on the available literature, resveratrol has been demonstrated to exhibit different antibacterial activities against numerous strains of foodborne pathogens including *Staphylococcus aureus, Bacillus cereus, Bacillus subtilis, and Listeria monocytogenes, E. coli* O157:H7, *Salmonella* Typhimurium, *Vibrio cholera, Campylobacter jejuni, Campylobacter coli, Arcobacter butzleri*, and *Arcobacter cryaerophilus* **(Ma et al., 2018)**.

Grape pomace is a potential source of natural antioxidant and antimicrobial agents. The phenolic compounds in grape pomace extracts exhibit antioxidant, anticancer, and antidiabetic properties **(Ruberto et al., 2007; Hogan et al., 2009; Parry et al., 2011; Zhou and Raffoul, 2012; González-Centeno et al., 2013; Snopek et al., 2018)**, as well as antibacterial activity against *E. coli, L. monocytogenes,* and *S. aureus* **(Ozkan et al., 2004; Darra et al., 2012)**.

More recently, the impact of the gastrointestinal digestion step on the phytochemical content in food, and on their bioactivities (mainly antioxidant capacity), have attracted special attention, which is evidenced by a great number of publications dedicated to this theme

(Gumienna, Lasik and Czarnecki, 2011; Tavares et al., 2012; Correa-Betanzo et al., 2014).

The aim of this work was to demonstrate the antimicrobial properties of resveratrol and red grape pomace extract towards both Grampositive and Gramnegative bacteria as well as yeasts. The microorganisms' sensitivity to resveratrol and red grape pomace extract were determined using the disk diffusion method, while the broth microdilution method was selected to determine the minimal inhibitory concentration (MIC).

Scientific hypothesis

Antimicrobial activity of the resveratrol against bacteria and yeasts.

Antimicrobial activity of red grape pomace extracts against bacteria and yeasts.

To find the lowest minimal inhibition concentration of resveratrol and pomace extract.

To find the most sensitive and most resistant microorganisms to resveratrol and pomace extract.

MATERIAL AND METHODOLOGY

Grape

Ripe grapes from wine cultivars grown in Vrbové (48° 37′ 12″ N, 17° 43′ 25″ E) Slovakia were collected. For the antimicrobial activity, the red variety Blue Frankish grape pomace extracts were used (Figure 1).

Resveratrol

Pure reveratrol was obtained from Sigma Aldrich.

Pomace extract preparation

Pomace extracts were prepared from a single production lot. A portion of the pomace samples (50 g) was immediately freeze-dried after receiving. The samples were extracted with 96% ethanol at a 1:10 ratio (m/v) using overnight shaking. The extracts were filtered through Whatman No. 2 filter paper to remove unwanted residues. After evaporating the organic solvent, the filtrates were dissolved in dimethyl sulfoxide (DMSO) at 20 $mg.mL^{-1}$ as the stock solution and stored at -20 °C for further investigation.

Figure 1 Grape Blue Frankish.

Microorganisms

Nine strains of microorganisms were tested in this study, including three Grampositive bacteria *Staphylococcus aureus* CCM 2461, *Enterococcus faecalis* CCM 4224 and *Listeria monocytogenes* CCM 4699; three Gramnegative bacteria *Escherichia coli* CCM 3988, *Pseudomonas aeruginosa* CCM 1959 *and Salmonella enteritidis subsp. enteritidis* and three yeast strains: *Candida albicans* CCM 8186, *Candida glabrata* CCM 8270, *Candida krusei* CCM 8271 and *Candida tropicalis* CCM 8223. All tested strains were collected from the Czech Collection of microorganisms (Brno, Czech republic). The bacterial suspensions were cultured in the Muller Hinton broth (MHB, Oxoid, Basingstoke, United Kingdom) at 37 °C for 24 h and yeasts were cultured in the Sabouraud dextrose broth (SDB, Oxoid, Basingstoke, United Kingdom) at 25 °C for 24 h.

Some aspects were considered for the selection of the microorganisms in this study: *S. aureus*, *E. faecalis, L. monocytogenes, S. enteritidis* and *E. coli* are known to cause foodborne diseases, *P. aeruginosa* is commonly resistant to multiple antibiotics **(Stover et al., 2000)** and *C. albicans*, *C. tropicalis* and *C. krusei* are the main fungi responsible for invasive bloodstream fungal infections, a significant cause of mortality in immunocompromised patients **(Selvarangan et al., 2003)**.

Disc diffusion method

The agar disc diffusion method was used for the determination of antimicrobial activity of the pomace extracts. Briefly, a suspension of the tested microorganism (0.1 ml of 10^5 cells mL^{-1}) was spread onto Mueller Hinton Agar (MHA, Oxoid, Basingstoke, United Kingdom) and Sabouraud dextrose agar (Oxoid, Basingstoke, United Kingdom) at 25 °C. Filter paper discs (6 mm in diameter) were impregnated with 15 µL of the pomace extract and placed on the inoculated plates. Tetracycline was used as a positive control to determine the sensitivity of the studied microorganisms. The plates were kept at 4 °C for 2 h and subsequently incubated aerobically at 37 °C for 24 h and 25 °C for 48 h for bacteria and yeasts, respectively. The diameters of the inhibition zones were measured in millimeters. All the tests were performed in triplicate.

Determination of minimum inhibitory concentration

The minimum inhibitory concentration (MIC) is the lowest concentration of the sample that will inhibit the visible growth of microorganisms. Pomace grape extracts were dissolved in DMSO (conc. 20 $mg.mL^{-1}$). MICs were determined by the microbroth dilution method according to the Clinical and Laboratory Standards Institute recommendation (**CLSI, 2019**) in Mueller Hinton broth (Oxoid) for bacteria and Sabouraud dextrose broth (Oxoid) for yeasts. Briefly, the DMSO solutions were prepared as serial two-fold dilutions to obtain a final concentration ranging from 3.9 to 2000 $µg.mL^{-1}$. The range of resveratrol concentrations tested was 2 – 512 $µg.mL^{-1}$, before the addition of the cells. Each well was then inoculated with the microbial suspension at the final density of 0.5 McFarland. After a 24 h incubation at 37 °C for

bacteria and 25 °C for yeasts, the inhibition of microbial growth was evaluated by measuring the well absorbance at 570 nm using an absorbance microplate reader Biotek EL808 with shaker (Biotek Instruments, USA). The 96 microwell plates were measured before and after the experiment. Wells without resveratrol and pomace extract were used as positive controls of growth. Pure DMSO was used as a negative control. This experiment was done in eight-replicates for a higher accuracy of the MICs of used pomace grape extracts. The results were expressed in $\mu g.mL^{-1}$.

Statistic analysis

All experiments were carried out in triplicate and the results are reported as means with standard deviations. The experimental data were subjected to analysis of variance (Duncan's test), at the confidence level of 0.05 using the XL STAT 2019 software.

RESULTS AND DISCUSSION

The disk diffusion method shoved that resveratrol exhibited a better antibacterial activity against all tested Grampositive bacteria (Table 1), when compared to Gramnegative bacteria. The lowest antimicrobial activity was found against yeasts which is consistent with previous studies using similar strains **(Paulo et al., 2010)**. The antimicrobial activity using the disc diffusion method ranged from 10.00 ±2.00 (*C. albicans*) to 22.67 ±2.08 (*E. faecalis*).

Similar results were found in case of the pomace extract. The best antimicrobial activity was found against *E. faecalis* while the lowest antibacterial activty was detected against *C. krusei*.

The high antimicrobial effect was observed in the variants with grapevine seeds against *E. coli* **(Jakubcová et al., 2015)**.

In study of **Chan (2002)** established that resveratrol conferred the antibacterial effect. DMSO did not reduce the growth of the tested bacteria, except for a slight decrease in the case of *E. faecalis* at 3.3%. When present at 171 $\mu g.mL^{-1}$ of resveratrol in 1.7% DMSO, the growth of *S. aureus* was inhibited by 80 – 90%. A similar degree of inhibition was observed in case of *E. faecalis* and *P. aeruginosa* at 342 $\mu g.mL^{-1}$ of resveratrol in 3.3% DMSO.

In our work, resveratrol concentrations ranging from 2 to 512 $\mu g.mL^{-1}$ have been tested, and its MIC for all Grampositive bacteria (S*taphylococcus aureus, Enterococcus faecalis and Listeria monocytogenes*), Gramnegative bacteria (*Escharichia coli, Pseudomonas aeroginosa* and *Salmonella enteritidis*) and yeasts (*Candida albicans, Candida krusei* and *Candida tropicalis*) were determined. The microorganism that presented the highest sensitivity towards resveratrol was *Enterococcus faecalis* (MIC 64 $\mu g.mL^{-1}$), followed by *Staphylococcus aureus* and *Listeria monocytogenes*, which have presented with a MIC of 128 $\mu g.mL^{-1}$ (Table 2). Similar results with similar bacteria were obtained in the study by **Paulo et al. (2010)**. In this work, resveratrol concentrations ranging from 3.125 to 400 $\mu g.mL^{-1}$ have been tested, and its MIC for all Grampositive bacteria (*Bacillus cereus*, *Staphylococcus aureus* and *Enterococcus faecalis*) was determined. The microorganism that presented the highest sensitivity towards resveratrol was *Bacillus cereus* ATCC 11778 (MIC 50 $\mu g.mL^{-1}$), followed by *Staphylococcus aureus* ATCC 25923 and *Enterococcus faecalis* ATCC 29212, with a MIC of 100 $\mu g.mL^{-1}$.

It was not possible to obtain resveratrol concentrations higher than 400 $\mu g.mL^{-1}$ due to its poor solubility **(Jeandet et al., 2002)**, and therefore its MIC on Gram-negative bacteria was not determined. Consequently, the efficacy of inhibition (in terms of percentage) presented by different

Table 1 Screening of antimicrobial activity of resveratrol using the disk diffusion test in mm.

Bacterial strains	Resveratrol	Pomace extract
Staphylococcus aureus	22.33 ±1.15^{a}	16.66 ±1.53^{b}
Enterococcus faecalis	22.67 ±2.08^{a}	17.67 ±1.53^{a}
Listaria monocytogenes	19.00 ±1.00^{a}	16.67 ±1.53^{b}
Escherichia coli	14.33 ±2.08^{a}	9.00 ±1.00^{b}
Pseudomonas aeroginosa	15.67 ±1.15^{a}	13.00 ±1.73^{b}
Salmonella enteritidis	15.00 ±1.00^{a}	13.33 ±1.53^{b}
Candida albicans	10.00 ±2.00^{a}	6.00 ±1.00^{b}
Candida krusei	12.33 ±2.52^{a}	4.67 ±0.58^{b}
Candida tropicalis	11.33 ±1.53^{a}	5.33 ±0.58^{b}

Note: mean ± standard deviation; different letters in column denote mean values that statistically differ one from another.

Table 2 Screening of antimicrobial activity of resveratrol using the broth microdilution method in $\mu g.mL^{-1}$.

Bacterial strains	Resveratrol	Pomace extract
Staphylococcus aureus	128	500
Enterococcus faecalis	64	250
Listaria monocytogenes	128	250
Escherichia coli	512	1000
Pseudomonas aeroginosa	256	500
Salmonella enteritidis	256	500
Candida albicans	512	500
Candida krusei	512	1000
Candida tropicalis	256	1000

concentrations of resveratrol was used to evaluate its activity against these bacteria. At a concentration of 400 $\mu g.mL^{-1}$, the inhibition percentages observed for *Escherichia coli*, *Salmonella typhimurium* and *Klebsiella pneumoniae* were respectively, 81, 80 and 58%. In addition, it was not possible to determine the MBCs, since the maximum tested concentration was 400 $\mu g.mL^{-1}$.

Kačániová et al. (2018) tested four strains of bacteria (two Gram-positive bacteria *Staphylococcus aureus* CCM 2461, *Bacillus cereus* CCM 2010; two Gram-negative bacteria *Escherichia coli* CCM 3988, *Pseudomonas aeruginosa CCM 1959)* and four yeasts strains (*Candida albicans CCM 8186, Candida glabrata CCM 8270, Candida krusei CCM 8271 and Candida tropicalis CCM 8223*). For the detection of the antimicrobial activity, the grape pomace extracts of white variety Pálava and red variety Dornfelder were used. *Pálava pomace* extracts were less efficient against the microorganisms tested and Dornfelder extracts were more active against Grampositive bacteria and yeasts. The best antimicrobial activity of pomace extract Blue Frankish grape in our study was found to be similar to resveratrol against Grampositive bacterial strains. The antibacterial activity of four grape pomace extracts was evaluated in the study of **Xu et al. (2015)**. All extracts exhibited antibacterial activity against *L. monocytogenes* and *S. aureus*, but no antibacterial activity was detected against *E. coli* O157:H7 and *S. typhimurium*. Our results partially agree with previous studies on the antimicrobial activity of whole grapes or grape pomace extracts against both Gram-positive and Gram-negative bacteria, with the most pronounced effects against Gram-positive bacteria **(Darra et al., 2012)**.

CONCLUSION

The present study showed that resveratrol and red pomace extract of Blue Frankish grape showed better antibacterial activity against Grampositive *Staphylococcus aureus, Enterococcus faecalis and Listeria monocytogenes* when compared with Gramnegative bacteria and yeasts using both methods, the disc diffusion and the minimal inhibiotn concentration.

TIN COMPOUNDS IN FOOD – THEIR DISTRIBUTION AND DETERMINATION

Miroslav Fišera, Stanislav Kráčmar, Helena Velichová, Lenka Fišerová, Pavla Burešová, Pavel Tvrzník

ABSTRACT

The aim of this work was optimization of the methods of trace- and ultratrace analysis, such as ICP-OES, ETA-AAS for charting the resources of individual forms of tin in foodstuffs. Increase of the sensitivity of the method of ICP-OES was achieved using the techniques of generation of hydrides, which was also optimized. Based on the information available on the occurrence of the different forms of tin, it appears that many of these organometallic compounds are contained in marine animals; attention has mainly focused on organisms such as marine fish, crustaceans, molluscs and algae. Tin compounds of predominantly inorganic origin can be found in foods and beverages which are packed in cans with a protective tin coating, too. The above mentioned methods have been applied to the analysis of selected beverages with low content of tin such as Coca Cola, Sprite, Fanta, Gambrinus 10°, PowerKing, and milk in the cans. Furthermore samples of animal origin as Sardines in oil, and Hunter's salami were examined, too. Prior to the determination of tin, samples need to be appropriately modified or analysed. Decomposition of the samples was done in the microwave system. Low pressure ion exchange chromatography with on-line detection of ICP-OES was used for separation of inorganic tin compounds. Separation of organically bound tin compounds was performed by HPLC on a column of ACE C-18, 3 µm, 15 cm × 1.0 mm with off-line detection by ETA-AAS. All of the above forms of tin compounds can be separated with this column. Due to the improvement in the detection of organically bounded tin, HPLC with identical ACE C-18 column coupled online for example with ICP-MS or spectrofluorimetry could be recommended.

Keywords: foods; tin; speciation of organotin; HG-ICP-OES; HPLC-ETA-AAS

INTRODUCTION

One of the indicators of the toxicological quality of food is the content of toxic mineral compounds. Lead, cadmium, mercury and arsenic belong among the most toxic elements. In higher concentrations trace elements such as, tin, chromium, cobalt, copper, molybdenum, nickel, selenium, vanadium, and others may show toxic effects. For these elements, the maximum allowed quantity, the permissible maximum quantity or special dose are specified in food legislation in the Czech Republic.

For humans or for other animals, tin is an essential element, but in larger quantities it appears as toxic. Its biological importance for humans has not yet been fully elucidated; it is assumed that it is indispensable for optimal growth and the formation of blood. Tin compounds are primarily located in the Earth's crust and also due to the human activities in the air and water flow.

The most dangerous form of tin are the compounds where tin is organically bounded in organometallic compounds. In spite of its potential toxicity, tin is used in large quantities in plastic and canning industry and for destruction of pests in agriculture, where it gets into agricultural products and from there into the food. Toxic effects of tin are known, but its use is increasing.

Humans can absorb tin from food, during breathing, and through the skin. Absorption of tin can enter human organism in the digestive system, thus food control has been emphasized quite intensively recently.

The average content of tin in the Earth's crust is about 3.0 $mg.kg^{-1}$. In nature, tin occurs as the mineral cassiterite (stannic oxide SnO_2,) and as an ingredient in some sulphides.

Metal tin is an important component of common alloys (bronze). The tinplate cans are made of steel sheets used in the food industry. Consumption of tinplate in food packaging is still growing and the largest share goes to the production of cans for the distribution of beer and other beverages **(Greenwood and Earnshaw, 1993)**.

A large quantity of tin is consumed for the production of organometallic compounds. Tin is used as a component of special paints for ships and other bodies subjected to the long-term effects of the sea water. Tributyltin compounds are used for the preservation of wood. Tributyltin oxide

$O(SnBu_3)_2$ is an excellent agent for protection of the wood. R_3SnX is also used as an antimicrobial agent to exterminate of slime mould in the paper and pulp.

Triphenyltinacetate and triphenyltinhydroxide are applied in agriculture as fungicides. For example, Bu_2SnOH and Ph_3SnOAc inhibit the growth of fungi, such as potato blight and similar infections, in sugar beet, peanuts and rice. Tin also serves as a mite-killer on apple and pear trees. Other R3SnX compounds are effective at killing insects as chemosterilant or by killing of larves **(Velíšek, 1999)**.

Dibutyldilaurate and analogue octyltin compounds are used as stabilizers for plastics (PVC). The most effective stabilizer compounds (R_2SnX_2 – R = octyl-, X = laurate, maleate). For the packaging of food products, the polymeric cis-butenedioic and ($Oct_2SnOCOCH$ = CHCOO)n and $Oct_2Sn(SCH_2COO\ Oct)_2$, with S,S´-bis (isooctyl-mercaptoethanolate), which is used in cases where a colorless, non-toxic, highly transparent material is essential, were approved.

Another no less important application of organotin compounds is their use as curing agents in vulcanization of silicone under normal temperature **(Greenwood and Earnshaw, 1993)**.

On other hand, the inorganic forms of tin are less toxic for human organism. Inorganic tin is just difficult to be absorbed by the organism and is usually excreted in the urine. According to the study from 1997, tin (II) is more toxic than tin (IV). Due to the presence of humic acids in the ground waters that reduce tin (IV) on tin (II) its concentration is increasing **(Pawlik-Skowronska, Kaczorowska and Skowronski, 1997; Rüdel, 2003)**. Inorganic tin is not carcinogenic or teratogenic.

Tin in all organic industrial compounds is tetravalent. Organic alkyl or aryl groups are groups that are covalently bonded with the central atom of tin. Mono-, di- and trisubstituted butyltin, phenyltin, and their derivatives are considered its most important compounds. The solubility of organically bounded tin compounds depends on pH, ionic strength and temperature of environment.

Degradation of organotin compounds occurs in biotic or abiotic processes. The transformation is similar for both cases **(Rüdel, 2003)** it leads through the dealkylation or dearylation on inorganic tin compounds **(Hoch, 2001)**.

The European Union (EU) limits maximum levels for certain contaminants with a view to reduce the content of these substances in foods at such a low level, which is yet to be achieved in compliance with the good manufacturing or agricultural practices. The aim is to achieve a high level of public health protection, especially for vulnerable groups of the population: children, allergies, etc. **(Commission Regulation (EC), 2006)**.

Tin gets into tinned food via further decomposition of the inner walls of tinned food cans. The decomposition of tinplate is dependent on the food matrix, pH, the presence of oxidizing substances (anthocyanines, nitrates, ions of iron and copper), and the presence of air (oxygen) in the area of food, time and storage temperature.

Nowadays, corrosion and dissolution of tin cans will be suppressed by a varnish, which greatly reduces the penetration of tin in food products.

Tin cans contain mainly canned vegetables, fruits, juices and other beverages, fruits in sweet pickle, mixed fruits in brine, canned milk and pickled mushrooms (Figure1).

For the determination of trace elements as well as for detection of tin in foodstuffs, it is necessary to choose the analytical methods, which are able to detect very low, trace amounts of analyte. Atomic Spectrometry methods – atomic absorption, emission and mass spectrometry are suggested for analyses of tin in food.

The most common method is atomic absorption spectrometry (AAS). When you use flame atomization the limit of detection is on the level of 0.1 $mg.L^{-1}$; using the electrothermal atomization even decreases this limit. Additional options for the determination are represented by different extractants (e.g. with hexane, toluene, chloroform r methanol), conversion of the compounds into volatile derivatives (by reaction with Grignard´s reagents or reaction with $NaBH_4$ result in volatile hydrides usable for atomic absorption spectrometry determination) and separation by gas chromatography. It is also possible to use liquid chromatography with mass spectrometer with ICP (inductively coupled plasma).

These methods offer for many elements excellent limit of detection, so they are suitable for the determination of trace amounts of elements in biological materials. Comparable results are achieved using sensitive electroanalytical methods, mainly a modification of polarography and voltamperometry, electrogravimetry or fluorescence.

For the determination of organically bounded forms of tin, in particular of tributyltin compounds (including degradation products – di- and monobutyl derivatives) are also used the above methods (AAS, ICP-OES and ICP-MS), in connection with sepraing in on-line or off-line arrangement (Figure 4).

To determine total tin detection of different forms (separation of inorganic and organically bound forms of tin) is performed both via complete mineralization of samples and in dry (combustion and subsequent dissolution in acid) or wet way (oxidation reactions in the strongly acidic environment). Mineralization by the wet way can be further performed under the hood in an open or closed system. Mineralization in a closed system can be done under high or low pressure and either common or

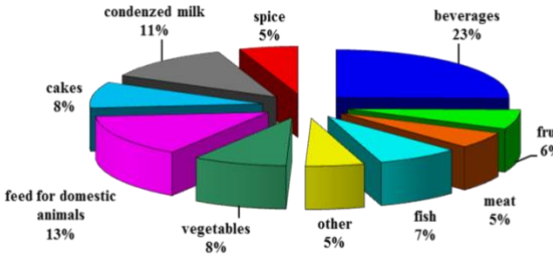

Figure 1 The most frequently observed types of canned food on the tin content **(Perring and Basic-Dvorzak, 2002)**.

microwave heating can be employed **(Mader and Čurdová, 1997)**.

If the determination of the different forms of tin is required, treatment of samples keeping tin compounds in their original form is essential and also maintaining their initial relationship in the sample is crucial. For these purposes very gentle procedures must be employed. They are based on the extraction with helping of ultrasonic wave or with the support of many microwaves in pH buffered environments. If the separation or isolation of the individual forms in one step is impossible, it is necessary to use a multi-step extraction or specific extraction or the conversion of other forms, and then multi-step analysis must be carried out **(Simon et al., 2002)**.

Scientific hypothesis

Since the determination of the tin compounds in foods is of great importance, particularly in terms of the occurrence of organotin compounds that accumulate in human adipose tissue, many techniques have been used for this purpose. Studies using different techniques, such as graphite furnace atomic absorption spectrometry (GF AAS) and cold vapour atomic absorption spectrometry (CV AAS), have been reported.

The inductively coupled plasma optical emission spectrometry (ICP-OES), which makes it possible simultaneous determinations on more different wavelength and allows rapid an effective analysis, is also reported. The design of experiments is an important approach and has been successfully employed in sample preparation procedures to identify the optimum conditions and select the proportions between the reactants, allowing a faster acquiring of results, minimizing costs and time involved. The use of diluted reagents in decomposition or extraction procedures, which leads to media with reduced acidity and also decreases the amount of corrosive substances, is an example of the experimental design application. Chemometric tools were used to establish the appropriate experimental conditions for determination of total tin content by CV AAS or by hydride generation atomic emission spectrometry with inductive coupled plasma (HG ICP-OES) and combination of separation step (EC or HPLC) with the same methods of detection for determination of tin (II) and tin (IV) and organotin compounds in biological samples.

Thus, this paper purpose is a multivariate optimization of an analytical method through all parameters outside the device parameters conclude selection the most suitable wavelength, concentrations of reagent solutions, correction of interferences and inlet flows of gases and solutions to determine the individual species of tin employing ICP-OES.

MATERIAL AND METHODOLOGY

Material and reagents

All reagents used were analytical grade, and solutions were prepared with ultrapure deionized water obtained from a reverse osmosis water purification system and ultrapure system (Aqua Osmotic 02 Tisnov, CR and Purelab ULTRA, Elga, UK). The nitric acid (68%), hydrochloric acid (37%) and hydrogen peroxide (31%) used were of Analpure Ultra (Analytika, s.r.o., CR). External calibration was prepared from stock solution of tin of 1000 $mg.L^{-1}$ (Astasol®). Also, 1000 $mg.L^{-1}$ stock solutions organotin compounds were prepared from dibutyltin dichloride (97%), triphenyltin chloride (95%) and tributyltin chloride (95%), Sigma – Aldrich s.r.o. CR and diluted according to the working range required. The calibration curves were prepared in a suitable range of concentrations in accordance with the purpose.

Other reagents such as sodium tetrahydridoborate NaBH4, NaOH, KOH for hydride generation used and organic solvents and acids (methanol, acetonitrile, acetic acid and triethanolamine) were HPLC grade from Sigma – Aldrich s.r.o. CR.

The glassware used in the experiments was previously decontaminated with a nitric acid solution (10% v/v) for 24 h **(Dantas et al., 2013)**, subsequently washed with ultrapure water and dried at room temperature.

Instrumentation

For the analysis of the food samples an inductively coupled plasma optical emission spectrometer with axial view (ICP-OES, Thermo Jarrell Ash, IRIS/AP,USA) and an atomic absorption spectrometer with electrothermal atomisation (Thermo Elemental, Solaar M6, UK) were used, and the operating conditions are detailed in Table 1 and Table 2. For preparation of samples for total tin content analyses a microwave digestion system MLS 1200, Milestone it was used and for separation of organotin forms an HPLC system (Dionex RS 3000 Ultimate, USA) was used.

Optimization strategy and analysis of the data

In order to achieve the best working conditions providing the lowest detection limit were performed an optimization, which includes the choice of the best wavelength for tin and appropriate instrument settings. Sensitive wavelengths for tin have been selected from a database of TEVA™ (Thermo Elemental Validated Analysis, ICP-OES software, v. 1.4.0. for controls the optical emission spectrometer with inductively coupled plasma). It was tested a total of six wavelengths, which is able for the tin determination. Of these six wavelengths were chosen two (Table 2), which was the signal for tin the best response (SBR).

Other parameters were setting the input of the plasma on 1150 W, auxiliary gas flow 1 $L.min^{-1}$, the uptake of the sample to the nebulizer 1.85 $mL.min^{-1}$.

Statistic analysis

Validation of analytical method

The precision of the method was evaluated via the repeatability and can be expressed as the relative standard deviation (RSD) of a set of measurements. Accuracy expresses the difference between the value found experimentally and a reference value. In this study, Trace elements in CRM material fish tissue (NIES-11) was used to establish the accuracy through the values calculated using the Eq. (1). This approach is directly related to international standards.

Recovery (%) = [found value/certified value] x 100 (1)

Where found value is the analyte concentration determined by the proposed method and the certified value is the concentration value of the analyte reported in the SRM certification document. The precision and accuracy expressed as RSD (%) and recovery (%), respectively, obtained for the optimized analytical method calculated on the certified values and the found values for CRM. The recovery between the certified values and the found values ranged from (87.0 ±1.0) % (for tributyl tin) and about (92.0 ±5.0) % for total tin content, and the RSD values obtained were better than 5% (n = 3).

The tin content in different samples of foods was measured by HG-ICP-OES. Samples before the determination were decomposed in the microwave device by mineralization step. As samples were selected common beverages: Coca Cola, Sprite, Fanta, Gambrinus 10°, PowerKing and picnic in the cans. It was also determined a total content of the tin in caned Sardines in vegetable oil and in the hunter salami as a potential possible source of organotin compounds.

Samples of drinks before mineralisation step in the ultrasonic bath were degassed. For the decomposition of samples of beverages and foodstuffs was take up 10 mL or 1.0 g of samples and added 8 ml of HNO_3 and 2 mL of HCl. After this operation the sample was evaporated to near dryness, almost added to it 1 mL of HCl and volume was fill up on 10 mL. Values measured during both the wavelengths used are listed in Table 8.

The analysis of the data obtained from the experimental design was performed using Statistica® 12.0 software (StatSoft, USA). The measurements were performed in triplicate and the data are expressed as mean ±95% confidence interval (CI).

RESULTS AND DISCUSSION

Optimization of the hydride technique

The hydride generation technique was used for the reduction of the limit of detection. This technique based on reaction of $NaBH_4$ with acid to produce hydrogen, which generate volatile hydride with suitable ions of metal. These ions are then carried into the carrier gas stream into discharge of the ICP. If we compare the direct method of measuring tin and the hydride generation technique we can change measurement extent from the range ppm ($mg.L^{-1}$) to ppb ($\mu g.L^{-1}$) levels. The optimization of the concentration of sodium tetrahydroborate for the hydride generation for the correct determination was performed.

Optimization of the concentration range $NaBH_4$ was selected on the literature **(Hosick, Ingamells and Machemer, 2002)** where the optimum of concentration was about 2.4% of $NaBH_4$. Therefore, the optimization of reducing reagents at concentrations of 0.5; 1; 1.5; 2; 2.5; 3; 3.5; 4; 5% of the $NaBH_4$ dissolved in 0.1% KOH was performed.

Similarly for the acidification of the samples has been used 0.10; 0.25; 0.50; 0.75; 1.0 M hydrochloric acid.

As the most sensitive appeared wavelength of tin 189.989 nm (with the highest ratio of intensities (IR), which is the ratio of full intensity to the intensity of background or blank on the same selected wavelength), therefore the final optimization was carried out and the final results of processing of the content of tin was expressed only at this wavelength. The results of the optimization steps with a concentration of 100.0 ppb tin are presented in Table 3 and Table 4.

Calibration of hydride technique for the determination of different form of tin

The calibration solutions of standards of different forms of tin were measured at wavelengths 189.989 and 242.949 nm. The concentration of the calibration solutions was selected 50; 100; 150 $\mu g.L^{-1}$ and as blank was used a 0.25 M solution of HCl. The calibration solutions of Sn (IV) species were prepared from standard calibration solution 1.0 $g.L^{-1}$ in 0.25 M of HCl solution into the 100 mL flasks. Calibration solutions of Sn (II) were prepared by loading the appropriate amount of $SnCl_2.2H_2O$. This amount was transferred to 100 mL volumetric flask and fill up with deionised water. From this stock solutions have been further prepared calibration solutions of the above concentration.

Evaluation of the operating conditions obtained for the ICP-OES

This procedure made it possible to select the more sensitive lines, free of interference (Table 1), that were used to calculate the limits of detection (LOD) and the limits of quantification (LOQ) through the background equivalent concentration (BEC) and the signal-to-background ratio (SBR). The LOD and LOQ values were calculated using the BEC and the SBR, according to International Union of Pure and Applied Chemistry (IUPAC); $BEC = C_{standard} / SBR$, where $SBR = (I_{standard} - I_{blank}) / I_{blank}$; Cstandard is the reference element concentration in the solution; and Istandard and Iblank are the emission intensities for the reference element and blank solutions, respectively at the selected wavelength **(Da Costa et al., 2013, Schiavo et al., 2009)**.

The LOD was then calculated as ($3 \times RSD_{blank} \times BEC / 100$) and the LOQ as ($3.3 \times LOD$), where RSDblank is the relative standard deviation of ten measurements of the emission intensity of the blank solution.

Separation of inorganic forms of tin by ICP-OES method

Ion-exchange chromatography

Forms of tin were separated by ion-exchange chromatography with on-line detection of ICP-OES. The measurement was done by using the time scan module in the TEVA software. Before choosing a suitable sorbet is necessary to find out as much as possible information about samples, which considered the properties of the matrix and the analyte, and based on this knowledge, then choose the type of phase and size of columns. Offer of sorbents is similar as for filling for liquid chromatography. All sorbents, which were used, had to be activated at first. Activated sorbents under reduced pressure using the sorption apparatus were implemented in polypropylene columns. After filling the columns were washed up with deionised water.

Tin in the compounds occurs in the form cations Sn (II) and Sn (IV). Therefore ion changers were selected as cation exchangers. The most appropriate cation exchanger is like this the tin ions are relatively closely retained and they are not washed up with water. Another important parameter is the selection of appropriate eluent reagents.

Due to the stability of the plasma is not appropriate use of elution agents containing higher amount of organic compounds or high concentrations of salts.

In work were tested exchangers Amberlite IRC 50, Cellulose CM 23, Servacel CM 3, Dowex 50WX, Trisacryl M CM and Sephadex CM 50 with elution reagents 1 M HCl and 0,5 M NaOH. The most of them - Amberlite IRC 50, Cellulose CM 23, Trisacryl M CM and Sephadex CM 50 – were suitable for separation of Sn (IV). Perfect separation of Sn (II) and Sn (IV) ions is complicated how is describe in literature **(White et al., 1998)** that the solutions of salts of Sn (II) ions are very unstable, easily oxidized by air and especially on light. Therefore, the study was focused on time dependency of Sn (IV) conversion on Sn (II) species on the light. In the previous chapter, it was found that when using a column filled with exchanger Amberlite IRC 50, tin in the form Sn (II) is washed out at the sampling and Sn (IV) is retained on the exchanger and washed out with 1 M HCl. This phenomenon was used for determining the time conversion dependency Sn (II) on Sn (IV) species. The functional range of the pH for ion exchanger which was used Amberlite IRC 50 is 5-14, in order to the pH of the sample is not need regulate. Results of measuring dependences of peak areas on time in derivation and logarithmical modes are shown in Table 5 and Figures 2 and 3.

Determination of tin compounds by ETA–AAS method

Optimization of method

For the determination of tin in samples by electrothermal atomisation in graphite furnace an ELC (Extended Life Cuvette) and Sn hollow cathode lamp has been used. According to literature **(Chen et al., 1996)**, where it was performed by optimizing the working conditions for the determination of Sn by ETA AAS method. For background correction a Zeeman correction method has been selected and as matrix modifier a combination of Palladium and Ascorbic acid was used. The unit was setting to the basic working conditions recommended by the manufacturer (Table 6 and Table 7).

Application of optimized method to food samples

After settinμ the optimal conditions a calibration method for different forms of tin was performed. Calibration solutions were measured at a wavelength of 224.6 nm with calibration functions y = 0.0073x + 0.0502 and R^2 = 0.9977 for tributyltin chloride; y = 0.006x + 0.0524 and R^2 = 0.9975 for dibutyltin dichloride and y = 0.004x + 0.0457, R^2 = 0.9962 for triphenyltin chloride. The concentration of the calibration solutions 10, 30, 50 $\mu g.L^{-1}$ has been prepared. A solution of 50 $\mu g.L^{-1}$ of different forms of tin with the addition of 0.5 ml 65% HNO_3 into a 50 ml volumetric flask and added a mixture of MeOH: H_2O (40: 10) has been prepared from standard solutions **(Schiavo et al., 2009)**. As blank and dilution solution 0.65% HNO3 has been used. As a matrix modifier a solution of $Pd(NO_3)_2$ and 1% solution of ascorbic acid were used. This mixture with sample by autosampler was sampled to the ELC of ETA AAS.

Due to the improvement of the detection of organically bound tin and streamlining of analysis would be suitable HPLC with column ACE C-18 connect in on-line arrangement, for example with ICP-MS or fluorimeter (**Gonzáles-Toledo et al., 2001**).

Table 1 Characteristics and operating conditions used for analysis by ICP-OES with axial view.

Parameter	Characteristics
Radio frequency power (W)	1150
Plasma gas flow rate ($L.min^{-1}$)	15.0
Auxiliary gas flow rate ($L.min^{-1}$)	1.5
Sample uptake rate ($mL.min^{-1}$)	1.85
Nebulizer gas flow rate ($L.min^{-1}$)	1.00
Nebulizer type	Concentric
Spray chamber	Type cyclone
Replicates	3
Injector tube diameter (mm)	2.0
Signal integration time (s)	1.0
Wavelength (nm)	Tin 189.989
	242.949

Table 2 Wavelengths suitable for determination of tin.

Wavelength λ [nm]	Spectral order	relative intensity
189.989	136	150,000
242.949	107	100,000

Table 3 Values obtained for BEC, LOD and LOQ in the analysis of liquid samples of beverages by ICP-OES[a].

Analytical parameter	Sn(II) 189.989 nm Direct method	Sn(IV) 242.949 nm Direct method	Sn(II) 189.989 nm Hydride generation	Sn(IV) 242.949 nm Hydride generation
BEC ($mg.L^{-1}$)	0.2185	0.9422	0.0298	0.0967
LOD ($mg.L^{-1}$)	0.0036	0.0232	0.0006	0.0011
LOQ ($mg.L^{-1}$)	0.0107	0.0697	0.0017	0.0033

Note: [a] For solid samples values of LOD and LQD is necessary multiplied with factor for mass of 1.00 g of samples and completed to 10.0 mL with deionised water and expressed in $mg.kg^{-1}$.

CONCLUSION

In this work were simultaneously developed and tuned the three parts of the methodology on the determination of different forms of tin in food and beverages. The method for determination of total tin content in food materials by ICP-OES has been tuned. Increase the sensitivity of the method of ICP-OES was achieved using the techniques of generation of hydrides, which was also optimized. Hydride generation technique reduces the limit of detection, so it can be used for samples with low content of tin. This method has been applied to the analysis of real samples. Selected samples with low content of tin were drinks Coca Cola, Sprite, Fanta, Gambrinus 10°, PowerKing and picnic in the cans. Furthermore, Sardines in vegetable oil, and Hunter salami.

Simultaneously the method for separation of inorganic forms of tin was developed and at optimisation has been used low pressure ion exchange chromatography with on-line detection with ICP-OES. As appropriate ion exchangers shown cation exchangers Amberlite IRC 50, Cellulose CM 23, where elution reagent was 1 M solution of HCl and Trisacryl M CM, 50 CM-Sephadex, where elution reagent was 0.5 M NaOH solution. The best response was on Sephadex ion CM 50. The peak was detected during 40 seconds, and was sufficiently narrow and tall.

Similarly separation of organically bound tin was performed by HPLC on a column of ACE C-18 3 mm 15 cm × 1.0 mm with off-line detection by ETA AAS. Elution reagent was degassed mixture of acetonitrile-water-glacial acetic acid with 0.05% triethylamine (65: 23: 12) about pH 5. All of the above forms of tin can are with this column separated.

Since the performed analyses (inorganic forms of tin and organically bound tin) and information available on the occurrence of the forms of tin, it appears that many of these organometallic compounds are contained in marine animals, attention was necessary mainly focused on organisms such as marine fish, crustaceans, molluscs and algae. Based on these findings and the results of this work on the optimization of analytical procedures and the preparation of samples for analysis (homogenization, the selection of reagents and techniques for the extraction of individual forms, other modifications, such as pH adjustment, adding specific reagents, etc.) it will be possible to measure samples of the food and beverages by using this methodology that are created and optimized for the determination of the different forms of tin.

BIOGENIC AMINES IN SMEAR RIPENED CHEESES

Olga Cwiková, Gabriela Franke

ABSTRACT

Cheeses belong to high protein foods in which enzymatic and microbial activities form amino acids, which are then converted into biogenic amines (BAs) by the activity of bacterial decarboxylases. The most important conditions for BA formation include the presence of microorganisms, the availability of substrate, temperature and storage period, water activity, salt concentration, and the hygiene of the manufacturing process. Tyramine, histamine, 2-phenylethylamine, tryptamine, cadaverine, putrescine, spermidine and spermine were detected in smear ripened cheeses stored in different temperature regimes. The highest (p <0.05) total BA content was found when storing the cheeses at the end of BBD (best before date) after 35 days in storage regime (A) or (C). During storage in regime (B), the total BA content (p <0.05) after 49 days of storage was higher than on the production date (B/0). During storage, the tyramine content in regime (B) did not change (p >0.05), while in the temperature regimes (A) and (C), the highest levels of tyramine and putrescine content were recorded in cheeses at the end of BBD after 35 days ripening. The content of polyamines in cheeses was higher (p <0.05) at the end of storage than at the beginning, in all temperature regimes.

Keywords: biogenic amines; polyamines; smear ripened cheese;storage temperature and period

INTRODUCTION

Cheeses are food that is often associated with the content of biogenic amines (Bas) **(Poveda, Molina and Gómez-Alonso, 2016)**. During ripening, substantial changes in the composition of cheeses take place **(Pinho et al., 2004)**. Protein degradation leads to accumulation of free amino acids, which are then converted into BAs by bacterial decarboxylases **(Komprda et al., 2007)**. Contaminant microorganisms such as enterococci, Enterobacteriaceae and lactic acid bacteria, such as lactobacilli **(Madejska, Michalski and Osek, 2017)**, contribute to the formation of BA.

Among the most important BAs found in foods are tyramine, histamine, cadaverine, 2-phenylethylamine, tryptamine, putrescine, spermine, and spermidine **(Önal, Tekkeli and Önal, 2013)**. Smear ripened cheeses have a higher BA content compared with other types of cheeses, which is related to the high protein content, extensive proteolysis, and highly active microbes with decarboxylase activity **(Samková, Dadáková and Pelikánová, 2013; Torracca et al., 2016)**.

Typically, these cheeses contain up to hundreds mg.kg^{-1} of histamine, tyramine, putrescine, and cadaverine, up to tens mg.kg^{-1} of 2-phenylethylamine as well as minor content of tryptamine **(Standarová et al., 2010)**. Cheeses also contain polyamines (Pas), such as agmatine, spermidine, and spermine **(Novella-Rodríguez et al., 2003)**.

The aim of this paper was to find out if the storage temperature and period could affect the BA content in smear ripened cheeses.

Scientific hypothesis

The formation of BAs in cheeses is affected by the storage temperature – the higher the temperature, the higher the BA content.

The length of storage of cheeses affects their safety in terms of high BA content.

MATERIAL AND METHODOLOGY

The cheese for testing was delivered as small rounds (diameter 45 mm, height 10 mm), where a 100 g package contained 5 pieces of these round portions. Prior to shipment, the cheeses ripened for 7 days, while the best before date (BBD) on the package was 28 days. A total of 5 batches of the product were analysed.

The samples were divided into three groups designated as (A), (B), and (C) and stored in different temperature regimes. Sampling and subsequent analyses were performed on the day of manufacture (A/0 = B/0 = C/0), at the end of BBD (A/35, B/35, C/35), two weeks after BBD (A/49, B/49), and eight weeks after BBD (C/91).

Samples in the temperature regime (A) were stored at 6 °C after production for the entire BBD (7 days before and 28 days after shipment), i.e. 35 days. These cheeses

were then stored for 14 days after the BBD expired at 6 °C, i.e. 49 days in total (6 °C/35 days → 6 °C /14 days). Samples in the temperature regime (B) were stored at 6 °C after production for 28 days (7 days before and 21 days after shipment), i.e. 28 days, then they were frozen and stored at -18 °C for 7 days. Subsequently, after BBD (35 days), the cheeses were stored at 6 °C for 14 days, i.e. 49 days in total (6 °C/28 days → -18 °C/7 days → 6 °C/14 days). Samples in the temperature regime (C) were stored at 6 °C after production for the entire BBD (7 days before and 28 days after shipment), i.e. 35 days. They were then frozen and stored for 49 days (7 weeks) at -18 °C. After 49 days of freezing, the cheeses were stored at 6 °C for 7 days, i.e. 91 days in total (6 °C/35 days → -18 °C/49 days → 6 °C/7 days).

The analyses were carried out in the laboratory of the Institute of Food Technology, Faculty of AgriSciences of Mendel University in Brno.

BA Assay: A cheese sample was grated to a particle size of about 3 mm and 10 g was weighed into an 85 mL plastic centrifuge tube. After addition of 20 mL of 0.1 M HCl and 0.5 mL solution of internal standard (1,7-diaminoheptane) with concentration of 1 $mg.mL^{-1}$, the sample was extracted with a disintegrant for 2 minutes. The suspension was centrifuged at 755 g for 10 minutes at 4 °C in order to separate the solid and fat. The supernatant was filtered and the solid was re-extracted by the same procedure. The combined extracts were added up to 50 mL with deionized water and filtered through a nylon membrane filter. The BA derivatization was carried out with dansyl chloride, where 1 mL of extract or standard was mixed with 0.5 mL of saturated Na_2CO_3 (pH adjusted to 11.2). In a 4 mL sample vial, 1 mL of derivatizing agent (5 mg of dansyl chloride in 1 mL of acetone) was added and stirred for 1 minute on an agitator. Derivatization was carried out for 1 hour at 40 °C without light access with occasional shaking at 15 minutes intervals. After derivatization, 250 µL of 10 mM ammonia was added to remove unreacted dansyl chloride and again stirred for 1 minute on the agitator. Ammonia reacted with excess dansyl chloride and the resulting reaction product was eluted before BA. Containers with dansyl chloride acetone solution and all standards and extracts were immediately after adding packaged in aluminium foil because of their photolability. After a 30-minute reaction, the hydrophobic amine derivatives were extracted with diethyl ether (3 x 1 mL) while the hydrophilic amino acid derivatives remained in the aqueous phase. The organic phase was evaporated to dry state with a stream of nitrogen and the evaporation residue was dissolved in 0.5 mL ACN or in 1 mL ACN (standard) and the solution was again filtered through a 0.45 µm nylon membrane filter and dosed on a chromatographic column. The amount of the injected real sample was modified as needed, in the case of standard it was 10 µL.

Biogenic amines were separated on a Zorbax Eclipse XDB C18 column (150 mm x 4.6 mm, particle size 5 µm) with Meta Guard ODS 2 pre-column (30 mm x 4.6 mm, particle size 5 µm) at a flow rate of 0.8 $mL.min^{-1}$ using the HP 1100 Chromatograph. Separation after derivatization with dansyl chloride was carried out by gradient elution with H_2O/ACN (time 0 – 23 minutes: H_2O 35 – 0%, ACN 65 – 100%) followed by detection with a photometric UV/VIS detector at 254 nm. To identify the separated substances in the samples, a comparison of the retention times of the standards and the substances present in the sample was used. During the analysis, the UV spectra of the eluates were captured at peak and then compared with the spectra of the standard substances, and the identity of the substances was confirmed or refuted on the basis of the so-called identity factor.

All BA standards were supplied as hydrochlorides and their concentrations after derivatization with dansyl chloride were expressed in $mg.kg^{-1}$ of the original (fresh) sample (not per kg of dry weight) to better express the conditions at consumption. The BA concentration in a sample was corrected by the internal standard method. The internal standard was prepared by dissolving 100 mg of 1,7-diaminoheptane in 100 mL deionized water (concentration 1 $mg.mL^{-1}$).

The BA/PA standards stock solution was prepared as a mixed standard for all amines to be analyses (tryptamine, 2-phenylethylamine, putrescine, cadaverine, histamine, tyramine, spermidine, and spermine) by dissolving 100 mg of each of the amines (in the form of hydrochloride) in 100 mL of deionized water (standard concentration of each amine 1 $mg.mL^{-1}$). The BA/PA standard working solution was obtained by mixing 0.5 mL BA/PA standard stock solution with 0.5 mL internal standard solution and subsequent treatment to a volume of 50 mL. The final concentration of each amine was 10 $\mu g.mL^{-1}$. The 0.1 M HCl prepared by dissolving 3.5 mL of 35% HCl in deionized water and filled to 1 litre was used as the extraction agent. The derivatizing agent was prepared by dissolving 5 mg of dansyl chloride in 1 mL of propan-2-one.

The following biogenic amines were determined: tyramine, histamine, 2-phenylethylamine, tryptamine, cadaverine, putrescine, spermidine, and spermine. The amine content of each sample was measured in duplicate.

Statistical analysis

Statistical evaluation was performed in the Statistica Statsoft programme, version 12, and Microsoft Excel 2010. Basic statistical characteristics, such as mean and standard deviation of the mean were calculated.

In order to compare the BA content during the storage period within the given temperature regime, a simple scattering analysis method (ANOVA) including the Duncan post-hoc test was used. Normality was tested by the Shapiro-Wilk test. The proportion of factors (temperature and storage period including interactions) on the total variability of BA content in cheese was calculated using the general linear model (ANOVA with interactions).

RESULTS AND DISCUSSION

At the beginning of storage (A/0, B/0, C/0) the total content of the monitored BA was 64.9 $mg.kg^{-1}$ of cheese (Figure 1). During ripening in storage in the temperature regimes (A) and (C), the total BA content first increased (p <0.05) to 259.7 $mg.kg^{-1}$. Then it decreased (p >0.05) to 190.4 $mg.kg^{-1}$ in regime (A) and to 140.7 $mg.kg^{-1}$ in regime (C).

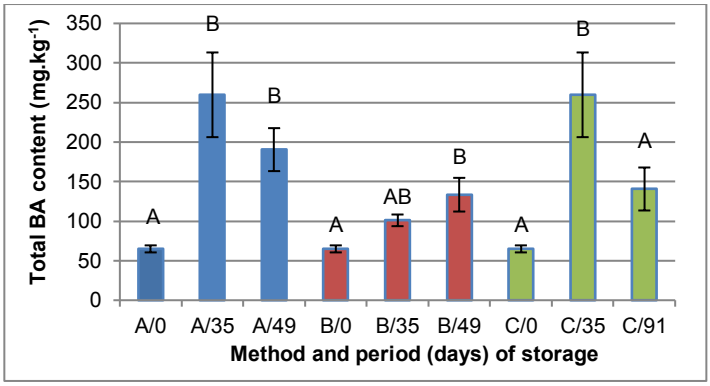

Figure 1 Comparison of the total content of biogenic amines (mg.kg^{-1}) in smear ripened cheeses stored in different temperature regimes (A, B, C) and analysed on the production date (0), at the end of the best before date after 35 days of ripening (A/35: storage at 6 °C/35 days, B/35: Storage at 6 °C/28 days and at -18 °C/7 days, C/35: storage at 6 °C/35 days) and at the end of storage after 49 or 91 days of ripening (A: storage at 6 °C/35 days and at 6 °C/14 days, B: storage at 6 °C/28 days and at -18 °C/7 days and at 6 °C/14 days, C: storage at 6 °C/35 days and at -18 °C/49 days and at 6 °C/7 days). Averages marked with different letters are statistically different within a given factor (storage period) (p <0.05); n = 15.

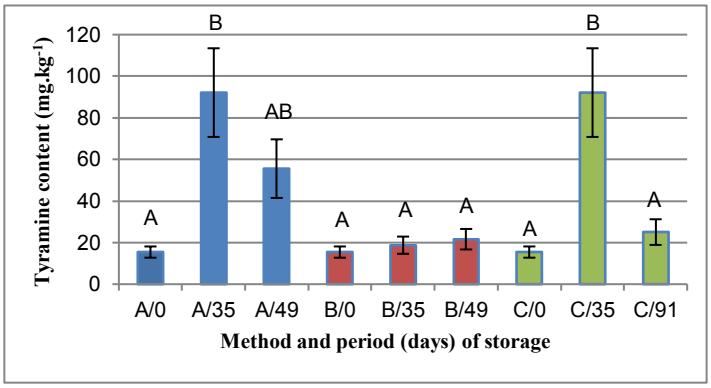

Figure 2 Comparison of tyramine content (mg.kg^{-1}) in smear ripened cheeses stored in different temperature regimes (A, B, C) and analysed on production day (0), at the end of the best before date after 35 days of ripening (A/35: storage at 6 °C/35 days, B/35: storage at 6 °C/28 days and at -18 °C /7 days, C/35: storage at 6 °C/35 days) and at the end of storage after 49 or 91 days of ripening (A: storage at 6 °C/35 days and 6 °C/14 days, B: storage at 6 °C/28 days and at -18 °C/7 days and 6 °C/14 days, C: storage at 6 °C/35 days and at -18 °C/49 days and at 6° C/7 days). Averages marked with different letters are statistically different within a given factor (storage period) (p <0.05); n = 15.

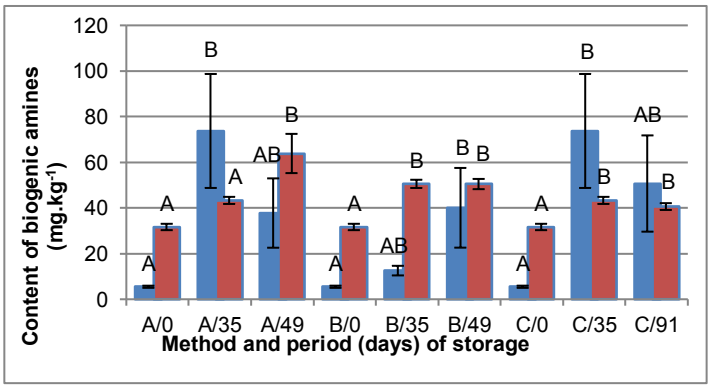

Figure 3 Comparison of putrescine and polyamine content (mg.kg^{-1}) in smear ripened cheeses stored in different temperature regimes (A, B, C) and analysed on production day (0) at the end of the minimum shelf life after 35 days of ripening (A/35: storage at 6 °C/35 days, B/35: storage at 6 °C/28 days and at -18 °C/7 days, C/35: storage at 6 °C/35 days) and at the end of storage after 49 or 91 days of ripening (A: storage at 6 °C/35 days and 6 °C /14 days, B: storage at 6 °C/28 days and at -18 °C/7 days and 6 °C/14 days, C: storage at 6 °C/35 days and at -18° C/49 days and 6 °C/7 days). Averages marked with different letters are statistically different within a given factor (storage period) (p <0.05); n = 15. Putrescine is marked blue, polyamines spermidine and spermine red.

The reduction in the total BA content of cheeses stored in temperature regime (C) was statistically significant (p <0.05); lower total BA content was recorded at the end of storage (C/91) than at the end of BBD (C/35). When stored in regime (B), the total BA content was higher (p <0.05) at the end of ripening (B/49) than on production date (B/0). The highest total BA value was recorded during storage in regime (A) after 35 days of ripening, namely 571.4 mg.kg^{-1} of cheese.

Higher total BA content compared to ours was detected in smear ripened cheeses by **Pleva et al. (2014)**, namely up to 1,000 mg.kg^{-1}. In 5 samples they show even higher values (1,000 – 6,000 mg.kg^{-1} of cheese). They ascribe the increased BA content to incorrect storage of cheese at stores. According to **Komprda et al. (2012)**, the impact of storage temperature on the variability of BA and PA content is 46% on average. The storage temperature has been reported by **Komprda et al. (2012)** for BA and PA variability has an average effect of 46%. Higher total BA content, as compared with our data, was also found by **Samková, Dadáková and Pelikánová (2013)** when cheeses were stored at 5 °C, namely 514 mg.kg^{-1}. After an additional two weeks of storage, the BA content further increased to 660 mg.kg^{-1}, with the highest recorded value of BA being 2,076 mg.kg^{-1} of cheese. **Standarová et al. (2010)** for the same type of cheese, and at the same conditions at the end of BBD, detected 1,500 mg.kg^{-1} BA; **Dičáková and Dudriková (2007)** 2,477 mg.kg^{-1}; **Rejchrtová (2015)** 593 mg.kg^{-1} and 66 days after the production 1,218 mg.kg^{-1}, which are much higher values than our results. According to **Standarová et al. (2009)**, there are also differences in BA content depending on the month of cheese production.

During storage, in temperature regimes (A) and (C) the overall BA content decreased. The reduction in the overall BA content between the 6th and 7th week of storage was reported by **Standarová et al. (2010)** for cheeses stored at 5 °C. In contrast, no significant changes in the overall BA content of long-frozen (-18 °C) cheeses were found by **Andiç et al. (2010)**, and they explain this finding by slowing down or cessation of microorganism activity. In our experiment, there was apparently for these reasons a reduction (p <0.05) in the overall content of the monitored BAs in regime (C).

Legislative limits on BA content in cheeses are currently not given. **Spanier, Bruin and Van Roode (1991)** state the content of histamine + tyramine + putrescine + cadaverine to be 900 mg.kg^{-1} of cheese on maximum. This value was not exceeded in our experiment.

During ripening, 8 biogenic amines were monitored. As for tryptamine, it was not detected in cheese at the beginning of storage at all. Its content was found in cheese only after 35 days of ripening in regimes (A) and (C), averaging 2.7 mg.kg^{-1}. Under conditions of storage regime (B), tryptamine was not detected in cheeses at all. The same results were obtained by **Standarová, Borkovcová and Vorlová (2008)** when analysing 215 samples of cheeses consumed in the Czech Republic. Tryptamine content in these cheeses was low or tryptamine was not detected at all. Low, up to 5.9 mg.kg^{-1}, or undetectable amounts of tryptamine were also found by **Standarová et al. (2009),** however in the Niva cheese taken from the Czech distribution network. **Samková, Dadáková and Pelikánová (2013)** found at the end of BBD of the same type of cheese tryptamine at 5.3 mg.kg^{-1}, after two more weeks of storage, the content of 5 mg.kg^{-1}, which is more compared to our results. **Pleva et al. (2014)** just like us did not detect any tryptamine in smear ripened cheeses.

According to **Novella-Rodrigues et al. (2003)** and **Buňková et al. (2010)** cadaverine along with tyramine and putrescine belong among the most important BAs in ripened cheeses. As in our experiment, these authors recorded the highest cadaverine values at the end of BBD after 35 days of storage. However, the values we found (26.9 mg.kg^{-1}) were more than ten times lower than those of the authors above. Higher cadaverine contents in cheese compared to our results (up to 2,400 mg.kg^{-1}) were reported by **Pleva et al. (2014)** and **Standarová et al. (2010)** after 28 days of storage at 5 °C (>400 mg.kg^{-1}). Also, **Samková, Dadáková and Pelikánová (2013)** report, compared to us, a higher cadaverine content of 176 mg.kg^{-1} at the end of BBD and 249 mg.kg^{-1} two weeks after the end of BB with the same type of cheese.

As for histamine, the highest values in our experiment were detected at the end of BBD during storage at 6 °C, with an average content of 17.5 mg.kg^{-1} of cheese and the highest recorded value of 49.5 mg.kg^{-1}. **Pleva et al. (2014)** report higher histamine content (373.8 mg.kg^{-1}) compared to ours for the same type of cheese. **Mayer, Fiechter and Fischer (2010), Standarová et al. (2010),** and **Loizzo et al. (2013)** also reported higher histamine content in smear ripened cheeses ranging between 168.3 mg.kg^{-1} and 500 mg.kg^{-1}. **Rejchrtová (2015)** also detected higher histamine levels at the end of BBD compared to our results to be 110 mg.kg^{-1} of cheese and after 66 days of manufacture to be 142 mg.kg^{-1}. **Samková, Dadáková and Pelikánová (2013)** found at the end of BBD when stored at 5°C the histamine content of 51.5 mg.kg^{-1} of cheese and after two more weeks of storage 55.3 mg.kg^{-1}, which is also higher than our results. Decrease in the histamine content (similar to our experiment) between 30th and 60th day of ripening was reported by **Martuscelli et al. (2005)** in the Pecorino Abruzzese cheese. **Dalgaard et al. (2006)** report that short-term freezing had a significant effect on the subsequent decrease in histamine content (in muscle tissue of sea pike). This corresponds to our results when, in regime (B) at the end of BBD, the average histamine content was 8.0 mg.kg^{-1} of cheese and in regime (A) 17.5 mg.kg^{-1} of cheese. **Standarov, Borkovcová and Vorlová (2008)** report that the histamine content of 100 mg.kg^{-1} of cheese may already induce intoxication in human organisms. However, this level of histamine content was not recorded in our experiment.

Cheeses typically contain up to tens of mg.kg^{-1} of 2-phenylethylamine. In our experiment, at the end of BBD in cheeses stored at 6 °C (regime A), we have detected 5.4 mg.kg^{-1} of 2-phenylethylamine and two weeks after BBD 1.4 mg.kg^{-1}. **Pleva et al. (2014)** reported higher content of 2-phenylethylamine in the same type of cheese than in our experiment, namely 11.6 mg.kg^{-1}. In contrast, **Samková, Dadáková and Pelikánová, (2013)** detected at the end of BBD in smear ripened cheeses a content of 2-phenylethylamine lower than ours**,** namely 4.3 mg.kg^{-1}. However, after two more weeks of storage compared to our data, the content of 2-phenylethylamine was higher (2.3 mg.kg^{-1}). **Standarová, Borkovcová and Vorlová**

(2008) reported that migraine can already be induced by 30 mg.kg^{-1} of 2-phenylethylamine. This value was not recorded in our experiment.

Tyramine

At the beginning of storage (A/0, B/0, C/0), the tyramine content in cheeses was 15.4 mg.kg^{-1}. During the ripening process (Figure 2), in storage in temperature regimes (A) and (C) there was first an increase (p <0.05) of the tyramine content to 92.1 mg.kg^{-1} of cheese, at the end of BBD after 35 days. At the end of storage in regime (A), lower values were recorded, namely 55.6 mg.kg^{-1}. In regime (C) the decrease (p <0.05) of tyramine content was more pronounced, namely up to 25.1 mg.kg^{-1} of cheese. During storage in regime (B), the tyramine content did not change in the course of ripening of the cheese (p >0.05). The highest value of tyramine was recorded in our experiment after 35 days of ripening in regime (A), namely 291.7 mg.kg^{-1} of cheese. The upper limit of tyramine content in food, according to **Halász et al. (1994)**, **Shalaby (1996)**, **Silla Santos (1996)** and **Eerola et al. (1997)** ranges from 100 to 800 mg.kg^{-1} of food. According to **Latorre-Moratalla et al. (2008)**, people taking MAO inhibitors tolerate 50 – 100 mg tyramine, however problems can even be caused by 6 mg.kg^{-1} **(Novella-Rodríguez et al., 2003)**. In samples stored at 6 °C (regime A), a "safe limit" of 100 mg.kg^{-1} was exceeded in 5 out of 15 analysed samples at the end of BBD. Tyramine content >100 mg.kg^{-1} was not detected during storage in temperature regime (B) for any cheese.

In the same type of cheese, **Standarová et al. (2010)** detected the highest tyramine concentration between the 5th and 6th week of storage at 5 °C, which corresponds to our results (A/35). **Rejchrtová (2015)** reported at the end of BBD in the same type of cheese at 5 °C higher tyramine content compared to ours (>800 mg.kg^{-1}). **Samková, Dadáková and Pelikánová (2013)** likewise recorded a slightly higher average tyramine values than in our experiment at 5 °C at the end of BBD, namely 140 mg.kg^{-1}. After two more weeks of storage the value was 163 mg.kg^{-1}, while the highest tyramine reading after extended storage in their experiment was 469 mg.kg^{-1} of cheese.

In our experiment, the tyramine content as well as histamine and total BA content decreased between the 5th and 7th week of storage (A/49). According to **Leuschner et al. (1998)**, one possible explanation can be the fact that some microorganisms have the ability to degrade tyramine and histamine. In testing 32 strains of *B. linens* and coryneform bacteria, it was found that 21 of them showed histamine or tyramine oxidase activity. These authors further state that *Brevibacterium linens* (LTH 456 and LTH 3686) were able to reduce the tyramine and histamine content for Munster smear ripened cheese by 55 to 70%. According to **Bergey and Holt (1994)**, **Leuschner, Heidel and Hammes (1998)** and **Dasu et al. (2006)**, also *Pseudomonas* sp., *Seratia marcescens, Kocuria varians,* and other bacteria can decompose the created BA. **Komprda et al. (2007)** found an increasing content of tyramine with time in a Dutch type cheese from two different manufacturers. **Standarová et al. (2009)** reported similar results for cheese with blue mould in dough and **Martuscelli et al. (2005)** for Pecorino Abruzzese cheese. The latter authors observed the most significant increase in tyramine content between the 14th and 30th day of ripening, which corresponds to our results.

Putrescine

At the beginning of storage (A/0, B/0, C/0), the putrescine content in the cheeses was 5.5 mg.kg^{-1}. During ripening (Figure 3), when stored in temperature regime (A) and (C), the content of putrescine in cheeses first increased to 73.7 mg.kg^{-1} (p <0.05). After expiration of BBD and further storage, putrescine content values in cheeses were lower, namely 37.8 mg.kg^{-1} in regime (A) and 50.7 mg.kg^{-1} in regime (C). In temperature regime (B), putrescine content increased (p <0.05) during storage, when after 49 days of storage (B/49) a higher putrescine content than on production date (B/0) was recorded.

Higher content of putrescine, compared to our data, was found by **Pleva et al. (2014),** when putrescine in smear ripened cheeses was detected at >2,000 mg.kg^{-1}. **Standarová et al., (2010)** also reported that the putrescine content was higher, when after 28 days of ripening at 5 °C its content was 212 mg.kg^{-1} in the same type of cheese. In our experiment, too, the highest average putrescine content was found after 35 days of ripening at 6 °C. However, the average content was lower at 73.7 mg.kg^{-1}, while the highest recorded value was 320 mg.kg^{-1} of cheese. **Samková, Dadáková and Pelikánová (2013)** detected a higher average putrescine content of 104 mg.kg^{-1} in smear ripened cheeses at the end of BBD when stored at 5 °C. After two more weeks of storage, the putrescine content increased even more to 137 mg.kg^{-1}.

In our experiment, however, the putrescin content decreased (p >0.05) after a further 2 weeks of storage at 6 °C (A/49). In contrast, in regime (B) the putrescine content of cheeses increased, when at the end of storage (B/49) a higher (p <0.05) content of putrescine than at the production date (B/0) was detected. An increase in the putrescine content during storage (of tuna) at low temperatures (-18 °C) was also reported by **Ben-Gigirey et al. (1998)**. However, during long-term freezing (regime C), there was a decrease in the putrescine content in cheeses, which is probably related to the decrease of enzymatic activity of microorganisms **(Andiç et al., 2010)**.

Polyamines

As regards PAs (spermidine and spermine), their content in cheeses was 31.7 mg.kg^{-1} at the beginning of storage (A/0, B/0, C/0). During storage, the PA (p <0.05) content has increased in all temperature regimes. At the end of the storage period, the cheeses had a higher (p <0.05) PA content than on the day of production (Figure 3).

At present, PAs and their precursor putrescine are classified differently from the BA group. PAs may originate in a different metabolic pathway and are characterized by different biological functions. **Pleva et al. (2014)** show higher PA values compared to ours (A/35) for the same type of cheese, namely 55.8 mg.kg^{-1} on average. In contrast, **Samková, Dadáková and Pelikánová (2013)** measured lower values of PAs at the end of BBD compared to ours, namely 33 mg.kg^{-1} for cheeses stored at 5 °C. After two more weeks of storage, they found a PA

content of 48.2 mg.kg^{-1} of cheese, which is also less compared to our values (A/49).

CONCLUSION

Our hypothesis regarding the effect of temperature on BA formation in cheeses was confirmed. Their content was higher at 6 °C than when stored at freezing temperatures. Freezing does not completely deactivate the enzymes, as enzyme reactions are slowly taking place even at freezing temperatures. However, it is important to keep in mind that low temperatures recommended for food storage were used in our experiment.

The highest (p <0.05) total BA content was found when storing the cheeses at the end of BBD (best before date) after 35 days (259.7 mg.kg^{-1}) in storage regime (A) or (C). During storage in regime (B), the total BA content (p <0.05) after 49 days of storage was higher than on the production date (B/0). During storage, the tyramine content in regime (B) did not change (p >0.05), while in the temperature regimes (A) and (C), the highest levels of tyramine and putrescine content were recorded in cheeses at the end of BBD after 35 days ripening (92.1 mg.kg^{-1}, resp. 73.7 mg.kg^{-1}). The content of polyamines in cheeses was higher (p <0.05) at the end of storage: 63.9 mg.kg^{-1} in storage regime (A), resp. 50.5 mg.kg^{-1} in storage regime (B) and 40.6 mg.kg^{-1} in storage regime (C), than at the beginning (31.7 mg.kg^{-1}).

Analyses performed (ANOVA with interactions) show that greater effect on the content of BAs (tyramine, putrescine) and PAs had the period of storage rather than the method of storage (temperature regime).

PREFERENCE MAPPING OF DIFFERENT VARIETIES OF GARLIC (*ALLIUM SATIVUM*)

Zuzana Drdolová, Patrícia Martišová, Lucia Benešová

ABSTRACT

In this work we evaluated different varieties of garlic. All varieties of garlic are rated from one harvest year. Compared samples were different in shape, taste, aroma and characteristics, which were likely to impact on consumer choice and deciding on purchases garlic. Selected indicators were part of internal sensory evaluations, which were evaluated by experts in the sensory laboratory. External part of the preference mapping was conducted among consumers relying on different varieties of garlic under their consumption. Using the internal part of the preferential mapping we summarize randomly selected characteristics within the textural properties and characteristics of taste in which we consider the possible impact on consumer´s choice. In the sensory evaluation assessors used 9 point scale to evaluate 15 selected properties across the texture, taste and aroma on 10 selected varieties according to the degree of preference. Garlic odour and textural properties were evaluated by the normal procedure, though the taste because of intense lingering aftertaste of has been evaluated in a prepared mixture after cooking. For external evaluation, we designed a questionnaire in which consumers can express their preference for individual samples based on photo and variety characteristics, using a hedonic scale from 1 to 9. Obtained data from sensory evaluation and a questionnaire survey were evaluated using statistical software XLSTAT. Preferential map summarise results from internal and external evaluation. We identified characteristics affecting the degree of consumer preferences according to the visualization of our results.

Keywords: garlic; preference mapping; aroma; taste

INTRODUCTION

Preferential mapping is a way to statistically combine analytical sensory results, consumer information and product perception. Using analytical sensory data and consumer technology, it is possible to obtain a complete product image **(Risvik, McEwan and Rødbotten, 1997)**. Preferential mapping uses a set of statistical methods aimed at detecting consumer preferences of the compared products using sensory profiles. This method is used in the food industry to develop new products, especially according to consumer requirements **(Meullenet, Xiong and Findla, 2007)**. Preferential mapping was used in previous studies of fresh fruit, including raspberries **(Villamor et al., 2013)**, apples **(Jaeger et al., 1998)**, strawberries **(Lado et al., 2010)** and tomatoes **(Sinesio et al., 2010)** to confirm product attributes on the basis of which the consumer decides. These studies focused on taste intensity, texture and appearance/colour, which are important for consumer acceptance of the product **(Oltman, Yates and Drake, 2016)**. The perception of the sensory characteristics (appearance, colour, taste, smell, texture), which determine the so-called "organoleptic characteristics", is essential to create consumer perceptions about food quality. Based on the outputs of the sensory profiles, it is possible to subtract the information obtained from the analyses **(Vietoris et al., 2014)**. External factors (size, colour, appearance) of tomatoes have been shown to be important to consumers as well as taste **(Hetherington and MacDougall, 1992; Pagliarini, Monteleone and Ratti, 2001)**. The texture also plays a major role in consumer perception of quality and taste **(Causse et al., 2003; Aurand et al., 2012)**. Taste is the biggest indicator of quality for consumers **(Aurand et al., 2012)**, but texture and appearance are crucial for fresh fruits and vegetables purchased on the basis of external characteristics where taste or taste cannot be directly assessed. By texturing is mean all mechanical, geometrical and surface properties of the products, perceptible by mechanical, tactile or auditory and visual receptors **(Dimitreli and Thomareis, 2007)**. **Oltman, Jervis and Drake (2014)** have recently demonstrated with target groups and pooled research that appearance and strength were the main drivers of buying fresh tomatoes.

Garlic (*Allium sativum* L.) is one of the oldest cultural plants used both for food and for medical use. It is a rich source of several phyto-nutrients recognized as important elements of the Mediterranean diet but is also used in the treatment and prevention of many diseases. These effects are associated with thiosulfinates and volatile sulphur compounds, which are also responsible for the distinctive, pungent odour and taste of this vegetable **(Lanzotti, 2006)**. Various varieties of garlic are available on the market, which differ from each other in their properties, size, shape, colour and taste. By determining the odour and taste components more closely, differences were found between examined garlic varieties. Their chemical composition and variety also suggest various changes in the use or changing properties after adding to the product **(Calle, 2016)**.

Scientific hypothesis

The aim of the study was to determine consumer preferences to selected varieties of garlic. By selecting different varieties, we wanted to highlight the diversity of garlic offered on market and identify the properties that are decisive for the consumer.

MATERIAL AND METHODOLOGY

We evaluated ten samples (Figure 1) of winter garlic varieties obtained from one grower harvested in one harvest year stored one month under the same storage conditions and temperature regime. Groups of thirty assessors familiar with evaluation methodologies have compared the shape, size, colour, appearance to cut, hardness, odour intensity, spicy, sweet, sour and earthy odour, authentic taste, spicy, sweet, sour, and earthy taste. We used two types of scale, an intensity scale to assess the intensity of a certain property, and a hedonic scale to assess the degree of acceptability. The assessors wrote their perceptions on a pre-prepared paper form.

Apples were used as a neutralizer for odour determination. We have included the odour neutralizer in the review due to the intense sensory burden of the evaluators that we have been alerted to during the trial evaluation. Similarly, due to the extreme sensory load and the long-lasting aftertaste when using a raw garlic sample, we chose to evaluate the taste properties of the mixture. The prepared appetite blend comprised: 250 g of chicken, 15 extruded garlic, 2 g of salt, 1 g of pepper and 2 g of red pepper. The mixture was heat treated. Garlic was added to the mixture 2 minutes before the end of the heat treatment. The external part of the evaluation was done by using a questionnaire. The questionnaire included a description of the characteristics of the varieties with the attached photographs. The evaluators had the opportunity to express their preferences on a 9 point hedonic scale. 150 respondents were involved in the evaluation.

Statistic analysis

The data obtained from sensory evaluation and questionnaire survey, were evaluated using the XLSTAT statistic software (v. 2019.1.2, Addinsoft). Internal data sets from the sensory analysis were evaluated by principal component analysis (PCA). External data sets were evaluated by agglomerative hierarchical clustering (AHC). By combining these data set we have obtained preference map.

RESULTS AND DISCUSSION

From the PCA (Figure 2), we can observe that four groups of samples have been specified. Samples 1, 5, 9, 7, 3 and 8 show similarity in all of the odour, texture, and taste characteristics. Sample 10 obtained a higher rating compared to the other samples when evaluating the sour smell of odour intensity, colour, and sour taste. Samples 6 and 4 had similar ratings.

Figure 1 Samples of winter garlic varieties.

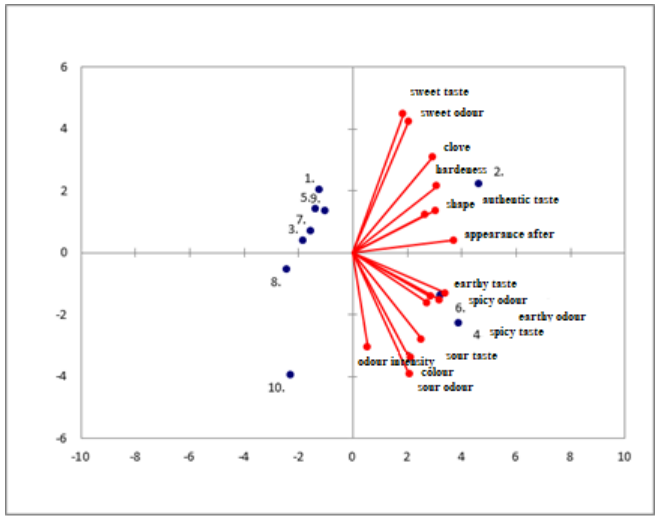

Figure 2 Evaluation using principal component analysis (PCA).

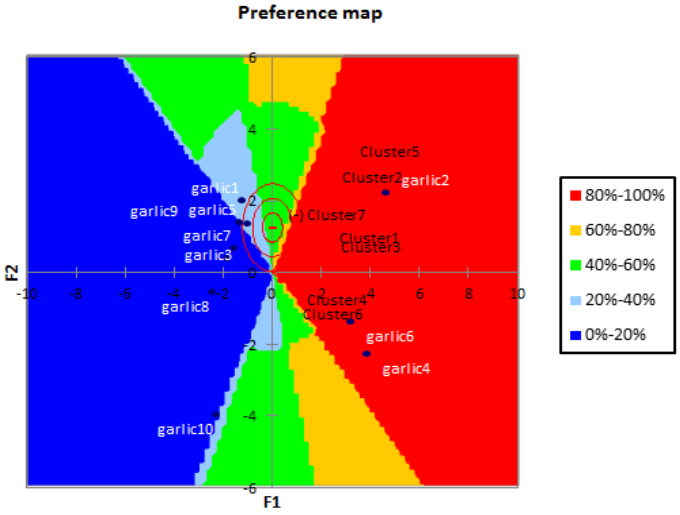

Figure 3 Preference map.

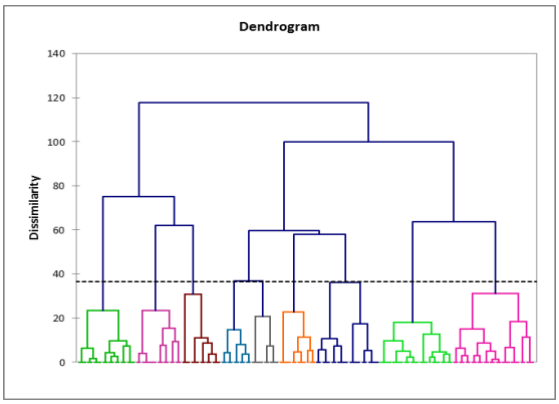

Figure 4 Agglomerative hierarchical clustering.

High values have been observed in the evaluation of the earthy taste, spicy odour, earthy odour and colour. In general, these samples, along with sample 2, had high ratings in all selected properties. Sample 2 recorded slightly lower ratings when assessing the odour intensity, spicy, sour odour and colour. **Drdolová, Golian and Vietoris (2015)** analysed the chemical composition of garlic by gas-chromatographic analysis (GC-MS) of an Agilent 6890N gas chromatograph coupled with Agilent 5973 inert mass spectrometry detector. Differences in the chemical representation of individual varieties of garlic have been noted in the intermodality. Significant differences in relative abundance have been reported for dialyl disulfide, methyl-allyl-thioacetate, and allyl-methyl-

disulfide, which are important compounds in terms of flavor formation and garlic odour. In assessing the rate of representation of these compounds, a varying proportion of the identified compounds has been demonstrated in the cross-industry comparison.

By processing the survey data for the 150 respondents (Figure 3), we reached the following results. In the highest consumer preference zone (80 – 100%), a sample of 2, 4 and 6 was placed on the basis of the specific characteristics of the products included in the survey. These samples, based on the analysis of PCA showed the following characteristics: shape, size, colour, appearance after cutting, hardness, odour intensity, spicy, sweet, sour, earthy odour, authentic taste, spicy, sweet, sour and earthy taste. The lower scoring was observed for sample 2 when evaluating colour and odour intensity. Sample 4 reported a lower rating for the sweet odour and sweet taste. Sample 6 did not report a low score in either of the endpoints, however, it received moderate evaluations in assessing hardness and spicy taste.

Samples placed in the lower consumer preference zone 5, 9 and 1 received average ratings in assessing the shape, size, appearance after cutting, hardness, sweet and earthy odour, sweet and earthy taste. Low ratings have received these samples in evaluating colour, odour intensity, spicy and sour odour, authentic taste, spicy and sour taste. Samples 3, 7, 8, and 10 were placed in the lowest consumer preference zone (0 – 20%). These samples were evaluated based on a PCA of average rating for colour, sour and earthy odour, authentic taste, spicy and sour taste. Samples 3, 7, 8, and 10 received a low rating in assessing the shape, size, appearance after cutting, hardness, sweet and earthy taste. In consumer studies on tomatoes, the consumer's emphasis on commodity appearance was more pronounced than the taste of subsequent tasting **(Sinesio et al., 2010)**.

In a similar study comparing the importance of external and internal properties of tomatoes on the market, the colour was the most significant attribute, followed by size and juiciness (evaluated after slicing), followed by strength after hand pressure, the taste itself was much less important **(Oltman et al., 2014)**. The current results from tomato evaluation confirm the importance of tomato taste and aroma, which is a key attribute for the variety modification progress. However, during the evaluation of appearance, colour, colour intensity, and size for evaluation, the assessors proceeded as in previous tomato market studies **(Oltman et al., 2014)**.

Eight clusters (Figure 4) were selected for data analysis. By a more detailed analysis of the clusters, it was found that the vast majority of the respondents, who were involved in the research, focused on garlic-based textural properties, especially shape, colour, size and hardness. The observations also show that the basic indicative characteristics of the evaluation are the sweet and spicy taste and smell as well as the degree of acidic and earthy taste and aroma in evaluating the taste and odour characteristics of garlic. **Oltman et al. (2016)** in his study distinguished consumer clusters according to the specific taste of tomatoes, which correlated with colour, taste/aroma and textural properties. Clusters consisting of assessors who consume tomatoes often submitted samples and their properties as more differentiated and concretized their evaluated properties.

Consumers focus on textural features when buying **(Causse et al., 2003)**. Another study identified a group of tomato consumers where the external strength assessed by touch was as important as the sliceability and compliance of tomatoes in the mouth. High strength was characterized in the best rated varieties in the tomato study, which was aimed at analyzing variable physico-chemical and sensory parameters and their role in the perception of tomato taste **(Piombino et al., 2012)**.

Kitchen garlic is a plant which is very often used in traditional and modern gastronomy. It is part of many foods and food products. Garlic with its distinctive taste and odour characteristics is a diversification of every meal. There are many varieties of garlic in the world that differ from those native to garlic, which are significant in addition to the taste and smell indications of their broad-spectrum positive health effects. Evaluators of garlic are very demanding, and it is necessary to select a sensitive methodology to achieve the desired result. Especially the intense smell and the long-lasting aftertaste of garlic, which prevents the ingestion of multiple samples in a row in the raw state, is a complication in sensory analysis. For this reason, we evaluated the scent neutralizer and the taste evaluation in the mixture after the heat treatment to evaluate the flavour intensity and its overwhelming after ingestion. By processing the data, we found that the evaluators in the internal evaluation section, as well as the respondents involved in the external part of the preference mapping, were key features for decision-making colour, hardness, size and appearance after cutting, and thus predominantly textural features of the evaluated plant commodity. In the highest consumer preference zone (80 – 100%), samples 2, 4 and 6 was placed on the basis of the specific characteristics of the products included in the survey. These samples, based on the analysis of the PCA of the evaluation of the characteristics examined, showed the following characteristics: shape, size, colour, appearance after cutting, hardness, odour intensity, spicy, sweet, sour and earthy odour, authentic taste, spicy, sweet, sour and earthy taste. The lower scoring was observed for sample 2 when evaluating colour and odour intensity. Sample 4 reported a lower rating for the sweet odour and sweet taste. Sample 6 did not report a low score in either of the endpoints, however, it received moderate evaluations in assessing hardness and spicy taste.

Samples placed in the lower consumer preference zone 5, 9 and 1 received average ratings in assessing the shape, size, appearance after cutting, hardness, sweet and earthy odour, sweet and earthy taste. Low ratings have received these samples in evaluating colour, odour intensity, spicy and sour odour, authentic taste, spicy and sour taste. Samples 3, 7, 8, and 10 were placed in the lowest consumer preference zone (0 – 20%). Based on the PCA, these samples received average ratings for colour, odour, sour and earthy odour, authentic taste, spicy and sour taste. Samples 3, 7, 8, and 10 received a low rating in assessing the shape, size, appearance after cutting, hardness, sweet odour, sweet and earthy taste.

CONCLUSION

Based on the results we would like to state that the samples with attractive appearance are partly overestimated by the assessors in all evaluated properties. The findings from the internal part of the evaluation were confirmed by the analysis of the clusters, which suggests that the vast majority of respondents in the research focus on garlic based on the perception of textural properties of garlic, especially shape, colour, size and hardness. The observations also show that the basic indicative characteristics of the evaluation are the sweet and spicy taste and odour as well as the degree of acidic and earthy taste and aroma in evaluating the taste and odour characteristics of garlic.

COMPARISON OF QUALITY PARAMETERS OF THE COOKED SALAMI „GOTHAJSKÝ“ IN DEPENDENCE ON USED SALT CONTENT AND ADDITIVES

Miroslav Jůzl, Markéta Piechowiczová, Kamila Řehůřková

ABSTRACT
Consumers in Czech Republic have high income of salt from food, therefore, there are efforts to reduce its content in meat products. The subject of this work was to examine differences in sensory evaluation of sliced cooked salami (Gothajský salami), manufactured according to various recipes. This type of meat product is well known primarily to the older generation of consumers, so the aim was to find out the differences in the perception of various samples between generations. The monitoring factors were salt content (1.6% or 2.0%), presence of monosodium glutamate (PG = presence or AG = absence) and group of evaluators (YC = 18 – 26 years old or OC = more than 60 years old). Older sensory panellists (OC; against YC) significantly (p <0.05) evaluated all samples more positively, especially in the taste and odour descriptors. Samples with monosodium glutamate (PG1.6 and PG2.0) were rated in the taste significantly better (p <0.05), regardless of the age of the assessors (YC and OC). Samples with reduced salt, without glutamate (AG1.6) were significantly worst evaluated (p <0.05) by both the groups (YC and OC) than PG2.0 samples.

Keywords: colour; sensory evaluation; saltiness; monosodium glutamate

INTRODUCTION
The content of salt in meat products continues to be of interest to consumer organizations and health professionals **(WHO, 2013)**. Processed meat products and bread including cereals in the group are the largest source of sodium (salt) in the European diet **(Kloss et al., 2015)**. The health consequences of excess sodium in the diet are more serious than consumers admit. with hypertension and leads to an increased risk of strokes and fatal vascular diseases **(He and MacGregor, 2010)**. There are several ways to reduce salt content. The salt content of meat products can be reduced to a level that does not affect the technological or organoleptic properties of the product. By further reducing the sodium content, it may be partly or completely replaced by other substances that do not adversely affect the sensory and technological properties. Potassium, calcium, magnesium, and sodium and potassium lactate are most commonly used **(Desmond, 2006)**. According to **Aaslyng et al. (2014)** that salt reduction from 2.2% to 1.7% did not alter the sensory properties in sausages. It is commonly assumed that sensory impairments occurring with age negatively affect older people's intake of foods in terms of both quality and quantity. Because of anatomical changes in all the senses involved in human food perception, on average seniors perceive a lower flavour intensity than younger adults, are less sensitive to changes in the flavour profile of foods and show a decreased ability to discriminate between different intensity levels of flavour and/or taste attributes. However, despite these differences in their sensory perception of foods, young adults and seniors seem to differ less in their initial hedonic appraisal of food products **(Doets and Kremer, 2016)**. Multidisciplinary approach includes evaluating psychological issues such as attitudes, beliefs, and expectations; sensory properties such as appearance, texture, flavour and odour; and marketing-related aspects such as price and brand **(Font-i-Furnols and Guerrero, 2014)**. Older consumers are more conservative in their preferences. Consumer protection and detecting of adulteration is very important and has a wide societal impact in the economic sphere **(Drdolová et al., 2017)**. Traditional consumer testing provides important information regarding acceptability but may miss important unconscious responses of consumers **(Torrico et al., 2018)**.

Unfortunately, the Czech Republic is in the income of salt content and the occurrence of diseases with this problem associated with the leading countries. However, sodium chloride and sodium nitrite have a key role in meat production. Reducing the salt content in consumers´ of known meat products is a way to rationally reduce sodium in food. Rather than developing new recipes or making a major legislation-regulated adjustment, recommendations should be made for manufacturers. Together with an assessment of such an adjustment, could be a guideline, especially for smaller producers in the regional market. This can better meet the demands of different consumer groups and will not require legislation or major

interventions in large-scale meat production **(Jůzl et al., 2018b)**. Nevertheless, the major issue when using lower salt concentrations in processed meat products is to be able to maintain the product quality characteristics without affecting the shelf-life or the economic viability of the product **(Desmond, 2006)**. Salt is predominantly used to enhance food flavour, making even unpalatable food taste better. However, taste and preservation are not the only reasons for the use of high levels of sodium in foods. The sodium level is generally kept high due to the additional functional roles it provides. The presence of salt (1.5% – 2.5% w/w) in meat products solubilizes meat proteins, activates extraction of proteins, enhancing hydration, and water holding capacity (WHC) **(Ruusunen and Puolanne, 2005)**. Colour and material of surface of packaging are important parameters for consumers **(Géci et al., 2017)**. **Tobin et al. (2013)** wrote about a problem with low-salt meat products. Main reason is that, along with saltiness, reducing sodium will also affect product texture and flavour intensity. However, lowering the salt content to 1.4% NaCl in cooked sausages has been shown to be possible while keeping an acceptable perceived saltiness, firmness, water-binding and fat retention. The meat industry is pushed to the lowest price by the retail chain, which causing meat content reduction in the products **(Fekete et al., 2016)**. One way is following the trends moving towards enhancing hygienic quality using antioxidants **(Bobko et al., 2017)** or antimicrobial agents **(Kročko et al., 2015; Kročko et al., 2017)** in recipes. Therefore, it is an attempt to reduce the use of classically used additives such as flavour enhancers (sodium glutamate), colourants (carmine) or sodium nitrite in salt mixtures **(Jůzl et al., 2018a)**.

Scientific hypothesis

We are expecting the significant effect of salami´s recipes on consumer tests by sensory evaluation. The aim of this study was to examine the importance of reduced the salt content of meat products according to the presence or absence of monosodium glutamate (MSG) for various groups of consumers.

MATERIAL AND METHODOLOGY

The cooked salamis were produced due to in three repetitions according to the quality standard of ON 57 7231 (Gothajský salami, beef H3 or H4, pork V4, pork V5 or V6 and V8 according to Czech Meat Processors Association). Samples were prepared in the pilot plant CZ 22067 (approved by the State Veterinary Administration, Czech Republic) of Mendel University in Brno. This cooked salami named Gothajský salami has name associated with city in Germany. It is delivered for retail use on shop counter where they are sliced. This salami is spiced with paprika, cumin and coriander. Due to Czech legislation, this salami is typical of pieces of pork lard, size predominantly up to 8 mm. The meat content should be min. 40% and a maximum fat content of 40%. The product must not contain mechanically separated meat or poultry mechanically separated meat. It is filled into artificial PE packaging, in our case red BETAN, calibre 75 mm, length 50 cm. For production were used typical standard machines used in industrial production (cutter, filler, smoker). Both spice mixtures from two different companies contained the E450, E451 and E452 stabilizers, spices (paprika, cumin and coriander), antioxidant E300 and E160c (pepper extract), but they differ in presence or absence of monosodium glutamate. Weights of nitrite salt mixture were weighed to produce 2.0% or 1.6% salt in the final samples. So, they were summatically produced four recipe variants PG2.0 or PG1.6 (presence of monosodium glutamate, 2.0 or 1.6% salt) and AG2.0 or AG1.6 (absence of monosodium glutamate, 2.0 or 1.6% salt). After receiving, the raw meat was kept in 2 °C and second day was coarsely ground to obtain meat emulsion in cutter (Seydelmann, Germany). Lard prepared previously to regular cubes was frozen (-18 °C) and during the production incorporated in cutter during production to the desired mosaic. Than were and filled (HTS 150, Germany) in PE casings (75/50) and treated (70 °C, 10 min in the product core) in smoker (Bastramat, Germany).

Quality evaluation of cooked salami

For chemical and sensory analysis were used commonly available methods. For the instrumental measurement of the surface colour, the spectrophotometer and CIE colour space (L*a*b*) were used. Salamis was measured and evaluated in the sixth day after production. Shelf life (in 2 – 4 °C) is set at 3 weeks. The product was sliced on a commercial rotary cutter before sensory evaluation in slices (0.5 mm).

Chemical analysis

The dry matter ($g.100g^{-1}$), the salt content ($g.100g^{-1}$) and the fat content ($g.100g^{-1}$) after homogenization of the sample (250 g) were analysed for each group (PG2.0, PG1.6, AG2.0, AG1.6) **(AOAC, 2005)**. All analysis was undertaken in duplicate.

Colour measurement

Colour space L*, a* and b* was used to determination differences in colour. The CM 3500d spectrophotometer (Konica Minolta, Japan) was used and the samples were measured (D 65, 6500 °K) on the surface in centre of the slices with SCE (Specular Component Exluded) and 30 mm slot in triplicate (3 pairs and in 2 batches). Colour variation was determined as total colour difference ΔE^*_{ab} **(Saláková, 2012)**.

Sensory analysis

Sensory analysis was evaluated by two consistently identical different groups of panellists (n = 48). Selection was based on submitted questionnaires received from trained meat products consumers. To be selected, they had to belong to a group of consumers who ever ate cooked salamis (Gothajský salami) and consumed meat products from 1 to 3 times a week. The number of women and men was not equivalent, so this factor was not evaluated. One group of young consumers (YC) was selected from students (18 – 25 years, n = 24) of course Meat Technology (bachelor study Chemistry and Food Technology, second year, MENDELU). Seniors, older consumers (OC, n = 24) were selected from the class of Institute of Lifelong Learning, members of the University of the Third Age, MENDELU. Both groups of panellists were briefly trained in the basics of sensory evaluation and the use of questionnaires. The evaluation was ongoing

under ČSN ISO 6658 (560050) condition. Sensory analysis was undertaken at special sensory laboratory with ten chambers (Department of Food Technology).

All panellists buy and consume Czech meat products regularly. For each sample, assessors were asked to indicate their score on a 100 mm line scale. It is ranging from 0 at the left to 100 at the right. Descriptors expressed as the hedonic scores. Minimum was 0 (left) and maximum of pleasure 100 (right side of scale). Analysis were chosen as sensory panel with following descriptors: appearance, colour, texture, fat composition, consistency, odour, saltiness and taste. The samples were presented to panellists randomly and marked with a numeric code. Water and non-salted bread were used as neutralizers.

Statistical analysis

The data has been sorted and processed by analysis of variance (one-way ANOVA) and Tukey´s test to compare groups of samples according to its salt content or presence of monosodium glutamate in cooked salami´s recipes by the groups of panellists in programme STATISTICA 12. Samples were considered significant at 95% confidence level (p <0.05) and data were tested for normality by Shapiro-Wilk test.

RESULTS AND DISCUSSION

Although the recipe was free from substitutes and contained beef, it can be considered as a standard meat product of standard quality. Chemical analysis of the samples showed results that did not exceed the limit set by **Decree No. 69/2016 Collection of Laws** (40% fat) or significantly differ from the values given in the ČSN 57 7231 standard and the corresponding scheme for products of quality category (above 47 to 50% dry matter, 39 to 42% fat, 2.0 ±0.6%). Even though we were based on the norm, the fat content was lower than the standard. The reason is probably lower fat content in pork than in ČSN 57 7231. Fat content in pork has changed since the original calculations and compared to the state more than thirty years ago. There were no differences (p >0.05) in fat and protein content or in dry matter between groups of samples (Table 1). Of course, the salt content of the product varied (p <0.05) in groups with different salinity (PG2.0, AG2.0 versus PG1.6 and AG1.6). It should be noted, results could depend on the type of analysis used. State authorities

Note: YC – consumers 18-26 years old, OC – consumers more 60 years old; PG2.0 or PG1.6 = presence of monosodium glutamate, 2.0 or 1.6 % salt; AG2.0 or AG1.6 = absence of monosodium glutamate, 2.0 or 1.6% salt; Means with different superscripts in the same rows show significant differences (p <0.05); Means with * designation show significant differences (p <0.05) between panellists groups YC and OC; Descriptors expressed as the hedonic scores, where 0 is the sign minimum and 100 is maximum of pleasure.

responsible for supervision of safety, quality and labelling of foodstuffs in the Czech Republic require sodium analysis, in our case we have used the determination through chlorides. However, it should not be a significant difference.

However, **Kameník et al. (2017)** states in his work that salt level determined by the two methods strongly correlated and did not differ in any meat product. After all, the results presented by **Kameník et al. (2017)** are not different from our chemical analysis.

The appearance of the food, its colour and its stability are essential for meat products to be offered to consumers at the shelves of the shops in a sliced form. This also contributes to the lighting that is in the room. In general, products with a more pronounced colour are better evaluated (higher values for red and * and yellow b *). Table 2 shows the colour values. Lightness of cooked

salamis was measured in the range of L* = 55.19 to 58.10, depending more on the salt content. Also, for parameters a * and b * for red and yellow colour (resp.) was found significantly differences (p <0.05) between groups according to its content of salt. Groups with lower saltiness had higher lightness and lower colour coordinates a* and b*. Lightness L*, it depends on the type of product. Salt, specifically sodium chloride and especially nitrite, is expressed in several ways in the meat product: it contributes to the colouring of the product, to the aroma formation, has a preservative and antioxidant effect **(Saláková et al., 2013)**. It is obvious that the lower salt content has a significant effect (p <0.05) on the colour of the products, but it did not depend on the presence of MSG (Table 2). Results showed similar colour values as at work **Jůzl et al. (2018a)**.

Table 4 shows the sensory assessment of cooked salamis and their comparison between two groups of evaluators. There were not found statistical differences (p >0.05) in appearance between groups of samples according to the content of salt in both groups of panellists. It has been confirmed that the salt content is an important aspect of the acceptability of the meat product. Older evaluators were more receptive to this, although younger evaluators would have sensible senses. It depends on the experience and popularity of the meat product. This shows the greater popularity of this product in the older generation **(Doets and Kremer, 2016)**. Those in the younger generation had the problem of distinguishing the difference in salt content.

Some strategies for innovations can be done by, for instance, not only directly lowering the amount of salt and fat in the recipe, which is the first possibility. However, some authors **(Horita et al., 2016)** describe using a salt substitute (e.g. potassium chloride or herbs), or by using animal fat replacements (e.g. starch or oil from non-animal sources), depends on consumer´s experience. Sensory evaluation has shown significant differences in taste and salinity in a group of younger panelists (YC) compared to older (OC). The presence of MSG shows that the low salt content is not so noticeable. Recent studies have even shown that sodium reduction can be beneficial for a part of the population that is defined as salt-sensitive. Senior consumers are more conservative, and have a more accurate awareness of the standard, at least in this case and cooked salamis has been confirmed. It is true that consumers are generally interested in the content of substances in food hazardous to health. Nitrites are thus negatively perceived by different consumer groups. However, nitrite replacement is a complicated intervention in the product recipe regarding its sensory and microbiological quality **(Jůzl et al., 2018b)**.

CONCLUSION

The results of the model production and analysis of four variants of cooked salamis with different spice mixtures or salt content indicate that the salt content affected the product quality parameters, however they were not considered negatively. Gothajský salami were rated more positively by older panellist group. There were also recorded several differences. From the above, it follows that the choice of seasoning mixture, the presence of other additives influences the sensory quality of the cooked salami. No significant negative result was found in the sensory evaluation, which would not reduce the salt content of the meat product's recipe.

SOMATIC CELL COUNT DURING FIRST AND SECOND LACTATION IN EWES

Kristína Tvarožková, Vladimír Tančin, Michal Uhrinčať, Lucia Mačuhová, Martina Vršková, Marta Oravcová

ABSTRACT

The aim of this study was to describe the frequency of distribution of ewes in SCC groups on the basis SCS (somatic cells score) per lactation and estimate changes of SCC from 1st lactation on 2nd lactation. The experiment was carried at seven farms in 1st observed period (2016 and 2017) and at eight farms in 2nd observed one (2017 and 2018). Within each of periods the same animals were sampled on their 1st and following 2nd lactation in next year of study, only. Totally 1199 milk samples from 159 ewes and 1653 milk samples from 219 ewes were collected during 1st period and 2nd period, respectively. Milk sampling were taken monthly from April to August in both periods. For evaluation only ewes with minimum three sampling per year (minimum six samples per animal) were included in the study within both periods. The ewes were divided into the five SCC groups on basis of their SCS per lactation: G1 = SCC <200 × 10^3 cells.mL^{-1}, G2 = SCC ≥200 <400 × 10^3 cells.mL^{-1}, G3 = SCC ≥400 <600 × 10^3 cells.mL^{-1}, G4 = SCC ≥600 <1000 × 10^3 cells.mL^{-1} and G5 = SCC ≥1000 × 10^3 cells.mL^{-1}. In total statistically significant impact of parity on SCC in 2nd period was detected (p <0.0001) only. From the farm point of view in 1st period only in two farms and in 2nd one in five farms significant effect of parity was found out. Thus in some farms no increase of SCC from first to second lactation was observed. When comparing the changes in SCC from the first to the second lactation in both first and second periods, 6.92% and 10.96%, respectively ewes moved from SCC group G1 to G5. The significant effect of farm management and parity on SCC was demonstrated.

Keywords: ewes; milk; somatic cell count; farm; milking

INTRODUCTION

Somatic cells in milk represent epithelial cells and leukocytes **(Paschino et al., 2019)**. Somatic cell count (SCC) is considered from many aspects as an indicator of udder health and generally is used for detection of subclinical mastitis in ewes **(Gonzáles-Rodríguez, Gonzalo and San Primitivo, 1995; Pengov, 2001; Olechnowicz and Jaskowski, 2005)**. However, there is still a big discussion among scientists about the physiological level of SCC in milk of ewes for detection of their udder health **(Persson et al., 2017)**.

Berthelot et al. (2006) reported in their study SCC <500 × 10^3 cells.mL^{-1} for healthy ewes and for infected ewes SCC >1000 × 10^3 cells.mL^{-1}, if SCC was in flock >650 × 10^3cells.mL^{-1} it showed 15% incidence of udder disease to have subclinical mastitis. The results of **Kern et al. (2013)** indicated threshold of SCC 400 × 10^3 cells.mL^{-1} in meat breeds of sheep, 300 × 10^3 cells.mL^{-1} in dairy breeds and 100 × 10^3 cells.mL^{-1} in extensive breeds as right value in detecting problems with udder health. **Hussein, El-Khabaz and Malek (2015)** determined value of SCC ≥400 × 10^3 cells.mL^{-1} in Ossimi sheep as limit for detection subclinical mastitis. The limit for the detection of subclinical sheep mastitis was determined by **Swiderek et al. (2016)** as 200 × 10^3 cells.mL^{-1}. Similar threshold of SCC for diagnosis of mastitis in Sarda sheep was considered at 265 × 10^3 cells.mL^{-1} **(Caboni et al., 2017)**. **Sutera et al. (2018)** in their study showed value SCC >500 × 10^3 cells.mL^{-1} as a possible limit in relation to milk quality.

In the study in our breeding practise **Idriss et al. (2015)** reported 78% of the samples of individual ewes <600 × 10^3 cells.mL^{-1}. **Vršková et al. (2015)** found out that 76% of Tsigai had SCC <300 × 10^3 cells.mL^{-1}. In recent study **Tančin et al. (2017)** found out that 82.03% individual milk samples were <400 × 10^3 cells.mL^{-1}, 71.79% milk samples were <200 × 10^3 cells.mL^{-1} and only 8.89% milk samples were >1000 × 10^3cells.mL^{-1}. **Oravcová, Mačuhová and Tančin (2018)** found out 60% samples with SCC ≤200 × 10^3cells.mL^{-1}.

The aim of this study was to describe the frequency of distribution of ewes in SCC groups on the basis somatic cell score (SCS) per whole lactation and estimate changes of SCS from1st lactation to SCS in 2nd lactation. The effect of farms was evaluated too.

Scientific hypothesis

The parity significantly influences the SCC in milk.

The most of the ewes have low SCC in milk. The udder heath in previous lactation affect the udder health in following lactation. The farm has impact on SCC in milk.

MATERIAL AND METHODOLOGY

The experiment was carried out during two periods in dairy practice. Seven ewes' dairy farms were involved in the study during 1st observed period in 2016 and 2017 and at eight farms during 2nd observed period in 2017 and 2018. On the farms they were kept Tsigai breed, Lacaune and on one farm Slovak dairy sheep. Tsigai (TS) breed were kept on farm 1st, 2nd, 3rd, 4th and farm 5th. Lacaune (LC) breed were kept on farm 6th, 7th, 8th and farm 9a th. On farm 9b th they were kept Slovak dairy sheep (SD) in 2nd observed period only. Within each of the period the same animals were sampled on their 1st and following 2nd lactation in next year of study. In 2 farms (1st, 3rd) hand milking was performed and remaining 7 flock were milked by machine milking. Milk sampling were taken once a month as a part of milk recording service. Milk samples were taken from April to August in 1st and 2nd observed periods. Analysis of milk samples has been performed in the certificated Central laboratory of Breeding services of the Slovak Republic (Plemenárske služby š.p. SR Bratislava).

For evaluation only ewes with minimum 3 and more sampling during each lactation within both 1st and 2nd periods were included into study. Thus minimum six observations were available per animal. A total of 1199 milk samples from 159 ewes (140 TS, 19 LC) were collected during 1st observed period. From 219 ewes (130 TS, 63 LC, 26 SD) were collected 1653 milk samples during 2nd observed period.

Statistic analysis

On the basis of SCC from milk recording the ewes were divided into the five SCC groups: G1 = SCC <200 × 10^3 cells.mL^{-1}, G2 = SCC ≥200 <400 × 10^3 cells.mL^{-1}, G3 = SCC ≥400 <600 × 10^3 cells.mL^{-1}, G4 = SCC ≥600 <1000 × 10^3 cells.mL^{-1} and G5 = SCC ≥1000 × 10^3 cells.mL^{-1} to evaluate the distribution of ewes into SCC groups in different parity and years of study. Animals were individually divided into above mentioned SCC groups on the basis of their SCS per lactation calculated as a mean from transformed individual SCC data into SCS obtained during milk recording throughout lactation. SCS was calculated according formula:

$$SCS = LOG_2(SCC/100000) + 3$$

Thus distribution of ewes on the basis of SCS into SCC groups was done by conversion of linear scores to somatic cell counts. The results were mathematically processed using the Microsoft Excel program. It was used paired t-test when comparing differences variables between first and second lactation (within observed periods). Data are presented as mean ± standard deviation. The statistical model using SAS (Mixed procedure; SAS/STAT 9.1, 2002 – 2003) can be written in the following form used for each observed period separately:

$$y_{ij} = \mu + FARM_i + YEAR_j + e_{ij}$$

y_{ij} = the measurements for SCS; μ = overall mean; $FARM_i$ = the fixed effects of farms; $YEAR_j$ = fixed effect of YEARS (two years, within each observed period), $u_l \sim N(0, \sigma c2)$; e_{ij} = random error, assuming $e_{ij} \sim N(0, I\ \sigma^2_e)$. Data are presented as LSmeans (Least squares means) ± standard error.

RESULTS AND DISCUSSION

Impact of parity on SCC was not statistically significant in 1st observed period (p <0.0868) but was significant in 2nd observed period (p <0.0001). Similar results were reported by **Romero et al. (2017)**. They found out that multiparous ewes had significant higher SCC compared with primiparous ewes (205 × 10^3 cells.mL^{-1} and 102 × 10^3 cells.mL^{-1}, resp.). Also **Takano et al. (2018)** showed in their study that multiparous Lacaune ewes had a higher incidence of intramammary infections during early lactation than primiparous ewes. SCC were higher in multiparous than in primiparous goats **(Diaz et al., 2011)**. The youngest ewes had the lowest SCC, while the oldest ewes showed in general the highest SCC **(Arias et al., 2012).** Subclinical mastitis occurred less frequently in primiparous ewes than those with two or more lactations significantly (p <0.05) and ewes on 3rd lactation had the most cases of subclinical mastitis **(Sani, Mahdavi and Moezifar, 2015)**.

Although the effect of parity on SCS in between 1st and 2nd lactation wasn´t detected in 1st observed period, we found out the effect of parity on SCC at the level of individual farms. During 1st observed period we detected the effect of parity on SCS in farm 4th and farm 9a th (Table 1). Significant effects of parity on SCS during 2nd observed period, and at farm level in farm 1st, 3rd, 5th, 8th and farm 9b th (Table 2). Breeds didn´t have impact on change of SCS in monitored farms (Table 3). Significant differences between farms with the same breed could indicate the effect of management level on farms.

Distribution of ewes in SCC groups during 1st observed period (2016 and 2017) was as followed: G1 (38.99%, 33.96% resp.), G2 (32.02%, 23.90% resp.), G3 cells.mL^{-1} (6.92%, 10.69% resp.), G4 (6.29%, 6.29% resp.) and G5 (15.72%, 25.16% resp.). During 2nd observed period (2017 and 2018) there were following distribution of ewes in SCC groups: G1 (57.99%, 35.16% resp.), G2 (21%, 20.09% resp.), G3 (6.39%, 9.13% resp.), G4 (3.2%, 8.68% resp.) and G5 (11.42%, 26.94% resp.). If compare changes from 1st to 2nd lactation in both observed periods the following changes occurred: In 1stmonitored period there were 8.81% ewes in SCC group with <200 × 10^3cells.mL^{-1} during 1st lactation which moved into SCC groups ≥600 × 10^3 cells.mL^{-1} during 2nd lactation. Even 6.92% from these mentioned ewes moved into SCC group ≥ 1000 × 10^3 cells.mL^{-1}. In 2nd observed period 15.53% of ewes were in SCC group with <200 × 10^3 cells.mL^{-1} during 1st lactation, which moved into SCC groups ≥600 × 10^3 cells.mL^{-1} in the following lactation. Even from these ewes 10.96% moved into SCC group ≥ 1000 × 10^3 cells.mL^{-1}.

Figure 1 Frequency of distribution of ewes in SCC groups during first and second lactation in farm with machine milking.

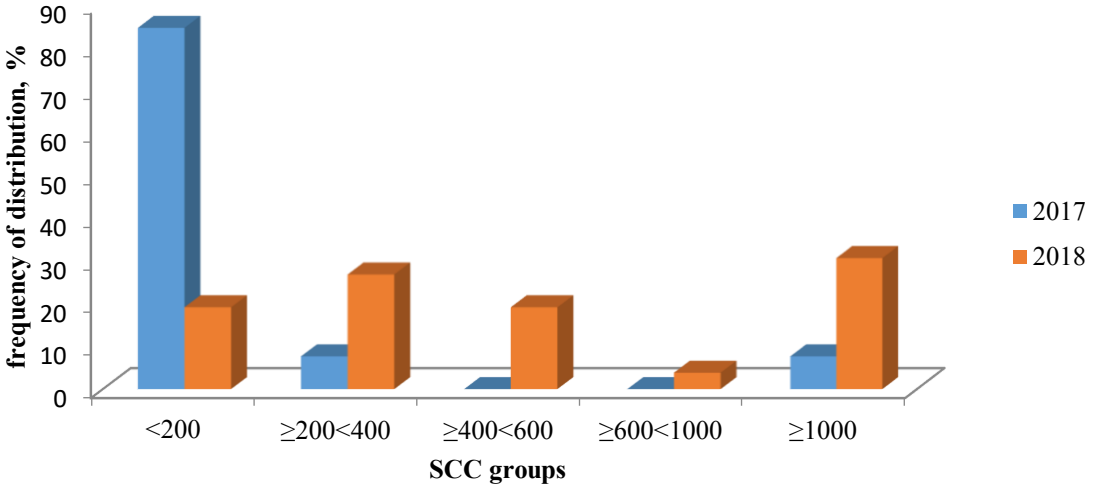

Figure 2 Frequency of distribution of ewes in SCC groups during first and second lactation in farm with hand milking.

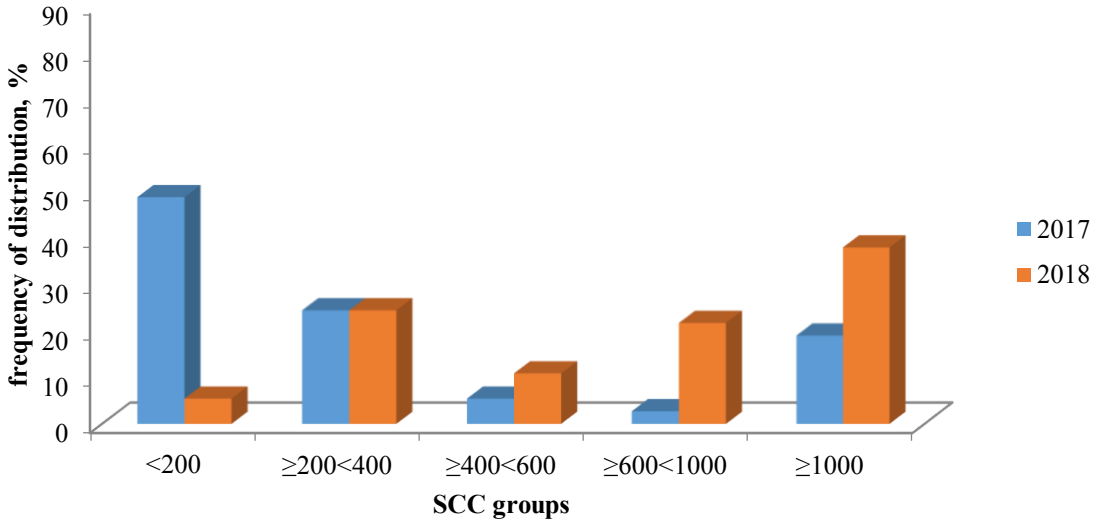

These changes from 1st to 2nd lactation among SCC groups and clear increase of percentage of samples in SCC group ≥1000 × 10^3 cells.mL^{-1} in 2nd lactation indicate higher prevalence of subclinical mastitis. **Persson et al. (2017)** detected significant association between intramammary infection and high SCC in ewes. In contaminated samples were significantly higher SCC as compared with uncontaminated milk samples **(Ozenc et al., 2011)**. From preliminary results of **Tančin et al. (2018)** there was shown that high SCC in milk samples were associated with presence of pathogens. **Romero et al. (2017)** observed significant higher SCC in milk of primiparous and multiparous ewes with mastitis. Early diagnosis and treatment of subclinical mastitis can significantly eliminate clinical forms of mastitis **(Zigo et al., 2017)**.

Data shown in Figure 1 and Figure 2 represent examples of frequency of distribution of ewes from one farm with machine milking and another farm with hand milking during their 1st and 2nd lactation. On both figures there are presenting changes of udder heath from 1st to 2nd lactation by clear demonstration of difference between count of ewes in SCC group <200 × 10^3 cells.mL^{-1} and in SCC group ≥1000 × 10^3 cells.mL^{-1}. In both farms during the 2nd lactation there was a decrease in the distribution of ewes in the SCC group <200 × 10^3 cells.mL^{-1} regardless on the milking technique. Increase of percentage of ewes in SCC groups ≥1000 × 10^3 cells.mL^{-1} could be due to the increase prevalence of subclinical mastitis in these farms. In other

study **Marogna et al. (2010)** found out that hand milking was associated with 62% higher risk of bacterial positive samples compared to machine milking which we did not confirmed in our study. **Marogna et al. (2010**) also observed that machine milking with portable devices was associated with 40% higher risk of bacterial positive samples compared to machine milking with fixed plants. **Queiroga (2017)** detected significantly higher prevalence of subclinical mastitis in herds with machine milking than those with hand milking (p <0.0001). **Vasileiou et al. (2018)** reported increased prevalence of mastitis in farms with hand milking.

CONCLUSION

In conclusion, high percentage of ewes had SCC <200 × 10^3 cells.mL^{-1} during 1st lactation only. During 2nd but not during 1st observed period the ewes on 2nd lactation had higher SCC compared with primiparous ewes, however, clear individual farm effect was recorded in both observed periods. Also significant effect of farm management on SCC was demonstrated without connection to hand or machine milking. Thus the level of management in dairy farm has to be considered.

COMPARISON OF CHEMICAL COMPOSITION OF EGGS FROM LAYING HENS HOUSED IN DIFFERENT PRODUCTION FACILITIES: A MARKET STUDY

Jaromír Pořízka, Adam Michalec, Pavel Diviš

ABSTRACT

Eggs as a part of human diet dates to the prehistoric period. After the domestication of *Gallus* species, *Gallus gallus domesticus* and their eggs spread across the globe. Eggs proved to be one of the best and affordable sources of nutritionally important components in human diet, such as proteins, vitamins, lipids and some dietary significant elements. Progress in egg production methods, in European union, is recently mostly focused on the improvements in the field of welfare of laying hens, which is part of the plan set by European union council directive 1999/74/EC. Nowadays there are 4 main egg production systems divided by the way of keeping laying hens – Enriched cage, Free range, Barn and Organic. The aim of this study was to evaluate the impact of different hens housing systems on elemental (Ca, K, Mg, Na, P, Ca, K, Zn), total protein and lipid composition of whole eggs, yolk and albumen. Elemental analysis was performed by ICP-OES, total lipid content by Kjehldahl method and total lipids by Soxhlet extraction. Differences in whole egg were found in 8 from 9 tested parameters – K, Mg, Ba, Fe, P, Zn, total lipids and proteins. Assessment of the differences were done by ANOVA and Tukey`s test. Production systems were also successfully differentiated by principal component analysis. It was found that eggs from alternative production systems did not exhibit higher nutritional value than eggs from conventional cage facilities. In the case of total protein, conventional eggs contained highest average amount. It was also evident, that impact on chemical composition is difficult to assign to production system in general, which was confirmed by alternative studies from this field, which in many cases considerably differs.

Keywords: eggs; laying hens; housing; elemental analysis; proteins

INTRODUCTION

Eggs as a part of human diet dates to the prehistoric period. After the domestication of *Gallus* species, *Gallus gallus domesticus* and their eggs spread across the globe. Eggs proved to be one of the best and affordable sources of nutritionally important components in human diet, such as proteins, vitamins (A, B_5, B_7, B_9, B_{12}, K, D, E), lipids and some dietary significant elements (P, Na, K, Ca, Mg, Fe). It is also having relatively high average energy value of 547 kJ.100g^{-1} of whole raw egg **(Belitz et al., 2009; Finglas et al., 2015; Bulková, 1999)**. World egg production rises by 18 percent from 2006 to 2016 to almost 74 million metric tons, as demand for eggs is growing due to rising population, incomes and dietary acceptance. Production in the European union is projected to be quite steady with rising in next decade from 7.7 in 2016 to 8.2 million metric tons in 2026 **(WATT, 2018)**. Progress in egg production methods, in European union, is recently mostly focused on the improvements in the field of welfare of laying hens, which is part of the plan set by European union **council directive 1999/74/EC**. This regulation banned barren battery cages which were replaced by enriched cages with more space, height and nesting area. Conventional enriched cages system covered 53.2% of EU egg production in 2017 and nowadays there are 4 main egg production systems divided by the way of keeping laying hens – Enriched cage, Free range, Barn and Organic. Special group of eggs are those produces in home breeding conditions. Information about the production system must be shown as a part of code on the egg shell.

There are various motivations of modern consumers to select alternatively produced eggs - especially from organic production. This motivation is mainly driven by demand for healthy, nutritionally balanced food products and also by increased perception of the area of environmental friendliness and animal welfare. **(Kralik et al., 2008; Filipiak-Florkiewicz et al., 2017; Shafie and Rennie, 2012; Schleenbecker and Hamm, 2013)**. A growing interest of consumers for non-conventional foods prompted the research activity to assess the real impact of different egg production systems on overall quality of product. **Filipiak-Florkiewicz et al. (2017)** conducted comparison of organic, nutraceutical and conventional

eggs with focus on fatty acid profile, elemental analysis and some physical parameters like colour and rheological properties of mayonnaise made from studied eggs. Results of this study revealed significant differences ($p \leq 0.05$) in the chemical composition. Organic and nutraceutical eggs were characterized to be nutritionally more beneficial in comparison with conventional production. Similar study was proceeded by **Anderson (2011)**, focused on comparison of fatty acid, cholesterol and vitamin A and E composition of eggs from cage and rage production facilities. Significant differences ($p \leq 0.05$) were found in total fat content, which was higher in eggs from range housing. It is also worth mention a market study carried out by **Hidalgo et al. (2008)**. This paper deals with comparison of Italian eggs from barn, cage, free range and organic housing in terms of 41 physical and chemical parameters. Differences were found in whipping capacity, foam consistency, albumen quality and shell resistance to breaking. Multivariate statistical analysis differentiated cage eggs from alternative (organic, barn and free range). It was also concluded, that apart of psychological and ethical motivations, differences in quality of eggs did not justify the higher prices for alternatively produced eggs.

The aim of this study is to evaluate the impact of different hens housing systems on elemental (Ca, K, Mg, Na, P, Ca, K, Zn), total protein and lipid composition of yolk and albumen.

Scientific hypothesis

This study is based on hypothesis whether different approaches of laying hens housing can be significantly reflected in basic chemical composition of eggs. Testing of this hypothesis is an extension of previously published studies, enriching the field by actual data from Czech Republic egg market and by analysis of domestically (home) produces eggs and eggs from improved cage lined by litter material.

MATERIAL AND METHODOLOGY

Samples and sample preparation

Total of 20 batches of eggs from 5 different laying hens housing systems were obtained - Enriched cage, Enriched cage with litter bedding, Free range, Home and Organic. Every batch contained 6 eggs of M size (53 – 63 g) with similar laying period of first week in February 2018. All the batches were from different producers from Czech Republic and were acquired in standard commercial retail network. Eggs produces by home breeding and laying were obtained directly from small village farmers in Brno countryside region (Czech Republic).

Sample preparation

Every batch of 6 eggs was divided into 2 parallel parts of 3 eggs. Albumen and yolk were mechanically separated and was dried on petri dishes at 70 °C for 8 hours. Dried samples were homogenized. Total of 40 sub-samples from 5 different systems were prepared. Microwave digestion system was used for the preparation of samples for elemental analysis on ICP-OES. Amount of 200 mg of albumen and yolk samples were transferred into the teflon cartridges with 5 mL of 65% HNO_3 and 2 mL of concentrated H_2O_2 (Analytika Praha, Czech Republic). Digestion itself was performed by microwave digestion system Milestone 1200 (Milestone, USA). After the decomposition, samples were transferred into 25 mL volumetric flasks, diluted with deionized water (Elga purelab Classic, Veolia water systems, UK) and filtrated through 0.45 µm nylon syringe filters.

Determination of total proteins

Total proteins in samples of albumen and yolk were determined by standard Kjelhdahl method. Mineralization was done by mineralization unit KT-8s (C. Gerhardt & Co, Germany). Digestion of 1 g sample was proceeded at 420 °C for 90 min. Distillation of ammonia was performed by Vapodest steam distillation instrument (C. Gerhardt & Co, Germany) and collected into titration flask with 0.05 M H_2SO_4. Excess of sulfuric acid was titrated with 0.1 M NaOH. Conversion factor from nitrogen to protein content was 6.25, which is standard for eggs.

Determination of total lipids

Determination of total lipids was realized only in samples of yolk due to trace concentration level in albumen **(Finglas et al., 2015)**. Soxhlet method was selected for the extraction of lipids. Lipids from 4 g of yolk sample were extracted into 150 mL of petroleum ether by automatic extraction Soxhlet instrument Soxtherm (C. Gerhardt & Co, Germany). Extraction proceeded for 2 hours at 150 °C. Petroleum ether was distilled away from extraction flask and fats content was determined gravimetrically.

Determination of elemental composition

Elemental analysis of yolk and albumen was performed by ICP-OES Horiba Jobin Yvonne Ultima 2 (Horiba Scientific, France) with measurement conditions of 15 rpm of peristaltic pump; RF power 1300 W, argon plasma gas flow 14 $L.min^{-1}$, auxiliary gas flow 0.15 $L.min^{-1}$, sheath gas
0.7 $L.min^{-1}$ (K, Na, Mg, Ca) and 0.2 $L.min^{-1}$ (P, Zn, Fe, Mn). Instrument was calibrated by standards made from individual 1 $g.L^{-1}$ stock solutions (Analytika Praha, Czech Republic). Calibration was prepared by the standard addition method into the blank solutions used for sample digestion.

Statistical analysis

Data analysis and statistical evaluation were performed in Microsoft Excel (Microsoft, USA) and XL-stat (Addinsoft, France). Results were processed by various statistical approaches. Before the main data analysis, results were tested for outliners and data distribution. The Grubbs test for outliners did not revealed any outlined values between the 5 tested groups of eggs and data showed a normal Gaussian distribution.

Analysis of variance (ANOVA) was used to evaluate chemical parameters which exhibited statistically significant differences between the groups of eggs from different production systems. *p*-values as a result of this analysis is provided. Tukey pair test was used for evaluation of inter-group comparison.

Principal component analysis (PCA) based on Pearson correlation was used for multivariate characterization of samples and to find specific links between observations (egg samples) and original variables (chemical

composition). The main goal of this analysis was to find similarities and dissimilarities between different groups of eggs to obtain a potential sample grouping according to a corresponding egg production system. Results of PCA were visualized by the projecting the observations onto biplot of principal components and original variables.

RESULTS AND DISCUSSION

Total proteins and lipid content, combined with elemental composition, are important factors indicating the basic nutritional values of the eggs. All these chemical components are distributed differently in yolk and albumen. Summary of the analysis of eggs, produced by different production facilities are presented in Table 1. Results are divided into three parts for whole egg samples and for dried yolk and albumen.

Proteins are probably most important dietary element of eggs and has a high level of digestibility in human organism **(Geissler and Powers, 2010)**. Differences in protein content (connected to housing systems) were found to be statistically significant (p = 0.007). Deeper analysis confirmed these differences only in albumen part of tested eggs. Highest average protein content was found in eggs from free range breeding (42.6 ±8.2 g.100g^{-1}). Almost similar results were observed in eggs from conventional cage facilities (42.5 ±2.9 g.100g^{-1}). Lowest concentration of total proteins was determined in eggs from home and organic systems (31.1 ±7.1; 31.1 ±7.1 g.100g^{-1}). Comparison of these results with other studies showed inconsistency in assessment of egg production systems influence on protein composition of eggs. **Filipiak-Florkiewicz et al. (2017)** and **Minelli et al. (2016)** reported that organic eggs contained more proteins that the eggs from conventional production. On the contrary, **Matt et al. (2009)** proved that conventional eggs contained higher amounts of proteins than organic. They tested eggs

Table 1 Mean values ±SD of chemical components of yolk and albumen. ANOVA p-value significance testing and Tukey`s test.

laid in winter season (January), which is similar to our study.

It could be assumed, that conventional cage system is providing stable condition during the year, but it is not supported by the results from another cage system – with litter bed. Eggs from this system contained approximately 10% less proteins than from standard cages. It is also necessary to mention the variability of production. Highest variability of results was observed in group of eggs produces in home breeding conditions and in free range facilities. It was highly expected for eggs produces in domestic conditions due to the high variability in feed and breeding conditions. Eggs from both cage systems on the other hand showed lowest standard deviation within the observations. Overall, the correlation between the housing systems and the protein composition of eggs is not easily feasible, unless the analysis is expanded by more detailed information about feed, age, breed, climatic and other conditions. As **Lordelo et al. (2016)** concluded, those parameters are difficult to control in systems based on free movement of hens (including organic). Most problematic is observation of amount of time the hen spends in exterior where they can feed on wild plants and insects.

Another statistically significant influence (p <0.0001) of production systems was found in total lipid content in egg yolk. Highest average amount of fat was found in yolk of home produces eggs (55.2 ±0.33%). On the basis of consultation with small farmers was found, that hens are mostly fed by corn, beet, boiled potatoes, sunflower, maize and fatty pastries. It is not an exception that chicken diet is supported by rest of the meat and the offal. All these feeds are rich in lipids, which was reflected in high amount in yolk. Beside the non-standard domestic production, the lipids were most abundant in eggs from both cage systems (52.5 ±1.23 and 51.8 ±1.41%). It is probably caused by minimal possibility of animal free movement and by specific and unified diet. Fodder mixtures in cage systems are based on corn and soybean enhanced by feed fat with minimal contribution of vegetables. As in the case of proteins, eggs from organic production contained significantly lower content of fat than other tested samples (43.3 ±3.9%). The fact, that eggs from free range system contained the second least fat content (50.2 ±0.49%) offers explanation in free movement of hens. Articles published in this field again showed various results in assessment of impact of egg production systems on total lipid content. Similar results, like in presented article, was found in research of **Lordelo et al. (2016)** with lowest amount of total fatty acid in eggs labeled as organic. **Matt et al. (2009)** also proved, that conventional eggs are better source of lipids. In opposite, there is a study from **Filipiak-Florkiewicz et al. (2017**), with the finding, that organically produced eggs contained 9.2% more fat than conventional. **Anderson (2011)** found higher fat content in the eggs from the range production environment than from the cage facilities. It was explained by the contribution of wild seeds and insects on feed composition of hens. This effect will be probably weaker in winter time of year which was the case of our study. **Samman et al. (2009)** discovered only little difference between the fatty acid composition of eggs and no differences in total lipid content of conventional and organic eggs. This result is supported by the study of **Hidalgo et al. (2008)** with non-significant differences between the eggs from cage, free range, barn and organic facilities.

Among mineral compounds, statistically significant differences (p <0.05) were found within all tested elements except for calcium which exhibit stable level among all the tested samples.

The most abundant element in whole eggs was potassium. Average concentration ranges from average 3.42 to 4.2 mg.g^{-1}. Highest average concentration of K was observed in eggs from domestic farms and in eggs from cage system supported with litter bed (4.18 ±0.021 and 4.2 ±0.477 mg.g^{-1}). Laying hens can feed on straw bed in cage, which is mostly from wheat. This kind of straw contains more than 10 g.kg^{-1} of potassium **(Plazonić et al. 2016)**. Lowest average concentration was determined in eggs from free range production (3.42 ±0.12 mg.g^{-1}). In comparison with alternative studies, **Filipiak-Florkiewicz et al. (2017)** and **Matt et al. (2009)** discovered relatively higher concentration of K in organic eggs compared to conventional.

Another significant difference (p = 0.015) in microelement group was found in average concentration of **s**odium. Differences were found, similarly to potassium, only in yolk part of eggs. Highest amount of Na was observed in eggs from both cage systems (3.88 ±0.552 and 3.88 ±0.552 mg.g^{-1}). According to Tukey`s test, organic eggs were also involved in this group. The group with low concentration of potassium included eggs from home and free-range systems (3.17 ±0.085 and 3.14 ±0.117 mg.g^{-1}). It is obvious, that eggs from hens with natural free movement contains lower amount of Na, which is probably utilized in larger quantities as an electrolyte in animal organism **(Lehninger et al., 2013)**.

Content of magnesium was also significantly affected by the egg production systems. Magnesium is mostly presented in egg shell, but it can be also found in edible part of egg. If we neglect non-standard domestic production, highest average concentration of Mg was determined in eggs from conventional cage production (0.341 ±0.059 mg.g^{-1}), but according to Tukey`s test, this set of eggs belong to same group with litter and organic samples (p = 0.05). It only differs from free range production with lowest average concentration (3.14 ±0.117 mg.g^{-1}). These results can be compared with work of **Filipiak-Florkiewicz et al. (2017)**. It was confirmed that yolk of conventionally produces eggs contained higher amount of magnesium. It is likely to be caused by the stable addition of mineral additives into the feed of hens housed in cages. However, **Küçükyılmaz et al. (2012)** did not found significant differences (p >0.05) between magnesium content in edible part of conventional and organic eggs. In terms of phosphorus content, it was most abundant in eggs from free range production, but with relatively high standard deviation (3.3 ±0.571 mg.g^{-1}). Lowest average of phosphorus concentration was determined in eggs from organic and conventional cage system (2.48 ±0.221 and 2.51 ±0.052 mg.g^{-1}).

Microelements are also dietary important components of eggs, especially Fe and Zn. These elements play a role in many metabolite pathways, redox reactions and are often part of metalloproteins and its bioavailability from eggs is similar like from meat and cereals **(Geissler and Powers, 2010)** According to analysis of variance, statistically

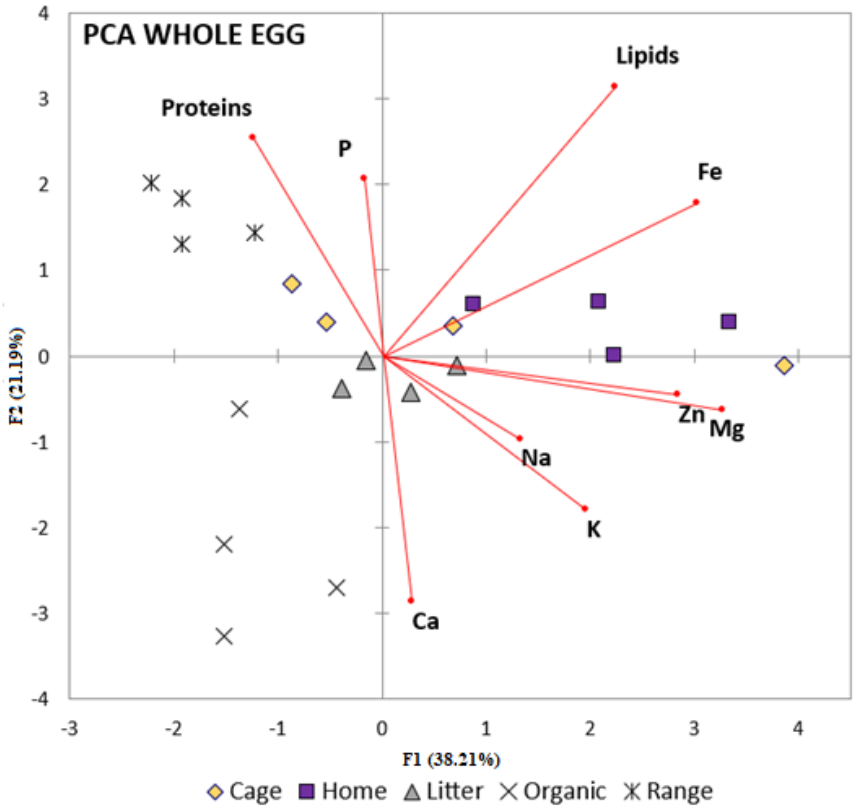

Figure 1 PCA biplot of whole egg observations with original variables projected into a 2-D factor plane of principal components F1 and F2.

significant differences were found (p = 0.019 for Fe and p = 0.014 for Zn).

Highest average concentration of iron and zinc, which are mostly presented in yolk of eggs, was found in eggs from home production (0.015 ±0.002 mg.g^{-1} Fe and 0.058 ±0.017 mg.g^{-1} Zn). This is probably caused by the fact, that domestically housed hens are often fed by animal diet based on meat and offal, which is rich source of iron and zinc. Differences between other 4 standard production systems did not exhibit significant differences (p >0.05). **Küçükyılmaz et al. (2012)** and **Filipiak-Florkiewicz et al. (2017)** determined higher content of iron in conventionally produced eggs compared to organic. Cages and its corrosion can be source of iron and zinc, which is one of probable causes of this phenomenon.

As an addition to univariate data analysis by ANOVA and Tukey`s test, multivariate classification of samples was evaluated by Pearson correlation PCA. Results of this analysis are presented in Figure 1 as a biplot of observation and variables from whole egg data (sum of yolk and albumen content) projected into 2-D plane of principal components F1 and F2. Dimension of 9 input variables was reduced to 4 principal components with eigenvalue >1 according to Kaiser`s criterion: F1 (32.75%) F2 (20.26%), F3 (17.98%) and F4 (11.86%). These components together carried 82.85% of variability. Best visual representation of PCA was obtained by 2-D factor plane of components F1 and F2. Components were correlated with original variables. Component F1 was mostly positively correlated by Mg, Fe, Zn. Component F2 positively with total lipid and proteins content, negatively with Ca. Relative clustering of observations is visible on Figure 1. There is obvious separation of egg samples from organic and free-range production, which are situated in left hemisphere of the graph with negative score for component F1. Observations from both cage systems are situated in the centre of graph and not completely differentiated which points to the fact, that overall composition of eggs from these two systems did not differentiated significantly. Another separate group was formed by observation of home-produced eggs in area of positive scores for F1. It is obvious, that even though univariate analysis by ANOVA did not provide clear picture of impact of hens housing systems on composition of eggs, it was possible to achieve classification using multivariate approach.

CONCLUSION

Results of this study confirmed the initial hypothesis and proved, that different approaches of laying hens housing can be significantly reflected in basic chemical composition of eggs. Statistical differences ($p \leq 0.05$) were defined in 8 from 9 tested parameters. It was found that eggs from alternative production systems did not generally exhibit higher nutritional value than eggs from conventional cage facilities. In the case of total protein, whole conventional eggs contained highest average amount of 39.4 ±2.9% in comparison of 29.6 ±3.7% in organic eggs. Another significant differences (p <0.0001) were found in total lipid content. Organic eggs proved to be least fatty (43.3 ±3.9%), approximately 18% less than eggs from conventional cage production (52.5 ±1.2%). This was probably closely connected with limited free movement of lying hens in cage production. This system is also characteristic with diet based mainly of corn and soybean,

which is rich on lipids. Another significant difference was found in elemental composition of eggs, specifically K, Mg, Na, Fe, P, Zn. Thanks to the combination of elemental composition and total lipid and protein content was possible to obtain clustering of observations by multivariate PCA. All tested groups of production systems were clearly separated, and it proved its important influence on chemical composition of eggs.

Important aspect of this work was comparison of presented results with other studies in this field. Common conclusion of all these studies is confirmation of significant effect of different housing systems on chemical composition and quality aspects of eggs. However, evaluation of influence of production systems, in many cases, differs considerably between studies and it was not possible to define general conclusions. For the unification of results will be necessary to expand research by more complex data about feed, climatic and other conditions and study the production in long term.

From the point of view of the consumers, these differences were in many cases negligible and the motivation to buy pricier alternative products should be still more driven by ethical and psychological aspects than desire for healthier and more nutritious product.

IDENTIFICATION AND ANTIBIOTIC SUSCEPTIBILITY OF BACTERIAL MICROBIOTA OF FRESHWATER FISH

Alīna Klūga, Miroslava Kačániová, Margarita Terentjeva

ABSTRACT

The fish meat is an essential part of human diet. However, fish may be contaminated with different microorganisms, including pathogens. Antimicrobial resistance of fish microbiota may facilitate the spread of resistant microorganisms causing serious consequences for human health. The aim of the present study was to detect bacterial contamination in fish gill, gut and skin and to determine antimicrobial susceptibility of the bacterial isolates. Rainbow trout (*Oncorhynchus mykiss*) and bream (*Abramis bram*) were obtained from the market in Jelgava city. Chub (*Leuciscus cephalus*), crucian carp (*Carassius carassius*) and tench (*Tinca tinca*) were collected from fishermen. Fish samples were examined for the total bacterial count (TBC), coliforms, *Enterobacteriaceae*, *Pseudomonas* spp. and *Aeromonas* spp. Testing was done in accordance with International Organization for Standardization (ISO) standards. Identification of all bacteria was accomplished with the Matrix Assisted Laser Desorption Ionization – Time of Flight Mass Spectrometry (MALDI-TOF MS) method. The disc diffusion method was used for the detection of antibiotic susceptibility of isolated bacterial species. TBC ranged from 2.70 to 7.00 log CFU.g^{-1}, coliforms from 0 to 2.67 log CFU.g^{-1}, *Enterobacteriaceae* from 0 to 2.85 log CFU.g^{-1}. The highest contamination with *Pseudomonas* spp. and *Aeromonas* spp. was observed in chub gut samples with 1.60 log CFU.g^{-1} and 2.23 log CFU.g^{-1}, respectively. Altogether, 16 microbial genera and 31 bacterial species were identified. The dominant bacterial species belonged to *Pseudomonas* spp. (54%) and *Enterobacteriaceae*. *Pseudomonas* spp. were resistant to ticarcillin, susceptibility to ciprofloxacin showed 88% of isolates. All *Enterobacteriaceae* isolates were susceptible to imipenem. The microbial quality of the fish was acceptable, but the presence of antibiotic resistant bacteria may further cause a negative impact on public health.

Keywords: bacteria; freshwater fish; MALDI-TOF MS; antibiotic

INTRODUCTION

The bacterial contamination of freshly caught fish depends to a great extent on the quality of surrounding water. The microbiota of fish is very diverse, its composition and amount can be influenced by many different factors, such as microbial population of water and bottom mud, water source type, fish species and the conditions of their habitat. The majority of microorganisms in fish were located in gills, gut and in mucus on the fish skin, while the internal organs and muscle tissue were relatively sterile **(Austin, 2006; Cwiková, 2016)**.

Enterobacteriaceae and coliforms are indicator microorganisms that are permanently present in the intestine of humans and animals. They are not harmful to the host's organism, but under the appropriate conditions can cause a disease. The presence of indicator microorganisms in external environment indicates the contamination with human or animal faeces and could be detected with quantitative isolation of indicator microorganisms. The contamination rates are important for microbiological safety because of ability to indicate the presence of human and animals' pathogens of intestinal origin. *Enterobacteriaceae* are widespread in the nature and can be found in soil, water, fruits, vegetables, grains, flowering plants and trees **(Tosun, Üçok Alakavuk and Mol Tokay, 2016)**. *Salmonella*, *Shigella*, *Yersinia*, *Escherichia* of *Enterobactericeae* can cause intestinal foodborne infections and are transmitted by the fecal-oral or oral route with contaminated water, food or due to direct contact. Other *Enterobactriaceae* may serve as an opportunistic pathogens and *Escherichia*, *Klebsiella*, *Enterobacter*, *Citrobacter*, *Proteus*, *Providencia*, *Serratia* were reported to cause infections with non-intestinal clinical signs – bacteraemia, meningitis, wound infections, genitourinary and respiratory tract injuries **(Flores-Tena et al., 2007; Dekker and Frank, 2015)**. The studies on composition of fish microbiota has been conducted in different countries but mostly the sea fish were studied **(Yagoub, 2009; Oliveira, Oliveira and Pelli, 2017)**.

Antimicrobial resistance is one of the most serious threats to public health, environmental health and food safety. Antimicrobial resistance is increasing to threateningly high levels throughout the world.

Antimicrobial resistance reduces the effectiveness of treatment of infections in humans and animals, contributes to the increase in morbidity, mortality and leads to significant economic losses **(Petersen et al., 2002; Wamala et al., 2018)**. The use of antibiotics in aquaculture for therapeutic and preventive purposes is a growing problem for world livestock and environmental health. From aquaculture, the antimicrobials may be spread in the environment in the concentration sufficient to cause microbial imbalance in animals and human with the emergence of antimicrobial resistance in the society. It has been proved that the antibiotic-resistant bacteria may be present in fish with their subsequent transfer to humans via the consumption of fish or contaminated environment **(Heuer et al., 2009)**.

The consumption of the fish in the EU is continuously increasing, however, the fish products were frequently associated with gastrointestinal infections in humans **(EFSA and ECDC, 2017)**. Nowadays, people tend to follow a healthy lifestyle by choosing fresh foods or food with optimal nutritional value like fish and fish products, which are known as the source of protein, contain omega-3 amino acids, vitamins and minerals such as phosphorus. However, the risk for consumers related to the eating of fish contaminated with non-pathogenic and pathogenic microflora with variable antimicrobial resistance rates is concerning **(Da Silva et al., 2010; Cwiková, 2016)**. Therefore, the aim of the present study was to detect bacterial contamination in fish gill, gut and skin and to determine antimicrobial susceptibility of the bacterial isolates.

Scientific hypothesis

The scientific hypothesis of this study was that the freshwater fish were contaminated with bacteria, and the bacterial isolates are resistant to antibiotics.

MATERIAL AND METHODOLOGY

Selection of samples

Altogether, 15 fish samples were collected, including 2 rainbow trout (*Oncorhynchus mykiss*) and 3 bream (*Abramis brama*) samples were obtained from the market and 3 chub (*Leuciscus cephalus*), 4 crucian carp (*Carassius carassius*) and 3 tench (*Tinca tinca*) were collected from the fishermen in June 2017 in Jelgava. Fish were caught in the river Lielupe. All fish were placed in the sterile polyethylene sampling bags, and transported n ice to the laboratory. The investigations were initiated within 2 h after deliver to the laboratory.

Sampling

Aseptically, 1 g of sample was taken from each fish skin, gills and gut. Skin samples were taken from the lateral line of the fish. Operculum was opened, and gills were dissected for preparation of gill samples. Gut samples were taken by cutting of the abdomen till the anal fin and after opening the body cavity.

Bacteriological analyses

The sample suspension of 1:10 with 0.1% peptone water (OXOID, UK) was used for bacteriological testing. An amount of 1 mL was plated onto Tryptone Soy Agar (TSA, OXOID, UK) for detection of total bacterial counts. After incubation at 30 °C for 72 h, all colonies were counted. For the detection and enumeration of coliforms, the sample suspension was plated onto Violet Red Bile Lactose Agar (VRBL, OXOID, UK). Inoculated agars were incubated at 37 °C for 24 h and all typical colonies from dark red to deep purple coloured colonies were counted **(ISO 4832:2006)**. MacConkey agar (MAC, OXOID, UK) were used for detection of *Enterobacteriaceae* and inoculated agars were incubated at 37 ºC for 24 h, and after that the typical colonies were enumerated - lactose fermenting bacteria produced red to pink and non-lactose fermenting bacteria have colourless and transparent colonies **(ISO 21528:2017)**. Pseudomonas CFC Selective Agar (OXOID, UK) were used for detection and enumeration of *Pseudomonas* spp. **(ISO 13720: 2010)**. Agar plates were incubated at 30 °C to 48 h and examined for the presence of colonies. All grown colonies were counted. Aeromonas Agar (Ryan, OXOID, UK) was used for detection of *Aeromonas* spp. The plates were incubated at 37 °C for 24 h, after that were examined for the presence of dark green, opaque colonies with dark centres.

Identification of bacterial species with MALDI-TOF Biotyper MS

MALDI-TOF Mass Spectrometry model Microflex LT/SH biotyper (Bruker Daltonics, Germany, Bremen) was used for identification of bacteria species isolated from fish. Typical bacterial colonies were selected from all agars, picked up and suspended in 300 µL of sterile distilled water and mixed. Then, a 900 µL of absolute ethanol (99%, Sigma-Aldrich, USA) was added. The solution was centrifuged at 13 000 × g for 2 min. Supernatant was removed, ethanol pipetted, and the pellet was allowed to dry at a room temperature. At first, the pellet was added and mixed with formic acid (10 µL, 70%) and then with acetonitrile (10 µL, 100%). The solution was centrifuged at maximum speed for 2 min. The supernatant was placed on a polished MALDI plate (Bruker Daltonics, Germany) and after drying a 1 µL of the matrix solution (HCCA: α-cyano-4-hydroxycinnamic acid (Bruker Daltonics, Germany), 50% acetonitrile with 0.025% trifluoroacetic acid (TFA) (100%, Sigma-Aldrich, USA)) was added in the spots. Sample processing was performed with MALDI-TOF MS (Microflex LT/SH, Bruker Daltonics) using the MALDI Biotyper software package (version 3.0) and data were obtained with Realtime Classification software (RTC) (Bruker Daltonics). Data processing was carried out by Biotyper software, where sample mass spectrum was compared with the reference mass spectrum and the score values were calculated.

Antibiotic susceptibility testing of bacterial isolates

Antimicrobial resistance of *Pseudomonas* and *Enterobacteriaceae* bacteria confirmed with the MALDI TOF MS Biotyper (Brucker Daltonics) was tested with the disc diffusion method. Suspension of bacterial isolates in Mueller Hinton broth was placed onto Mueller Hinton agar (MHA, OXOID, UK). The antimicrobial discs were placed on the MHA (OXOID, UK) surface after the inoculation, agars were allowed to dry out at room temperature and

were incubated at 37 °C for 24 h. *Pseudomonas* spp. isolates were tested against ticarcillin (75 μg), cefotaxime (30 μg), ciprofloxacin (10 μg), imipenem (10 μg) and doripenem
(10 μg) (Oxoid, UK). *Enterobacteriaceae* were tested against ticarcillin (75 μg), cefepime (30 μg), ciprofloxacin (10 μg), imipenem (10 μg) and tobramycin (10 μg) (Oxoid, UK). Antimicrobial susceptibility testing was performed according to the CLSI guidelines and the results were interpreted in accordance with EUCAST breakpoint tables **(EUCAST, 2018)**.

Statistical analyses

Statistical analyses were performed by R software, version 3.4.3, for data management RStudio was used. Bacterial counts were expressed in decimal logarithms. T-test was used for calculating differences among the total bacterial count (TBC), coliforms and *Enterobacteriaceae* in fish gills, gut and skin samples. The one-way analysis of variance (ANOVA) was used to detect significant differences between the bacterial contamination rates of fish gills, gut and skin samples (p <0.05).

RESULTS AND DISCUSSION

TBC ranged from 2.70 to 7.00 log CFU.g^{-1} in all fish samples. The highest TBC was detected in gut of bream and tench, while the lowest in rainbow trout skin (Table 1). Coliforms were not detected in crucian carp gill and tench skin samples, while the highest numbers of coliforms were found in crucian carp and tench gut with 2.67 and 2.51 log CFU.g^{-1}. The highest *Enterobacteriaceae* counts of 2.85 and 2.75 log CFU.g^{-1} were identified in bream gill and crucian carp gut, while *Enterobacteriaceae* were not isolated from the chub gill, bream skin and tench gill and skin samples. *Pseudomonas* spp. and *Aeromonas* spp. were not found in rainbow trout, crucian carp and tench samples. The highest contamination with *Pseudomonas* spp. was observed in chub gill and gut samples with 1.46 and 1.60 log CFU.g^{-1}. The most contaminated fish species with *Aeromonas* spp. was the chub – 1.93 log CFU.g^{-1} in gill, 2.23 log CFU.g^{-1} in gut and 0.60 log CFU.g^{-1} in skin.

The microbiological criteria as total bacterial count (TBC) and *Enterobacteriaceae* are applied widely to ensure the microbiological quality and safety of foods. The TBC shows the general level of contamination and the shelf-life stability while the coliforms and *Enterobacteriaceae* indicate the presence of faecal contamination and possible pathogens in foods **(Tortorello, 2003)**. In the present study, the TBC were in line with **Eizenberga et al. (2015)** reported for freshwater fish from Usmas lake in Latvia with gill, skin and gut contamination rates from 1.26 to 8.08 $\log_{10}$ CFU.g^{-1}, from 1.04 to 8.61 $\log_{10}$ CFU.g^{-1} and from 1.45 to 7.36 $\log_{10}$ CFU.g^{-1}, respectively. However, our results were lower than **Terentjeva et al. (2015)** stated for bream obtained from Usmas lake in Latvia with 5.48 log CFU.g^{-1} for skin contamination with TBC and 7.24 log CFU.g^{-1} with *Enterobacteriaceae*.

Aeromonas spp. are distributed in freshwater habitats worldwide. **Stratev, Vashin and Daskalov (2015)** found the contamination with *Aeromonas* spp. in cooled rainbow trout and trout fillets at retail markets. **Abd-El-Malek (2017)** reported that the raw fish in Egypt were contaminated with *Aeromonas* spp. and majority of the isolates were identified as *A. hydrophila*. This bacterium is pathogenic not only for humans but also for fish and is commonly found in water. Inhabited in an aquatic environment, *A. hydrophila* is reported to be the cause of secondary infection of wounds, sepsis, cellulitis, pneumonitis, gastroenteritis and necrotizing fasciitis. **(Hassan and Farag, 2006)**. High prevalence psychrophilic bacteria, especially proteolytically active microorganisms

Table 1 Bacterial contamination of freshwater fish.

Fish species	Sampling site	TBC log CFU.g^{-1}	Coliforms log CFU.g^{-1}	*Enterobacteriaceae* log CFU.g^{-1}	*Pseudomonas* spp. log CFU.g^{-1}	*Aeromonas* spp. log CFU.g^{-1}
Rainbow trout (*Oncorhynchus mykiss*)	Gills	3.16[a]	1.52	2.03	0	0
	Gut	3.37[b]	1.04	1.68	0	0
	Skin	2.70[a]	1.43	2.25	0	0
Chub (*Leuciscus cephalus*)	Gills	3.58[a]	2.11	0	1.46[e]	1.93[e]
	Gut	2.97[b]	1.77	2.35[d]	1.60	2.23
	Skin	3.18[a]	0.30	0.78	0	0.60
Bream (*Abramis bram*)	Gills	3.15[a]	0.60	2.85	0.3	0
	Gut	7.00[b]	1.78[c]	2.36[d]	0	0
	Skin	3.23[a]	0.30	0	0	1.38
Crucian carp (*Carassius carassius*)	Gills	3.08[a]	0	1.18	0	0
	Gut	3.18[b]	2.67[c]	2.75[d]	0	0
	Skin	2.74[a]	0.30	1.30	0	0
Tench (*Tinca tinca*)	Gills	3.39[a]	1.04	0	0	0
	Gut	7.00[b]	2.51[c]	2.60[d]	0	0
	Skin	2.79[a]	0	0	0	0

Note: [a] no significant differences between TBC in tested fish gill and skin samples were observed (p >0.05);
[b] TBC in bream and tench gut was significantly higher than in gut of rainbow trout, chub and crucian carp (p <0.05);
[c] coliform counts in bream, crucian carp and tench gut were significantly higher than in gill and skin samples (p <0.05);
[d] *Enterobacteriaceae* counts in chub, bream, crucian carp and tench gut samples were significantly higher than in gill and skin samples (p <0.05);

– *Pseudomonas* spp. and *Aeromonas* spp. can predispose fish to a more rapid process of microbiological deterioration of fish meat quality **(Cipriano and Dove, 2011; Larsen, 2014)**.

Tested fish bacterial microbiota contained 16 microbial genera, from which the most abundant were *Pseudomonas* spp. (54%) (Figure 1). *Shewanella* spp. (5%) and *Serratia* spp. (5%) were also among the most frequently isolated. Other genera isolated were *Escherichia* spp., *Lelliottia* spp., *Leclercia* spp., *Bacillus* spp., *Citrobacter* spp. and *Rahnella* spp., *Morganella* spp., *Acinetobacter* spp., *Achromobacter* spp., *Aromatoleum* spp., *Burkholderia* spp., *Arthrobacter* spp. and *Staphylococcus* spp.

Our results agreed with **Kim, Brunt and Austin (2007)**, who found *Aeromonadaceae*, *Enterobacteriaceae* and *Pseudomonadaceae* to be the most abundant microflora in rainbow trout intestine samples. Our study confirms the findings of **Yagoub (2009)** who isolated similar bacteria genera from fish samples.

Bacterial species isolated from freshwater fish gill, gut and skin samples are shown in Table 2. Overall, 31 bacterial species were identified with MALDI-TOF mass spectrometry. The gill microbiota was more diverse than the microbiota of gut and skin with only some *Pseudomonas* spp. were present in fish skin. *Pseudomonas proteolytica*, *P. brenneri*, *P. cedrina*, *P. veronii* and *Lelliottia amnigena* were dominant bacteria species isolated from gills and skin. Intestinal bacterial microbiota consisted of species, which were specifically found in gut – *Arthrobacter monumenti*, *P. grimondii*, *P. gessardii*, *P. synxantha*, *P. libanensis*, *P. tolaasii*, *Achromobacter xylosoxidans*, *Aromatoleum alkani*, *Burkholderia thailandensis*.

In previous studies, the skin and gill microbiota were evaluated together due to influence of water pollution on the fish microflora **(Larsen, 2014)**. **Fernandes (2009)** found that the Gram-negative bacteria were predominant. Several genera as *Bacillus* spp., *Pseudomonas* spp., *Leclercia* spp., *Acinetobacter* spp., *Citrobacter* spp., *Achromobacter* spp., *Escherichia* spp., *Serratia* spp., *Rahnella* spp. and *Staphylococcus* spp. found in our study, have been previously associated with microbiota of gill, gut and skin **(Austin, 2006)**.

Pseudomonas spp. are widespread in nature and have been isolated from aquatic environment and fish. Some species can cause a negative effect on animal and human health, eg. *P. fluorescens* is a potential pathogen that can influence the physiological processes of neurons **(Picot et al., 2001)**. Other pseudomonas can cause diseases in fish and contribute the spoilage processes of fish meat. *Pseudomonas* spp. were considered to be relatively resistant to antibiotics **(Kačániová et al., 2017)**. The members of the *Shewanella* spp., specially *S. baltica* were described in spoilage of chilled marine products **(Ge et al., 2016)**. In agreement with **Starliper (2001)** and **Aydin, Erman and Bilgin (2011)**, *Serratia liquefaciens* is a potential fish pathogen, which can lead to high mortality, causing economic losses. **Altun et al. (2013)** refers about pathogenicity of *Citrobacter braakii* isolated from rainbow trout in Bursa. *Leclercia adecarboxylata* infection was rarely reported in humans and the infection were described in patients with impaired immunity. *L. adecarboxylata* is expected to be the pathogen related to the aquatic environment **(Keren et al., 2014)**. *R. aquatilis* is prevalent in the environment and has previously been isolated from various water reservoirs, soil, clinical specimens and foodstuffs. *R. aquatilis* is an opportunistic pathogen that can cause a variety of serious gastrointestinal, urinary, respiratory and cardiovascular diseases. The consequences can be even dangerous for human life **(Alikunhi et al., 2017)**. *Bacillus cereus* is widespread in nature, it causes two types of food-borne diseases: toxicosis caused by previously produced toxin and toxicity caused by bacterial cells that produce enterotoxins in the small intestine

Pseudomonas tolaasii	1	1 (100)	0 (0)	0 (0)	1 (100)	1 (100)
Pseudomonas taetrolens	1	1 (100)	0 (0)	0 (0)	0 (0)	0 (0)

Note: TIC: ticarcillin; FEP: cefepime; CIP: ciprofloxacin; IMP: imipenem; DOR: doripenem.

Table 4 Antibiotic susceptibility of *Enterobacteriaceae* isolates from fish samples.

Bacterial isolates	No. of isolates	TIC	CTX	CIP	IMP	TOB
		No. of resistant isolates (%)				
Lelliotia amnigena	2	2 (100)	0 (0)	1 (50)	0 (0)	1 (50)
Escherichia vulneris	2	2 (100)	1 (50)	0 (0)	0 (0)	1 (50)
Staphylococcus equorum	1	0 (0)	1 (100)	0 (0)	0 (0)	0 (0)
Rahnella aquatillis	1	1 (100)	1 (100)	0 (0)	1 (100)	1 (100)

Note: TIC: ticarcillin; CTX: cefotaxime; CIP: ciprofloxacin; IMP: imipenem; TOB: tobramycin.

(Rasool et al., 2017). *B. cereus* was isolated from fish in India and tropical fish from Shivajinagar area of Bangalore, India **(Rasool et al., 2017; Prasad, 2014)**.

Emetic disease caused by *B. cereus* associated with tuna fish consumption was reported **(Doménech-Sánchez et al., 2011)**. *Escherichia vulneris* was originally isolated from human skin lesions, but recently the microorganism was isolated from water and fish. *E. vulneris* is present in the intestinal tract of animals, so the bacterium can cause environmental pollution **(Aydin, Celebi and Akyurt, 1997)**. Proportion of the microorganisms isolated in this study can contribute to the spoilage processes of fish and also act as infectious agents for fish and consumers.

All *Pseudomonas* species isolated from freshwater fish were resistant to ticarcillin (Table 3). *P. grimondii*, *P. fluorescens*, *P. synxantha*, *P. tolaasii*, *P. taetrolens* and *P. gessardii* were susceptible to cefepime (64%). Susceptibility to ciprofloxacin showed 91% of the isolates. Resistance to imipenem demonstrated 73% of the isolates. Most of the isolates (91%) except *P. taetrolens* were resistant to doripenem. *P. taetrolens* was sensitive to antibiotics including cefepime, ciprofloxacin, imipenem and doripenem. This study shows the high prevalence of antibiotic-resistant *Pseudomonas* spp. strains in fish. Our results agreed with **Kačániová et al., 2017** about occurrence of antibiotic-resistant *Pseudomonas* spp. in freshwater fish. Some antimicrobials were effective against *Pseudomonas* spp. in **Kholil et al. (2015)** study, who showed *Pseudomonas* spp. susceptibility to ciprofloxacin. Oxytetracycline, tetracycline and ciprofloxacin were found to be effective against *Pseudomonas* spp. also by **Mastan (2013)**.

Results on antimicrobial resistance of *Enterobacteriaceae* from fish samples are shown in Table 4. *L. amnigena* isolates were resistant to ticarcillin, however, showed susceptibility against other antibiotics. *E. vulneris* showed 100% resistance to ticarcillin and 50% to cefotaxime and tobramycin. *Staphylococcus equorum*

were resistant only to cefotaxime. *R. aquatillis* showed resistance to ticarcillin, cefotaxime, imipenem and tobramycin. Totally, 83% of isolates expressed susceptibility to ciprofloxacin with only one isolate of the *L. amnigena* was resistant. Susceptibility to imipenem was 83%, but resistance to cefotaxime was 50% among *Enterobacteriaceae* isolates. Resistant *Enterobacteriaceae* were found in water sources previously **(Guyomard-Rabenirina et al., 2017)**. **Stock and Wiedemann (1999)** reported *E. vulneris* was the species the most susceptible to ticarcillin. The antimicrobial resistance become emerging problem with international organizations and the EU institutions have recognized that the development of antimicrobial resistance raises severe consequences for human and animal health and well-being **(Singer et al., 2016)**. The present study showed the occurrence of resistant bacteria in freshwater fish.

CONCLUSION

The results of our study confirm that freshwater fish are contaminated with bacteria, but in general, the microbial quality of freshly caught fish is acceptable. Fish gill, gut and skin microflora was very diverse with *Pseudomonas* spp. and *Enterobacteriaceae* were the most abundant. Groups of microorganisms. Our results confirm that antibiotic resistant bacteria could be found in fish that represents possible public health consequences.

ANTIOXIDANT PROFILE OF MULLED WINE

Dordevic Dani, Simona Jancikova, Bohuslava Tremlova

ABSTRACT
The aim of the study was to compare chemical and nutritional profile of wine and heat-treated wine, called mulled wine. The experiment was focused on simulation of ordinary produce mulled wine by the majority of consumers. Cabernet Moravia (bottled in Velkobílovická vína s.r.o., Czech Republic) was used for the experimental production of mulled wine. Following spices were added to wine during cooking: cloves (Vitana, Czech Republic) and cinnamon (KOTÁNY, Austria). The samples of wine were heat treated in stainless steel pot for 5 minutes. The relative density, acidity, alcohol content, phenol content and antioxidant capacity were monitored in experimentally produced wine and mulled wine. The gained results showed that samples of mulled wine with added cloves had statistically significant (p <0.05) higher phenol content and higher antioxidant properties in comparison with wine before heat treatment and spices addition. The results clearly showed that mulled wine can be considered as the product with better health beneficial nutritional profile than wine from which it is produced; in addition, mulled wine sample had significantly (p <0.05) lower alcoholic content (8.27 ±0.04 vol.%).

Keywords: Cabernet Moravia; mulled wine; spice; clove; cinnamon; antioxidant

INTRODUCTION
Consumers interest in the binominal diet (diet related to health) has been constantly increasing due to clear evidences how specific dietary patterns can reduce a chronic diseases development **(Zorraquin-Peña et al., 2019)**. The most often diet connected with health benefits is the Mediterranean diet and the most common food commodity in this type of diet is wine **(Chiva-Blanch et al., 2013; Artero et al., 2015)**. Wine health benefits are mostly connected with high polyphenols content and their positive influence on human health, beside organoleptic properties **(Snopek et al., 2018; Zorraquin-Peña et al., 2019)**.

Nowdays, wine is broadly consumed and used in culinary preparation. Wine is very often thermally threated when it is added to certain meals. It is also consumed as a warm beverage with addition of spices. This popular drink is called mulled wine and its physical-chemical properties are changed due to processing **(Mudnić et al., 2011)**. It is well known that high phenol content means food with higher antioxidant activity due to phenols ability to donate hydrogen. The role of phenols in so complex system such as food is hard to predict due to the presence of other antioxidants, polyphenols, oxidative enzymes, metals, etc. This statement is crucial for food that is fortified with different polyphenols and it means that each food fortifcation should enclude a specific experimental study **(Pinelo et al., 2004)**. It was also found that thermally treated wine still posses high antibacterial properties **(Boban et al., 2010)**. Thermal treatment of wine even at lower temperatures, such as 45 ºC during 20 days, also can make changed in wine chemical and sensorial properties. It was found that this kind of treatment significantly changed floral character of the wines and increased aromas described as oak, honey and smoky **(Leino et al., 1993)**.

Cabernet Moravia is a wine variety that was made by crossing of Zweigeltrebe and Cabernet Franc. It is grown mostly in Moravian region in the Czech Republic. This wine variety contains a high content of anthocyanins, pigments and polyphenols content **(Balík and Kumšta, 2008; Bajčan et al., 2016)**.

The most often used spices for the preparation of mulled wine are cloves (*Eugenia caryophyllata*) and cinnamon (*Cinnamomum cassia*). Cloves are already known for their medical usage and antimicrobial activities. Cloves are also known to serve as preservative during shelf life of different food products **(Santin et al., 2011; Sukorini, Sangchote and Khewkhom, 2013)**. Cinnamon (*Cinnamomum cassia*) has been the one of the most commonly used spice since 2800 BCE. Cinnamon used as a spice has many beneficial effects encompassing antioxidant, antiinflamatory, antidiabetic, antibacterial and anticancer **(Ben-Arfa et al., 2019)**.

Scientific hypothesis

Mulled wine is better solution for consumers than heat not treated wine without spices addition.

The aim of the study was to evaluate heat treated wine (mulled wine) with and without spices addition and compare their antioxidant profile and chemical-physical parameters.

MATERIAL AND METHODOLOGY

The mulled wine was prepared from Moravian Country wine, dry red wine Cabernet Moravia (bottled in Velkobílovická vína s.r.o., Czech Republic). The mulled wine was made with the addition of spices: clove (*Eugenia caryophyllata*) (Vitana, Czech Republic, batch: L1104182) and cinnamon (*Cinnamomum cassia*) (KOTÁNY, Austria, batch: L327392111511). The addition of spices was done according to the Table 1.

The samples 2 to 5 were boiled in stainless steel pot during 5 minutes. In the samples 3 to 5 the spices **(**clove/cinnamon**)** were added before boiling (Table 1). The sample 1 was control sample including only wine (Cabernet Moravia).

The relative density was measured with the use of capillary tube pycnometers (capacity: 10 mL). The samples' weights were measured in analytical balance with 0.0001 g precision **(Cepeda and Villarán, 1999)**. The blank sample was distilled water and it was measured according to the following equation:

*ρv = (mpv – mpp)/Vp

*mpv: weight of pycnometer filled with wine sample; mpp: weight of empty pycnometer; Vp: volume of the pycnometer

The pH of each sample was measured by the pH meter GRYF 259 (GRYF HB, Czech Republic) with electrode PCL 124 (GRYF HB, Czech Republic).

The determination of titratable acidity was measured by the titration of sample by 0.1 M NaOH with the bromthymol blue as an indicator up to the color change to green. The concentration of titratable acid was calculated as the content of tartaric acid ($g.L^{-1}$) by formula: TA = a·0.75; where a is the volume of 0.1 M NaOH. This method is recommended by the Compendium of International Methods of Wine and Must Analysis **(OIV, 2009)**.

The determination of alcohol was measured by Ebulliometer 160450T (Laboratories DUJARDIN-SALLERON, France).

The total polyphenols content (PCA) was measured with the Folin-Ciocalteau solution diluted by water (1:10) and Na_2CO_3 (75 $g.L^{-1}$) by **Talcott, Howard and Brenes (2000)** with slightly modification. The sample of wine was diluted 100 times and then 1 mL was used for analysis. 5 mL of Folin-Ciocalteau solution and 4 mL Na_2CO_3 and then the sample was incubated in dark for 30 minutes. The absorbance was measured at 765 nm and the gallic acid was used as the standard **(Talcott, Howard and Brenes, 2000)**.

The determination of FRAP – ferric reducing/antioxidant power was measured at the absorbance of 593 nm. FRAP reagent was prepared by mixing 10 volumes of 300 $mmol.L^{-1}$ acetate buffer with 1 volume of 10 $mmol.L^{-1}$ TPTZ (2,4,6-tripyridyl-s-triazine) in 40 $mmol.L^{-1}$ hydrocloric acid and with 1 volume of 20 $mmol.L^{-1}$ ferric chloride. The dilution of sample in reaction mixture was 1:34. Absorbance readings were done after 8 minutes of incubation.

The determination of polyphenols by high pressure liquid chromatography (HPLC). A 2 g of baked cookies sample was weighed into 200 mL volumetric flask and 50 mL methanol/water (50/50, v/v) was added. The samples were left for 5 days in the dark. Extracts were then filtered by a syringe filter (Agilent Captiva Premium Syringe Filter Regenerated Cellulose, 0.45 µm, 25 mm, p/n 5190 5111) and filtrates were used directly for injection.

The HPLC mobile phase was following: A) water + 1% phosphoric acid; B) acetonitrile; with the following gradient: 10% B, from 0 to 20 min; 20% B, from 20 to 25 min; 30% B, from 25 to 35 min; 40% B, from 35 to 40 min; post time was 10 minutes. The column was Agilent ZORBAX Eclipse Plus, 4.6 × 250 mm, 5 µm. Detection was done with the use of diode array detector (DAD) at 324nm. The method was slightly modification of the method developed by **Naegele (2013)**.

Statistic analysis

Statistical significance at $p < 0.05$ was evaluated by one-way ANOVA analysis of variance, and parametric Tukey post hoc test (in the case when Levene's test showed equal variances $p > 0.05$) and nonparametric Games–Howel post hoc test (in the case when Levene's test showed unequal variances $p < 0.05$) for finding differences within individualgroups. Principal component analysis (PCA) was done (with Promax rotation) for finding overall differences among wine and experimentally produced mulled wine samples. SPSS 20 statistical software **(**IBM Corporation, Armonk, NY**)** was used.

RESULTS AND DISCUSSION

Alcohol percentage, titrated acids content and pH value of wine and developed mulled wine samples are shown in Table 2.

Titrated acids were the highest in the sample of mulled wine that was prepared with cloves addition, which can be explained by low pH of clove oil (2.81) **(Santin et al., 2011)**. Alcohol content in evaluated samples was significantly (p <0.05) reduced in mulled wine samples (samples number: 2, 3, 4, 5) due to heat treatment. In the study of **Boban et al. (2010)** during 45 minutes heat treatment of wine at 75 ºC and 125 ºC alcohol content in mulled wine was also lowered by 20% and more than 90%, respectively. The content of alcohol was almost at the same level in the both mulled wines (45 minutes treatment at 125 ºC) and dealcoholized wines (under vacuo in rotary evaporator) **(Boban et al., 2010)**. Alcohol content in wine can be up to 15% **(**vol/vol**)** in wines produced in warmer climate regions due to higher sugar content **(Contreras et al., 2014)**. At the present time there is a trend of producing wines with reduced alcohol content due to public health recommendations to lower alcohol consumption **(Grant, 2010; MacAvoy, 2010)**. The results obtained by analysis of total phenol content represented as gallic acid ($mg.L^{-1}$) and antioxidant capacity (FRAP) are shown in Table 3.

The total phenol contents in were the highest (p <0.05) in mulled wine samples with cloves addition (samples 3 and 5). The increment can be explained by cloves addition which is known as good source of phenolic compounds **(Gulcin et al., 2004)**, but also wine heat treatment leads to increase of phenolic compounds due to loss of volume **(Boban et al., 2010)**. Though, Authors **(Boban et al., 2010)** found that heat treatment and dealcoholizing of wine result in the loss of some individual phenolic compounds, but total phenol content increases. On the other side, wine and especially mulled wine represent the model of mixed polyphenolic compounds that are well protected during heating. It was also indicated that certain polyphenolic compounds serve as polyphenols' protector during heat-induced decomposition **(Yamaguchi et al., 2003)**. Although, heat-induced polyphenol interactions are very hard to predict and their paths toward degradation or increment **(Pinelo et al., 2004)**. The complexity of mulled wine phenolic content changing is also supported by the observation that even small physical-chemical properties changes of hydroalcoholic polyphenolic solutions significantly affect their solubility, perception behavior and also their interactions with other compounds, such as proteins **(Serafini, Maiani and Ferro-Luzzi, 1997; Zanchi et al., 2008)**. The differences in polyphenolic profile among wine and experimentally produced mulled wine sample can be also seen in Figure 2 that is clearly showing the increase of polyphenolic compounds, especially in samples with added cloves. Antioxidant capacity represented as ferric reducing antioxidant power (FRAP) was the highest (p <0.05) among mulled wine samples with cloves addition (samples 3 and 5). These results are corresponding with higher polyphenol contents in these samples. The finding is supported by the observation of previous studies that found higher antioxidant activity in heat treated food product in comparison to raw materials. This swift to higher antioxidant capacity is explained by two possibilities: i) the production of stronger antioxidants during heating and ii) oxidative enzymes are inactivated by thermal processing **(Boban et al., 2010)**. **Mudnić at al. (2011)** found the increase of phenol content in heat treated wine (mulled wine). The authors also stated that thermal degradation of phenolic compounds is still poorly understood and that it is hard to predict these process.

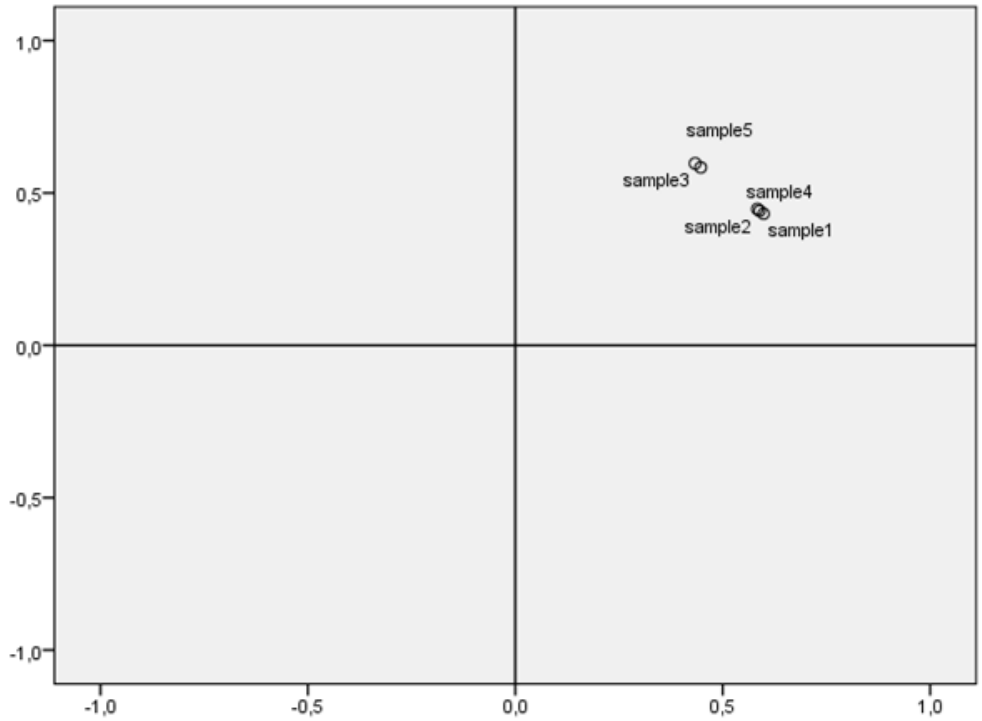

Figure 1 Principal component analysis (PCA) of wine and mulled wine samples.

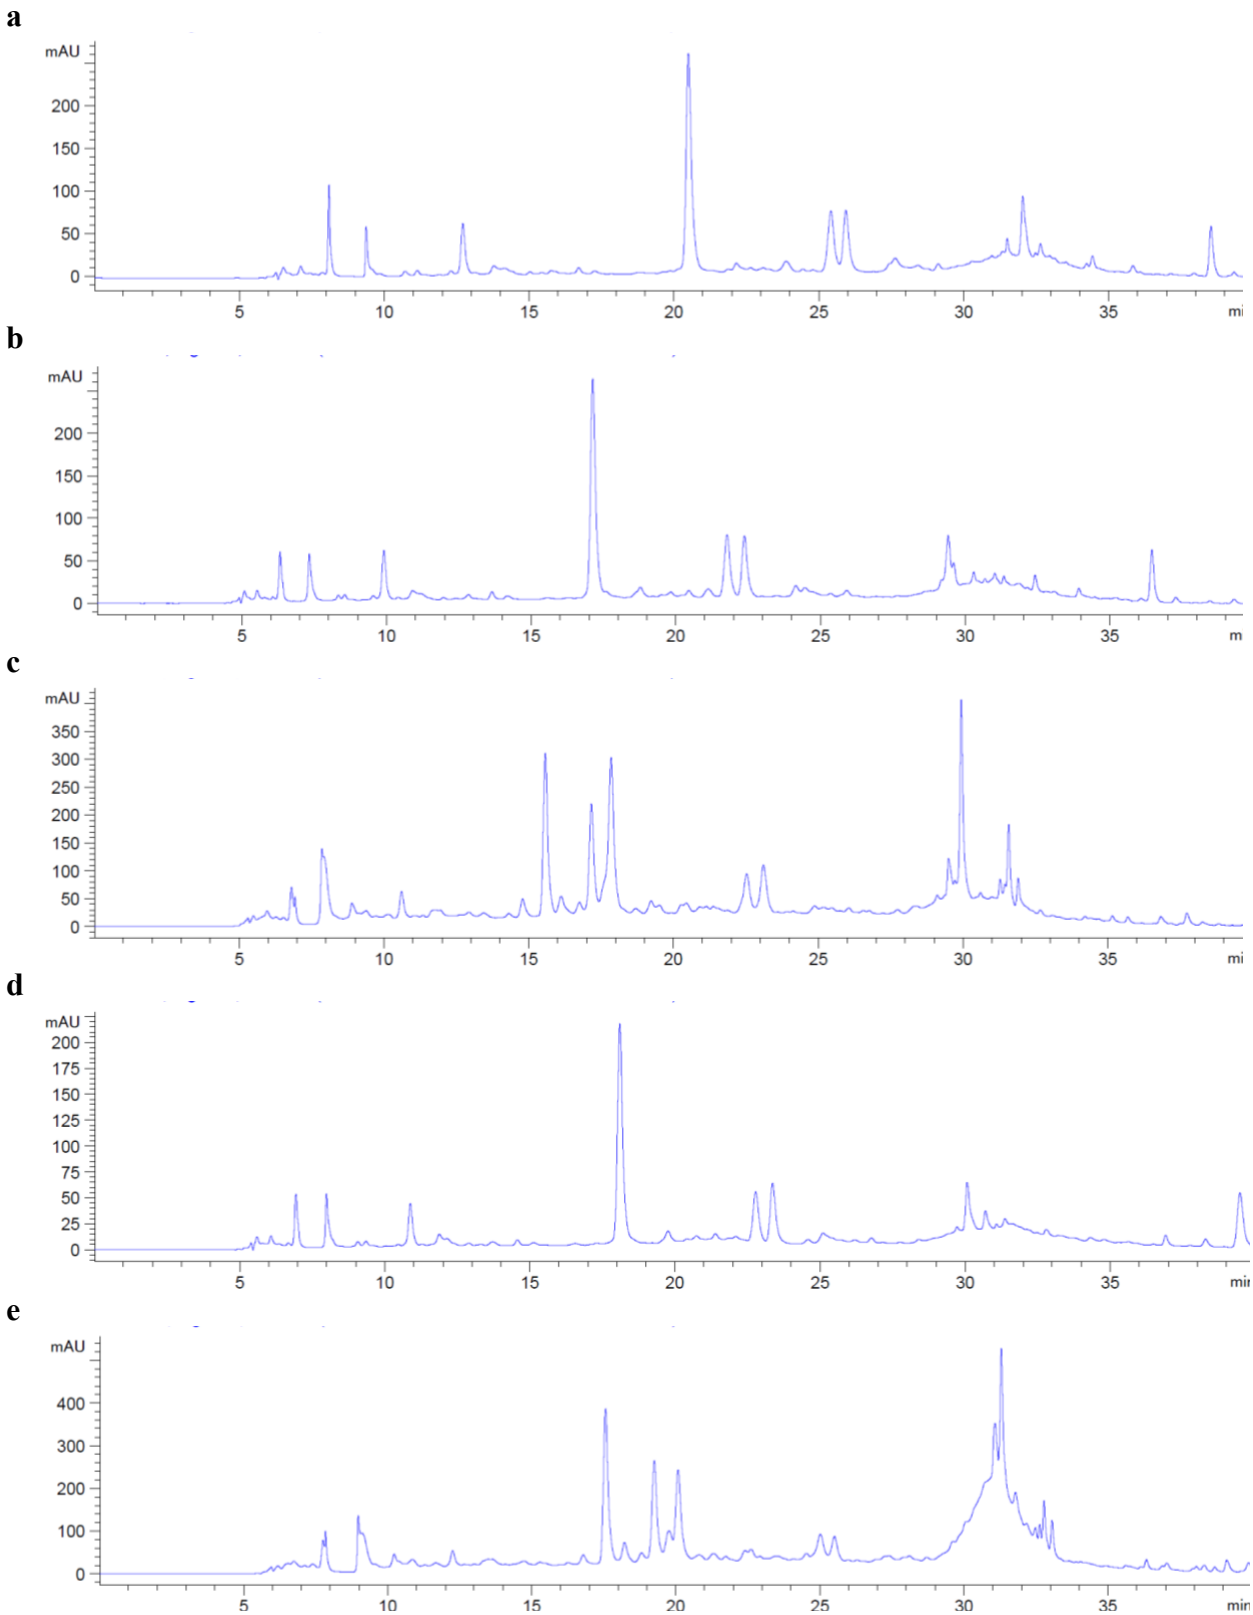

Figure 2 Polyphenolic profile of wine and mulled wine samples.
Note: *a: sample 1; b: sample 2; c: sample 3; d: sample 4; e: sample 5. According to Table 1.

Table 1 The samples used in the experiment.

Samples	Composition	Thermal treatment	Wine + spices
1	Wine	No	Wine (only wine)
2	Mulled wine without spices	Yes	Mulled wine (only wine)
3	Mulled wine + cloves	Yes	600 mL + 18 g
4	Mulled wine + cinnamon	Yes	600 mL + 17 g
5	Mulled wine + cinnamon + clove	Yes	600 mL + 17 g + 18 g

Table 2 PH, relative density, titrated acids and alcohol content in mulled wines.

	pH	Titrated acids (tartaric acid g.L^{-1})	Alcohol (vol.%)	The relative density (g.cm^{-3})
1	3.62 ±0.02	7.00 ±0.00	11.96 ±0.18^{a}	0.99 ±0.00
2	3.55 ±0.01	7.35 ±0.21	9.03 ±0.06^{c}	0.99 ±0.00

Table 3 Total phenol content and antioxidant capacity of wine and mulled wine samples.

	Total phenol content (gallic acid mg.L^{-1})	Antioxidant capacity FRAP (μmol.L^{-1})
1	2 375.04 ±0.00^{a}	238.69 ±2.73^{a}
2	2 499.69 ±0.00^{b}	268.76 ±1.87^{c}
3	4 019.90 ±0.00^{c}	718.23 ±1.98^{d}
4	2 284.47 ±0.00^{d}	239.85 ±0,61^{acb}
5	4 165.99 ±0.00^{e}	717.61 ±1.71^{d}

Note: *different letters (a, b, c, d, e) indicate statistically significant (p <0.05) differences.

Temperature and pH affect the most degradation of phenolic compounds, though the degradation was found to be not so intense since the temperature of 111 °C degrades gallic acid during 30 minutes only by 1.3% **(Tanchev et al., 1997)**. The overall differences between wine and mulled wine samples can be seen in Figure 1. Principal component analysis found 2 seperate groups: group 1 – samples 1; 2 and 4; group 2 – samples 3 and 5 **(**Figure 1**)**.

CONCLUSION

The study clearly gives the picture about differences between wine and experimentally produced mulled wine. The health benefits of wine consumption are almost exclusively connected with high phenolic content and consequently high antioxidant properties. The sharing of this fact in many countries has raised the consumption of wine significantly. On the other hand, alcohol content of wine is the subject of constant evaluation of medical studies. The results gained by our research are indicating that during heating process of mulled wine consumption phenolic profile is not interrupted and can be even improved by the addition of regular spices the most often used to produce mulled wine, such as cinnamon and cloves. Concurrently, the heating process is significantly reducing alcohol content. Certainly, the effects of heating on wine, as representative of highly complex polyphenolic matrix, will be the subject of future studies since interection between polyphenolic compounds between them and also between other compounds present in wine has not been still explained enough.

EFFECT OF INTRAMUSCULAR FAT CONTENT ON PHYSICAL-CHEMICAL PARAMETERS OF PORK FROM MANGALITSA AND THEIR CROSSBREEDS

Petra Lípová, Ondrej Debrecéni, Ondřej Bučko, Klára Vavrišínová

ABSTRACT

The aim of study was to evaluate the effect of intramuscular fat content on physical parameters and proximate composition in *musculus longissimus dorsi* (MLD) from Mangalitsa breed and Slovak Large White x Mangalitsa crossbreed. In the study, sixteen pigs of Mangalitsa and twenty-two pigs of Slovak Large White x Mangalitsa crossbreed were used. The pigs were reared under intensive condition and all animals were fed *ad libitum* with complete fattening feed mixture. The fattening period started from 30 kg of live weight. Then the pigs were slaughtered at 100 kg of live weight. Chemical analysis showed that MLD from Mangalitsa had lower protein content, higher moisture content (p <0.05) and higher content of intramuscular fat compared to Slovak Large White x Mangalitsa crossbreed. As regarding the cholesterol content in MLD, no significant differences were found between genotypes, but the cholesterol content was higher in MLD from Mangalitsa than in MLD from crossbreeds. The MLD from Mangalitsa exhibited lower CIE L* (p <0.01) and CIE b* (p <0.01) values 45 min *post mortem* compared to crossbreeds. Colour parameters increased after 7 days *post mortem*, which is normal due to the maturing process of the meat. Then the CIE L* value was lower in MLD from Mangalitsa (p <0.01), but CIE a* value was higher in relation to crossbreeds (p <0.05). As regards the Warner-Bratzler shear force, the meat from Mangalitsa was tenderer than in crossbreeds (p <0.05). Intramuscular fat in the meat positively correlated with colour parameter CIE a* (r = 0.324; p <0.05) as well as cholesterol content (r = 0,656; p <0.001). In contrast in the study was found negative correlations between intramuscular fat in meat with moisture content (r = -0.399; p <0.05) and protein content (r = -0.812; p <0.001). It can be concluded that the percentage of intramuscular fat significantly influenced the physical and the chemical parameters of pork. The meat from Mangalitsa is more suitable for production of special meat products (fermented and smoked).

Keywords: crossbreeds; intramuscular fat; Mangalitsa; *musculus longissimus dorsi*; pork

INTRODUCTION

Meat quality is evaluated according to quality parameters such as pH, colour or intramuscular fat content. Meat colour is one of the main quality properties which influence consumer's acceptance, but also reflects the quality of meat **(Estévez, Morcuende and Cava, 2003; Alonso et al., 2009)**. Within the qualitative parameters of meat, evaluating percentage of intramuscular fat seems to be the best way to separate indigenous pigs from commercial breeds **(Pugliese and Sirtori, 2012)**, because it is usually observed that intramuscular fat content in important cuts of pork is less than 1.5% in pig meat breeds **(Hamill et al., 2012)**. **Jeong et al. (2010)** indicated that intramuscular fat content is important factor that contribute to eating quality and it is influenced by genotype, gender, age and diet. Some reports indicate that when intramuscular fat content increases from 1% to 3%, the qualitative parameters increase at high rate. However as intramuscular fat content increase from 3% to 6%, the qualitative traits also improve, but at the lower levels.

The indigenous breeds such as Iberian and Mangalitsa are known to have desirable quality properties of meat that could be of interest to farm, giving the possibility to produce unique high-quality meat products. These indigenous breeds have a high intramuscular fat content **(Straadt, Aaslyng and Bertram, 2013)**. Mangalitsa is one of the most popular rustic pig breeds in Europe, because the meat has excellent properties, such as taste, marbling and low cholesterol content **(Pârvu et al., 2012)**. This breed is also characterized by dark colour of meat, robust constitution and slower growth rate with higher content of fat in carcass (65% – 70%) and reduced content of meat (30% – 35%) in carcass compared to commercial breeds **(Egerszegi et al., 2003; Stanišić et al., 2013)**.

In the intensive pig production, the most common crossbreeding program is to use breeds such as Large White, Duroc, Pietran, to improve some production parameters as

well as qualitative traits in meat **(Alonso et al., 2015)**. In the last several decades, pigs have been crossed for the rapid production of lean meat and to increase the slaughter yield. According to this, most recent pig breeds have less than 2% of intramuscular fat in meat with exception of Duroc breeds **(Suzuki et al., 2003; Sheard et al., 2005; Alonso et al., 2009)**.

Literature is controversial if the percentage of meat intramuscular fat in affects several quality traits. With this purpose, *the objective of this experiment* was to evaluate the effect of intramuscular fat content on physical parameters and proximate composition in *musculus longissimus dorsi* (MLD) from Mangalitsa breed and their Slovak Large White x Mangalitsa crossbreed.

Scientific hypothesis

Created crossbreeds Slovak Large White and Mangalitsa will have fattening as well as production comparable to Slovak Large White, at which the qualitative traits of meat will be a prerequisite for the production of specific products based on fermentation, smoking and drying.

MATERIAL AND METHODOLOGY

Biology material

The experiment was implemented in the Experimental centre of animal at the Slovak University of Agriculture (SUA) in Nitra. Thirty-eight pigs were studied, and they were divided into two groups with different genotype: Mangalitsa breed (n = 16) and Slovak Large White x Mangalitsa crossbreed (n = 22).

Feeding and rearing conditions

Pigs of Mangalitsa breed were reared under intensive conditions. The pens were situated outdoor. The pen consisted of concrete floor and the straw was used as bedding. The Mangalitsa pigs were housed in groups of 4. The pigs were fed by feed mixture (FM) for fatteners (Table 1), which received this feed mixture and drinking water by *ad libitum* system. The crossbreed Slovak Large White x Mangalitsa (SLW x Ma) were reared under intensive system in the indoor conditions. The size of pen was 3.10 m x 1.07 m. The pen was divided into bedding area (2.54 m^2) differenced by defecating area (0.96 m^2). The floor in the bedding area consisted of agro-pavage and the floor in defecating area was composed of grate. The crossbreeds SLW x Ma received complete feed mixture applied at the different growth phases: until 35 kg OS-03, from 35 kg to 65 kg OS-04 and above the 65 kg OS-05. The composition of complete feed mixtures and nutrient content are presented on Table 1. The pigs received drinking water and feeding with *ad libitum* system.

Sampling

Pigs were slaughtered upon reaching 100 kg of live weight, so the fattening period lasted from 30 kg to 100 kg of live weight. Pigs were slaughtered in the slaughterhouse at the Experimental centre of Animals (SUA in Nitra). Firstly, the animals were electrically stunned by electric forceps during 4 s with voltage 250 V and the amperage 1.3. The stunned animal was hooked for Achilles tendon and then was killed by bleeding. The slaughtering was realized according to **Government regulation (SR) no. 432/2012** of the coll. of Slovak Republic establishing the protection of animals during the slaughter. Samples of *musculus longissimus dorsi* (MLD) were dissected from the right-half carcasses. The MLD was taken at the level of the last *thoracic vertebra*. The dissection of carcasses was done performed according to standard practices of fattening-status and slaughter values in Slovakia.

Analysis of pH, electric conductivity and drip loss

pH values 45 min (pH_{45}) and 24 h (pH_{24}) *post mortem* in MLD were measured by pH meter Hanna HI99161 in units $log.molc^{(H+)}$. The electric conductivity was determined 45 min (EC_{45}) and 24 h (EC_{24}) *post mortem* by using an instrument Tecpro in unit $mS.cm^{-1}$. Drip loss in MLD was

measured 24 h *post mortem* by the method according to **Honikel (1998)**.

Instrumental colour and Warner-Bratzler shear force

Meat colour was measured in MLD 24 h and 7 days *post mortem* by using spectrophotometer CM-2600d with CIE Lab space and illuminate D65 (Konica Minolta, Japan). **Commission Internationale de l'Eclairage (1975)** determined the following colour coordinates: L* (lightness, white ± black), a* (redness, red ± green) and b* (yellowness, yellow ± blue). Values were recorded from the average of three random readings across each muscle surface. After 7 day – storage at temperature 4 ±1 °C, the Warner-Bratzler shear force was analysed. The samples were heated to internal temperature of 71 ±1 °C for 30 minutes and subsequently chips in 1x1 cm sheared across fibers. Warner-Bratzler shear force of meat was determined using a Warner-Bratzler shear device Chatillon (U.S.A), in accordance with **Goodson et al. (2002)**. The shear of device was set up according to producer (capacity of tensometer was 5 kg; speed was constant 0.005 $m.s^{-1}$).

Proximate composition

The basic chemical parameters such as total water, total protein and intramuscular fat content were measured by the FT IR method (FourierTransform InfraTed) by using device Nicolet 6700 (Thermo Scientific, USA). FT IR is method of infrared spectroscopy. The homogenized sample is placed on the imagine opening of the integration sphere and absorbs infrared radiation. The final spectrum is shown molecular absorption and wavelength transmission (4000 – 10 000 nm) using an interferogram, what is made as fingerprint of sample.

Statistical analysis

The effects of genotype on studied parameters were analysed by the analysis of variance (ANOVA) using the Statistic Analysis System (SAS) package: SAS 9.2 using of application Enterprise Guide 5.1. **(SAS Institute Inc., 2012)**. Means and standard deviation (*SD*) are presented in Tables. When ANOVA was significant the means were compared using Tukey's test. The correlation between intramuscular fat content in meat and physico-chemical parameters were analysed by calculation of Pearson's coefficient. The correlation between intramuscular fat content and protein content, cholesterol content as well as Warner-Bratzler shear force was expressed by linear regression.

RESULTS AND DISCUSSION

The results of physical and chemical parameters of MLD from genotypes are presented in Table 3 and Table 4. The pH 45 min and 24 h *post mortem* was not influenced by genotypes. The values of pH decreased after 24 hours *post mortem*, what agrees with studies of **Lindahl et al. (2006)** and **Young, Bertram and Oksbjerg (2009)**. MLD of Mangalitsa pigs had slightly higher values of pH 45 min and 24 h *post mortem* than crossbreeds SLW x Ma. Similarly, **Tomović et al. (2016)** confirmed that MLD of Mangalitsa had higher values of pH compared to their crossbreed (ph_{45min} 6.37 vs. 6.26; pH_{24h} 5.72 vs. 5.53). **Sirtori et al. (2011)** indicate that indigenous breed Cinta Senese had higher value of pH in MLD compared to crossbreed Italian Large White x Cinta Senese. The indigenous pig breed Chato Murciano had also higher value of pH in MLD than their crossbreed Chato Murciano x Iberian pig, what is obtained by **Galián et al. (2007)**.

Electric conductivity (EC) 45 min *post mortem* was lower in MLD of Mangalitsa pigs compared to crossbreeds SLW x Ma. The EC increased after 24 hours *post mortem*, whereby Mangalitsa pigs had lower EC_{24} than crossbreeds SLW x Ma, Electric conductivity (EC) 45 min *post mortem* was lower in MLD of Mangalitsa pigs compared to crossbreeds SLW x Ma. The EC increased after 24 hours *post mortem*, whereby Mangalitsa pigs had lower EC_{24} than crossbreeds SLW x Ma, indicating statistical significance ($p < 0.05$). In the same way, values of drip loss were lower in MLD of Mangalitsa in relation to crossbreeds SLW x Ma. Most commonly, pH and electrical conductivity are used as indicators for pale, soft, exudative (PSE) meat **(Warriss et al., 1998; Josell, Von Seth and Tornberg, 2003; Altmann et al., 2005)**. **Mörlein et al. (2007)** applied strict levels for determination of PSE meat, when pH_{45} <6.0 – 5.8 are used as threshold levels. Then, EC_{24} values above 9 – 7 $mS.cm^{-1}$ were applied as PSE meat. Threshold parameters for drip loss were above 7 – 9% within 48 h *post mortem*. On the basis of this fact, it was found in our study PSE of meat from Mangalitsa pigs fed by LFM. According to **Lee et al. (2000)** exist linear relationship between drip loss and electric conductivity, what is in consistent with our results. In our study was not determined pale, soft and exudative (PSE) meat. As regards Warner-Bratzler shear force (W-B), the MLD from Mangalitsa showed lower values of shear force (2.63 $kg.cm^{-2}$) compared to crossbreed SLW x Ma (3.14 $kg.cm^{-2}$; $p < 0.05$). The values were notably lower than those obtained by **Stanišić et al. (2015)** in Mangalitsa breed and Landrace as well as by **Tomović et al. (2016)** in MLD of Mangalitsa and Large White. Data confirmed that Mangalitsa has more tender meat than Landrace and Large White.

As regards the instrumental colour of MLD measured 45 min *post mortem*, the value CIE L* was higher in MLD from crossbreed SLW x Ma ($p < 0.01$) compared to MLD from Mangalitsa. Similarly, the value CIE b* was higher in MLD from crossbreed SLW x Ma ($p < 0.01$) and the value CIE a* was lower compared to MLD from Mangalitsa. However, no significant differences were found in CIE a* value due to genotype after 24h. The colour parameters (CIE L*, a*, b*) in MLD increased after 7 days *post mortem*, which is common due to the maturation process of the meat. This fact agrees with studies of **Estévez, Morcuende and Cava (2003), Lindahl et al. (2006)** and **Stanišić et al. (2016)**. The CIE L* and CIE a* values were significantly influenced by genotype where Mangalitsa exhibited darker (CIE L*; $p < 0.001$) and redder (CIE a*; $p < 0.05$) MLD compared to crossbreed SLW x Ma. Although were not found significant differences for CIE b* in MLD, Mangalitsa had lower values than crossbreed SLW x Ma. It is in accordance with **Stanišić et al. (2016)**.

Table 3 Physical parameters of *musculus longissimus dorsi.*

Parameters	Mangalitsa (n = 16) Mean ±*SD*	SLW x Ma (n = 22) Mean ±*SD*	*p* <value
pH_{45min} (log.molc$^{(H+)}$)	6.09 ±0.27	6.02 ±0.19	0.425
$pH_{24hours}$ (log.molc$^{(H+)}$)	5.69 ±0.07	5.68 ±0.11	0.850
EC_{45min} (mS.cm^{-1})	3.31 ±1.27	3.92 ±0.47	0.284
$EC_{24hours}$ (mS.cm^{-1})	9.31 ±1.91	10.86 ±2.25	0.019
Drip $loss_{24hours}$ (%)	7.15 ±2.99	8.22 ±2.78	0.262
$Colour_{24hours}$ CIE L*	53.06 ±4.34	58.12 ±4.93	0.002
$Colour_{24hours}$ CIE a*	3.21 ±1.36	2.50 ±1.51	0.139

$Colour_{7days}$ CIE L*	54.51 ±4.67	60.46 ±4.58	0.001
$Colour_{7days}$ CIE a*	6.67 ±2.98	5.03 ±2.01	0.044
$Colour_{7days}$ CIE b*	13.14 ±2.56	14.04 ±1.92	0.228
Warner-Brazler shear force (kg.cm^{-2})	2.63 ±0.75	3.14 ±0.65	0.031

Note: SW: slaughter weight, SLW x Ma: crossbreeds Slovak Large White x Mangalitsa, SEM: Standard error of mean.

Comparing our results with those obtained by **Franci et al. (2005)**, we found that their results for CIE L* and CIE b* were lower, but CIE a* value was higher. In their study pure breed Cinta Senese exhibited darker (CIE L*) and redder (CIE a*) meat, but lower value of index b* compared to crossbreed Large White x Cinta Senese. Similarly, **Szulc et al. (2012)** obtained that pure breed Zlotnicka spotted had higher values of CIE L*, CIE a* as well as CIE b* compared to crossbreed Zlotnicka spotted x Polish Large White. On the contrary **Poto, Galián and Peinado (2007)** worked with Spanish indigenous breed Chato Murciano and they found lower values of colour parameters in MLD from crossbreed Chato Murciano x Large White than in indigenous breed Chato Murciano. On the other hand, **Renaudeau and Mourot (2007)** studied differences on meat quality between indigenous pigs Creole and Large White, where Creole pigs had lower colour parameters in relation to Large White. **Bednářová et al. (2014)** analyzed samples of pork 72 hours *post mortem* from different supliers. L* value from *m. semimenbranosus* was found from 46.13 to 48.53

Regarding the proximate parameters, water content was significantly higher in MLD from Mangalitsa than in MLD from crossbreed SLW x Ma (p <0.05). The MLD from Mangalitsa had lower protein content (p <0.05), but higher percentage of intramuscular fat than MLD from crossbreed SLW x Ma, where the difference did not reach the significance. **Franci et al. (2005)** observed that pure breed Cinta Senese had lower water content as well as protein content compared to their crossbreed Large White x Cinta Senese and the percentage of intramuscular fat was higher. Data are in accordance with our results except to water content in MLD. Our results showed higher values of water content and protein content, but lower percentage of intramuscular fat than in study of **Sirtori et al. (2011)** and **Parunović et al. (2013)**. In their study, the indigenous breeds such as Cinta Senese, compared to Mangalitsa, had lower percentage of water as well as protein content and higher percentage of intramuscular fat in meat compared to commercial breeds. According to **Serra et al. (1998)**, the pure breed Iberian had lower water and protein content, while the percentage of intramuscular fat was higher than Landrace pig meat. The results of cholesterol content were in accordance with percentage of intramuscular fat content in MLD, however no significant differences were found due to genotype. As regards the cholesterol content, **Pârvu et al. (2012)** determined, that Large White pig meat had higher cholesterol content with lower percentage of intramuscular fat (cholesterol content 41.64 mg.100g^{-1}; IMF 23.21%) compared to Mangalitsa (cholesterol content 61.24 mg.100g^{-1}; IMF 10.69%). These results are in contrast with ours. The cholesterol content of MLD was in the study of **Parunović et al. (2013)** and **Parunović et al. (2015)** higher than in our results, but they confirmed that Mangalitsa had higher value of cholesterol compared to Swedish Landrace pig meat. Similarly, **Salvatori et al. (2008)** found that indigenous pigs Casertana had higher cholesterol content in MLD than their crossbreeds Casertana x Large White. On the other hand, **Stajić et al. (2011)** indicated that Mangalitsa had lower cholesterol content in meat in relation to Landrace. Although it is saying that Mangalitsa pigs had lower cholesterol content in the meat, it can be confirmed by our study that Mangalitsa had higher cholesterol content than their crossbreeds.

Table 5 shows coefficients of Pearson's correlation between physico-chemical parameters and intramuscular fat content in *musculus longissimus dorsi*. The percentage of intramuscular fat (IMF) in MLD was positively correlated (p <0.05) with CIE a* 7 days *post mortem* (r = 0.324) and also with cholesterol content (r = 0.656; p <0.001). The relationship between percentage of intramuscular fat and cholesterol content in meat is shown by Figure 1. In contrast, the IMF in MLD was negatively correlated with percentage of water (r = 0.399; p <0.05) and with protein content in MLD (r = -0.812; p <0.001). These results are in accordance with study of **Vranic et al. (2015)** and **Tomović et al. (2016)**. Figure 2 represents the relationship between intramuscular fat content and protein content in meat by linear regression. As regarding the Warner-Bratzler shear force, no significance was found between intramuscular fat and tenderness of meat. The results are in accordance with **Jeong et al. (2010)**. On the contrary, **Barlocco et al. (2006)** found positive correlation between Warner-Bratzler shear force and intramuscular fat content in the meat. In other parameters, no significant correlations were found.

Table 4 Chemical parameters of *musculus longissimus dorsi.*

Parameters	Mangalitsa (n = 16)		SLW x Ma (n = 22)		*p* <value
	Mean	*SD*	Mean	*SD*	
Total water (%)	73.53	0.61	73.01	0.58	0.017
Total protein (%)	24.15	0.66	24.56	0.34	0.019
Intramuscular fat (%)	1.93	0.91	1.66	0.59	0.286
Cholesterol (mg.100g^{-1})	43.01	7.16	38.91	10.41	0.203

Note: SW: slaughter weight, SLW x Ma: crossbreeds Slovak Large White x Mangalitsa, *SD*: standard deviation.

Table 5 Pearson's correlation coefficient between physico-chemical parameters and intramuscular fat content in *musculus longissimus dorsi* of the pigs.

Parameters	IMF
pH_{45min}	0.071
$pH_{24hours}$	-0.186
EC_{45min}	-0.134
$EC_{24hours}$	-0.161

Cholesterol	0.656***

Note: IMF: intramuscular fat content, ***: p <0.001,*: p <0.05

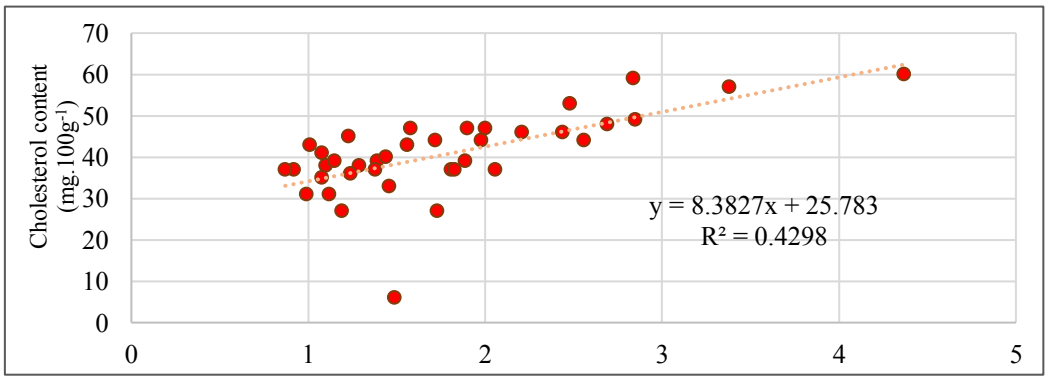

Figure 1 Intramuscular fat content in meat in relation to cholesterol content (%).

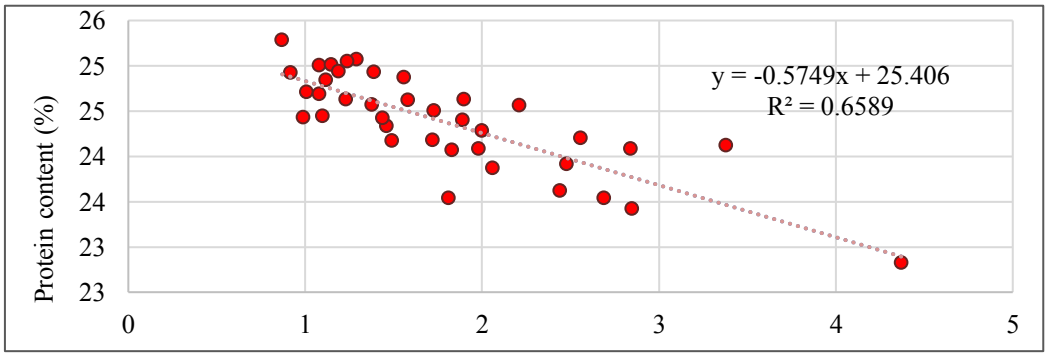

Figure 2 Intramuscular fat content in meat in relation to protein content (%).

CONCLUSION

Chemical analysis showed that MLD from Mangalitsa had lower protein content (24.15, resp. 24.56%) and higher content of intramuscular fat (1.93, resp. 1.66%) compared to Slovak Large White x Mangalitsa crossbreed. As regards the Warner-Bratzler shear force, the meat from Mangalitsa was tenderer than in crossbreeds (p <0.05). Intramuscular fat in the meat positively correlated with colour parameter CIE a* (r = 0.324; p <0.05) as well as cholesterol content (r = 0.656; p <0.001). Cholesterol content was found statistically non-significant difference (Mangalitsa 43.01 and SLW x Ma 38.91 mg.100 g^{-1}).

It can be concluded that the percentage of intramuscular fat significantly influenced the physical and the chemical parameters of pork. As regards the differences between genotypes, Mangalitsa has darker, redder and tenderer meat with lower moisture content and higher intramuscular fat content compared to crossbreeds Slovak Large White x Mangalitsa. The meat from Mangalitsa is more suitable for production of special meat products (fermented and smoked).

ADHESION EFFECT ON ENVIRONMENT PROCESS INJECTION

Igor Yaroslavovych Stadnyk, Volodymyr Piddubnyi, Halyna Karpyk, Mykhail Kravchenko, Volodymyr Hidzhelitskyi

ABSTRACT

The analytical analysis of roller impact on the medium and its behavior at deformation influences are carried out, ways of choosing an optimal variant of the process for providing the maximum or minimum value of parameters (criterion) are proposed. The physical essence of the equation of energy flows of the intensity of deformation of the mass of the medium, which depends on the method of applying mechanical forces, the degree of its previous dispersion (recipe) and its physical and mechanical properties, is considered. To reveal the essence and understanding of the general research execution, a number of hypotheses for the determination of adhesion are given and a generalized approach to the definition of adhesion is given. The proposed scheme of causal relationships between the medium and roll, divided into three groups, and determine the change in the process of injection dough. The nature of the maximum increase of the forces of interaction of the dough with the high contact of the roller working body in the injection nozzle of the fuming machine is established. Violation of these mutual relations leads to the production of low-quality products and a decrease in the efficiency of the machine. These phenomena are little studied today, and the nature of adhesion requires research. It is noted that the determination of deformation processes during the passage of the process of injection of the medium by roller working bodies plays an important role in calculating the design of molding, roll-over equipment. The deformation in the knot of the injection dough by rolls and the dependence of the work performed on the influence of adhesion on the flow process in the molding machine are revealed. The contact area of the adhesive and the component forming work for overcoming the adhesion and deformation of the environment in determining the criteria that influence the process, according to each particular period of the deformation stage, are substantiated. The obtained data provide an answer to a number of questions about the possibility of regulating the process of the work of agents on the environment.

Keywords: dough; adhesion; adhesive; substrate; forming channel; deformation; stress

INTRODUCTION

Improvement of the technology of pumping, injection, mixing, separation, formation of the environment (non-Newtonian fluids) and the creation of high-performance technological equipment is an actual scientific task. Therefore, the development and calculation of new processes and equipment requires a thorough and comprehensive study of the impact of the most significant physical and mechanical properties of semi-finished baking and confectionery industries. A significant adhesive property of the environment significantly complicates the process and causes additional energy costs. This direction is given insufficient attention; therefore, the physical nature of adhesion is still not fully explored.

Adhesion refers to surface phenomena that arise when contacting heterogeneous bodies. There are different approaches to the definition of adhesion. According to the theory **(Believ, Egorenkov and Pleskachevsky, 1971)**, they can be divided into three groups:

- determination of adhesion as a process (gradual change of state);
- definition of adhesion as properties that characterize the feature of this system;
- definition of adhesion as a state (external and internal circumstances that characterize the state of the system).

Determination of adhesion as a process was given by Rebinder PA: "Adhesion (adhesion) - the appearance of a connection between the surface layers of two heterogeneous (solid or liquid) bodies (phases) that touch each other. A similar definition was given in some other sources **(Berlik and Basik, 1969; Deryagin, 1963; Li, 1979)**. That is, adhesion is interpreted as a process of convergence and removal of bodies from one another.

Often the nature of adhesion is explained by diffusion and electric theory. Adhesion is always the result of the intermolecular interaction of surfaces, different in nature.

According to this theory, with the contact of two bodies due to the Macrobroun motion, there is a rearrangement of the molecules. This occurs in such a way that large particles of molecules approach the contact surface, establish hydrogen bonds with the same molecules or with the polymer groups of the contacting body. This causes an adsorption bond in equilibrium. The influence of pressure and temperature during their increase contributes to the fairly rapid establishment of equilibrium.

In the food industry, there are many processes in which both the forces of friction and adhesion interact simultaneously. These phenomena arise when the relative displacement of the contacting surfaces of two bodies. In studies **Deryagin (1963)** established the connection between the aunt and the adhesion of the expression:

$$P = \mu N + \mu p_0 S_0$$

Where:

μ – actual friction coefficient; S_0 – contact area, m^2; N - normal load, N; p_0 – specific adhesion at the site S_0, Pa; P – external friction force, N.

The author **(Pawel et al., 2016; Stadnyk, Novak and Matenchuk, 2018)** revealed the properties of a dough for the production of bagels, which has elastic, viscous and plastic properties, that is, refers to elastic - visco-plastic bodies. Accordingly **(Gorbatov, 1979; Zimon and Yevtushenko, 1985)** noted that the adhesion of such bodies, as well as the cogenesis of particles, fluids and films, depends on the area of contact of the medium (adhesive) with the rough metal working surface of the machine.

Summarizing the above theories, we can conclude that adhesion is caused by a number of mechanisms that act on the molecular and supramolecular levels and are determined by the properties of these surfaces: physical, chemical or electromagnetic.

By the value that evaluates (determines, measures) adhesion, as a feminogenic phenomenon, a force is adopted that is defined as the force applied perpendicular to the sample, acting on a unit area and sufficient to separate it from the surface:

$$P_a = P/F_0$$

Where:

P – specific power N.m^{-2}; P_a – normal power, N; F_0 – contact area, m^2.

In this case, it is advisable to speak of adhesion strength. When separating structured masses, adhesion strength comes into competition with the cohesive strength of the mass. At tearing away the deformation and flow of the mass itself, determined by the rheological properties of the product itself. That is, it can be adhesive, cohesive and cohesive-adhesive type.

The dependence for the determination of the adhesion force was determined by M. Stefan **(Gorbatov, 1979)**:

$$P = \frac{2\eta R^2}{4\tau_0}\left(\frac{1}{h^2_1} - \frac{1}{h^2_2}\right), \quad \text{(a)}$$

Where:

R – skradius, m; $\boldsymbol{\tau_0}$ – time off (disk difference) from a distance $\mathbf{h_1}$ to $\mathbf{h_2}$, c; $\boldsymbol{\eta}$– fluid viscosity, Pa.s.

If the "adhesion" or the "force of adhesion" is evaluated by dependence (a), then such a process takes place in time, that is, adhesion is evaluated as a process that must be performed for sample discontinuation, and the distance of disc diffusion (h1 and I12) can characterize the phenomenon of cohesiveness.

Finding new ways to reduce adhesion is possible only after studying the physical nature of this phenomenon. Adhesion arises from adsorption of medium molecules (dough) on the surface of the working organ in the thinnest (up to 20 nm) surface layer. At the same time, these molecules are related to the main volume of the medium. Therefore, at all stages of the action of the roller working body on the relative displacement, the environment molecules that are adsorbed on its surface, rotate with it (Figure 1). If the forces of the intermolecular compound in the medium become weaker than the adsorption forces, then the rupture of its mass passes at a distance from the surface of the roll. Such phenomena occur in the period of tightening, compression and rolling of the medium in the formation gap formed between the rotating rolls.

Consequently, adhesion depends on the rheological properties of the medium at the time of the process, the degree of surface treatment of roller working bodies, the thickness of its layer. Investigation of the influence of physical and rheological properties of the environment and the structural features of cylindrical rolls with grooves on improving the quality of products at injection - the problem is relevant and needs to be solved in mathematical dependencies.

Analysis of model approximations of medium types.

Processes in the working chamber under the action of rollers occur with different effects on the environment. This process is accompanied by large deformations, which is facilitated by the profile of the roller surface and the design of the working chamber. Special attention in the study of the process of injection of rolls focuses on creating favourable conditions for tightening and compressing the environment.

For roller working valves in the injection nozzle of a fumiving machine, the maximum increase in the forces of the interaction of the dough with the high contact of the roll is characteristic. Violation of these mutual relations leads to the production of low-quality products and a decrease in the efficiency of the machine. These phenomena are little studied today, and the nature of adhesion requires research.

There are several hypotheses to determine adhesion:

- in accordance with Absorption theory Debrajina and Mc-Laren **(Berlik and Basik, 1969)**, adhesion is related to the action of intermolecular forces: physical, van der Waals or chemical, for example, covalent ion .;
- according to electrical theory B. Deryagina **(Deryagin, 1963)** - adhesion is connected with the difference in potentials on the boundary of heterogeneous bodies, that is, with the appearance in the contact area of a kind of electric molecular capacitor, caused by a double electric layer;
- according to the electromechanical theory, adhesion is associated with electromagnetic interaction, that is, with the emission and absorption of electromagnetic waves by atoms and molecules, which can be realized in condensed bodies;
- in accordance with the diffusion theory S. Vosotsky and B. Deryagin's **(Berlik and Basik, 1969)** adhesion is associated with the diffusion of ends of macromolecules through the boundary of the initial contact, resulting in the boundary (finite) case, the interface of the phases may disappear;
- according to the mechanical theory, adhesion contact is formed due to the mechanical adhesion of molecular and supramolecular formations with microniveness of the surface;
- according to the thermodynamic theory, adhesion is associated with a surface tension, which, according to the theory **(Wake, 1982)**, causes the solid-body solid-liquid surface to replace the solid-liquid interface.

In his writings **Zimon and Yevtushenko (1985)** gives preference to intermolecular interaction and partly to the Coulomb force, which determines the primary formation of the relationship between two surfaces. The forces begin to act in direct contact and a certain period after the violation of the contact.

The second group of forces, unlike the first one, manifests itself only when two bodies are contacted. These forces act as a result of primary adhesion and become one of its causes. This group includes chemical bonds, forces of electric and capillary interaction, as well as adsorption and diffusion, which are the result of contact.

With adhesion of liquid and elastic-plastic food masses, a chemical bond may occur.

To a large extent, the adhesion of the food mass depends on the presence of moisture, which can manifest itself as a capillary force.

In the gap between the contacting parts there is a meniscus of fluid. In this case, it seems to charge the particle and the surface. The value of adhesion in this case will be determined by the capillary force:

$$F_K = 4\pi\sigma_ж r$$

Where:

$\sigma_ж$ - surface tension of a liquid (water), the vapor of which is condensed between the contacting bodies.

In a liquid medium, the adhesion of the parts is less than in the air **(Zimon and Yevtushenko, 1985)**. In this case, there is a disjoint action of the thin layer of the liquid, which is on the surface of the bodies.

Among the components of the viscous medium (dough), the greatest energy of adsorption to metals is water. If it is removed from the surface of the semi-finished product, the adhesion should be reduced. At the same time, the intensity of evaporation of the surface moisture should be very large, so that the resulting thin moss on the surface of the environment prevented the removal of moisture from its volume. Such conditions can be obtained **(Stadnyk et al., 2018)** only at very high velocities - the leakage of the medium under pressure through the opening of the profile channel formed between the rotating rolls. Based on the properties of the viscous medium and the deformation of the rolls, a number of new designs of roller working valves have been proposed **(Derkach, Stadnyk and Stadnyk, 2016)**. Interestingly enough is the detection of the action of the surface of the new working body with screw grooves (Figure 2) on the adhesion properties of the medium.

In the course of the forced flow of the medium layer under the action of roller working bodies, there is a temporary slip on them at a speed. In the future, when the surface layer is squeezed and its slip on the surface of the roll, the medium layer is sealed, and the alignment of the structure takes place. This layer acquires increased gas- and form-retaining ability and penetration of water molecules (diffusion) into it inside with swelling and volume increase.
