Scope of the Potravinarstvo Slovak Journal of Food Sciences

Articles published in the journal are peer reviewed and freely available online. Journal covers areas including: food hygiene, food safety and quality, food microbiology, food laws and regulations, ingredients and ingredient functionality, nutraceuticals, product formulation, sensory science and sensory statistical analysis, process control and its contribution to food processing operations, food chemistry, food toxicology, food engineering, food technology and biotechnology, nourishment, public health, primary production of food, food adulteration, food economics and marketing, environmental effect on food and food machinery.

Open Access

We are providing free online access to all published articles in our journal. You are free to:

- Share — copy and redistribute the material in any medium or format.
- Adapt — remix, transform, and build upon the material for any purpose, even commercially.
- The licensor cannot revoke these freedoms as long as you follow the license terms.

If you decide to use articles published in our journal you have to:

- Make statement (citation), that article was published first time in our journal according to the example presented below in the copyright.

EDIBLE WILD PLANTS GROWING IN ADJACENT SPONTANEOUS VEGETATION OF ENERGY PLANTATIONS IN SOUTHWEST SLOVAKIA

Lýdia Končeková, Daniela Halmová, Alexander Fehér

ABSTRACT
This paper evaluates the potential and perspectives of wild plant species and macrofungi from short rotation coppice. The research was conducted during the years 2014 – 2018 in stands of short rotation coppice willow and miscanthus grass in southwest of Slovakia. Evaluated wild plant species and macrofungi were divided into four groups (green vegetables, fruits and seeds, flowers and nectar, subterranean parts). The results showed that ground flora of short rotation coppice consisted of 74 edible species from 34 botanical families. *Asteraceae, Rosaceae*, *Poaceae*, *Polygonaceae* and *Cichoriaceae* families were represented the most. From the evaluated categories the most species belonged to the category with consumable aerial parts like leaves and shoots (59 species). The similar representation of species was found in the category of wild fruits and seeds consumed in the raw or preserved state and in category of edible subterranean parts (27 species and 22 species respectively). Principal component analysis showed that the edible parts with the strongest effect on the functional group differentiation were the fruits, seeds and subterranean parts.

Keywords: edible plant; miscanthus; short rotation coppice; SW Slovakia; wild plant

INTRODUCTION
The wild flora has played an essential role in human feeding **(Torija-Isasa and Matallana-Gonzáles, 2016)**. The interest in wild edible plants is not only in terms of increasing dietary balance (sufficient trace elements, vitamins and minerals) but also due to their link to human health **(Tardío, Pardo-de-Santayana and Morales, 2006)**. At present, wild plants play an equally important role in protecting biodiversity and providing various ecosystem services. **Rowe, Street and Taylor (2009)** state that miscanthus and short rotation coppice (SRC) stands have a positive potential impact on biodiversity. Compared to arable land use, they create different structural and functional biotope types with a greater diversity of species due to their longer rotation period, less number of disturbances and chemical inputs and richer spatial structure **(Fry and Slater, 2009; Dauber, Jones and Stout, 2010; Rowe et al., 2011; Verheyen et al., 2014)**.

The benefits that SRC stands can provide consist of provisioning services (production of food, category nutrition – food, crops, wild foods) **(MEA, 2005)**. In the past, wild plant species were collected and used for food, medicine and social issues (during times of famine or conflicts). Nowadays, the increasing interest is based on efforts to provide food security in times of agricultural crisis or use in regional/local cuisine **(Turner et al., 2011; Łuczaj, 2012; Simkova and Polesny, 2015)**. The gathering of wild plants is not only an active living custom **(Christanell et al., 2010)** but it is also a source of cultural identity (cultural services) that is forming an important knowledge about the environment and sustainable living known as traditional ecological knowledge **(Turner et al., 2011)**. While the issues/reviews of the traditional use of edible plants have been evaluated in several works in Slovakia **(Łuczaj, 2012; Stoličná, 2016)** and abroad **(Dogan et al., 2004; Dénes et al., 2012; Di Novella et al., 2013; Guarrera and Savo, 2016; Kuklina and Vinogradova, 2018)**, the prospective use of such species from energy plantations has not yet been studied.

Scientific hypothesis
Taking into account the specific ecological environmental and cultivation-technological conditions of the stands of energy plants, we assumed a high diversity of vascular spontaneous plant species, providing the possibility of occurrence of species with edible parts.

MATERIAL AND METHODOLOGY
The research was carried out on permanent experimental plots established in the agricultural land on a research base of the Slovak University of Agriculture in Nitra in the catastral area of the Kolíňany village (Nitra district area, SW Slovakia). The area belongs to the moderately warm and moderately humid climate region with a sum of

temperatures of 2200 – 2500 °C and an average annual rainfall of 550 – 700 mm. The soil is medium-heavy, the soil type is gley fluvisol. The stands of the species used for energy purposes were established in 2009, consisting of the Swedish willow varieties Tordis (*Salix schwerinii* × *S. viminalis*), Inger (*Salix triandra* × *S. viminalis*) and energy grass (*Miscanthus* ×*giganteus*).

The study of herbaceous species and macrofungi in SRC undergrowth was carried out in the growing periods of 2014 – 2018 at 14-day intervals. The permanent research plots had an area of 2 m x 12 m. The willow varieties were planted from the cuttings in a double-row spacing configuration resulting in a plant density of 8889 plants per ha. The rhizomes of energy grass were planted in 1 x 1 m spacing on an area of 100 m^2 (10,000 plants per ha). A three-year harvest cycle is applied for the willow varieties and the harvest cycle for *M.* × *giganteus* is one year. Based on soil analysis carried out at the beginning of the research period (2014), the soil pH ranged from 7.22 to 7.30. The average humus content was 2.31% and the average nitrogen content was 1479 $mg.kg^{-1}$. The herbicides were applied only prior to the establishment of the research plots in 2009. The vegetation structure was studied using phytocoenological reléves. The presence of species and their relative abundance were assessed using the modified Braun-Blanquet cover-abundance scale for estimating species quantities **(Braun-Blanquet, 1964; Mueller-Dombois and Ellenberg, 1974)**.

Individual identified species were divided into four categories (VEG, FRU, SUB and FLO). The category green vegetables "VEG" consisted of species whose above-ground parts (leaves and stems) were used raw, cooked or fried. Wild fruits and seeds consumed in the raw or preserved form represented the "FRU" category. Plants with edible subterranean parts (rhizomes, roots and tubers) were included in the "SUB" category and species with flowers whose nectar was consumed raw or flowers were added in larger quantities to meals and beverages were categorized as "FLO". In this paper, the classification of species to individual categories was based on a partially modified methodology used in **Łuczaj (2012)** and **Simkova and Polesny (2015)** and the literature sources listed in the References. The nomenclature of the lower and higher plants has been unified according to **Marhold and Hindák (1998)**.

Statistical analysis

Ordination analysis of the species importance in terms of providing edible parts was conducted by the principal component analysis (PCA) in Canoco for Windows version 4.5 and CanoDraw 4.0 **(Braak and Smilauer, 2002)**.

RESULTS AND DISCUSSION

Of the 92 species found in the undergrowth of the trees and plants grown for energy purposes, 74 were edible species. These species represented 73 vascular plants and 1 fungus (Table 1a and Table 1b). The species belonged to 34 botanical families. The list of the edible species included 9 tree species, 4 shrub species, 32 perennial species, 22 annual species and 7 biennial species. The most common families of the edible species were *Asteraceae* and *Rosaceae* (8 species each), *Poaceae* (7 species), *Polygonaceae* and *Cichoriaceae* (5 species each). The most represented was the category of green vegetables with 59 species. The category of fruits (raw or preserved) included 27 species and 22 species belonged to the category of wild plants with edible underground parts (subterranean parts). The least represented was the category of flowers with 17 species.

According to the ethnobotanical review of wild edible plants of Slovakia **(Łuczaj, 2012)**, the most frequently used wild edible plants in Slovakia included the fruits of *Rubus idaeus, Fragaria* spp., *Rubus* subgenus *Rubus, Vaccinium myrtillus, V. vitis-idaea, Fagus sylvatica, Corylus avellana, Prunus spinosa, Pyrus* spp., *Malus* spp., *Crataegus* spp. and the leaves of *Urtica dioica, Rumex acetosa, Chenopodiaceae* species, *Cardamine amara, Glechoma* spp., *Taraxacum* spp. *and Oxalis acetosella*. This species list is similar to our observations (cf. Recorded species of *Rubus* genus, *Prunus spinosa*, *Carataegus* spp., *Urtica dioica*, *Chenopodiacea* species, *Glechoma* spp. and *Taraxacum* spp.) and we can confirm that similar or identical plant species with high edibility potential have been collected for food by local people in Slovakia. The category of green vegetables consisted of plants whose above-ground parts (leaves and stems) are edible raw or cooked, steamed or fried. The most represented were the families *Asteraceae*, *Poaceae* and *Rosaceae* that had the same number of species (6). The second was the family *Cichoriaceae* with 5 species (Figure 1).

Despite the high number of identified species in the category of fruits and seeds (27 species), the most represented family of *Rosaceae* included only 6 species in this category. Other families consisted of two species (fam. *Brassicaceae*, *Poaceae*, *Polygonaceae* and *Solanaceae*) and/or one species with fruits or seeds edible in the raw or preserved state (Figure 2).

The category of edible subterranean parts (roots, rhizomes and tubers) included mostly species of the *Asteraceae* family (4 species). Other families had a similar number of species as the category of fruits and seeds. The families *Brassicaceae*, *Poaceae*, *Rosaceae* and *Violaceae* had two species each. Other families had only one species within this category (Figure 3).

The category of flowers and their nectar eaten raw or flowers added in larger quantities to dishes and beverages consisted of the *Asteraceae* family with three species and the *Violaceae* family with two species. The other families were represented in lower numbers (Figure 4).

The results of the species assessment based on their proportion to the supply of edible parts for human consumption (directly or processed) showed that different species contributed differently in their supply. Differences were apparent also at higher taxonomic levels, e.g. at the genera level and/or the family level. The indirect linear ordination method of PCA (Figure 5) showed that the taxa differentiation was clearly visible on the biplot, therefore the relation detrending was not necessary. The first two component axes of PCA accounted for 65.0% of explained variance. The clusters of species based on the edible part showed that the strongest effect on the differentiation of functional groups (clusters) had the species in the

categories of fruits, seeds and subterranean parts. Categories of flowers and green vegetables showed less effect. The category of flowers was supported by a small number of species (*Capsella bursa-pastoris, Tripleurospermum perforatum* and *Humulus lupulus*). The category of green vegetables was represented by the largest number of species and therefore became a general criterion and not very useful in the formation of functional plant groups (e.g. *Anagallis arvensis, Stellaria media, Lactuca serriola, Mentha longifolia*, etc.). Groups of species were formed also at various transition gradients.

There was a stronger link between the categories of flowers and subterranean parts, while the link was weaker between the categories of green vegetables and fruits. The species of the *Asteraceae* family were scattered relatively evenly but were centred in the axis areas of the VEG, SUB and FLO categories. A similar situation occurred in the case of *Poaceae* species that traced the distribution of *Asteraceae* species in the VEG and SUB categories. However, grasses were surprisingly lacking in the FRU category (edible grains in spikelets are common for the species of the *Poaceae* family). An exception was *Echinochloa crus-galli*. Some typical synanthropic families (e.g. *Chenopodiaceae* and *Amaranthaceae*) have accumulated in the VEG and FRU categories. Representatives of the *Rosaceae* family (*Cerasus, Crataegus, Padus, Prunus, Rosa* and *Rubus* species) behaved similarly, but representatives of the herbaceous species of this family were found in the transition between the SUB and VEG categories (*Geum urbanum* and *Potentilla anserina*). It is an interesting result confirming that there may be different edibility of organs depending on the species lignification even in the same family. Taxa of the *Cichoriaceae* family were typically represented in the VEG category (genera *Lactuca*, *Lapsana* and *Sonchus*).

Our results are in accordance with the synthesis of knowledge on wild food as an ecosystem service in Europe **(Schulp, Thuiller and Verburg, 2014)**. The same is true for Central-Eastern Europe. In the Czech Republic, the use of 175 vascular plant species (the highest number of taxa belonged to families *Rosaceae*, *Asteraceae* and *Ericaceae*) **(Simkova and Polesny, 2015)**, in the part of the Carpathians and the Carpathian Basin (Hungary and adjacent countries) 236 plant species belonging to 68 families **(Dénes et al., 2012)** and in the Pannonian region of Croatia a total of 44 plant taxa belonging to 25 families (the highest number of taxa belonged to families *Asteraceae*, *Lamiaceae* and *Rosaceae*) were recorded **(Žuna Pfeiffer et al., 2019)**. Considering the high number of edible wild plants in the spontaneous vegetation of SRC the perspective of edible wild plants collection is high in comparison with the avarage number of collected edible wild plants in Central-Eastern part of Europe.

Our research evaluated the potential of edible wild plants only but the potential provisioning ecosystem services are not necessarily collected and used by people **(Rasmussen et al., 2016)**. In spite of that, the high value of ecosystem services from small forest patches in agricultural landscapes **(Decocq et al., 2016)** and values of wild foods in agricultural systems **(Bharucha and Pretty, 2010)** are of high importance.

CONCLUSION

Based on the results, it can be concluded that:

-SRCs are characterized by a high diversity of species (92 species found), with the vast majority (74 species) of edible species (whole plants or some parts consumable),

-the most numerous were the *Asteraceae*, *Rosaceae* (8) and *Poaceae* (7) families,

the most frequent species (59) were in the VEG category, the above-ground parts of which are edible raw state or processed,

a similar representation of species was found in the FRU (27 species) and SUB (22 species) categories,

the PCA showed that based on the edible part, the most important effect on the differentiation of functional groups had the species in FRU and SUB categories,

a strong correlation was found between the FLO and SUB categories.

The results confirmed the high diversity of vascular plant species (92) with a high proportion of species with edible parts (74).

THE EFFECT OF PROCESSED TEMPEH GEMBUS TO HIGH SENSITIVITY C-REACTIVE PROTEIN (hsCRP) AND HIGH-DENSITY LIPOPROTEIN (HDL) LEVELS IN WOMEN WITH OBESITY

Desti Ambar Wati, Fika Shafiana Nadia, Muflihah Isnawati, Mohammad Sulchan, Diana Nur Afifah

ABSTRACT
Obesity causes chronic inflammatory reaction is characterized by elevated levels of high sensitivity c-reactive protein (hscrp). Hscrp and hdl could be used as an early marker of cardiovascular disease risk. *Tempeh gembus* contain fiber, unsaturated fatty acids and antioxidants, which can reduce the inflammatory reaction. This study determines the effect of processed *Tempeh gembus* on hsCRP and HDL in obese women. This study included in experimental studies with randomized post-test only control group design involving 40 obese women aged 20 – 50 years. Subjects were randomized into two groups: a control group was given a standard diet low in calories 30 calories/kg body weight, and the treatment group was given a standard diet low in calories 30 calories/kg body weight and *Tempeh gembus* for 28 days. hsCRP and HDL levels were measured before and after the intervention, food intake was measured by using a 3 x 24-hour recall and physical activity (IPAQ form). HsCRP levels were measured using the ELISA method, whereas HDL levels were measured using the CHOD-PAP method. Wilcoxon test (hsCRP levels) and paired *t*-test (HDL levels) used to test differeces before and after intervention each group. Mann Whitney test (hsCRP levels) and independent sample test (HDL levels) used to test differeces before and after intervention between groups. There are differences in hsCRP levels before and after the intervention in the control group ($p = 0.00$) and the treatment group ($p = 0.00$). There are differences in HDL levels before and after the intervention in the control group ($p = 0.00$) and the treatment group ($p = 0.00$). There are differences in the decrease hsCRP levels between the two groups ($p = 0.00$). There are differences in the increase in HDL levels between the two groups ($p = 0.03$). *Tempeh gembus* 150 grams/day can decrease hsCRP levels and increase HDL levels in women with obesity.

Keywords: *Tempeh gembus*; hsCRP; HDL; women; obesity

INTRODUCTION
Obesity is excessive fat accumulation due to an imbalance between energy intake and energy released by the body so that it can interfere with health **(WHO, 2016)**. Obesity is the cause of half the cases of hypertension that increases the risk of cardiovascular disease **(Sizer and Whitney, 2017)**. Cardiovascular disease is caused by narrowing, blockage of coronary arteries and reduced elasticity of blood vessels due to atherosclerosis **(Herrington et al., 2016)**. Atherosclerosis is a progressive disease, even estimated to have occurred since the age of 10 – 20 years with the formation of fat streaks walking slowly and continues to grow by 3% per year since past the age of 20 years. Atherosclerosis occurs due to the interaction of various risk factors, including obesity, hypertension, diabetes mellitus, smoking habits, the aging process, atherogenic dyslipidemia, and pro-inflammatory conditions **(Badimon, Robert and Gemma, 2011)**.

Obesity can also lead to the occurrence of the reaction inflammation due to their secretion of cytokines and pro-inflamator **(Harford et al., 2011)**. Inflammatory reactions cause damage to endothelial function resulting in an increase in stroke volume and cardiac output. Excessive adipose tissue causing chronic inflammatory reactions due to cytokine secretion and proinflamator by adipocyte cells are characterized by increased levels of high sensitivity C-reactive protein (hsCRP), Tumor Necrosis Factor (TNF-α), interferon-gamma (IFN γ) and interleukin-6 (IL-6) **(Guillen et al., 2008; Libby, Ridker and Maseri, 2002)**. hsCRP is a biomarker that is sensitive to the occurrence of inflammation in the body and is a strong predictor of the incidence of cardiovascular system disease **(Tully et al., 2015)**. Increased levels of hsCRP in the long term indicates a process of chronic inflammation **(Pravin and Devang, 2011)**.

Increased adipose tissue in obesity is closely related to the consumption habits of foods that are high in fat and

low in fiber. Excessive fat intake will affect adipose tissue especially visceral fat to express responses to various stimuli, one of which is an increase in the release of free fatty acids by adipose tissue which can stimulate increased secretion of very low density lipoprotein (VLDL) in the liver which in turn results in increased triglycerides, low density lipoprotein (LDL), and decreased high density lipoprotein (HDL) **(Wang and Peng, 2011)**. Low HDL levels are not able to prevent the activation of pro-inflammatory mediators in the form of cytokines such as TNF-α, IL-6 and CRP. The results showed that subjects with HDL levels greater than 60 mg/dL had a lower risk of developing coronary heart disease because an increase of 1 mg/dL HDL levels could reduce the risk of coronary heart disease by 2% in men and 3% in women **(Rajagopal, Suresh and Alok, 2012)**.

Prevention and management of cardiovascular disease can be done by optimizing the consumption of functional foods with high protein fermented foods that are suspected to be able to prevent cardiovascular disease **(Bowen et al., 2018; Anand et al., 2016)**. *Tempeh gembus* is one of Indonesia's original food products made from fermented tofu-based fermentation that functions as a substrate then the tempeh mushroom (*Rhizopus oligosporus)* is added as a microorganism. The main content of *Tempeh gembus* is fiber. The fiber content in 100 grams of *Tempeh gembus* is 3.93 grams, three times more than the fiber content in soybean *Tempeh* **(Sulchan and Endang, 2007; Li, Qiao and Lu, 2012)**. High-fiber diet (≥25 grams of soluble fiber and ≥47 grams of insoluble fiber) per day can reduce the risk by up to 50% of stroke in the population **(Casiglia et al., 2013)**. Other research shows that the *Tempeh gembus* which is processed into snacks, namely *Kerupuk Gembus* contains quite high fiber as much as 54.4 – 67.4% **(Afifah et al., 2019a)**. The fiber content in *tempeh gembus* has anti-inflammatory, anti-carcinogenic effects, can reduce gastrointestinal transit time which is good for treating diarrhea and constipation **(Gropper, Smith, and Groff, 2012)**. Fresh *Tempeh gembus* contains 1.87% fat, 11.09% fiber, 4.90% protein, 89.67% protein digestibility, 14.03% amino acids, 48.07% antioxidant activity, 0.05% genistein, and 0.07% daidzein **(Afifah et al., 2019b)**. In addition *Tempeh gembus* also contains unsaturated fatty acids linoleic acid (21.51%), linolenic aid (1.82%) and oleic (16.72%) **(Sulchan and Endang 2007; Sulchan and Rukmi 2007)**. **Damanik et al. (2018)** showed that the saturated fatty acid content in *Tempeh gembus* (12.55%) was higher than the saturated fatty acid in soybean (12.01%) and tofu residue (12.41%). The content of oleic acid in *Tempeh gembus* can suppress the production of pro-inflammatory cytokines. Giving *Tempeh gembus* in rats fed atherogenic diet can reduce hsCRP levels **(Dewi et al., 2018)**. Research conducted by **Noviana et al. (2018)** on *Tempeh gembus* hydrolyzate which was given 5000 ppm and 8000 ppm bromelin enzymes were able to prevent the microbial activity of *S. aureus*, *B. subtilis*, and *S. mutans*. *Tempeh gembus* also contains fibrinolytic protease-producing microbes, namely *Bacillus pumilus* 2 g (AB968524). Pure fibrinolytic enzymes from Bacillus pumilus 2 g are included in the serine protease group of subtilin which can degrade the α and β chains of fibrinogen quickly so that it has the potential to prevent cardiovascular **(Afifah et al., 2014)**. *Tempeh gembus* has also been shown to reduce oxidative stress. Giving *Tempeh* as much as 25 $g.kg^{-1}$ of Sprague Dawley rats for 28 days on an atherogenic diet, can reduce levels of malonaldehyde and homocysteine. A significant decrease occurred in the administration of fresh *Tempeh gembus* and gembe gembus which were given bromelain enzyme 25 ppm **(Kurniasari et al., 2017)**. Giving *Tempeh gembus* with a dose of 8% and 12% for 5 weeks in experimental animals showed a decrease in levels of total cholesterol, LDL cholesterol and increased HDL **(Afifah et al., 2014)**.

Scientific hypothesis

We investigate several hypotheses in our study:

a. Provision of processed *Tempeh gembus* affects the decrease in levels of high sensitivity c-reactive protein (hsCRP),
b. Provision of processed *Tempeh gembus* has an effect on increasing levels of high density lipoprotein (HDL).

MATERIAL AND METHODOLOGY

This study is a true experimental study using a pre-post randomized control group design **(Sastroasmoro and Ismael, 2011)**. Subjects were divided into two groups, namely the control group and the treatment group. The independent variable of this study was the administration of 150 grams of processed *Tempeh gembus* for 28 days while the dependent variable was the levels of hsCRP and HDL. Researchers have obtained Ethical Clearance from the Ethics Commission of the Faculty of Medicine at Sultan Agung University Semarang, Indonesia with number 33/I/2019/Bioethics Commission.

The study was conducted in March 2019 on 40 female prisoners of Class II Penitentiary in the City of Semarang. Subject retrieval is done based on inclusion criteria, namely women aged 20-50 years, body mass index ≥23 $kg.m^{-2}$, do not have a history or are undergoing liver disease, kidney, cancer, coronary heart disease, stroke, do not smoke, are willing to participate in this study by signing an informed consent .

Physical activity level data were obtained through direct interviews using the IPAQ form and then calculated using the Physical Activity Level (PAL) formula **(WHO, 2011)**. Categorizing the level of physical activity is light (1.40 – 1.69 units), moderate (1.70 – 1.99 units), and heavy (2.00 – 2.40 units). Data on Body Mass Index were obtained based on measurements of body weight and height. Data on nutrient intake was obtained through direct interviews using a food recall form and then analyzed using Nutrisurvey software.

Determination of the subject of this study using consecutive sampling method, and found as many as 73 people were willing to have blood drawn for the initial screening process. There were 40 subjects who met the inclusion criteria which were then divided into 2 groups: one control group and one treatment group with each group consisting of 20 subjects. The control group was given a diet limiting the intake of 30 calories/kg body weight/day while the treatment group as many as 20 people were given a dietary intake limiting the intake of 30 calories/kg body weight/day + processed 150 grams of *Tempeh gembus*/day.

Food intake restriction intervention is done by reducing

Figure 1 Tofu waste fresh.

Figure 2 Preparation of *Tempeh Gembus*.

Figure 3 Addition *Tempeh* yeast.

Figure 4 *Tempeh Gembus* has been ermented for 36 hours.

Figure 5 *Tempeh Gembus* Balado.

Figure 7 *Tempeh Gembus* Bacem.

Figure 8 *Tempeh Gembus* Pepes.

Figure 9 *Tempeh Gembus* Satay.

to the nutritional value **(Redman and Ravussin, 2011)**. Limitation of food intake is given in stages as much as 30 kcal.kg^{-1} body weight/day through food menus provided by the correctional institution which refers to a low calorie diet for obesity by considering the gender and physical activity of the subject **(Wahyuningsih, 2013)**. The Japan Atherosclerosis Society (JAS) recommends limiting food intake for obese subjects with mild physical activity levels of 25 – 30 kcal.kg^{-1} body weight day, 30 – 35 kcal.kg^{-1} body weight/day for subjects with moderate physical activity levels and >35 kcal.kg^{-1} body weight/day for subjects with heavy levels of physical activity **(Kinoshita et al., 2017)**. Interventions in the two groups were carried out for 28 days.

The independent variable of this study was the administration of 150 grams of processed *Tempeh gembus*. *Tempeh gembus* which will be given as treatment material is made by researchers and the team, in the Laboratory of Food Technology laboratory polytechnic health of Semarang using tofu waste obtained from tofu craftsmen food portions while still paying attention in the Cinde-Lamper region of Semarang City, *Tempeh* yeast used is Raprima yeast. *Tempeh gembus* is processed into 5 types of cuisine, namely: bacem, satay, oseng, pepes, and balado.

The dependent variable of this study is the levels of hsCRP and HDL. HsCRP levels were measured using the Enzyme Linked Immunosorbent Assay (ELISA) method **(Crowther, 2009)**. Whereas HDL levels were measured by laboratory workers using the Cholesterol Oxidase-Peroxidase Aminoantipyrine Phenol (CHOD-PAP) method **(McPherson and Pincus, 2016)**. Blood samples were taken by Semarang CITO Laboratory officials twice, namely on the first day before being given an intervention and 1 day after the intervention (the 29th day).

Statistic analysis

Data were analyzed using the version 16.0 of Statistical Package for the Social Sciences (SPSS). Differences in hsCRP levels before and after treatment were analyzed using the Wilcoxon test because the data were not

normally distributed. Differences in treatment effect between the two groups were analyzed using the Mann Whitney test. Differences in HDL levels before and after treatment were analyzed using paired *t*-test because the data were normally distributed. Differences in treatment effect between the two groups were analyzed using the independent sample test.

RESULTS AND DISCUSSION

Subject characteristics consisting of age, level of physical activity, Body Mass Index before and after treatment are presented in Table 1. All subjects in the study were in the age group of 21-50 years. The mean age in the control group (35.05 ±8.54 years) was lower than in the treatment group (36.50 ±9.37 years). The Mann Whitney test showed that there was no significant difference in age between groups (p = 0.64), so age was not a confounding variable in the study. The mean level of physical activity during the study in the control group (1.52 ±0.17 units) was higher than the treatment group (1.48 ±0.10 units). The Mann Whitney test showed that there was no difference in the average level of physical activity between groups (p = 0.84), so the level of physical activity was not a confounding variable in the study. Based on **WHO (2011)**, the level of subject activity in this study was included in the mild category (1.40 – 1.69 unit). Table 1 also shows that the average Body Mass Index (BMI) before and after the study in the control group (30.00 ±5.61 $kg.m^{-2}$; 29.63 ±5.42 $kg.m^{-2}$) than the treatment group (28.22 ±2.49 $kg.m^{-2}$; 27.32 ±2.50 $kg.m^{-2}$). The Mann Whitney test showed that there was no difference in mean Body Mass Index before (p = 0.51) and after research (p = 0.16), confounding in the study.

Table 2 shows data on energy, protein, fat and carbohydrate intake patterns before the study. The mean energy intake before the study in the control group (2306.96 ±545.24 kcal) was higher than in the treatment group (2057.70 ±241.06 kcal), the Mann Whitney test showed that there were significant differences in energy intake between groups (p = 0.01) so that energy intake before the study becomes confounding variable. The mean protein intake before the study in the control group (84.86 ±19.08 grams) was higher than the treatment group (72.59 ±19.16 grams), the independent sample test showed that there were significant differences in energy intake between groups (p = 0.04) so that protein intake before it can become confounding variables. The mean fat intake before the study in the control group (86.8 ±31.84 grams) was higher than the treatment group (60.57 ±18.75 grams), the independent sample test showed that there were significant differences in energy intake between groups (p = 0.00) so that fat intake before the study can be a confounding variable. The mean carbohydrate intake in the control group (296.79 ±77.45 gram) was higher than the treatment group (276.42 ±35.50 gram), but the independent sample test showed no difference in carbohydrate intake before the inter-group study (p = 0.29) so that carbohydrate intake before the study did not become a confounding variable.

Nutrient intake data subject control and treatment groups during the study are presented in Table 3. Table 3 Based on average energy intake in the control group (1924.35 ±218.62 kcal) is higher than that of the treatment group (1883.81 ±187.89 kcal), independent sample test showed that there were no significant differences in energy intake between groups (p = 0.53) so that energy intake was not a confounding variable in the study. The mean protein intake in the control group (p = 0.53) was higher than the treatment group (96.21 ±10.93 gram), the independent sample test showed no significant differences in protein intake between groups (p = 0.53) so that protein intake is not a confounding variable in the study. The mean fat intake in the control group (42.76 ±4.85 grams) was higher than the treatment group (41.86 ±4.17 grams), the independent sample test showed no significant difference in fat intake between groups (p = 0.53) so that fat intake does not become a confounding variable in the study. The mean carbohydrate intake in the control group (288.611 ±32.75 grams) was higher than the treatment group (282.54 ±28.16 grams), the independent sample test showed no significant difference in carbohydrate intake between groups (p = 0.53) so that carbohydrate intake is not a confounding variable in the study.

Table 4 shows the levels of hsCRP before and after the intervention. In the control group, the mean hsCRP level before the intervention was 7.31 ±0.75 $mg.L^{-1}$ whereas after the intervention the mean hsCRP level became 5.65 ±0.88 $mg.L^{-1}$. In the treatment group, the mean hsCRP level before intervention was 5.63 ±1.23 $mg.L^{-1}$, whereas after the intervention was 3.69 ±1.35 $mg.L^{-1}$. There was a significant difference between the mean levels of hsCRP before and after the intervention in the two groups (p = 0.00; p = 0.00). The mean hsCRP level before the intervention in the control group (7.31 ±0.75 $mg.L^{-1}$) was higher than the treatment group (5.63 ±1.23 $mg.L^{-1}$), there was a significant difference to the average hsCRP level before the intervention between the two group (p = 0.00). The mean hsCRP level after intervention in the control group (5.65 ±0.88 $mg.L^{-1}$) was higher than the treatment group (3.69 ±1.35 $mg.L^{-1}$), there was a significant difference to the average hsCRP level after the intervention between the two group (p = 0.00). There was a significant difference in the decrease in hsCRP levels after the intervention in both groups (p = 0.03).

In this study, the mean hsCRP level in the treatment group decreased by 1.94 ±0.29 $mg.L^{-1}$. This shows that giving as much as 150 grams of *Tempeh gembus* per day for 28 days is effective in reducing levels of hsCRP. The decrease in hsCRP levels in the treatment group can be caused by the presence of fiber in *Tempeh gembus*. Low fiber intake can increase proinflammatory cytokines IL-6), TNF-α, and IL-18. Increasing IL-6 can consistently increase CRP levels. High fiber intake can reduce fat oxidation resulting in decreased inflammation. Fiber is a protective factor to counter increasing CRP levels **(Ma et al., 2006)**. Other studies have shown that fiber in fermented soybeans can reduce cholesterol levels so that it contributes positively to the anti-inflammatory effect. The fiber in fermented soybean consists of several monosaccharides including glucose, arabinose, galactose, and uronic acid which are components of cellulose and non-cellulose polysaccharides. The main non-cellulose polysaccharide from soybean fiber is arabinogalactant. The positive effect on the anti-inflammatory effect can be seen significantly in decreasing the levels of C-Reactive Protein **(Kim et al., 2014)**.

Besides fiber, *Tempeh gembus* also contains antioxidants in the form of isoflavones (daidzein and genistein) and unsaturated fatty acids (oleic, linoleic and linolenic fatty acids) which include essential fatty acids **(Sulchan and Endang 2007; Sulchan and Rukmi 2007)**. The anti-inflammatory mechanism by isoflavones is carried out by inhibiting the NF-kB transcription system and modulating arachidonic acid (AA) metabolism and Nitric Oxide (NO) production by inhibiting protein levels and the activity of proinflammatory enzymes (phospholipase A2 (PLA2), lipoxygenase (LOX, COX-2, and iNOS) **(Jie et al., 2016)**. This study is in line with other studies that show that interventions with soy-based foods can reduce high sensitivity levels of C-Reactive Protein by 25% **(Kone, 2014)**. Apart from isoflavones, antioxidant activity *Tempeh gembus* probably derived from amino acids/peptides bioactive. *Tempeh gembus* containing amino acids such as tyrosine, methionine, histidine, lysine, cysteine and tryptophan. Activity of antioxidants in soybean gembus with ABTS method was 63.14 ±1.16% **(Agustina et al., 2018)**.

Table 5 shows data on HDL levels before and after the intervention. In the control group, the mean HDL level before the intervention was 29.25 ±5.05 mg.dL^{-1} whereas after the intervention the mean HDL level was 35.45 ±3.79 mg.dL^{-1}. In the treatment group, the mean HDL level before the intervention was 32.50 ±5.62 mg.dL^{-1} whereas after the intervention the average HDL level was 41.90 ±2.73 mg.dL^{-1}. There was a significant difference between the mean HDL levels before and after the intervention in the two groups (p = 0.00; p = 0.00). The mean HDL levels before the intervention in the control group (29.25 ±5.05 mg.dL^{-1}) were lower than the treatment group (32.50 ±5.62 mg.dL^{-1}), there were no significant differences in the mean HDL levels before the intervention between both groups (p = 0.06). The mean HDL levels after the intervention in the control group (35.45 ±3.79 mg.dL^{-1}) were lower than the treatment group (41.90 ±2.73 mg.dL^{-1}), there were significant differences in the mean HDL after the intervention between the two groups (p = 0.00). There was a significant difference in the increase in HDL levels after the intervention in both groups (p = 0.00). In this study, the mean HDL levels in the treatment group increased by 9.40 ±4.48 mg.dL^{-1}. The provision of 150 grams of processed Tempeh gembe for 28 days is effective in increasing HDL levels in the treatment group.

The main content of *Tempeh gembus* is fiber. High fiber intake can increase the excretion of bile acids and cholesterol through feces thereby reducing bile acids to get back into the liver. The reduction of bile acids to the liver causes an increase in the use of cholesterol to bile acids so that it has an effect on increasing HDL **(Buse, Kenneth and Harles, 2017)**. Besides fiber, the increase in HDL levels in the treatment group was due to the presence of flavonoids in *Tempeh gembus.* Flavonoids can increase the amount of Apolipoprotein A-1. Apolipoprotein A-1 acts as an enzyme cofactor for LCAT and as a ligand of interaction with lipoprotein receptors in tissues in HDL. An increase in Apolipoprotein A-1 is expected to increase HDL levels **(Gropper, Smith, and Groff, 2012)**. According to the American Association of Clinical Endocrinologists **(AACE, 2012)** HDL levels of 60 mg.dL^{-1} can reduce the risk of coronary heart disease **(Jellinger et al, 2012)**. However, in this study there were no respondents with HDL levels reaching 60 mg.dL^{-1} after the intervention. Increased levels of HDL that do not reach optimal values are caused by several factors, one of which is exercise **(Whitney and Sharon, 2015)**. Other studies have shown that adult women who exercise regularly, such as aerobic exercise three times a week, can experience increased levels of HDL **(Wang and Peng, 2011)**. WHO states that aerobic exercise performed by adults aged 18-64 years with moderate intensity for 150 minutes/week or high intensity for 75 minutes/week can increase HDL levels and be beneficial for heart health **(WHO, 2011)**. Regular exercise can improve the work function of Apolipoprotein A-1 as an HDL receptor in reducing cholesterol from blood vessel walls **(Kingwell and Michael, 2013)**. In this study, respondents only did aerobics once a week so this might be the cause of HDL cholesterol levels not reaching optimal values. In addition to lack of exercise, respondents' physical activity is also included in the mild category. The types of activities most frequently carried out by respondents were sleeping, watching TV, sweeping, washing clothes, cooking and making batik.

Changes in HDL and hsCRP levels also occurred in the control group. This is presumably due to the provision of restriction of food intake through a low calories diet of 30 calories per kg body weight/day in the control group. Based on the results of the study, it is known that the control group's diet before the intervention was 2306.96 kcal while during the intervention it decreased to 1924.35 kcal.

Changes in calorie intake resulted in an increase in HDL levels of 6.20 ±2.35 mg.dL^{-1}, from 29.25 ±5.05 mg.dL^{-1} to 35.45 ±3.79 mg.dL^{-1}. Foods that have been consumed will undergo metabolic processes and produce energy in the form of adenosine triphosphate (ATP) to carry out physical activity **(Rodwell et al., 2018)**. When doing physical activity, energy needs will increase, so if glucose as the main energy source is insufficient there will be an increase in fat metabolism. This causes a decrease in body fat percentage and an increase in HDL cholesterol **(Whitney and Sharon, 2015)**. Research on obese subjects shows that food intake restrictions affect changes in lipid profile, including increased levels of HDL **(Fothergill et al., 2016)**. Food intake restrictions are also able to protect against age-related diseases including inflammation by reducing oxidative stress **(Omodei and Luigi, 2011; Rebrin, Michael and Rajindal, 2011)**.

Interventions in the form of limiting food intake in the control group also resulted in a decrease in hsCRP levels of 1.65 ±0.57 mg.L^{-1}, from 7.31 ±0.75 mg.L^{-1} to 5.65 ±0.88 mg.L^{-1}. A decrease in subject's hsCRP levels can be caused by a decrease in fat intake. It is known that the mean fat intake in the control group before the intervention is 86.58 ±31.84 grams to 42.76 ±4.85 grams after the intervention. Fat intake is excessive will affect visceral fat to express a response to various stimuli one of them is an increase in spending of free fatty acids by adipose tissue that can stimulate increased secretion of VLDL in the liver which in turn will result in an increase in triglycerides, LDL and decrease HDL **(Gropper, Smith and Groff, 2012; Wang and Peng, 2011)**. This increase

will trigger the release of HDL from the liver to carry cholesterol in the circulation (reverse cholesterol transport).

HDL is esterified into cholesterol esters which can be directly carried to the liver to be directly excreted or exchanged with triglycerides from VLDL and chylomicrons. When cholesterol esters are excessive, triglyceride-rich HDL (low density HDL) is broken down by hepatic lipase, thus reducing circulating HDL levels. As the result the reverse cholesterol transport process is reduced and cholesterol levels in the circulation and tissue increase **(Murray, Granner and Rodwell, 2017)**. In one condition, an increase in excess cholesterol levels in the circulation causes an abnormal reaction that causes the activation of the scavenger macrophage. This macrophage is responsible for cleaning cholesterol and low-density

HDL from circulation by phagocytosis. Macrophages that are full of cholesterol will then become foam cells that cause activation of pro-inflammatory cytokines (IL-1, IL-6, and TNF α). Activation of pro-inflammatory cytokines is an early sign of inflammation. Continued inflammation will cause CRP expenditure from the liver **(Pitsavos et al., 2006)**. Other studies have shown that low fat intake can inhibit cytokine release and reduce levels of hsCRP in the blood **(Camhi et al., 2010)**. This is due to adipose tissue reducing the expenditure of free fatty acids causing a decrease in total cholesterol, LDL, triglyceride levels and an increase in HDL that affect macrophages, thereby impacting on decreasing hsCRP levels **(Murray, Granner and Rodwell, 2017)**.

Intervention in the form of limiting long-term food intake has a very strong protective effect on the risk of atherosclerotic cardiovascular disease (CVD) as evidenced by a decrease in blood pressure, LDL cholesterol, hsCRP, IL-6, TNF-α, and an increase in HDL cholesterol levels **(Dolinsky and Dyck, 2011)**. Restricted food intake has been shown to improve mitochondrial function, reduce oxidative stress and increase nitric oxide production involved in the prevention of atherosclerosis, reduction in blood pressure, weakening of left ventricular hypertrophy, resistance to myocardial ischemic injury and prevention of heart failure **(Weiss and Luigi, 2011)**.

CONCLUSION

The administration of processed *Tempeh gembus* for 28 days can reduce high sensitivity c-reactive protein (hsCRP) by 1.93 $mg.L^{-1}$ and increase HDL levels by 9.40 $mg.dL^{-1}$ in obese women in penitentiary class II Semarang city, Indonesia. Changes in hsCRP and HDL levels also occurred in the control group. This is thought to be due to a standard diet of 30 calories/kg body weight/day for 28 days.

INTERACTION OF POLYPHENOLS EXTRACT FROM *POLYGONUM MULTIFLORUM* THUNB. ROOTS WITH GELATIN AND TOXICITY OF EXTRACT IN MICE

Le Pham Tan Quoc

ABSTRACT
The roots of *Polygonum multiflorum* Thunb. (Vietnamese name: Ha-thu-o-do, HTOD) are used in processed form or the raw state in traditional Vietnamese medicine for many diseases and in extract form in the food industry. Some studies pointed out that HTOD extract had toxicity in humans. However, the toxicity of this herb plant currently remains unclear. In addition, this material contained a large amount of bioactive compounds, especially phenolic compounds. They have a strong antioxidant capacity and they can also interact with many different substrates such as protein, enzyme, lipid and carbohydrate. In this study, the received extracts from HTOD had the polyphenols concentrations of 415, 277, 208 and 166 (mg GAE.L^{-1}), respectively. Besides, we only evaluated the gelatin-polyphenols interaction and the toxicity of HTOD extract in Swiss mice. The results show a strong gelatin-polyphenols interaction and no acute or subacute toxicity in mice. The polyphenols extract of HTOD at the concentration tested in this study is safe to use in food.

Keywords: Interaction; gelatin; polyphenols; root; toxicity

INTRODUCTION
Polygonum multiflorum Thunb. is a wild herbal plant distributed throughout the mountainous regions of North Vietnam (Cao Bang, Lang Son, Lai Chau, Hoa Binh province, etc.). It is known as Ha-thu-o-do (HTOD) in Vietnamese. In addition, HTOD is found in many other Asian countries such as China, Korea, Japan, etc. Ethnomedical uses of HTOD have been recorded for many centuries, and it contains more than 100 chemical bioactive compounds, for example, tannins, anthraquinones, stilbenes, flavonoids, phospholipids **(Lin et al., 2015)**, saponins, and alkaloids **(Quoc and Muoi, 2018)**. Thus, it can be used as a traditional spice in Chinese food **(Li and Gao, 2015)** or drugs to prevent some diseases, such as certain forms of cancer **(Way et al., 2014)**, and for its anti-aging effects, tonic tension **(Lim et al., 2014)**, and antioxidant activity **(Wang et al., 2008)**. Nowadays, polyphenols extract from HTOD is used in food processing, for example, it serves as an antioxidant during the storage of minced red tilapia **(Le and Nguyen, 2018)** or combine with edible film (alginate) to store fresh-cut papaya **(Quoc and Muoi, 2016)**. Moreover, HTOD has also been used in wine processing **(Hoang and Thuat, 2015)**.

There are many methods to extract phenolic compounds from HTOD with various solvents (water, acetone, methanol, ethanol, etc.), such as the decoction method **(Li et al., 2007)**, microwave-assisted extraction **(Quoc and Muoi, 2015)**, ultrasound-assisted extraction **(Wu et al., 2012)**, pectinase-assisted extraction **(Quoc and Muoi, 2017)**, etc. The total polyphenols content, antioxidant capacity, and type of phenolic compounds in all methods are significantly different. Thus, these results can strongly affect the protein-polyphenols interaction and toxicity of polyphenols extract in mice.

Recently, many studies reported that HTOD can have hepatotoxic effects **(Huang, Zhang and Sun, 2011; Wu et al., 2012)**; other studies noticed that HTOD is good for the liver **(Huang et al., 2007; Bhadauria, 2010)**. The results of the above-described studies appear to be contradictory. Until now, there have been no studies on the interaction of gelatin with polyphenols extract from HTOD. Therefore, the main aim of this research was to investigate the gelatin-polyphenols interaction and toxicity of polyphenols extract in mice.

Scientific hypothesis
The objective of this study was to determine the capacity for interaction between polyphenols extracts of *Polygonum multiflorum* Thunb. roots and protein (gelatin). This interaction results in precipitation of the protein. An additional objective of the study was to determine the effect of the toxicity of various polyphenols extract

concentrations in mice. We are expecting an insignificant effect of the extract on acute and subacute toxicity in mice.

MATERIAL AND METHODOLOGY

Extract preparation

Polygonum multiflorum Thunb. roots were harvested from Cao Bang province (Vietnam). The roots were then cleaned with tap water, sliced, and dried at 60 °C until the moisture level was less than 12%. The slices were then ground into a fine powder (diameter less than 0.5 mm) and vacuum-packed. Polyphenols from the dried powder of *Polygonum multiflorum* Thunb. roots were extracted in a microwave system with an acetone concentration of 57.35%, solid/solvent ratio of 1/39.98 (w/v), extraction time of 289 sec, and microwave power of 127 W. The crude extract was filtered through Whatman paper **(Quoc and Muoi, 2015)**. The filtered extract was evaporated at 45 °C until the solvent was completely removed and the extract was used for the preparation of 415, 277, 208 and 166 mg GAE.L^{-1} solution in distilled water.

Chemicals and reagents

Folin-Ciocalteu reagent and gallic acid were purchased from Merck (Germany). All organic solvents and other chemicals were of analytical reagent grade.

Determination of total polyphenols content (TPC)

The TPC in the extracts was slightly modified and determined by the Folin-Ciocalteu colorimetric method **(Siddiqua et al., 2010)**. The results were based on a standard curve obtained with gallic acid. TPC was expressed as mg of gallic acid equivalents per gram of dry weight (mg GAE.g^{-1} DW) or per gram of solution volume (mg GAE.L^{-1}).

Interaction of polyphenols extract with gelatin

Reactions took place in 10 mL volumetric flasks. Polyphenols were dissolved in water to 415, 277, 208 and 166 (mg GAE.L^{-1}). Gelatin solutions in water, at concentrations varying from 30 to 120 mg.mL^{-1} were prepared. Polyphenols and gelatin solutions were mixed quantitatively in flasks with shaking. After standing for 24 h at 25 °C, the mixture was centrifuged (3000 rpm, 20 min), and the suspended substances (reaction products) were removed. The supernatant was analyzed at 280 nm in a UV spectrophotometer. Assuming that a polyphenols solution with a fixed concentration has an initial absorbance (A_o), and after interaction with gelatin the absorbance decreases to A, RA can be defined as $RA = (A_o-A)/A_o$ **(Bi, He and Haslam, 1995)**.

Animals

Male and female Swiss mice (approximately 22 g) were obtained from the Pasteur Institute (Ho Chi Minh city, Vietnam). All mice were maintained in plastic cages under standard environmental conditions at 28 ±2 °C with a relative humidity of 75 ±10%. The mice were fed on a standard chow diet and given water ad libitum. The mice were used for experimentation after 7 days' acclimatization. All experiments were performed during the daytime. The experimental procedure was strictly in compliance with the "Declaration of Helsinki" in 1964.

Acute toxicity

Both male and female healthy mice were fasted overnight and only allowed to access to water ad libitum. They were randomly divided into five groups (10 animals per group). The mice of the first group (control group) were fed with water only. All groups were given 0.2 mL of the extract on the first day by oral gavage. The mice of groups 2 – 5 were treated with acetone extracts of *Polygonum multiflorum* Thunb. root at doses of 138, 276, 414, and 552 mg dry extract.kg^{-1} of body weight per day. The dosages were equivalent to 25, 50, 75, and 100 times the upper dosage for humans recommended in the study of **Le and Nguyen (2018)** (415 mg GAE.L^{-1}, approximately 607 mg dry extract.L^{-1} or 5.52 mg dry extract.kg^{-1} of body weight). The dosage was set at a high level to uncover any potential toxicity in order to investigate the hepatic risk. The general behavior, hazardous symptoms, and mortality of the mice were monitored for a period of 3 days after treatment. The LD_{50}, clinical biochemistry analysis, gross morphology, and histology of the liver were also evaluated in this test.

Subacute toxicity

Both male and female healthy mice were also randomly divided into four groups (10 animals per group). The mice of the first two groups (control groups) were fed with water only. The mice of groups 3 and 4 were treated with the acetone extracts of *Polygonum multiflorum* Thunb. root for 3 and 6 weeks. Treated groups were given 0.2 mL extract at a concentration of 415 mg GAE.L^{-1} (approximately 607 mg dry extract.L^{-1} or 5.52 mg dry extract.kg^{-1} of body weight, the dosage for humans recommended in the study of **Le and Nguyen (2018)**). The body weight of the mice was recorded weekly, and signs of abnormalities in the mice were recorded during the treatment period. The clinical biochemistry, gross morphology, and histology of the liver/kidney were also evaluated every 3 weeks.

Histopathologic examination, biochemical analysis, and hematological parameters

The mice were dissected to collect the livers/kidneys for histopathologic examination. Biochemical analysis was performed for alanine aminotransferase (ALT), aspartate aminotransferase (AST), Urea/BUN (Blood Urea Nitrogen), and creatinine. In addition, a total leukocyte count and total hemocyte count were also performed.

Statistical analysis

The experimental data were analyzed by one-way analysis of variance (ANOVA) and significant differences between the means from triplicate analyses at $p < 0.05$ were determined by Fisher's least significant difference (LSD) procedure using Statgraphics software (Centurion XV). The values obtained were expressed as mean ± standard deviation (SD).

RESULTS AND DISCUSSION

Research on the gelatin-polyphenols interaction

Polyphenols concentrations of 415, 277, 208, and 166 (mg GAE.L^{-1}) react with gelatin concentrations of 30, 60, 90 and 120 mg.L^{-1} (gelatin/polyphenols ratio=1/1, v/v). The results show that relative absorbance (RA) increases with with an increase in the polyphenols concentration, and these results were significantly different (p <0.05).

The minimum and maximum RA are 0.246 and 0.718, meaning that 24.6% of the gelatin was precipitated at the minimum polyphenols concentration of 166 mg GAE.L^{-1} and the minimum gelatin concentration of 30 mg.L^{-1}. Besides, 71.8% gelatin was also precipitated at the maximum polyphenols concentration of 415 mg GAE.L^{-1} and the maximum gelatin concentration of 120 mg.L^{-1} (Figure 1). These results demonstrate that the interaction between gelatin and polyphenols is strong and significantly affects the RA. This is concordant with a study by **He, Lv and Yao (2007)**, who noted that polyphenols in tea extract interact with gelatin at a low gelatin concentration of 20 mg.L^{-1} and a polyphenols concentration of 50 mg.L^{-1} (22% of the gelatin was precipitated). The precipitate increased to 84% with an increase in the gelatin concentration (160 mg.L^{-1}) and the polyphenols concentration (150 mg.L^{-1}).

Gelatin was chosen in this study because gelatin is proline-rich, and has an open, random-coil conformation and a molecular weight of 100 kDa, thus it has a high affinity for polyphenols **(He, Lv and Yao, 2007; Frazier et al., 2010)**. Phenolic compounds can form strong hydrogen bonds easily with the protein's carboxyl group. They must be small enough to penetrate the inter-fibrillar regions of protein molecules but large enough to crosslink peptide chains at many points on the protein molecule **(Mulaudzi et al., 2012)**. The protein-polyphenols interaction depends on many factors, such as pH, temperature, the type of protein, and the structure of polyphenols **(Ozdal, Capanoglu and Altay, 2013)**.

This interaction has both advantages and disadvantages. On the one hand, it can protect the polyphenols's activity, and prevent oxidation of the surrounding environment **(Jakobek, 2015)**. On the other hand, it decreases protein quality **(Yuksel, Avci and Erdem, 2010)**, for example, by affecting protein solubility **(Rawel et al., 2002)** and by decreasing the in vitro digestion properties of proteins **(Petzke et al., 2005)**.

Acute toxicity of polyphenols extract

This extract was concentrated and was administered to each treatment group at single doses of 25, 50, 75, and 100 times the upper dosage for humans as recommended by **Le and Nguyen (2018)** (approximately 138, 276, 414, and 552 mg dry extract.kg^{-1} of body weight), respectively, by oral gavage. The control groups were treated with the same volume of distilled water (0.2 mL).

After a one-hour exposure to the extract, drowsiness and exhaustion were observed in all mice in the extract-treated group. No death or obvious clinical signs were found in any groups throughout the study. None of the extract-treated rats showed signs of toxicity in their skin, fur, eyes, sleep, salivation, diarrhea, and behavior after 72 hours. Table 1 shows that changes in clinical biochemistry analysis were not significantly different (p >0.05) at various concentrations compared with the control sample, and these results were also similar to those of other studies **(Dieu, 2009; Wu et al., 2012; Ha et al., 2015)**.

Gross morphology and histology of the liver did not show any unusual signs (Figure 2 and Figure 3). There was no difference in parenchymal tissue, portal space and central vein structures in all experimental liver sections. Hepatocytes in all experimental groups had a polygonal shape with the nucleus in the middle of the cell and were well organized in plates. The structure of the portal space was normal without inflammation, and there were no degenerative lesions in the surrounding hepatocytes. Hence, polyphenols extract from *Polygonum multiflorum* Thunb. root did not cause acute toxicity in mice, and the LD_{50} could not be estimated at the studied concentrations.

Subacute toxicity of polyphenols extract

Using a polyphenols concentration of 415 mg GAE.L^{-1} (5.52 mg dry extract.kg^{-1} of body weight), we evaluated semi-chronic toxicity over 6 weeks. After 6 weeks, all groups gained the same amount of weight, and no statistically significant differences in clinical biochemistry analysis and hematological parameters were noted between the control and treated groups at the third and sixth weeks (p <0.05) (Table 2). Gross morphology and histology of the liver/kidney did not show any injuries or unusual signs. In addition, the glomerulus had a normal structure with wide Bowman's capsules, and the renal tubes were lined by a simple cuboidal epithelium with a uniform appearance. Furthermore, no damage to the structure of hepatocytes and nephrocytes was observed (Figure 4 and Figure 5). Therefore, there was no subacute toxicity at this polyphenols concentration.

This result shows that the extract concentration employed in this study is safe for human health. Our results also differ from those of **Wu et al. (2012)**, who noticed that both acetone and water extract from fresh *Polygonum multiflorum* Thunb. roots were toxic and had dose-dependent hepatotoxicity. On the contrary, many studies reported that extract from this material is good for the liver **(Huang et al., 2007; Bhadauria, 2010)**, thus the toxicity of the extract depends on many factors, such as the extraction method, the composition of the material, solvent, etc. Moreover, toxicity was also related to the following factors: improper drug compatibility, dose, mode of administration, physical condition of the patients, and processing methods. The above-described studies appear to be contradictory. However, *Polygonum multiflorum* Thunb. roots have still been used in different ways for a long time, such as in Heshouwu tea, Heshouwu wine, Heshouwu soup, etc. in Chinese daily meals **(Li and Gao, 2015)**.

Note: Different lowercase letters in the same row for 3 weeks denote a significant difference (p <0.05). Different uppercase letters in the same row for 6 weeks denote a significant difference (p <0.05).

CONCLUSION

In summary, polyphenols acetone extract from *Polygonum multiflorum* Thunb. roots can interact strongly with gelatin. At the same time, polyphenols extract at the studied concentrations was not acutely or subacutely toxic in mice.

SLOVAK CONSUMERS´ PERCEPTION OF BAKERY PRODUCTS AND THEIR OFFER IN RETAILS

Ľubica Kubicová, Kristína Predanocyová, Zdenka Kádeková, Ingrida Košičiarová

ABSTRACT
Bakery products represents an important part of the diet and have an irreplaceable role in the proportion of nutrients, but their popularity in the diet of Slovak consumers continues to decline. For this reason it is necessary to address the issue of bakery products with regard to their consumption. The aim of the paper is to point out the development of consumption of bakery products in the Slovak Republic and to identify the main factors determining their purchase from the perspective of Slovak consumers. Secondary and primary data were used to meet this aim. Secondary data were obtained from the Statistical Office of the Slovak Republic in order to describe trends in consumption of selected foodstuffs in the period 2009 – 2018, as well as to predict the development of consumption of wheat and durable bread by 2020. The development of consumption is influenced by a number of factors, which may include, in particular, the price of products, the existence of substitution products, changes in eating habits and preferences of Slovak consumers, consumer health restrictions, as well as the taste factor. The primary data were obtained through consumer and business-oriented research in the Slovak Republic. The results of the consumer survey showed both rationality and irrationality in consumer decisions when buying bakery products. Rational aspects in the purchase of bakery products are factors of composition and durability. Irrationality in consumer behavior when buying can be accompanied by psychological factors, which include the perception of freshness of bakery products, the perception of prices, the perception of the country of origin, as well as sensory aspects such as taste. The achieved results were confronted with the results of a retail-oriented survey. The results showed that the commercial premises, when offering bakery products, mainly take into account the freshness, price and country of origin of selected foods.

Keywords: bakery product; consumer; factor; purchase

INTRODUCTION
The bakery industry belongs to the secondary processing industries **(Džupina, Hodinková and Kiková, 2016)**. Its raw material base are products of the food industry, which process commodities of agricultural primary production (eg mill, starch). This industry is directly influenced by the quality and price of grain, which depends on prices on world markets. The basic products of the bakery industry include durable bread, common bakery products (buns, rolls etc) and fresh bread. For most people, bakery products are a daily part of their diet. The importance of bakery products in human nutrition is significant because the products are the basis of the food pyramid and have a high nutritional value **(Al-Mussali and Al-Gahri, 2009; Nagyová, Sedliaková and Holienčinová, 2014; Kádek, 2018)**.

Hes (2009) noticed that when purchasing food, including bakery products, the consumer is influenced by the following factors. The first important aspect in the purchase of bakery products is their perceived quality and properties, which are mainly determined by sensory and health **(Stávková, Stejskal and Toufarová, 2008, Skořepa and Pícha, 2016; Wingert et al., 2014)**, and consumers are also interested in food security **(Golian et al., 2018; Adam, Hiamey and Afenyo, 2014)** and favor bakery products with higher nutritional properties (eg whole grain bread).

Nagyová et al. (2012) pointed out that consumers perceive quality on the basis of other subjective factors, such as the shape, appearance, color and taste of bread and pastry. For most consumers, the decisive factor is price **(Kubicová and Kádeková, 2011)**, which affects the purchase of specific bakery products, especially in the case of fine pastries. Another factor is the country of origin **(Kleinová and Lušňáková, 2011)**, which customers start noticing and prefer especially bakery products of Slovak origin. In the context of the country of origin, the brand is also an important factor to which consumers pay attention and choose the bakery products by specific producers or with a preferred brand name. The following factor determining the purchase of bakery products is the experience with the products, as customers prefer the bakery products with which they have a good experience. Customer automatically reaches for the bakery product he

was satisfied with and does not change his mind in the store. This situation can be described as "shopping blindness".

The recommendation can be considered as another factor positively influencing the purchase of a particular bakery product and represents an independent assessment of an unbiased person, which in some cases may have a greater impact on the customer than advertising **(Polakevičová, 2015)**. In the case of packaged bakery products, the packaging itself also affects the purchase. The packaging fulfills the communication and promotion function. The endeavor of the packaging is to attract the customer's attention, provide the customer with sufficient information about the product, its composition and thereby lead the customer to purchase. The shopping convinience and the time spent by shopping can also have a significant impact on the purchase of bakery products. The health aspect **(Šedík et al., 2019)** is another factor determining the purchase of food, including bakery products, as consumers increasingly pay attention to their health and healthy lifestyle **(Nagyová et al., 2019)** and adapt the choice of specific bakery products accordingly. In the context of the health aspect, consumers take into account the composition and nutritional value of foods **(Šedík et al., 2018)**, and in the case of bakery products they prefer whole grain ones, which are more nutritious.

The individual factors determining the purchase of bakery products can be taken into account with regard to the rationality and irrationality in consumer behavior in the choice of bakery products. **Horská et al. (2009)** combines the first approach with the rationality of consumer behavior. The purpose of this behavior is to maximize satisfaction or performance. Consumer behavior is characterized by prudence, awareness, experience, and the evaluation of alternatives **(Rovný et al., 2010)**. In the case of purchasing bakery products, consumers compare the types of bakery products, composition, method of production or prices. The second approach is linked to the irrationality of consumer decisions. **Karpińska and Krakowiak (2014)** include uncertainty, risk, limited time and access to information as factors limiting optimal purchasing choices. Consumer behavior is characterized by unpredictability, emotionality, impulsiveness or subconsciousness **(Komárková, Rymeš and Vysekalová, 1998)**.

A relatively high share of impulses and emotions is also recorded when purchasing bakery products. Purchasing decisions are influenced by several factors, including cultural, social, psychological and personal **(Géci, Nagyová and Rybanská, 2017)**. The behavior of consumers buying bakery products is mainly influenced by psychological factors, which may be decisive in re-purchasing a particular bakery product. The motivational aspect as a psychological factor may be to search for and purchase higher quality bakery products which are the basis of the food pyramid and their consumption positively affects the health of consumers due to the high nutritional value. Perception is another factor. Consumers perceive incentives and objects in bakery shops. Retailers should therefore be aware of the elements that raise or question the confidence of potential customers and should seek to understand in detail how trust affects the perception of a particular bakery product.

Personality of the consumer can also influence the choice of specific bakery products. Different types of personality choose bakery products from different perspectives, eg. depending on the type of flour, production method, aroma, color, taste. The last factor is the emotions that affect consumers, and can change depending on the experience with purchased bakery products **(Horská and Berčík, 2017; Rybanská, Nagyová and Košičiarová, 2014)**.

Scientific hypothesis

The aim of the paper is to point out the consumption of bakery products in the conditions of the Slovak Republic and to identify the main determinants affecting consumption from the perspective of the Slovak consumer. In the context of the set aim, the following hypotheses related to consumer and retails research were formulated as well.

Hypothesis 1: We assume that Slovak consumers evaluate the factors affecting the purchase and subsequent consumption of bakery products differently.

Hypothesis 2: We assume that there is a correlation between consumers' knowledge of the parbaked bakery produts in retails that are sold as the fresh baked ones and the perception of the difference in taste between parbaked and fresh baked bakery products.

Hypothesis 3: We assume that Slovak consumers perceive prices of different types of bakery products differently.

Hypothesis 4: We assume that retails assess criteria for supplier selection differently.

MATERIAL AND METHODOLOGY

The stated aim of the paper was achieved by using and processing secondary and primary data. Secondary data were obtained from the Statistical Office of the Slovak Republic. The obtained secondary data became the basis for calculating the average growth coefficient (k') and predicting the development of the consumption of bakery products by 2020 using the determination coefficient R^2.

The primary data were obtained through a consumer survey aimed at identifying key factors determining the purchase of bakery products in the Slovak Republic. The questionnaire survey was conducted on a sample of 649 respondents in the Slovak Republic in 2018, in electronic version, using the Google Forms platform. The respondents in the questionnaire survey were diversified into 8 categories in terms of gender (women 55.5%; men 44.5%), age (up to 24 years 28.4%; 25 – 39 years 20.6%; 40 – 54 years 28.4%; over 55 years 18.2%), educational attainment (basic 3.4%; secondary 57.6%; university 39.0%), permanent residence (countryside 55.3%; city 44.7%), economic status (student 29.3%; employed 44.8%; self-employed 8.0%; unemployed 3.1%; maternity leave 1.5%; pensioner 13.3%), monthly income of respondents (less than 400 € 38.4%; 401 – 800 € 32.8%; more than 801 € 28.8%), and number of household members (1 – 2 members 22.9%; 3 members 24.2%; 4 members 29.1%; 5 members and more 23.7%).

Another source of primary data was information obtained through a survey in retails. The aim of the survey was to identify the range of bakery products offer, how they approach the factors that determine consumers when purchasing bakery products, and the criteria that are

decisive in selecting a particular supplier of finished bakery products, bakery ingredients or frozen semi-finished products. The survey of retails was carried out on a sample of 107 stores in the Slovak Republic in 2018. Retails were divided according to the size of sales area (up to 400 m^2 81.3%; 400 – 2500 m^2 15.9% and more than 2500 m^2 2.8%) and geographic location (western Slovakia 72.9%; central Slovakia 14.0% and eastern Slovakia 13.1%).

Statistical analysis

The collected data were processed by using Microsoft Excel and subsequently evaluated in the statistical program XL Stat. The formulated hypotheses were tested by applying the following statistical tests:

- Chi square contingency test,
- Cramer´s coefficient,
- Friedman's test,
- Nemenyi method.

In hypothesis testing, if *p* value is lower than significant level, in case of XL Stat software by Addinsoft (version 2019.3.2), it is 0.05, the null hypothesis was rejected and alternative hypothesis was confirmed.

RESULTS AND DISCUSSION

The development of consumption of bakery products was monitored in the period 2009 – 2018. Bread consumption in the Slovak Republic in the analyzed period was at a stable level with an average annual decline of 2.1%. In the past, Slovaks could not imagine a day without a piece of bread, but at present its popularity is gradually decreasing. While approximately twenty years ago every Slovak consumed about 50 kg of bread per year, today we consume these bakery products in smaller quantities at 35 kg of bread per person per year. The trend of bread consumption development can be expressed through a linear function with the following parameters (1):

$$q_t = 41.773 - 0.8024 * t \quad (1)$$
$$R^2 = 0.9378$$

Based on the chosen linear function, it is possible to predict the evolution of bread consumption in the future, while the consumption trend is expected to decrease and in 2020 bread consumption should be at the level of 33 kg per person per year. In this context, it is important to point out the reasons for the relatively low consumption of bread, which may be affected by rising bread prices, consumer health constraints, a fairly wide assortment of plain and fine bread, a change in consumers' lifestyle, as well as various myths and falsities about bread **(Eglite and Kunkulberga, 2017)**.

Wheat bakery products consumption was slightly increasing in the period under review, ranging from 28.2 kg to 29.4 kg, which represents an average annual growth rate of 0.5%. This implies a relatively stable development of wheat bread consumption, with the highest decrease in consumption being recorded in 2013 at 27.8 kg and an increase in consumption was recorded in 2017 to the level of 30.6 kg per person per year (Figure 1**)**. We assume that by 2020 the consumption of wheat bread will slightly decrease to 29 kg per person per year. The development of the consumption of wheat bakeryproducts is positively influenced by the increasing popularity of fine pastries, among which we can include sweet buns, donuts, peelers, or modern croissants and muffins, with various fillings, toppings which feed and satisfy the appetite for sweet, at any time of the day. On the other hand, consumption is negatively influenced by several factors, which include rising prices of selected bakery products, consumer orientation towards cheaper substitutes, change of eating habits and preferences of Slovak consumers **(Kubicová and Predanocyová, 2018)**.

The last category of bakery products, the consumption of which we monitored, is durable bread. The development of durable bakery products consumption in the monitored period 2009 – 2018 was accompanied by an upward trend with an average annual growth of 1.1%. The lowest consumption of durable bakery products was recorded in 2009 and 2010, when it was 85.8 kg per person per year and the highest consumption was recorded in 2013 – 2015 and amounted to 9.8 kg per person per year. The trend of the development of the consumption of durable bakery products for the period under review can be described by the cubic function, which acquires the following parameters (2):

$$q_t = 8.1 + 0.5695 * t - 0.0731 * t^2 + 0.0029 * t^3 \quad (2)$$
$$R^2 = 0.4833$$

On the basis of the selected cubic function it is possible to predict the development of the consumption of durable bakery products in the future. By 2020, consumption of selected bakery products is expected to decline slightly to 9.5 kg per person per year. Relatively high consumption of durable bakery products can be caused by several factors, such as consumer orientation towards sweet and salty bakery products, which is readily available in stores and in packaged form, changes in preferences of Slovak consumers, taste of pastries, longer durability and the possibility of storage. The development of consumption of a given type of bread can be negatively affected by the price and wide range of substitution products **(Kubicová, 2008; Nagyová et al., 2012)**.

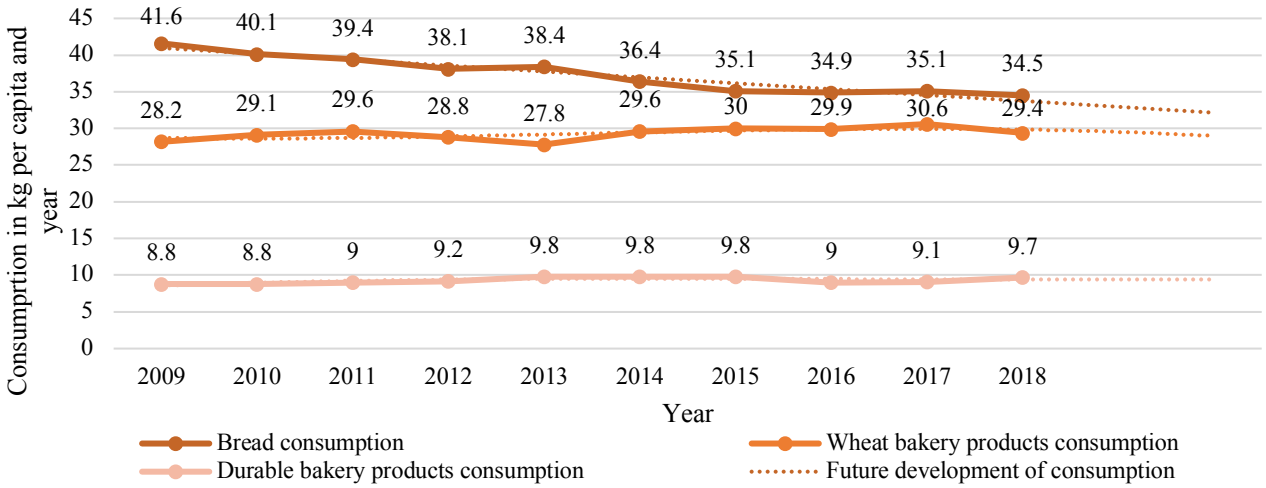

Figure 1 The development of bakery products consumption in kilograms per capita and year in the Slovak Republic. Note: **SO SR, 2019**.

Analysis of the development of consumption of individual types of bakery products showed that the consumption conditioned by the purchase of the given bakery products is influenced by a number of factors. For this reason, a questionnaire survey was carried out to identify the main factors determining the purchase and consumption of bakery products. The consumer survey for consumers of bakery products focused on the shopping behavior in the bakery products market. Based on the results of the research can be concluded that all addressed consumers buy bakery products, with the preference of fresh bakery products (99.4%) and durable bakery products (19.7%), as well as frozen bakery products that consumers bake and finish in domestic environment (18.6%). Furthermore, the obtained results show that the most preferred fresh bakery products are common bakery products such as rolls, buns etc. (82.3%), bread (70.6%) and fine pastry (35.4%).

When purchasing food, including bread, fine pastry and other bakery products, consumers make choices based on a number of criteria. We selected following ones: freshness, price, durability, composition, country of origin and taste. These were assessed by consumers involved in the questionnaire survey on the importance scale on a scale from 1 to 6, where 1 was the most important factor and 6 the least important factor. The results of the consumer survey showed (Figure 2) that the most important factors for consumers are freshness (88.9%), taste (64.3%), price (48.5%), durability (37.3%), composition (36.1%) and country of origin (25.9%). In connection with the evaluation of individual factors influencing the choice of bakery products by consumers, we found differences in the evaluation of these criteria among respondents. Based on the applied Friedman´s test, can be identified differences in factor evaluation, confirmed by a statistical calculation of the *p*-value (<0.0001), which is lower than the alpha significance level (0.05).

By using the Nemenyi method and based on the data in Table 1, we conclude that freshness is the most important criterion in the selection of bakery products (Group A), another group of important factors is flavor (Group B) followed by price (Group C). Next group of factors consisted of composition and durability (group D) and the last group of factors is the country of origin (group E). From the obtained results is possible to identify the rationality and irrationality in purchasing the selected type of food. Rational aspects in the purchase of bakery products are factors as composition and durability. The irrationality of consumers' purchasing behavior can be accompanied by psychological factors, which include the perception of freshness of bakery products, perception of the prices, perception of the country of origin, as well as sensory aspects such as taste. On a scale from 1 to 5, respondents rated the prices of bread, common bakery products (such as rolls, buns etc), fine pastry and durable bakery products, where 1 was representing very low prices and 5 very high prices. In the context of the question, we assumed that there was a difference between consumer perception of prices and the different types of bakery products and we confirmed our assumption by calculating the Friedman test (*p*-value = <0.0001). Based on the results of the questionnaire survey (Figure 4) can be concluded that most consumers perceive prices of fresh and durable bakery products as reasonable to high. **Gul et al. (2017)** found that the prices of bakery products are acceptable to consumers and consumers consider bakery products as reasonable and practice food from the point of nutritional importance. For consumers, the price perception is important from a psychological point of view. On the other hand, bread, fine pastry and common bakery products are included in the basic foodstuffs needed for nutrition of the population, which means that if the price of selected foodstuffs increases, their quantity will not change at all or only to a small extent. However, in the context of the above, it is important to note that consumers may tend to look for cheaper products within the range of bakery products, especially durable ones. The last psychological factor that is important for Slovak consumers when purchasing bakery products is the country of origin. Slovak consumers strongly perceive the country of origin when buying bakery products, especially with regard to fresh bakery products where they assume Slovak origin **(Nagyová et al, 2012)**. Consumers involved in the survey prefer the following bakery producers: Penam, a. s., Topoľčianske pekárne a cukrárne a.s., Vamex, a. s., Pekáreň Hochel, s. r. o., Lebeco, s. r. o., pekáreň Čierny

Balog, Slatinská pekáreň, s. r. o., Velapek, s. r. o., Mlyn a Pekáreň Školuda, Kamenica, Podvihorlatské pekárne a cukrárne, a. s., ERI, s. r. o., Pekáreň Gros, s. r. o., Slatinská pekáreň, s. r. o., Pekáreň ILaS, s. r. o., Trenpek, s. r. o., Gevis, s. r. o. Čachtická pekáreň, Pekáreň Beckov, s. r. o., PDP Veľké Uherce, Turpek, s. r. o., Pekáreň Juraj Oremus, s. r. o., Pekáreň Nela, Framipek, s. r. o., Prvá bratislavská pekárenská, a. s., Pekáreň Anton Antol, s. r. o., Faun, s. r. o., CPB, s. r. o., UNI, s. r. o., bakeries of retails Tesco, Billa, Lidl, Kaufland and local and regional bakeries. Gluten-free bakery products are particularly preferred from producers OLZ, Schär and JORDA´NS.

The psychological factors determining the purchase of bakery products, such as perception of freshness, perception of price and perception of the country of origin, may also be influenced by the amount of information available to consumers. Consumers obtain this information most often in stores (44.1%), where they also buy bakery products most often, and are interested in information including the composition, origin, coloring of the bread, production process, additives, production process, baking parbaked products, date of bakery production, time of baking fresh bakery products or reasons for price changes.

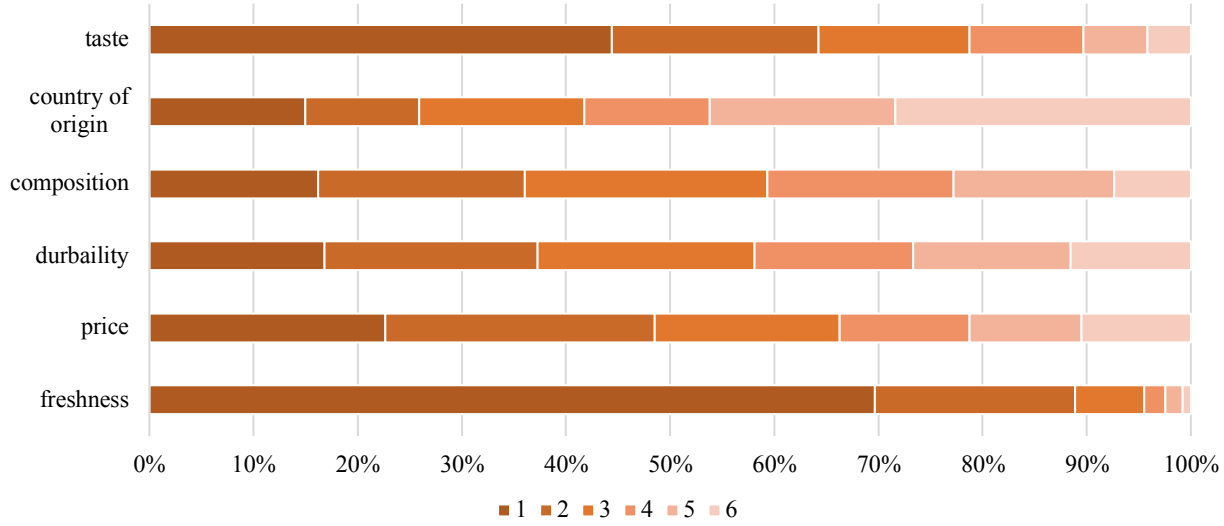

Figure 2 Factors affecting the purchase and consumption of bakery products. Note: questionnaire survey, 2018.

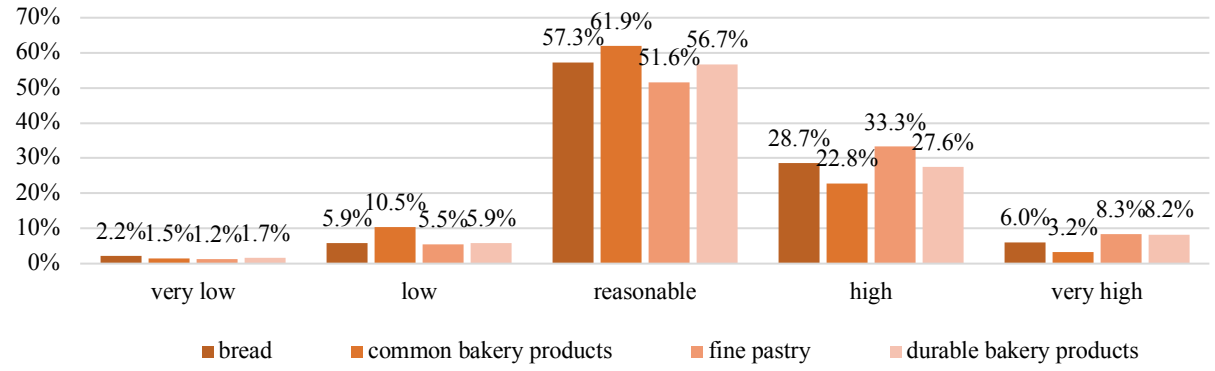

Figure 4 Perception of price of bread, common bakery products, fine pastry and durable bakery products. Note: questionnaire survey, 2018.

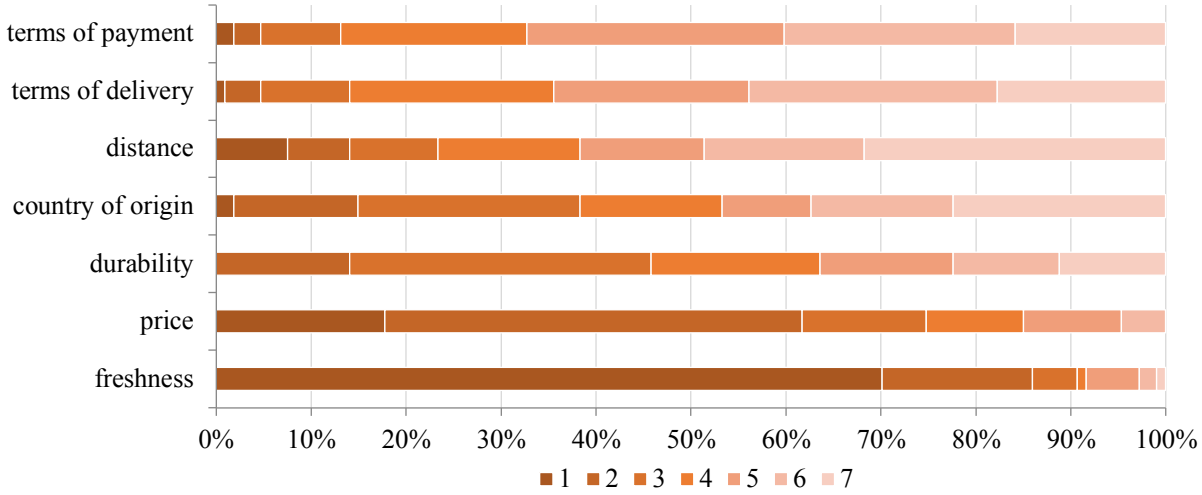

Figure 5 Factors affecting the purchase of bakery products. Note: questionnaire survey, 2018.

The obtained information then influences the perception of freshness, country of origin and prices of specifically selected bakery products by Slovak consumers.

We confronted the results of the consumer survey with the results of a retail-oriented survey. The aim of the retail survey, which also includes bakery products, was to identify the types of offered bakery products, how they approach the factors that determine consumers when purchasing bakery products and the criteria that determine the specific supplier of bakery products, bakery ingredients or frozen semi-finished products (parbaked ones). All retails involved in our survey offer bakery products, with 98.1% of the operations offering fresh bakery products, 73.8% durable bakery products and 45.8% parbaked bakery products.

As the fresh bakery products are the most preferred by consumers, we found out what kinds of these products select retails to their offer. Based on the results of the survey can be concluded that all retails offer bread, while common bakery products are available in 96.3% of retails, and 83.2% of them included in the assortment of fresh bakery products also fine pastry. Retails are trying to adapt to Slovak consumers, as fresh bread and pastries are still an essential part of the day and according to **Tovar&Predaj (2018)**, almost half of Slovak consumers who enjoy absolute freshness and crunchiness of bakery products go shopping for bakery products daily, including weekends.

Regarding the freshness, as an important factor in determining consumer purchasing behavior, we identified that 72% of the surveyed retails buy fresh bakery products from suppliers (bakers), 15% of retails buy raw ingredients from which they subsequently produce fresh bakery products and 13% of retails sell parbaked bakery products as the fresh ones. Consumer demand for fresh bakery products encourages retails to include bakery products that are warm and crunchy at the time of purchase. For this reason, they are increasingly focusing on parbaked products that are finished and baked in the store and arouse interest of customers with their smell, freshness and crispiness **(Retail Magazin, 2016)**.

As the price of bakery products is another important aspect for consumers when buying the bakery products, we were interested in factors that retails consider important in setting prices for selected types of food. Based on the results of the research can be stated that the pricing is mainly due to the prices of raw ingredients, especially wheat, which increased due to the unfavorable climate in our conditions, labor costs related to overnight work and last but not least the costs related to as fuel prices that continue to rise. In the light of the above, it can be stated that the prices of bakery products will have an increasing tendency that retails can not influence and future changes in consumer purchasing behavior are likely to be largely influenced by the amount of disposable income relative to the prices of bread and other bakery products.

The country of origin was identified as another factor determining the consumer's purchasing behavior to a significant extent, therefore we were interested how retails adapt the assortment to Slovak consumers. Research results proved that 98.1% of retails prefer Slovak producers of finished bakery products, raw materials or frozen semi-finished parbaked products. The range of fresh and durable bakery products is dominated by the following Slovak producers: Penam, Topec, Vamex, Oremus, Nella, Smatana, Pekáreň Coop Jednota, Hochel, bakery Chtelnica, Danubia, Vančo, Varipek, Labaš Nowaco, Danubia, Anton Antol, Slatinská pekáreň, Hapeko, Hopi, Duke, Bánov, Mlyn Pohronský Ruskov, Mive and smaller local bakeries. The assortment of frozen semi-finished parbaked products is provided mainly by Minit Dunajská Streda, Alfa R, Radoma Žilina and Ryba Košice, as well as by Polish suppliers. According to **Trend (2019)** and **Tovar&Predaj (2019)**, it is possible to conclude that producers of parbaked goods are doing well, as these bakery products currently account for about 30 – 40% of total baked goods consumption. In 2016, up to 43 thousand tons of parbaked bakery products were imported to Slovakia and approximately another 20 to 30 thousand tons were produced in Slovakia. Retails becomes increasingly oriented towards the purchase of parbaked bakery products, which is less costly for traders. This is also confirmed by **Tovar&Predaj (2019)** and highlights that if a supplier is the bakery, retailer have to order a certain amount of bakery products one day in advance, but the situation in operation is different every day. Accordingly, it may be the case that retail orders too much bread, which it does not sell or does not order enough. The popularity of parbaked bakery products is growing as it can provide hot bakery products throughout the whole day at the store. Retails oriented also on the sale of bakery products strive to meet the requirements of consumers, so they take into account different criteria when selecting suppliers of raw ingredients, finished bakery products and frozen semi-finished parbaked products. The selected criteria – freshness, price, durability, country of origin, distance, terms of payment and terms of delivery were ranked from 1 to 7, where 1 was the most important aspect in the selection of suppliers and 7 the least important aspect in the selection of suppliers. Research results proved that the most important criteria are freshness, price, durability and country of origin, which are also noticed by consumers when purchasing these foods. In the context of this question was established a hypothesis which assumed differences in the evaluation of the above mentioned criteria between individual retails. Based on the applied Friedman´s test, can be identified the differences in the criteria evaluation, confirmed by a statistical calculation of the *p*-value (<0.0001), which is lower than the alpha significance level (0.05).

CONCLUSION

Submitted paper focused on current issues related to the bakery industry in the Slovak Republic with a focus on the purchase and subsequent consumption of individual bakery products, as well as the identification of the main factors that determine it. We described the development trend of the bread and other bakery products consumption, which is influenced mainly by product prices, a wide range of products in retails, as well as constant changes in preferences of consumers and their purchasing behavior. The changes in consumers' eating habits are one of the most important factors affecting the consumption of selected foods. For this reason, we conducted a consumer survey. We found that the most important factors for consumers are freshness, taste, price, durability, composition and country of origin. From these factors it is possible to deduce both rationality and irrationality in the decision-making of Slovak consumers in the purchase and subsequent consumption of selected foods. Rational aspects in the purchase of bakery products are factors of composition and durability. The irrationality of consumers' purchasing behavior can be accompanied by psychological factors, which include the perception of freshness and smell of bakery products, perception of the price, perception of the country of origin, as well as sensory aspects such as taste.

Paper focused mainly on psychological factors. Consumers perceive the prices of bakery products as reasonable, which may also be due to the fact that pastries and products belong to the basic foods that the consumer is used to consuming every day. Freshness is another psychological factor that consumers perceive when purchasing the foodstuffs under review, with up to 78% of consumers being aware of the fact that retail chains fnish parbaked products in their bakeries, which are then included in the assortment of fresh bakery products. 54.5% of consumers even recognize the difference in taste between fresh bakery products and parbaked bakery products, suggesting that taste is a very important sensory aspect determining the purchase and subsequent consumption of chosen bakery products. The last identified psychological factor was the perception of the country of origin, to which consumers place a strong emphasis, as they assume Slovak origin, especially when buying fresh bakery products. We further confronted the results of the consumer survey with the results of a business-oriented survey focused on the sale of bakery products. As consumers are increasingly in demand for fresh and tasty bakery products, retail operations are encouraged to include bakery products that are warm and crunchy at the time of purchase. For this reason, they are increasingly starting to focus on parbaked bakery products that bake in their stores. Another important aspect is the price which can not be largely affected by the retials, mainly due to rising prices of raw ingredients, labor costs or transport costs. Retails offer bakery products mostly of Slovak origin due to the growing demands of consumers watching the country of origin when buying selected foods. The results also proved that the retails, when purchasing finished bakery products or bakery ingredients, take into account, in particular, the freshness, price, country of origin, durability of the bakery products as well as the distance of the suppliers.

DIETARY FIBRE CONTENT IN ETHNIC AND UNCONVENTIONAL VEGETABLES AND FRUITS GROWING IN BANGLADESH

Ruheea Taskin Ruhee, Samia Sams, Amena Begum, Mohammad Khairul Alam, Parveen Begum, Maksuda Khatun, Mahbuba Kawser, Silvia Saberin, Monira Ahsan, Sheikh Nazrul Islam

ABSTRACT
Dietary fibre is known to provide health benefit and protect against degenerative chronic diseases. Thus, the present study reports the total dietary fibre (TDF) content of sixty-nine selected ethnic and unconventional vegetables and fruits growing in Bangladesh. The samples were collected from different locations of Bangladesh and mixed together to ensure sample representativeness. Dietary fibre assay kit according to the AOAC method was utilized for the analysis of TDF in selected vegetables and fruits. In the ethnic varieties, the TDF content ranged from 1.02 ±0.16 to 7.16 ±0.16 g for leafy (LV), 0.18 ±0.01 to 6.71 ±0.49 g for non-leafy vegetables (NLV) and 1.21 ±0.12 to 5.29 ±0.20 g for fruits per 100 g edible portion (EP). In the unconventional items, it arrayed from 3.08 ±0.34 g to 7.75 ±0.13 g for LV and 1.02 ±0.06 to 8.82 ±0.40 g for NLV per 100 g EP. Among the analysed samples, the highest and lowest content of TDF was found in Orohordal and Mairabokong, respectively. The unconventional vegetables contained much higher content of TDF than the ethnics and the commonly consumed similar varieties. Data on TDF content in underutilized vegetables and fruits of Bangladesh is sparse. Thus, the finding of this study would fill up the data gap in the existing food composition table of Bangladesh and also would aware the people to take vegetables and fruits rich in fibres.

Keywords: Bangladesh; dietary fibre; ethnic vegetables and fruits; unconventional vegetables

INTRODUCTION
In the recent years, health benefits of dietary fibre in reducing the risk of many chronic diseases have extensively been addressed **(Venn and Mann, 2004; Streppel et al., 2008; Aune et al., 2011; Jurasová et al., 2011)**. Epidemiological and interventional studies reported that consumption of dietary fibre rich foods such as vegetables, fruits, and whole grains reduce the blood cholesterol, especially, low-density lipoprotein and blood pressure, promote weight loss and improve insulin sensitivity **(Anderson, 2003; Streppel et al., 2008; Ivanišová et al., 2017; Rana et al., 2019)**. Diet implicates the etiology of diabetes and fibre rich diets have low glycemic index and, thus, decrease diabetic incidence **(Meyer et al., 2000; Murtaugh et al., 2003; Venn and Mann, 2004; Kaline et al., 2007; Krishnan et al., 2007)**. Dietary fibre also reduce insulin need, slow down the absorption of sugar and prevent spikes after meals **(Takekawa and Matsumoto, 2012; Kamila et al., 2018)**. Risk of cancers incidence, particularly colon cancer, has also been reported to cut to those who consume high dietary fibre containing foods **(Aune et al., 2011; Dong and Qin, 2011; Alam et al., 2017a, b)**. Intake of high fibre diets also help alleviate constipation **(Dhingra et al., 2012; Stewart and Schroeder, 2013)**. Soluble fibre has been reported to improve immunity, to speed up elimination of toxic waste through the colon and to enhance digestion. They can help treat or prevent overweight or obesity **(Takekawa and Matsumoto, 2012; Kamila et al., 2018)**.

Data on dietary fibre are sparse. Bangladesh does not yet have its own dietary fibre data; some data are being generated for a few common foods. Dietary fibre data for ethnic or unconventional foods have not yet been generated or reported elsewhere. In our present-attempt to prepare a food composition database for Bangladesh with special reference to ethnic foods **(Islam et al., 2010; Islam et al., 2012; Shajib et al., 2013; Alam et al., 2016; Alam et al., 2019; Hossain et al., 2016; Islam et al., 2016; Rana et al., 2019)**, this article reports the analysis of total dietary fibre (TDF) for sixty-nine vegetables and fruits of ethnic and unconventional varieties. Data generated in present study would surely add to and enrich the existing Food Composition Tables and database for Bangladesh **(Islam et al., 2010; Islam et al., 2012; Shaheen et al., 2014)**.

Scientific hypothesis

The content of total dietary fibre was evaluated in different types of leafy vegetables, non-leafy vegetables and fruits consumed by specific tribal community of Bangladesh. We presumed that there exist a significant difference with respect to total dietary fibre, measured by AOAC method, in different indigenous leafy and non-leafy vegetables, as well as fruit species.

MATERIAL AND METHODOLOGY

Reagents

Total dietary fibre assay kit (TDF-100) was purchased from Sigma-Aldrich (Saint Louis, MO, USA). Reagent grade ethanol, acetone, dibasic sodium phosphate, sodium phosphate, sodium hydroxide, hydrochloric acid was procured from Merck (Darmstadt, Germany).

Food samples

This study included analysis of total dietary fibre content for sixty-nine vegetables and fruits of ethnic and unconventional varieties grown in Chittagong Hill Tracts comprised twenty-eight leafy and seventeen non-leafy vegetables and six fruits; and unconventional group consisted of fifteen leafy and three non-leafy vegetables.

Sample plan

Multi-region sampling plan was employed for collection of the food sample. To conform to the representative sample principle- "what the mass people consume' and from where they collect it"? **(Southgate and Greenfield, 2017)**, the ethnic samples were collected from weekly local markets at Rangamati and Bandarban, and the unconventional ones were collected from the specific local areas of Gazipur, Mymansingh and from some places of Dhaka, where they were grown. The samples were collected fresh, which were then water sprayed, packed into auto seal plastic poly bags and brought to the lab where the food samples were processed for analysis of dietary fibre. Depending on the availability, two to three samples were collected for each of the food from every market and growing area. These were then mixed to make three analytes or composite test samples.

Identification of vegetable sample

A taxonomist (Dr. Maksuda Khatun) of the Department of Botany, University of Dhaka, who was also accompanied the collection team, and confirmed the sample identity with name and family. The collected samples are listed in the Table 1a, Table 1b and Table 2. Photographs of some vegetables and fruits are also provided in the Figure 1, Figure 2 and Figure 3.

Sample processing

Each of the collected samples was cleaned with tap water and then rinsed with distilled water, gently swabbed with tissue paper to remove trace of water and air dried. The air-dried sample was diced or cut into small pieces (peeled where needed) using a clean stainless steel knife on a dried clean plastic cutting board.

The diced sample was mixed, and a weighted portion was spread in stainless steel plate(s) and then dried in air-oven at 100 – 105 ˚C to constant weight **(AOAC, 2007)**, which was then milled to 0.3 to 0.5 mm mesh powder. The powdered or milled sample was stored in desiccators for analysis of total dietary fibre.

Analysis of total dietary fibre

The total dietary fibre was estimated by the enzymatic and gravimetric method of the Association of the Official Analytical Chemists **(AOAC, 2007)** using a total dietary fibre assay kit (TDF-100A, Sigma-Aldrich, Saint Louis, USA). The assay procedure as described in the kit was strictly followed. In brief, the dried meshed sample was incubated with α-amylase at pH 6.0 for 15 min at 95 ºC for gelatinization, which was then digested by incubation with protease at pH 7.5 for 30 min at 60 ºC, then with amyloglucosidase at pH 4.5 for another 30 min at 60 ºC to remove protein and starch present in the sample. Ethanol was added in excess to precipitate the soluble dietary fibre.

The residue was filtered and washed with ethanol and acetone; which was then dried overnight in an air-oven until it reduced to constant weight or nearest 0.1 mg. After

drying, half of the sample was analyzed for protein and the other half was burnt to ash.

Total dietary fibre content in the samples was calculated according to the below mentioned formula.

$$TDF\ \% = [(R_{sample} - P_{sample} - A_{sample} - Blank)/SM] \times 100$$

Where: TDF= Total Dietary Fibres, R= average residue weight (mg), P= average protein weight (mg), A= average ash weight (mg), SM= average sample weight (mg), Blank (containing only solvent)= R_{blank}- P_{blank}-A_{blank}. Residues were corrected for protein, ash and blank in final calculation.

Statistical analysis

The analysis was carried out in triplicates. Descriptive statistics were performed and values were expressed as mean ± standard deviation. One-way analysis of variance (ANOVA) was employed to evaluate the differences among varieties for total dietary fibre content and was declared significant when p <0.05 at 5% level of significance. Minitab version 18.0. (Minitab Inc., State College, PA, USA) was used to analyze the data.

RESULTS AND DISCUSSION

Table 3 and Table 4 represent the total dietary fibre contents in the ethnic leafy and non-leafy vegetables and Table 5 and Table 6 represent the total dietary fibre contents in the ethnic fruits, and unconventional leafy and non-leafy vegetables. In the ethnic vegetables, the dietary fibre ranged from 1.02 ±0.16 to 7.16 ±0.16 g per 100 g fresh edible portion (pooled mean ±*SD*: 2.25 ±1.34) for leafy vegetables (Table 3), 0.18 ±0.01 to 6.71 ±0.49 g per 100 g fresh edible portion (pooled mean ±*SD*: 2.75 ±1.64) for non-leafy vegetables (Table 4) and in the ethnic fruits (Table 5), the content varied from 1.21 ±0.12 to 5.29 ±0.20 g per 100 g fresh edible portion (pooled mean ±*SD*: 3.11 ±1.44). Although the combined data for ethnic fruits showed high amount of dietary fibre compared to ethnic leafy- and non-leafy vegetables, but we did not observe any statistical significance. In unconventional vegetables (Table 6), the content ranged from 3.08 ±0.34 to 7.75 ±0.13 g per 100 g fresh edible portion (pooled mean ±*SD*: 5.79 ±1.42) for leafy vegetable and 1.02 ±0.06 to 8.82 ±0.40 g per 100 g fresh edible portion (pooled mean ±*SD*: 4.93 ±3.29) for non-leafy vegetable. Like ethnic vegetables and fruits combined data, unconventional vegetables also failed to show statistical significance between leafy and non-leafy vegetables.

	Non-Leafy vegetables	
67	Rakahlshosha	1.02 ±0.06^{j}
68	Orohordal	8.82 ±0.40^{a}
69	Jam alu	5.19 ±0.22^{gh}

Note: Different superscript letters in each column indicates the significant differences in the mean at p <0.05.

The present study indicates that amongst the vegetables and fruits those were tested, Orohordal contains the highest amount of total dietary fibre (8.82 ±0.40 g per 100 g fresh edible portion).

It was followed by Chimtishak, Telakucha, Betgach, Gondhobatali, Muktajhuri, Orhorpata, Oraibalai, Roktodrone, Tetulpata, Bondhonia, Sornolota, which also contain rich amount of dietary fibre ranging from 7.75 ±0.13 to 6.12 ±0.36 g per 100 g fresh edible portion. The other vegetables such as Jolpaipata, Jonglaam, Jamalu, Missayanu, Shimeful, Mulachi, Bonpalong, Titbegun, Vennapata, Rosko, Betagi, Kochi aampata, Sakumubakla also contain a high amount of TDF (5.74 ±0.06 to 4.06 ±0.30 g per 100 g fresh edible portion). For leafy vegetable, the lowest TDF was present in Simeialupata (1.02 ±0.16 g per 100 g fresh edible portion). Among the fruits, Jongliaam or Bonaam has the highest amount of TDF (5.29 ±0.20 g per 100 g fresh edible portion), followed by Rosko (4.38 ±0.46 g per 100 g fresh edible portion) and Jonglikola (3.06 ±0.09 g per 100 g fresh edible portion).

The study findings also indicate that the unconventional vegetables contain higher amount of total dietary fibre (5.65 ±1.85 g per 100 g fresh edible portion) as compared to the ethnic vegetables (2.52 ±1.48 g per 100 g fresh edible portion). In case of most food items, the content of dietary fibre in ethnic vegetables was found to be, somewhat, comparable to that of commonly consumed vegetables in Bangladesh **(Islam et al., 2010; Islam et al., 2012; Shaheen et al., 2014; Alam et al., 2016; Rana et al., 2019**) as well as in India **(Longvah et al., 2017)** and elsewhere **(Dhingra et al., 2012)**. From Table 5 it can be seen that, among ethnic fruits, Rosko, which looks like Plum or Black berry, was found to contain much higher amount of dietary fibre (4.38 g per 100 g edible fresh) than the Plum (2.80 g per 100 g edible fresh) or higher than or similar to the Black berry (3.50 or 4.35 g per 100 g fresh edible portion) **(Islam et al., 2012; Longvah et al., 2017)**.

Similarly, Jongliaam and Joglikola were found to contain higher amount of dietary fibre (5.29 and 3.06 g per 100 g fresh edible portion respectively) as compared to the mango (3.65 or 1.5 g per 100 g fresh edible portion) and banana (1.90 or 2.6 g per 100 g fresh edible portion) **(Islam et al., 2010; Islam et al., 2012; Shaheen et al., 2014)**.

In the ethnic Mulachi and Green Chilli, the total dietary fibre was found to be almost same (4.74 vs 4.90 g per 100 g fresh edible portion). The recommended dietary intake (RDI) of TDF for an adult human is 30 – 38 g per day and the consumption of these ethnic and unconventional vegetables and fruits can contribute up to 30% of RDI of TDF.

CONCLUSION

Some of ethnic vegetable and fruits such as Gondhobatali, Oraibalai, Shimeful, Rosko, Betagi, Kochi aampata, Jongliaam and most of the unconventional vegetables were found to contain rich amount of total dietary fibre. The findings of present study would encourage people to adapt dietary diversity. Cultivation and regular intake of plant foods rich in fibre might reduce the risk of many diseases. It would also go a long way in filling up the data gap that exists in food composition database for Bangladesh.

FEEDING AND WEANING PRACTICES AMONG MOTHERS OF UNDER-FIVE CHILDREN IN SELECTED PRIMARY HEALTH CARE CENTRES IN ADO-EKITI, EKITI, NIGERIA

Oluwaseyi Akpor, Tunrayo Oluwadare, Omotola Taiwo, Bukola Aladenika, Oghenerobor Akpor

ABSTRACT

An appropriate diet is necessary in the growth and health status of children especially in the first two years of life. This study determined the feeding and weaning practices among mothers of children below the age of five years in two selected Primary Healthcare Centres in Ado-Ekiti, Ekiti State, Nigeria. The study design was descriptive and cross sectional using an interviewer-administered questionnaire, 200 mothers who were purposely selected participated in the study. Statistical Package for Social Sciences was used for data analysis. Findings from the study revealed that the main practice of feeding of infants was breastfeeding, the majority of the mothers started to wean their children at about 6 – 7 months. Also, the major type of weaning practiced by mothers was abrupt weaning, majority of the mothers had good knowledge of feeding and weaning including how beneficial exclusive breastfeeding is, though it is just a few of them that practice exclusive breastfeeding. Therefore, complementary feeding education that will involve the use of various media most especially the primary health facilities is paramount for optimal health of infants. Also teaching should focus on the type of weaning and mothers should be educated on the consequences of abruptly weaning a child.

Keywords: feeding; weaning; mothers; break-feeding; complementary feeding

INTRODUCTION

Weaning is the process of gradually introducing an infant to adult foods while gradually withdrawing breast milk. The child is not abruptly taken off breast milk, the process of weaning should be started after the age of 6 months and natural weaning happens as the infant starts to accept increasing amounts and different variety of complementary feedings although still breastfeeding on request **(Mohammed, 2014; Ogunsuyi, 2016)**. Weaning is traditionally described as withdrawal from breast feeding i.e. when breast feeding is gradually replaced by semisolid food. The shift from exclusive breastfeeding to family foods is referred to as complementary feeding and complementary feeding is defined by World Health Organization (WHO) as the addition of energy as well as non-energy containing fluids, non-human milk and semi-solids or solids to children's diet which covers the time from 6 months to 18 – 24 months of age **(WHO, 2002; Chaudhry and Humayun, 2007)**.

The weaning period, which usually corresponds with the eruption of the child's major dentition implies that the child is ready to chew **(Aliyu et al., 2019)**. The weaning period is a very susceptible period, since it is the point in which malnutrition set offs in many infants. Infants are predisposed to malnutrition as a result of poor quality of weaning foods, improper feeding and weaning practices, which can also predispose the infants to growth retardation, infectious diseases and high mortality rate **(Rahul, Mohd and Rakesh, 2014; Mohammed, 2014)**.

It is indicated that poor infant feeding and their consequences are one of the world's major problems and a serious obstacle to social and economic development. During the first two years of life, poor feeding practices and weaning practices have both instant and long-standing consequences. Inappropriate feeding of infants has long been observed in our society to be one of the global problems responsible for about one-third of the cases of malnutrition worldwide **(Anoshirike et al., 2014)**. According to **Mohammed (2014)** about ten million children below the age of 5 years old die annually and more than half of the deaths occur because of malnutrition.

In Nigeria, complementary foods are usually semi-solids and they differ in homes but most homes use maize based cereal **(Aliyu et al., 2019)**. Due to introduction of westernized food and other factors like the advertising tactics taken up by most food and beverage companies and the readily preparation of most of these foods, these factors may influence the feeding practices like reducing the age of initiation of complementary feeding and early cessation of breastfeeding. Due to the high prevalence rate of malnutrition, there will be a burden on the economic

development because huge amount of money will be spent towards treating these children **(Aliyu et al., 2019)**.

Among preventive measures that would reduce the excess mortality for children under the age of five years, good quality complementary feeding, proper breastfeeding and complementary feeding practices have been listed as part and about 19% of this death can be prevented **(Kavitha, Nadhiya and Parimalavalli, 2014)**. Improved breastfeeding practices and reduction of artificial feeding is reported to save an estimated 1.5 million children a year **(Bhanderi and Choudhary, 2011)**. This study therefore investigated the feeding and weaning practices among mothers of under five children in selected Primary Health Centres in Ado-Ekiti Local Government Area of Ekiti State, Nigeria.

The theoretical framework for this study is the Health Belief Model (HBM), which is a psychological model that endeavours to describe and forecast human behaviours **(Janz and Becker, 1984)**. The HBM is an intrapersonal theory used in health promotion to design intervention and prevention programs, it is based on personal beliefs or perceptions about a disease and the schemes available to diminish its occurrence. The model proposes that people's viewpoints about health problems, perceived benefits of action and barriers to action, and self-efficacy enlightens commitment or lack of commitment in health promoting behaviour. A motivation, or cue to action must be present in order to set off the health-promoting behavior (Figure 1).

For the purpose of this study five concepts of the Health Belief Model are used. This study is based on the feeding and the weaning practices of mothers of under-five children; it involves the practices adopted by mothers to feed their children, the timing of feeding and weaning, and also the food used. Therefore, these concepts will explain how the theory is related to the study. The Health Belief Model is a framework for motivating people to take positive health actions that uses the desire to avoid a negative health consequence as the prime drive. For example, inappropriate feeding and weaning has many negative health consequences, and the desire to avoid the consequences can be used to motivate mothers into practicing safe and appropriate feeding and weaning.

Perceived severity is described as the severity an individual attach to a disease which can be as a result of the beliefs a person has about the complications that can arise as a result of the disease or its outcome on his or her health, in this case on the child's health. The main component of infant feeding is breast feeding; studies have shown that infants who are not exclusively breastfed develop some long-term medical consequences. If mothers understand the degree of health challenges that may occur due to inappropriate infant feeding and weaning, it is likely they will change for the benefit of the health of their child.

After understanding the severity of the illness that may likely occur i.e. malnutrition, mothers tend to engage in health promotion and illness prevention. And for those that are already affected they tend to find solutions before it is too late.

Perceived benefits involve one's opinion of how useful an action is in reducing the risks of developing a disease. In relation to this study, the perceived benefits include, benefits of breast-feeding, benefits of other options of infant feeding and of weaning, for example, it is

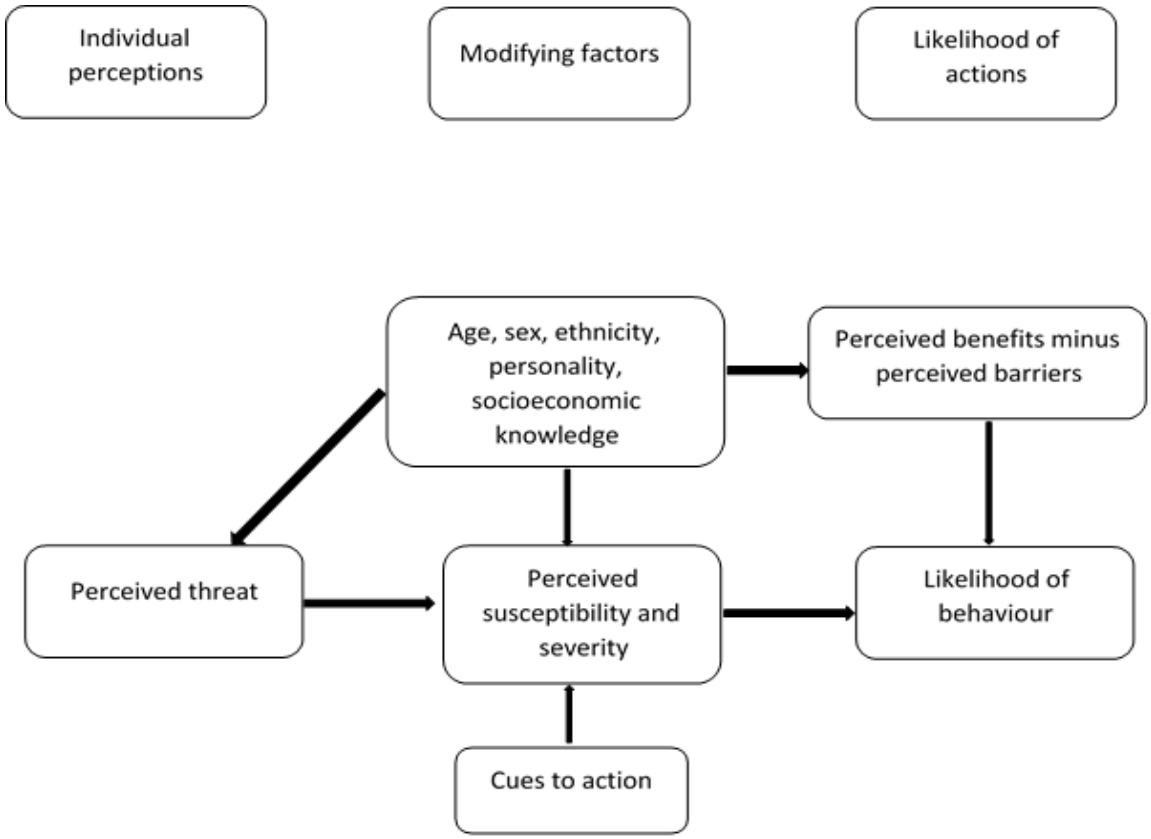

Figure 1 Diagrammatic representation of the health belief model **(Glanz, Rimer and Lewis, 2002)**.

advantageous to give thick porridge to infants above 6 months because they provide a lot of energy to the infant. Also, if a mother knows the benefit of breastfeeding for both her and her child, she is more likely to practice it. Most women do not practice the appropriate infant feeding and weaning because they are ignorant of the health risks associated, therefore, adequate enlightenment will go a long way in helping them.

Perceived barriers are the perceived obstacles that prevent an individual from taking a particular health action. It is a way of an individual assessing the barriers that will prevent him or her from adopting the new lifestyle.

There are so many obstacles encountered by women during the period of breast feeding that prevents the practice of exclusive breast feeding such as husband refusal, painful nipple, infants' refusal to suck and career. These obstacles might prevent the woman from achieving the new lifestyle, encountering difficulties with breastfeeding may cause a woman to wean her child off breast milk earlier than recommended or expected. Poverty is also a major obstacle to good weaning practices as it affects the quality and quantity of food fed to infants. Other barriers in relation to this study include, lack of education, tradition and lack of social support.

Cues to action is always essential for commitment in health promoting activities; it indicates one's willingness to assess a health facility. People who are at risk of a disease, after seeing public display on the condition tend to remember they have appointment with a medical practitioner, alarms, and reminders can also be used to keep to date. Psychological cues such as pain also serves as a reminder. The cues to action in this study include health education and counseling by the nurse. The nurse acts as a teacher, counselor and communicator to the woman which helps to promote the performance of health related behaviours such as the practice of exclusive breastfeeding.

Scientific hypothesis

Hypotheis 1: There is no significant relationship between respondents' level of education with feeding and weaning practices.

Hypothesis 2: There is significant relationship between respondents' age with feeding and weaning practices.

MATERIAL AND METHODOLOGY

Study design and setting

The study design was descriptive and cross sectional. Purposive sampling technique was used to select two Primary Health Care centres in Ado-Ekiti Local Government Area of Ekiti State, Nigeria. To maintain anonymity, the PHC were referred to as 'PHC A' and 'PHC B'.

The 'PHC A' is made up of a waiting room, examination room, labour ward and an admission ward. The services rendered in the Centre include antenatal services, delivery, circumcision, family planning, treatment of childhood diseases and immunization services. It is operated by four registered nurses and fifteen community health extension workers (CHEWS) with an average patient patronage of 744 per month.

The settings for 'PHC B' was similar to PHC A with five registered nurses and fifteen CHEWS. Services rendered in the clinic include, family planning, antenatal clinic, delivery, circumcision, treatment of childhood diseases, infant growth monitoring and immunization services. It has an average monthly patient patronage of 132.

Study population, sampling technique and sample size. The target population for this study comprised of women in the selected PHC centres whose confinement was not more than five years to avoid recall bias. Inclusion criteria included attending one of the selected PHC centres, have children below the age of five years who are being fed (bottle feeding or breastfeeding) or weaned. Potential participants had to be willing to participate in the study.

Purposive sampling technique was used to select 238 mothers that participated in the study while only 200 mothers returned fully completed questionnaire. The sample size was calculated, using the Fischer's formula for descriptive study. Although the calculated sample size of 217 and obtained, deliberate over-sampling was done to the tune of 10% (21.7) to make up for incomplete responses. Therefore, a sample size of 238 was used but only 200 questionnaires were fully completed.

Instrument and data collection

A semi-structured interviewer-administered questionnaire was used for data collection. The research instrument was developed by checking previous articles done on weaning and feeding practices and deducing questions from most of them. The questionnaire was divided into four sections, sections A and B contained the demographic data and the feeding practices applied by the participants, respectively. Section C assessed the weaning practices and foods used in weaning off the children, while Section D assessed the knowledge of mothers on feeding and weaning. The questionnaire was written in English language and participants were informed about the purpose of the study. Furthermore, pre-testing of the questionnaire was carried out using five participants that had similar characteristics with the study population but the findings were not included in the final data.

Mothers of children below the age of five were asked to participate in the study during their visit to the health care centres for ante-natal and post-natal services (booking, immunization) or family planning. Data was collected from March to April 2017. Guidelines for completion of the questionnaire was explained to the participants, questionnaires were collected and collated.

Ethical consideration

Before the commencement of the study, the research proposal was submitted to the Research and Ethics Committee of Afe Babalola University, Ado-Ekiti (ABUAD) for reviewed and permission to conduct the study was given. Likewise, an official letter was written to the two selected PHC centres and permission letters were obtained from the facility managers. Prior to data collection, each participant's right was explained and inform consent were obtained. The participants were assured that information provided will not be used against

them, no remuneration was offered and they were informed of the opportunity to withdraw at any stage of the research.

Statistic analysis

Data analysis was done with the aid of Statistical Package for Social Sciences (SPSS) version 20 and Microsoft Office Excel (2016) to generate figures and graphs. Descriptive statistics such as frequencies, percentages, mean were presented on tables, or charts.

RESULTS AND DISCUSSION

Socio-demographic characteristics of participants

With respect to the socio-demographic characteristics of participants, of the 200 participants, 50.5% of them were between the ages of 31 – 40. A total of 70.5% of the mothers were married. The vast majority (48.0%) of the mothers have 2 children, with only 1.0% of them having six children. Over 40% of the mothers had at least secondary school education (Table 1).

Feeding practices of participants

As shown in Table 2, more than half of the respondents (59.5%) fed their infants at least 6 times a day, 88.0% of the mothers breastfed their children and 63.0% did not give their children anything to drink other than breast milk in the first 3 days after delivery. Of the 37.0% of mothers who gave their infants anything other than breast milk in the first 3 days after delivery, more than half (54.1%) gave their baby glucose water.

Most mothers (60.0%) gave their children only breast milk and the minority. Almost half (42.0%) of the mothers fed their children with only breast milk till when they were 5 – 6 months, and 61.0% of the children were satisfied with only breast milk in the first 6 months.

Table 1 Socio-demographic characteristics of the participants.

Socio-demographic data		Frequency (n = 200)	%
Age distribution	20 – 30	77	38.5
	31 – 40	101	50.5
	41 – 50	22	11.0

Sex of infant	Male	87	43.5
	Female	113	56.5
Monthly income	5000	38	19.0
	6000 – 1 000	62	31.0
	11000 – 20000	52	26.0
	21000 – above	48	24.0

Table 2 Feeding practices of participants.

Feeding practice		Frequency	%
How many times do you feed your infant per day	3 Times	16	8.0
	4 Times	20	10.0
	5 Times	45	22.5
	6 Times	119	59.5
Feeding is usually?	On demand	120	60.0
	On schedule	41	20.5
	Whenever I feel like	39	19.5
Feeding method practiced	Breastfeeding	176	88.0
	Bottle feeding	8	4.0
	Spoon and cup	16	8.0
Anything to drink other than breast milk in the first 3 days after delivery?	Yes	74	37.0
	No	126	63.0
If YES, what?	Plain water	16	21.6
	Glucose water	40	54.1
	Powdered milk	12	16.2
	Infant formula	6	8.1
Which one of these milk feeding did you practice?	Breast milk only	120	60.0
	Breast milk with water	48	24.0
	Breast milk with other foods	24	12.0
	Any food available	8	4.0
How many months did you feed with only breast milk?	1 – 2 months	48	24.0
	3 – 4 months	46	23.0
	5 – 6 months	84	42.0
	6 – 7 months	22	11.0
Was your baby satisfied with breast milk in the first 6 months?	Yes	122	61.0
	No	78	39.0
How many months did you breastfeed in total?	6 months	121	60.5
	1 year	38	19.0
	1 year and above	31	15.5
	2 years and above	10	5.0
Do you practice night feeding?	Yes	162	81.0
	No	38	19.0
How frequently do you feed the child at night?	2 times	52	32.1
	3 times	41	25.3
	4 times	6	3.7
	On demand	63	38.9

Majority (60.5%) of the mothers breastfed for about 6 months, also vast majority (81.0%) of the mothers practice night feeding and close to one- third (38.9%) of the night feeding was on demand.

Weaning practices of the participants

As revealed in the study, more than one- third (39.5%) of mothers weaned their child within the age range of 6 – 7 months which is also the same age most of the mothers stopped breastfeeding their children. Close to half (44.0%) of the participants weaned their children because they had reached the weaning age, while 44.0% weaned their child off breast milk abruptly. Pap and milk (64.0%) were the food used the most by mothers during the period of weaning (Table 3).

The use of bitter substance (39.0%) was used by mothers the most as a method to take their child off breastmilk. More than half (57.5%) of the mothers gave their weaning food with a spoon and cup. A high percentage (70.0%) of the children was not selective of weaning food, 71.0% of the mothers responded that the weaning method affected the baby's weight. Majority (88.5%) of the mothers did not take drugs when they were pregnant (Table 3).

Knowledge on feeding and weaning practices

As shown in Table 4, about half (51%) of the mothers obtained their knowledge on feeding and weaning of their infants from health care workers and 82% of the mothers were familiar with the right meaning of exclusive breastfeeding (Table 4).

Almost half (51%) of the participants indicated that their knowledge on breast feeding was shown to have come from health workers (Figure 2). Generally, a vast majority (70%) of the participants were observed to have ideal knowledge of breastfeeding and weaning (Figure 3).

The majority of mothers in the study breastfed their children for at least six times daily, and breastfeeding was given for about six months in total.

Table 3 Weaning practices of participants.

Weaning practices		Frequency	%
At what age did you wean your child?	6 – 7 months	79	39.5
	8 – 9 months	66	33.0
	10 – 12 months	55	27.5
Reason for weaning child	Reached weaning age	90	45
	Not enough milk	22	11
	New pregnancy	4	2.0
	Mother/father's desire	60	30.0
	Return to work	24	12
Type of weaning practiced	Sudden	88	44.0
	Gradual	50	25
	Natural	36	18
	Mother led	26	13
Food used for weaning	Home-made food	28	14
	Ready prepared food	6	3
	Family food	82	41
	Infant formula	84	42

This study agreed with the findings of **Akeredolu et al. (2014)** and **Olatona, Odozi and Amu (2014)**, who asserted in their studies that majority of the mother's breastfed their children. In a related study, **Katepa-Bwalya et al. (2015)**, it was also observed that majority of mothers breastfed their children for varying periods of time. As revealed in the study, of the majority that practiced breastfeeding, only few (14.7%) breastfed exclusively. This is similar to the findings of **Mohammed (2014)** and **Katepa-Bwalya et al. (2015)**, where only 30.1% and 6.8% of mothers practiced exclusive breastfeeding respectively. Despite the fact that breast feeding is known to be a highly recommended and beneficial way to feed infants as it provides psychological and health benefit to both the mother and the child. Globally there has been a common decline in the practice of breastfeeding both in terms of occurrence and interval in the past few decades **(Berra, 2013)**.

The study further revealed that about 40.0% of the mothers in addition to breastfeeding included complementary foods for their children at 4 – 6 months of age. This contrast with the results obtained from some studies conducted in South-West, South-South and North-West regions of Nigeria where 76.7%, 79.9% and 80.1% respectively introduced complementary feeding before the expected 6 months of age **(Akeredolu et al., 2014; Osie-Efetie, Oyibo and Okperi, 2011; Matthew et al., 2009)**.

When breast milk is no longer adequate to meet the nutritional needs of the infant, complementary foods should be added to the diet of the child **(Kavitha, Nadhiya and Parimalavalli, 2014)**. Proper breastfeeding practices are effective ways for reducing childhood morbidity and mortality. While many mothers understand the significance of breastfeeding, others are less informed on the benefits of breastfeeding and weaning. **Anoshirike et al. (2014)** stated that, malnutrition in Nigerian infants is found to be as a result of inappropriate child feeding practices such as late introduction of complementary foods, small energy and nutrient density of foods offered, feeding in little quantity at meals, food limitations due to cultural beliefs, low birth-weight and high morbidity.

Hypothesis testing

Hypothesis 1:

From the chi-square test (Table 6), the null hypothesis of no significant relationship between respondents' level of education and deeding and weaning practices is rejected. Consequently, the alternative hypothesis of a significant

relationship between respondents' level of education with feeding and weaning practice accepted (Table 5).

Hypothesis 2:

As shown in Table 2, there was no significant relationship between respondents' age and feeding and weaning practices, hence the null hypothesis of a significant relationship between respondents' age with feeding and weaning practices was rejected (Table 7 and Table 8).

Adequate nutrition during infancy and early childhood is essential to ensure the development, health, and growth of children to their full potential. As stated by **Mohammed (2014)**, gradual weaning period should be introduced first which allows the child to receive the benefits from breastfeeding while also consuming necessary nutrients from complementary foods. This is contracts with the result obtained in this study where about 45% of mothers abruptly weaned their children from breast milk. According to **Razia and Naheed (2007)**, complete weaning can be introduced at about 2 – 4 years of age, and this is the total withdrawal from breast milk. The findings of the study showed that 39.5% of the mothers weaned their children at about 6 – 7 months and 45% of mothers weaned because they were of the opinion that the child is old enough. This is similar to the results obtained by **Kikafunda, Walker and Tumwine (2003)**, **Mohammed (2014)**, **Olatona, Odozi and Amu (2014)** and **Ogunsuyi (2016)**, where 42%, 91.6%. 48.4% and 55.6% respectively started the weaning process between ages 4 – 6 months. Feeding and weaning are important components for the physical and psychological well-being of a child. Feeding a child which involves breast feeding is a complex approach while weaning is a critical approach. According to **Kavitha, Nadhiya and Parimalavalli (2014)**, displacement of breast milk and increased risks of infections such as diarrhoea which further contributes to weight loss and malnutrition can be as a result of untimely introduction of complementary feeds before the age of six months. Thus, it is important that weaning should be gradual and not done abruptly. In addition, the findings revealed that during weaning, homemade food, infant formula and family food were given to the infants by the mothers.

The present study revealed that the majority of participants had good knowledge (70%) on feeding and weaning of their infants, with most indicating their knowledge came from the information provided by health workers. Poor infant feeding and their consequences are one of the world's major problems and a serious obstacle to social and economic development, therefore adequate knowledge on the feeding and weaning practices of the children is very essential. Nurses can assess the knowledge of mothers attending post-natal clinic towards feeding and weaning, certain educational programmes can be conducted for the mothers based on the needs which will help improve the mother's knowledge regarding feeding and weaning. Since health care workers serve as a strong means of disseminating health information to the community; they too need to be abreast of information **(Kambli, 2012)**.

CONCLUSION

This study assessed mother's feeding practices, their weaning practices and also their knowledge on the feeing and weaning practices. The findings from the result showed that the vast majority of the mothers have good knowledge about feeding and weaning of their infants.

The practices of mothers on the feeding of their children were good based on the fact that breastfeeding was the major practice by mothers and also the knowledge of mothers on feeding and weaning their children was good. Specifically, the results of this study provide a baseline data on the importance of establishing standard indigenous nutrition education programme for mothers of young children in Nigeria. Emphasis should be placed on including pregnant women and women of child bearing age as the target audience. This will facilitate the mothers understanding of nutrition which will in turn enhance the feeding practices and nutritional status of their children. There is need concerning health education program aimed at educating mothers on commencement of breastfeeding within one hour after birth, exclusive breastfeeding till six months of age and the value of night feed and the benefits of giving infants colostrum.

AUTHENTICATION OF WISTAR RAT FATS WITH GAS CHROMATOGRAPHY MASS SPECTOMETRY COMBINED BY CHEMOMETRICS

Any Guntarti, Ibnu Gholib Gandjar, Nadia Miftahul Jannah

ABSTRACT
Indonesia is a country with the largest Muslim population in the world, which is very concerned about halal food. The most problem that's very concerning nowadays was that food products were contaminated by unclean meat, such as rat meat. The purpose of this study was to authenticate rat fat using Gas Chromatography-Mass Spectrophotometry (GC-MS) combined with chemometrics. In this study, rat fat were heated in oven at 90 °C – 100 °C for approximately one hour until the oil came out. After that, the derivatization process was carried out to convert fat into methyl ester compounds using NaOCH3 and BF3. Methyl ester compound than injected into the GCMS instrument system. In addition to rat fat, other fat extraction were carried out, such as pigs, cows, chickens, wild boars, dogs, and goats. The combination of chemometrics Principal Component Analysis (PCA) was used to classify rat fat with other animal fat. Based on the results of the study showed that fatty acids in rats using GCMS produced 6 types of fatty acids, namely: myristat (0.15 ±0.09%), palmitoleate (0.73 ±0.54%), palmitate (19.08 ±3.54%), linoleate (30.14 ±16.90%), oleate (40.48 ±2.74%), and stearate (2.55 ±0.01%). Total content of rat fatty acids was 93.13%, with unsaturated fatty acids 71.35% and saturated fatty acids 21.78%. Chemometrics PCA from rat fat can be grouped with other animal fats.

Keywords: chemometrics; food; GC-MS; halal; PCA; Wistar rat fat

INTRODUCTION
Food is a basic human need, therefore food availability needs serious attention both in quality and quantity. Indonesia is a country with a Muslim majority of 207.2 million with a presentation of 87.18% in 2010 out of a total population of 237 million **(Muslim and Purwanto, 2013)**. In addition to food safety factors, the halal factor of a food product must also be of concern to the Muslim community. At present the awareness of the Muslim community to consume halal food increases along with the awareness of the Muslim community following Islamic laws **(Rohman et al., 2016)**. Along with the increase in people's income, the demand for meat consumption in various regions of Indonesia has increased. The price of basic ingredients which are quite expensive such as chicken meat, makes many producers mix it with meat which is relatively cheaper, one possibility is to use rat meat **(Guntarti and Prativi, 2017)**. Rat meat is a meat that is quite easy to obtain, even it can be obtained free of charge. Some media also reported the adulteration of beef meatballs with rat meat **(Lumakso et al., 2015)**. Examples of several cases on the market are forgery of chicken nuggets from pork, and nuggets from recycled materials **(Sari and Guntarti, 2018)**. Based on this, it is also feared that counterfeiting of processed chicken products using rat meat will also occur in Yogyakarta. Laboratory tests to determine fatty acid markers in the form of methyl esters in rats include using gas chromatography-gas spectrophotometry combined with chemometrics. This technique has been used in a variety of analyzes, such as food and pharmaceutical products **(Ronggo et al., 2007)**.

The chemometric method is one way to obtain important information about certain objects in the data by using statistical or mathematical techniques. The most commonly used types of chemometrics are (1) grouping techniques, such as Principle Component Analysis (PCA) and (2) quantitative analysis techniques with multivariate calibration, such as Partial Least Square (PLS).

Scientific hypothesis
The hypothesis in this study is that methyl esters from wistar rat animal fat can be analyzed using the Gas Chromatography Mass Spectrometry (GCMS) method. The methyl ester data combined with chemometrics is able to classify types of fat.

MATERIAL AND METHODOLOGY
Fat samples
Samples in the form of pork, beef, dog, goat, wild boar, chicken were obtained from the traditional market, Wistar white rats were obtained from other researchers' carcasses, the fat was taken. Materials used *n*-hexane (technical),

$NaOCH_3$ 0.2 N solution (E-Merck, pro-analysis quality), BF_3 solution (E-Merck, pro-analysis quality), saturated NaCl and anhydrous Na_2SO_4 (E-Merck, pro-analysis quality) **(Rohman and Che Man, 2011; Kumar et al., 2014)**.

Tools

GC-MS distributor from Ditek Jaya, Merck Shimadzu, Japan, type GCMS-QP2010 SE. The column used was Rtx-5ms, DB1-MS Restech, 30 m x 0.25 mm ID, 0.25 µm, stationary phase of polymethyl xiloxan, injector temperature of 230 °C, column temperature of 70 °C and increased to 300 °C with an increase of 10 °C.min^{-1}, and flow rate of 1.15 mL.min^{-1}. The mobile phase of Helium gas. MS Detector *Electron Multifier Detector* (EMD) 70 MeV. The mass spectrum was compared to the WILLEY147 & NIST47 library found in the GC-MS software. The methyl ester was injected as much as µL into the GC column in a manner of autosampler.

The Research Progress

Fat Extraction

Intake of fat was done by rendering at a temperature of 90 – 100 °C for approximately one hour in the oven. The resulting fat was then added with anhydrous Na_2SO_4 and then centrifuged at 3000 rpm for 20 minutes **(Rohman et al., 2012)**. The solution was stored in the refrigerator at -20 °C in a rolling test tube. The solution was used for the derivatization process.

Derivatization

Fat derivatization aims to convert fat into a form of fatty acid methyl ester by using NaOCH3 0.2 N and BF_3 solution. Derivative products containing fatty acid methyl ester derivatives (FAME) were taken and injected into the gas chromatograph system. A total of 1µL supernatant was injected into gas chromatography-mass spectrometry, replicated two times.

Statistical analysis

The results of the analysis in the form of a mass spectrum were compared with the WILLEY147 & NIST47 libraries contained in the GC-MS software. Data obtained from GC-MS was fatty acids in the form of methyl esters. The content of methyl esters of fatty acids from each animal fat was grouped using chemometrics PCA with minitab 16.

RESULTS AND DISCUSSION

Fat Extraction

Rendering extraction to obtain rat fat. The advantages of this method are that there are many extract yields, easy and inexpensive processing because it does not involve chemicals **(Rohman et al., 2016)**. The yield of 16.36%. The yields are influenced by the intake of food from the rats themselves, body fat taken, and the way the fat is extracted **(Lobb and Chow, 2007)**. The obtained lipid fraction was then carried out by the esterification process. The esterification reaction aims to convert the fatty acids into their methyl ester forms. The esterification process is carried out using BF_3 as a catalyst. BF_3 is an acidic compound **(Purbasari and Silviana, 2008)**. Figure 1 is a process of the esterification mechanism and the product of methyl ester is obtained.

Fatty Acid Composition in Wistar Rat.

Analysis of methyl esters from Wistar rat derivatization using gas chromatography-mass spectrometry (GC-MS) method. This instrument is a combination of gas chromatography with a mass spectrometer detector. Gas chromatography is used for the separation of fatty acid content in the form of methyl esters. In addition to the retention time (tR) of the separation results in gas chromatography, there is similarity index (SI) information to determine the proximity of the chemical structure of the type of fatty acids. The result of SI >90 shows the similarity of mass ion overflow to the target spectra/fat sample.

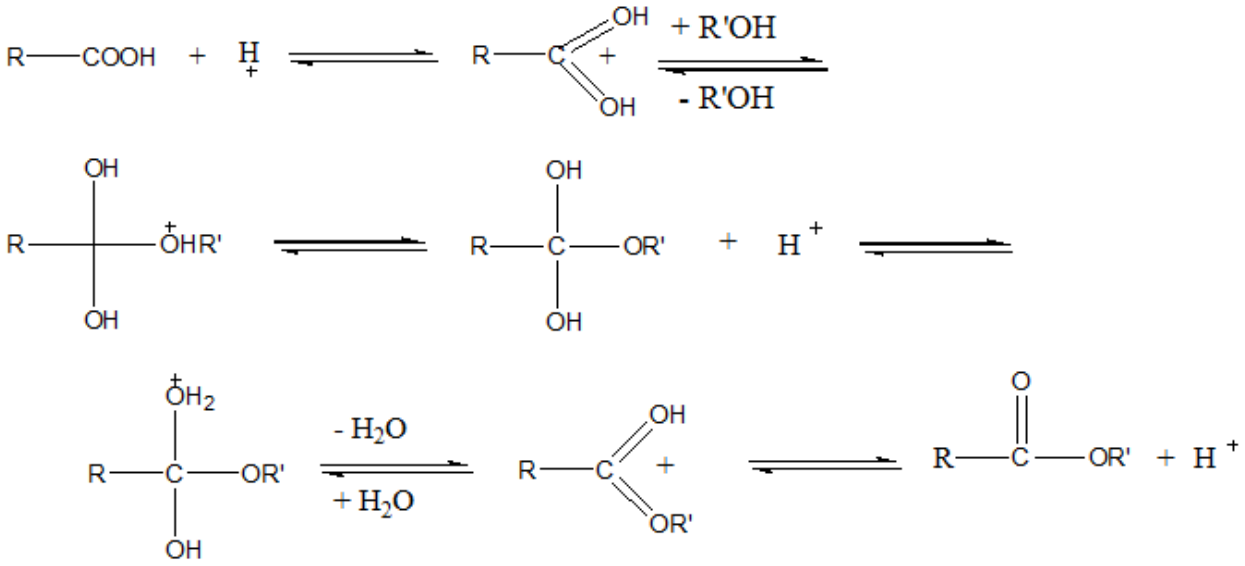

Figure 1 The Process of Esterification Reaction Mechanisms with Methanol and using Acid Catalysts (adapted from **Purbasari dan Silviana, 2008)**.

Table 1 Separation results and identification of compounds in Wistar rat fat with GC-MS.

Number	t_R (min)	% Area (x ±*SD*) (n = 2)	SI	MW	Compound Name
1	17.75	0.15 ±0.09	95	242	(C14:0) Methyl Myristate
2	20.34	0.73 ±0.54	96	268	(C16:1) Methyl Palmitoleate
3	20.81	19.08 ±3.54	96	270	(C16:0) Methyl Palmitate
4	25.60	30.14 ±16.90	86	284	(C18:2) Methyl oktadekadienoat/linoleate
5	25.93	40.48 ±2.74	88	296	(C18:1) Methyil Oleate
6	26.51	2.55 ±0.01	97	298	(C18:0) Methyl Stearate

Note: SI= *Similarity Index*, MW= Molecular weight.

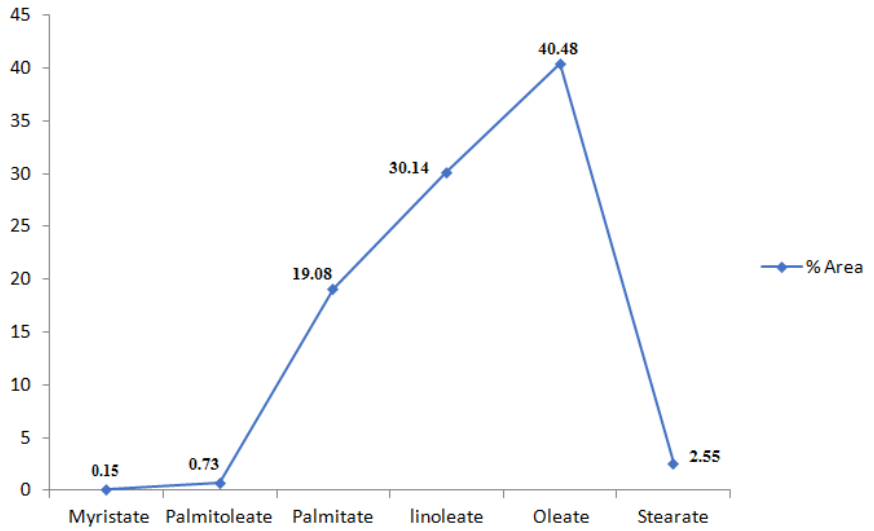

Figure 2 Line of the type of fatty acids in Wistar rat fat.

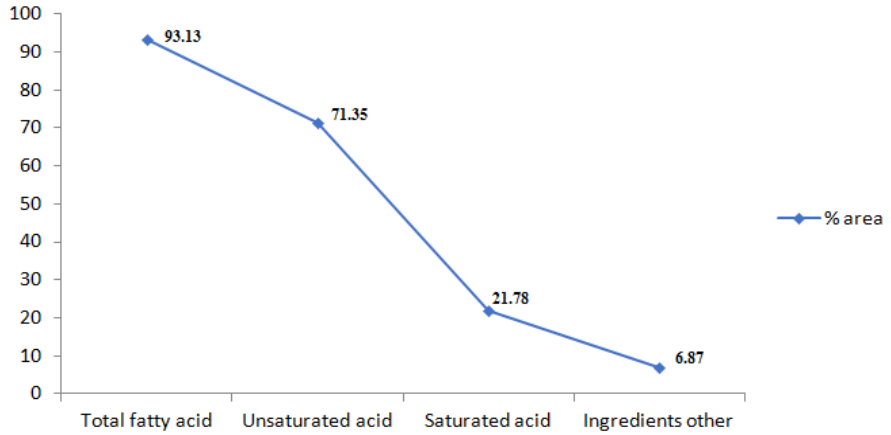

Figure 3 The Line of total fatty acid, saturated fatty acid, unsaturated fatty acid, and ingredients other content in Wistar rat.

Table 1 presents retention time (tR), % peak area, SI, molecular weight (MW) and estimated compounds and identification of white rat fat **(Guntarti and Amidin, 2018)**. The results of GC-MS analysis in Table I show the results of SI values >90 except oleic acid which is 88% and linoleic acid 86%. This shows that the target fatty acid type is suitable or similar to the comparison spectra. The fatty acid compound with a tR of 25.93 minutes and a SI value of 96% was similar to the comparison compound with the formula $C_{17}H_{36}O_2$ with m/z 296. The fatty acid was in the form of its methyl ester. Whereas if in the form of fatty acids, the compound formula is $C_{18}H_{33}O_2$.

Fat is an unstable component in the presence of light. The results of the analysis with GC-MS showed that oleic acid was the highest constituent component of fatty acids in rat fat with a percentage of 40.48%, followed by linoleic acid 30.14%, palmitic acid 19.08%, stearic acid 2.55%, palmitoleic acid 0.73%, and myristic acid 0.15%. The line of the types of fatty acids in Wistar rat fat is presented in Figure 2. unsaturated fatty acid with one double bond.

When viewed from unsaturated bonds, white rat fat contains many types of unsaturated fatty acids, namely palmitoleic acid (0.73%), linoleic acid (30.14%), and oleic acid (40.48%). Whereas saturated fatty acids are myristic acid (0.15%), palmitic acid (19.08%), and stearic acid (2.55%). If looked at the percentage of the content, then more unsaturated fatty acids is equal to 71.35%. Saturated fatty acids of 21.78% and 6.87% are ingredients other than methyl esters. Larger amount of unsaturated fatty acid content will affect the physical form of fat at room temperature and the stability of fat. Figure 3 presents a line of total fatty acid, saturated fatty acid, unsaturated fatty acid, and ingredients other content in Wistar rat.

Comparison of fat: Wistar rat, dog, wild boar, beef, pork, chick and goat.

Besides Wistar rat fat, other animals' fat used were: dog, beef, pork, chick, and goat. Fat retrieval is the same as done in white fat retrieval, which is by rendering with an oven at a temperature of 90 °C – 100 °C, for 30 – 60 minutes. The fat obtained is esterified to form its methyl ester with $NaOCH_3$ and BF_3 which are then injected into the GC-MS system. The results of analysis of dog, beef, pork, chick, goat, and wild boar fat are presented in Table II and Figure 4.

Based on Table II it can be seen that the fat of white rat and pork containing linoleic content (30.14%), and pork fat (21.49%). The highest oleic acid is in the content of pork (55.66%). Goat fat has the highest type of saturated fat, palmitate (23.55%) and stearic (47.13%).

In the results of previous studies **(Hermanto, Muawanah and Harahap, 2008)**, that pork and chicken fat contain margaric acid. Margaric acid content (C17: 0) in pork is 0.5%, and in chick 1.74% **(Hermanto, Muawanah and Harahap, 2008)**. **Guntarti (2018)** research results: beef fat has a high stearic acid (35.03%), while oleic acid is 14.90%. The results of this study, beef fat has a high oleic acid content (52.29%), while stearic acid is 12.59%. Except for goat fat, all animals contain the highest oleic acid; while goat fat, the highest is stearic acid. Figure 4 presents the content of saturated and unsaturated fat, and the total amount of fatty acids in various animals. Based on Figure 4, the saturated fatty acid content is high in goat fat (71.16%), wild boar fat (36.27%), beef fat (35.16%), dog fat (34.33%), lard/pork (27.78%), and the smallest is in chick fat (20.55%). The highest unsaturated fat content is in chick fat (73.2%), rat fat (71.35%), lard / pork fat (55.66%), dog fat (53.93%), wild boar fat (45.24%), and the smallest is in goat fat (19.19%). While the highest amount of total fat is in chick, followed by white rat.

Table 2 The results of the analysis of acid content in the fat of: Wistar rat, dog, wild boar, pork, chick, beef, and goat with GC-MS.

Methyl ester	Percentage of (%) methyl esters						
	Dog	Wild boar	Pork	Chick	Beef	Goat	White rat

Principal Component Analysis of wild boar and other animal fat.

PCA data interpretation is done by reducing data, in which the number of variables in a matrix is reduced to produce new variables while maintaining the information held by the data. The new variables generated are scores or main components **(Rohman and Man, 2012)**. PCA aims to group variables that are correlated with each other and replace them with new groups called main components (principal component) **(Coltro et al., 2005)**. PCA simplifies data by reducing a number of variables to a smaller number of orthogonal variables. This needs a correlation between variables. Although PCA reduces the number of initial variables, PCA retains variability and initial information. PCA also helps provide pattern visualization and correlation analysis **(Miller and Miller, 2010)**. PCA plot scores are presented in Figure 5. The results of replication greatly affect the location of the quadrants obtained, further showing that there are similarities in the physical chemical properties of the fatty acid content. Wistar rat fat is located between chick fat and lard. The results of replication measurements affect the proximity position of the grouping of animal fat.

The results of PCA analysis using Minitab resulted in 8 PCs presented in Figure 6. Each PC displays eigenvalue, proportion, and cumulative values. Eigenvalue variations can explain the data on each PC and show how much influence a variable on the formation of the characteristics of a matrix **(Miller and Miller, 2010).** In Table 3, PC1 with eigenvalue 3.8699 is able to describe 48.4% of the total original data variables while PC2 with eigenvalue 2.3938 is able to describe 21.90% of the total original variables, PC3 with eigenvalue 1.0508 is able to describe 13.10%. Thus, 3 PCs described the illustration data for discriminant analysis of 83.40%.

CONCLUSION

Mass spectroscopy gas chromatography method can be used to authenticate Wistar strain rat with fatty acids content.The content of that fatty acids in white Wistar strain rat is: myristate (0.15 ±0.09)%, palmitoleate (0.73 ±0.54)%, palmitate (19.08 ±3.54)%, linoleic (30.14 ±16.90)%, oleate (40.48 ±2.74)%, and stearic (2.55 ±0.01)%. Chemometrics PCA white rat, dog, wild boar, chick, pork, beef, and goat fat can be grouped.

OPTIMIZATION OF BREWING TIME AND TEMPERATURE FOR CAFFEINE AND TANNIN LEVELS IN DAMPIT COFFEE LEAF TEA OF ROBUSTA (*COFFEA CANEPHORA*) AND LIBERICA (*COFFEA LIBERICA*)

Dewi Melani Hariyadi, Cynthia Amelia Tedja, Elok Zubaidah, Sudarminto Setyo Yuwono, Kiki Fibrianto

ABSTRACT
Coffee constitutes a plant product high in economic value. Extremely abundant throughout Indonesia, different varieties can be found in each region. Coffee leaves represent a by-product of coffee production which are disposed of without being subjected to further processing. One advantage of coffee leaf waste is that it can be made into coffee leaf tea, to prevent various diseases. The caffeine and tannin content can be optimized by temperature and brewing time. Research on coffee leaf tea remains limited, with little study of Liberica coffee leaf tea. This investigation was to determine the optimal brewing time and temperature of Robusta (Coffea canephora) and Liberica (Coffea liberica) coffee leaf tea. This research used the Response Surface Methodology (RSM) method with Central Composite Design (CCD). Data analysis using RSM method was conducted incorporating two factors. The first factor was the brewing temperature with a minimum value of 91 °C and a maximum value of 99 °C. The second factor was brewing time with minimum and maximum values of three and seven minutes respectively. Identifying the optimal treatment was based on two factors, caffeine and tannin content. Optimized processes were applied to conduct organoleptic tests on 110 untrained panelists using the Rate-All-That-Apply (RATA) method to highlight the majority attributes experienced by the panelists. The optimal brewing temperature and duration for robusta coffee leaf tea were 93.43 °C and 4.80 minutes which produced caffeine and tannin levels of 74.90 mg.100mL^{-1} and 293.01 µg.g^{-1} respectively. In contrast, in the case of Liberica coffee leaf tea, the optimal brewing conditions comprised a temperature of 91.65 °C and duration of 4.84 minutes which produced caffeine and tannin levels of 72.52 mg.100mL^{-1} and 415.87 µg.g^{-1}. Results of sensory analysis showed that the majority produced five significant characteristics, namely: sweet flavor, fire flavor, sweet taste, bitter taste and astringent mouthfeel.

Keywords: caffeine; tannin; Robusta; Liberica; coffee leaf tea

INTRODUCTION
Coffee represents an extremely abundant plant commodity which can potentially be developed into an increasing source of income for Indonesia. The economic value of coffee is relatively high compared to that of other plantation crops. Moreover, its role as a major source of national income is based on its abundance and range of varieties in each region. According to statistics produced by the **General Directorate of Plantations (2016)**, in 2017 plantations in Indonesia occupied an estimated area of 1,227,787 hectares capable of producing 637,539 tons of coffee. The coffee plantations listed in the statistics include those in the community, state and private sectors. Dampit in East Java, at an altitude of 300 – 460m above sea level, is a renowned coffee producing area **(Malang Electronic Data Manager, 2014)**. According to the **Central Statistics Agency of Malang Regency (2018)**, the total coffee production of the Dampit Subdistrict was 2,387 tons from a total cultivated area of 3,373 ha, within which the seedling area covered 6 ha, the productive plant area 2,965 ha and the mature plant area 372 ha. In Indonesia, several varities of coffee have been developed, for example, Arabica, Robusta and Liberica. The two former types contain high levels of active compounds such as quilonic acid, pirogalic acid and, particularly, caffeine **(Ciptaningsih, 2012)**.

For farmers, the only productive part of coffee plants is their beans which can be processed into drinks or food additives. Being considered waste, coffee plant parts such as the leaves are pruned and disgarded. The purpose of pruning is, among other reasons, to improve the quality of coffee, reduce pest attacks and stimulate new growth **(Arief et al., 2011)**. Therefore, rather than discarding the coffee leaves, it is necessary to make further use of them in order to maximise coffee farmer income.

Coffee leaves are as delicious as coffee beans and in an example of product diversification, can substitute for tea leaves in the manufacture of tea drinks. Tea itself is a very

common everyday drink that represents the second most consumed beverage after water **(Damayanthi et al., 2008)**. Tea is made from steeping *Camellia sinensis* leaves which have a distinctive flavor and aroma much appreciated by consumers. However, tea can also be made from other plant parts such as rosella flowers, lemongrass stems, soursop leaves, avocado leaves and coffee leaves. This drink is commonly called herbal tea or tisane **(Somantri and Tanti, 2011)**.

At present, coffee leaf tea is relatively unknown, whereas in Sumatra, coffee leaves are used to produce a drink commonly referred to as "Aia Kawa", believed to contain alkaloids, caffeine, saponins, flavonoids and polyphenols that prevent various diseases **(Pristiana, Susanti and Nurwantoro, 2017)**. The caffeine content in coffee leaf drink is lower than that of coffee beans, rendering it an alternative for producers and individuals who want an affordable soft caffeinated drink. Moreover, tea contains tannin compounds and polyphenol, the latter of which functions as an antioxidant. Elements within coffee leaf tea such as caffeine and tannin are beneficial to the body, but must be optimized in order to maximize their positive effects.

Optimizing the beneficial contents of coffee leaf tea drink such as caffeine and tannin can be achieved based on the temperature and duration of brewing. According to **Schwalfenberg, Genuis and Rodushkin (2013)**, both the beneficial and harmful effects of tea depend on the manner in which it is brewed. The longer the tea is soaked, the more caffeine will be extracted, resulting in oxidation. Several previous studies, such as that conducted by **Retnaningtyas et al. (2016)**, have been limited to the use of Arabica and Robusta coffee leaves, while ones relating to Liberica remain rare. Furthermore, caffeine and tannin are yet to be extensively studied. Therefore, it is necessary to conduct research to optimize caffeine and tannin levels within the parameters of brewing temperature and duration. Moreover, such research should be conducted to determine consumer sensory responses to coffee leaf tea characteristics. Sensory responses are required because caffeine and tannin are compounds that contribute to the flavor of the tea. There would be differences between Robusta and Liberica Coffee leaves tea in terms of caffeine and tannin contents due to different brewing temperature and duration. Thus it may change perceived sensory attributes as well.

This research was aimed to provide information and recommendations to agencies with links to agricultural product development, especially coffee farmers, in order to promote greater use of coffee leaves in tea drinks as part of a food diversification program.

Scientific hypothesis

Temperature and brewing time optimization have an influence on caffeine and tannin levels as well as sensory attributes on Robusta and Liberica coffee leaf tea Dampit.

MATERIAL AND METHODOLOGY

Materials

The raw materials used in this study consisted of Robusta and Liberica coffee leaves obtained form the Dampit region of East Java. The testing materials comprised calcium carbonate, chloroform, distilled water, methanol, folin ciocalteau, Na_2CO_3, tannic acid and caffeic acid. The materials employed for organoleptic testing included mineral water and biscuits as palate cleansers. Dampit region is located in East Java, at an altitude of 300 – 460 m above sea level, is a renowned coffee producing area **(Malang Electronic Data Manager, 2014)**. The period of the harvest is every 4 to 6 months in every year.

Method

The raw materials used in this study were fresh Dampit old Robusta and Liberica coffee leaves. Fresh coffee leaves from older mature leaves were washed and then cut into small pieces. After being reduced in size, the coffee leaves were dried in an oven for three hours at a temperature of 90 °C. The dried coffee leaves were subsequently blended to produce coffee leaf powder. The characteristics of the raw materials analysed in this study were used to determine their chemical content consisting of fresh coffee leaves and coffee leaf powder. The chemical parameters adopted for the analysis of raw materials included water content, caffeine content and tannin content.

The methodology applied in undertaking this study was experimental in character, combining Surface Response Method (RSM) and Rate All That Applied (RATA) data. Application of the RSM method involved an optimization process incorporating the Center Composite design available in the Design Expert DX 9 application (Stat-Ease, Inc.) **(Maharjan et al., 2014; Montgomery, 2001; Montgomery, 2016)**. Chemical analysis related to optimization was conducted based on run provided by the software. The optimization process was conducted with three center points or repetitions to obtain 13 runs or experimental treatments, during which the caffeine and tannin levels were analyzed. The research factors applied were those of temperature and duration of the brewing process. The RSM method produced optimization data subsequently subjected to sensory analysis using the RATA method. A CATA evaluation of the product was conducted to determine the sensory attributes present in coffee leaf tea. As shown from the contents of Table 1, panelists were requested to complete the questionnaire by indicating the attributes they experienced when tasting the sample.

For sensory evaluation, the sensory evaluation based on consumer perception was conducted following RATA (Rate All That Apply) method. This experiment was observed according to Completely Randomized Block Design and the data was further analysed on Minitab 17 (Minitab, LLC, Pty Ltd, Australia) with General Linear Model (GLM) followed by Tukey Post-hoc Test.

The questionnaire results relating to the most prominent sensory attributes were further tested using the RATA method. The panelists were asked to complete the questionnaire by assigning ratings to the strength or dominance of the sensory attributes in the sample.

Data Observation and Analysis

The observations in this study were based on analysis of caffeine, tannin, water content, total acid, pH and color. The coffee leaf tea producing optimal levels of caffeine

and tannin was further analyzed by observing sensory properties using the RATA method.

Caffeine Analysis

Caffeine analysis was completed using the spectrophotometric method **(Maramis, Citraningtyas and Wehantouw, 2013)** which involved adding the sample to hot distilled water, agitating and filtering the resulting liquid prior to adding it to $CaCO_3$ (calcium carbonate). The coffee solution was placed in a separating funnel and extracted four times, with chloroform being added on each occasion. A bottom layer would be formed that could be removed, with the extract (chloroform phase) subsequently being placed in a rotary evaporator until all the chloroform had evaporated. The solvent-free caffeine extract was deposited in a measuring flask, diluted with distilled water and homogenized. The caffeine level was quantified by means of a UV-VIS spectrophotometer at a wavelength of 275 nm. The results having been obtained, a standard curve representing standard caffeine solution as the equation was $y = ax + b$ and resulted correlation coefficient value in each equation.

Tannin Analysis

Tannin analysis was performed using a spectrophotometric method **(de Godoy Pelozo, Carvalho Cardoso and Palazzo de Mello, 2008)**. The sample was extracted using methanol and the levels measured using a folin ciocalteu reagent that formed a complex with tannin producing a dark green blue color. Color intensity was measured using a spectrophotometer at a wavelength of 755 nm. The tannin concentration was quantified by comparing the sample with a standard tanic acid curve.

Sensory Response Analysis using the RATA Method

Sensory response analysis of coffee leaf tea was performed employing the RATA method. Conducting the test involved 110 untrained panelists, aged 18 – 29, drawn from the surrrounding areas of Universitas Brawijaya (Malang). The specified age range was selected because the older the panelists, the less acute their sense of taste **(Mojet, Heidema and Christ-Hazelhof, 2003)**. Sensory testing was performed by completing a questionnaire containing a combination of open and closed questions. The open questions related to the identity of panelists, while the closed questions were designed to elicit their opinions of with regard to the intensity of the perceived attributes of the sample. The resulting data was then recapitulated, processed and analyzed using Minitab to determine the significance of the sensory attributes of the sample. Each rating was scored, followed by the administering of an ANOVA test and a Fischer test.

Statistical analysis

The optimization method used is the Response Surface Method (RSM) method. The RSM methods use a Center Composite Design (CCD) by Design Expert 9 (DX 9) software. Whereas the sensory test uses the Rate-All-That-Apply (RATA) method which is analyzed by the General Linear Model and Fisher's Post-hoc test using the Minitab 17 software.

RESULTS AND DISCUSSION

Characteristics of Raw Materials

Chemical characteristics of raw materials including the analysis of moisture content, caffeine and tannin content are shown in Table 2.

The contents of Table 2 indicated that the water content contained in fresh Robusta coffee leaves was 75.89%, while that of fresh Liberica coffee leaves was 72.93%. According to **Angga et al. (2018)**, the water content of old tea leaves was approximately 70%. Moreover, research conducted by **Kristiningrum, Cahyanti and Wulandari** in **2016** into Jember Arabica and Robusta coffee leaves indicated that old coffee leaves had a moisture content of 75.79 – 82.82%. The moisture content of Robusta coffee leaf powder was 6.84%, while that of Liberica was 5.5%. The criterion of good tea quality is a maximum moisture content of 10% **(Čížková et al., 2008)**. The drying process can reduce the moisture content of fresh coffee leaves by approximately 60 – 70% **(Deb and Pou, 2016)**.

The caffeine level in fresh coffee leaves was higher than the level of caffeine in dried coffee leaf powder. The caffeine content of fresh robusta leaves was 0.63%, while that of the powder was 0.23%. The caffeine content of fresh Liberica leaves was 0.43% and the powdered caffeine level was 0.36%. According to the literature, the caffeine content of coffee leaves is relatively low compared to that of coffee beans which is 1.6 – 2.4% **(Khotimah, 2014)**. The amount of caffeine in coffee leaves can vary and is influenced by the cultivation area, growth conditions, environment, season, leaf age and specific production system **(Heckman, Weil and Gonzales de Mejia, 2010)**.

The tannin content of fresh coffee leaves was higher than the that of dried coffee leaf powder. The tannin content of fresh robusta leaves was 19.24%, while that of the leaf powder was 12.27%. The tannin content of fresh liberica leaves was 18.38%, while that of leaf powder was 13.83%. The literature on the subject states that tea leaves contain numerous tannin compounds amounting to 13.76%. These affect both astringence and bitter taste, but both decrease after processing **(Karori et al., 2007)**.

Optimization of Caffeine and Tannin Content of Robusta Coffee Leaf Tea

Optimization of Robusta coffee leaf tea was conducted using the variables of brewing temperature and brewing time. This approach was in accordance with the experimental design of Design Expert 9.0 using Response Surface Methodology (RSM). The observed responses consisted of the caffeine and tannin levels.

The results of the study of the relationship between brewing temperature and duration and the levels of caffeine and tannin are contained in Table 3.

Analysis of the 13 treatment combinations indicated that the response value of caffeine content tended to be low, namely; 67.85 $mg.100mL^{-1}$, when produced by a brewing process at a temperature of 89.34 °C and of five minutes' duration. The response value of the caffeine level tended to be high at 83.03 $mg.100mL^{-1}$ which occured in the

brewing process at a temperature of 99 °C and duration of seven minutes. According to the research conducted by **Putri and Ulfin (2015)**, caffeine content is influenced by the extraction conditions, namely; temperature and extraction duration. The highest caffeine level is found in the temperature of 100 °C. In addition, a longer extraction time can increase the caffeine level in tea. Caffeine is a compound that dissolves readily in hot water. At a temperature of 25 °C its solubility is 2.17 g.100mL^{-1}, while at 80 °C the solubility is 18 g.100mL^{-1}, and at 100 °C, the solubility is 67 g.100mL^{-1}**(Mumin et al., 2006)**.

The tannin level with a high tendency value of 314.857 µg.g^{-1} resulted from a brewing process at a temperature of 95 °C and of five minutes' duration. Meanwhile, tannin content with a value as low as 225.77 µg.g^{-1} was obtained at a brewing temperature of 89.33 °C and a brewing time of five minutes. According to **de Hoyos-Martínez et al. (2019)**, all forms of tannin dissolve in water, methanol, ethanol and acetone, demonstrating a high level of solubility that increases when dissolved in hot water. Tannin will break down into pyrogallol, pyrocatechol and phloroglucinol when heated to temperatures of 2,100 F – 2,150 F (98.89 °C – 101.67 °C).

Statistical analysis has demonstrated that increased caffeine content is affected by both the brewing temperature and brewing time. These factors have a significant effect on caffeine content where the higher the linear temperature, the higher the resulting level of caffeine.

Moreover, the higher the water temperature in the brewing process, the greater the ability of water to extract the chemical content of tea and the longer the brewing time. The latter will affect the level of dissolved ingredients, color intensity and aroma. Increasing the brewing time will lengthen the contact time between the hot water and tea, thereby rendering the extraction process more effective **(Saklar et al., 2015)**.

Optimization of Brewing Temperature and Time of Robusta Coffee Leaf Tea and Desired Responses

Solution for optimal process based on Design Expert 9.0 application was obtained by determining the desired variable and response criteria and can be seen in Table 4.

In Table 4, the variable criteria for brewing temperature and brewing time chosen were within a specific range. This was because it was expected that the brewing process would be carried out at a temperature and duration between the specified upper and lower limits. In the caffeine content response variable, the selected criteria chosen was that of minimize, because the desired caffeine content was the lowest, thereby rendering it safe for consumption by individuals sensitive to caffeine.

In contrast, the response of the desired tannin content was maximum because to maximize its functional properties such as astringent and antibacterial activity. Based on these criteria, the Design Expert program provides an optimization solution that can be seen in Table 5.

The data in Table 5 indicates that the solution provided by the program had a desirability level of 0.64 or a level of accuracy of the predicted value with an optimization value of 0.64. The desirability value was indicated by the value of 0 – 1, where the higher the value indicated the more suitable the combination of process parameters obtained to achieve the optimal combination with the desired response variable **(Melati, 2012)**. The recommended optimal processing point in terms of brewing temperature was 93.43 °C and of cooking time was 4.80 minutes. The predicted caffeine content following the brewing process was 74.90 mg.100mL^{-1}, while that of tannin was 293.01 µg.g^{-1}.

Optimization of Liberica Coffee Leaf Tea Caffeine and Tanin Content

Optimization of Liberica coffee leaf tea was carried out using variables in the form of brewing temperature and time and in accordance with the experimental design by Design Expert 9.0 using Response Surface Methodology (RSM). The observed responses were caffeine and tannin content. The results of the study of the relationship between brewing temperature and brewing time and caffeine and tannin content can be seen in Table 6.

The optimized caffeine content response represented the amount of caffeine contained in 100 mL of steeped Liberica coffee leaf tea. Based on the analysis of 13 treatment combinations, the response value of caffeine content, which tended to be low at 61.68 mg.100mL^{-1}, was produced by brewing for three minutes at a temperature of 91 °C. The response value of caffeine content which tended to be high at 91.83 mg.100mL^{-1} resulted from brewing at a temperature of 100.66 °C for five minutes.

The result showed that the highest caffeine content was found following the longest time again range at 100 °C.

The tannin content which had a high tendency value was 464.99 µg.g^{-1} obtained during a brewing process at temperature of 95 °C and of five minutes' duration. Tannin content tended to have a value as low as 280.57 µg.g^{-1} obtained at a brewing temperature of 99 °C and a brewing time of three minutes.

Statistical analysis indicated that brewing temperature and time exert a significant influence on caffeine content.

Optimization of Temperature and Time of Liberica Coffee Leaf Tea and Desired Response

The solution for optimal processes based on Design Expert 9.0 application is obtained by determining the desired variable and response criteria as shown in Table 7. In Table 7, the variable criteria for the brewing temperature and brewing time chosen were in a range. This was due to the expectation that the brewing process would be carried out at a temperature and duration between the specified upper and lower limits. In the caffeine content response variable, the criteria chosen was 'minimize', because the desired caffeine content was the lowest. Therefore, it was safe for consumption by those sensitive to caffeine. In contrast, the response to the desired tannin content was 'maximum', due to the optimizing of its functional properties. Based on these criteria, the Design Expert program produced an optimization solution that is contained in Table 8. The solution provided by the program quantified desirability as 0.69. In other words, the level of accuracy of the predicted optimization value was one of 0.69.

Table 1 Sensory Attributes.

Attributes		Description
Odor	Green	Resembling leaves, vegetables or herbal plants
	Floral	Reminiscent of jasmine and rose petals
	Spicy	Possessing the aroma of cloves, pepper or ginger
	Fruity	Similar to the odor of apples, melons, berries
	Marine	Resembling seaweed
	Gouda	Nuts, for example almonds and peanuts
	Sweet	Sweet like honey, sugar or caramel
	Fire	Burning like ash or smoke
	Minerals	Reminiscent of minerals such as metal or chalk
	Earth	Resembling the odor of soil, moss or compost
	Wood	Reminiscent of timber such as pine or oak
Taste	Sweet	Sweet taste
	Sour	Sour taste
	Bitter	Bitter taste
Flavor	Green	Resembling leaves, vegetables or herbal plants
	Floral	Similar to the flavor of jasmine and rose flowers
	Spicy	Spices such as clove, pepper, or ginger
	Fruity	Fruits like apples, melons, berries
	Marine	Resembling sea angina or seaweed
	Gouda	Nuts like almonds, peanuts
	Sweet	Sweet like honey, sugar, or caramel
	Fire	Burnt flavors such as ash or smoke
	Minerals	Resembling minerals like metal or chalk
	Earth	Resembling soil, moss, or compost
	Wood	Resembling timber such as pine, oak
Mouthfeel	Astringent	Dry and slightly viscous sensation in the mouth
	Oily	Oily sensation in the mouth

Table 8 Liberica Coffee Leaf Tea Optimal Temperature Point and Brewing Time.

No.	Brewing Temperature	Brewing Time	Caffeine Content	Tannin Content	Desirability	
1	91.65	4.84	72.52	415.87	0.69	Selected

Desirability value was indicated by a value between 0 and 1, where the higher the value the greater the suitability of the combination of process parameters obtained to achieving the optimal combination with the desired response variable **(Melati, 2012)**. The recommended optimal processing point was 91.65 °C for brewing temperature and 4.84 minutes for cooking time. The prediction result of caffeine content obtained from the brewing process was equal to 72.52 mg.100mL^{-1} with a tannin content of 415.87 µg.g^{-1}.

Sensory Characterization of Coffee Leaf Tea

Panelist Profiles

The panelists involved in testing the sensory characteristics of coffee leaf tea were untrained individuals of average intelligence who had not been formally trained, but were capable of differentiating and communicating the reactions resulting from orgnoleptic assessment **(Ayustaningwarno, 2014)**. The 110 participating panelists were composed of 24 males and 86 females as shown in Table 9.

The age range of panelists in this study was one of 18 – 29 years. Based on research conducted by **Hanspal (2010)**, tea is most popular among consumers within the 18 to 36 years age range. Significantly, the declining sense of taste of panelists will compromise their ability to differentiate between flavours from the age of 45 **(Choi, 2019)**.

Sensory Attribute Characterization of Robusta and Liberica Coffee Leaf Teas Using the RATA (Rate-All-That-Apply) Method

The measuring of sensory attributes used the RATA sensory evaluation method (Rate-All-That-Apply). This represents a sensory evaluation method utilizing a questionnaire instrument in which there are intensities for each sensor attribute. The RATA method requires panelists to select the intensity of sensory attributes of the product. Response boxes and can be left blank if no attributes are detected in the product **(Ares et al., 2014)**. The intensity used to describe the sensory attributes in the questionnaire ranged from numbers 1 – 5. Attribute number 1 represents 'Very lacking', number 2 'Lacking', number 3 'Moderate', number 4 'High' and number 5 'Very high'. After completion of the questionnaire, panelist responses to coffee leaf tea were presented in a spider chart contained in Figure 1. The responses represented the average intensity of the sensory attributes from 110 panelists.

Table 9 RATA Sensory Panelist Profile Analysis of Coffee Leaf Tea.

No.	Item	Item Options	Number of People
1.	Sex	a. Male (M)	24
		b. Female (F)	86
2.	Age	a. 18 – 21 (Late teen)	53
		b. 22 – 29 (Early adulthood)	57

Attributes	*p*-value (Coffee Leaf Type)
Sweet Flavor	0.005
Fire Flavor	0.001
Sweet taste	0.000
Bitter Taste	0.000

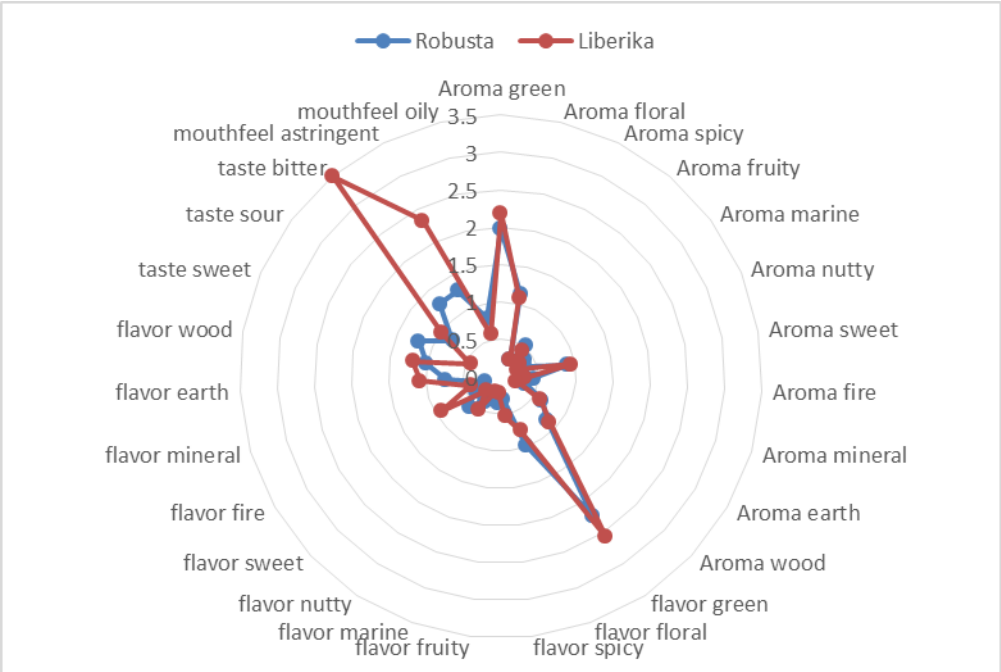

Figure 1 Average Response of the Intensity of Robusta and Liberica Coffee Leaf Tea Sensory Attributes.

Panelist Responses to Coffee Leaf Tea Sensory Attributes to Leaf Types

This study used samples of Robusta and Liberica coffee leaves brewed in accordance with the optimal brewing process solution obtained from the Design Expert application. Robusta coffee leaves were brewed at 93.43 °C for 4.80 minutes. In contrast, the Liberica coffee leaves were brewed at a temperature of 91.65 °C for 4.84 minutes. After sensory evaluation, the data was processed using ANOVA test on Minitab 17 software. The results of the *p*-value analysis of sensory attributes that differed significantly according to the specific variety of coffee leaves can be seen in Table 10.

Data analysis of *p*-value variance for the sensory attributes of the different types of Robusta and Liberica coffee leaves confirmed the existence of five significantly different sensory attributes (p-value <0.05), namely: sweet flavor, fire flavor, sweet taste, bitter taste and astringent. The results were significantly different indicating that the panelists experienced a difference in the intensity of the sensory attributes of coffee leaf tea present in the different types of coffee leaves. The analysis results were subsequently subjected to Fisher tests of significantly different sensory attributes.

Sweet Flavor

Sweet flavor is a flavor often associated with the impression of sweetness in items such as fruits and flowers. Sweet Flavor is also considered to be contained in sugar, honey, or caramel **(Lee and Chambers, 2007)**. The ANOVA test result indicated that the variance in sweetness in the different types of coffee leaves differed significantly. It can be concluded that the sweet flavor attribute will become stronger when approaching number 5 and weaker when approaching number 0. The different notation in each sample shows them to be significantly different. Sweet flavor in steeped tea leaves can be contributed to by simple sugars contained in coffee leaves such as glucose, sucrose, fructose, and various volatile compounds such as linalool, dihydroactinidiolide, coumarin, and phytol **(Lee, Chambers and Chambers, 2013)**. Compounds that also contribute to sweet flavor, include: nerol, phenylacetaldehyde, 5-octanolide, menalool oxide and geraniol **(Yashin et al., 2015)**. Liberica coffee leaves had a sweeter flavor because it contained more glucose, sucrose, fructose, and various volatile compounds than Robusta leaves.

Fire Flavor

Fire flavor is associated with the aroma of soil, ash, roasted pepper, coffee and smoke, in addition to heat in the throat **(Kim, Lee and Kim, 2016)**. ANOVA analysis of fire flavor response in the various types of coffee leaves indicated significant differences. It can be concluded that the fire flavor attribute strengthens when approaching number 5 and weakens when approaching 0. The different notation in each sample shows it to be significantly different. Fire flavor in steeped tea leaves can be contributed to by 1-ethyl-1H-pyrrole-2-carboxaldehyde, 3-ethyl-4-methyl-1H-pyrrole-2,5-dione, 3-ethyl-3-methyl-2,5- pyrrolidinedione, coumarone, and coumarine **(Yashin et al., 2015)**.

In addition, research undertaken by **Angga et al. (2018)** found five aromatic compounds burning in coffee leaves, namely: 2-furanmethanol, safranal, benzeneethanol (CAS), guaiacol and 3,5-cocoa pyrazine.

Liberica coffee leaves had a more fire flavor because it contained more safranal, guaiacol, coumarone and coumarine than Robusta leaves.

Sweet taste

Sweet taste is caused by aliphatic organic compounds containing hydroxy groups (OH), several amino acids, aldehydes and glycerol which are commonly found in food containing simple carbohydrates **(Diez-Simon, Mumm and Hall, 2019)**.

The results of ANOVA analysis of sweet taste response to the differences in the types of coffee leaves varied significantly. It can be concluded that the sweet taste attribute will become stronger when approaching number 5 and weaker when approaching number 0. The contrasting notation in each sample shows it to be significantly different. Sweet taste is often associated with aldehydes and ketones which contain carbonyl groups **(Chang, Waters and Liman, 2010)**. According to research conducted by **Angga et al. (2018)**, coffee leaves contain 15 aldehyde group compounds, six alcohol group compounds and four ketone group compounds. Furthermore, sweet taste is also considered a pleasant sensation produced by the presence of sugar and several other substances. Liberica coffee leaves had a sweeter taste because it contained more aldehyde and ketone than Robusta leaves.

Bitter Taste

Bitter taste is caused by the presence of phenol compounds, flavonoids, isoflavones, terpenes and glucosinolates which exude a bitter, sharp or astringent odor **(Drewnowski and Gomez-Cameron, 2000)**. The results of ANOVA analysis of bitter taste response to the differences in the types of coffee leaves varied significantly. It can be concluded that the bitter taste attribute will strengthen when approaching number 5 and weaken when approaching number 0. The contrasting notation in each sample showed that it was significantly different. Liberica coffee leaves had a much more bitter taste in the ratings because it contained more flavonoid and tannin than Robusta leaves.

Compounds that contribute to bitter taste in tea are phenolic compounds such as flavonoids (quercetin), flavans (catechins, epicatechin and epicatechin gallate, epigalocatechingallate). High levels of flavonoid and tannin in tea contribute to an increase in the bitter taste of tea **(Mahmood, Akhtar and Khan, 2010)**.

Astringent Mouthfeel

Mouthfeel is a physical sensation in the oral cavity caused by food or drink but which differs from taste **(Mouritsen and Styrbæk, 2017)**. Astringency constitutes dryness in the mouth and a slight sensation of stickiness caused by the presence of astringent substances in plants (in the form of leaves, flowers and fruit) that are not yet ripe **(Laaksonen, 2011)**. **Rossetti et al. (2009)** state that astringent substances are able to constrict body tissue where the lubricant is produced and disappears due to the

deposition of proteins contained in the saliva that lines and lubricates the oral cavity. The result of ANOVA analysis of astringent response to variations in the types of coffee leaves was significantly different. It can be concluded that the astringent attribute will get stronger when approaching number 5 and weaker when approaching number 0. Varying notation in each sample shows that the sample is significantly different. Liberica coffee leaves had a much more astringent mouthfeel because it contained more caffeine, tannin and catechin than Robusta leaves. Astringence is important in determining the sensory quality of drinks such as tea, coffee, juice or wine. The compounds that play the most dominant role in influencing astringence are tannin and catechin. Moreover, astringence is also caused by caffeine and flavonol glycosides **(Zhang et al., 2018)**. In addition to five significantly different attributes, 22 sensory attributes exist that are not significantly different from the various types of coffee leaves.

CONCLUSION

The temperature and length of time required to optimize caffeine and tannin levels in Robusta coffee leaf tea are 93.43 °C and 4.80 minutes respectively. The caffeine level of Robusta coffee leaf tea with optimal steeping amounted to 74.90 mg.100mL^{-1} and Robusta coffee leaf tea tannin level with optimal steeping amounted to 293.01 µg.g^{-1}. On the other hand, the brewing temperature and time required to optimize the levels of caffeine and tannin in Liberica coffee leaf tea are 91.65 °C and 4.84 minutes respectively. The caffeine level in Liberica coffee leaf tea with optimal steeping is 72.52 mg.100mL^{-1}, while the level of Liberica coffee leaf tea tannin with optimal steeping is 415.87 µg.g^{-1}. Sensory responses of consumers towards Robusta and Liberica coffee leaf tea that have been optimized for caffeine and tannin levels indicate five significant attributes, which are sweet flavor, fire flavor, sweet taste, bitter taste and astringent mouthfeel.

THE CHARACTERISTIC OF SHEEP CHEESE "BRYNDZA" FROM DIFFERENT REGIONS OF SLOVAKIA BASED ON MICROBIOLOGICAL QUALITY

Miroslava Kačániová, Ľudmila Nagyová, Jana Štefániková, Soňa Felsöciová, Lucia Godočíková, Peter Haščík, Elena Horská, Simona Kunová

ABSTRACT

The aim of our study was to describe microorganisms which occur in the traditional Slovak cheese „Bryndza". There were a total of 60 cheese samples collected from ten different farms during May 2019. The microbiota studies included the total bacterial count, coliforms, enterococci, lactic acid bacteria, yeasts and microscopic fungi. The total bacterial counts were cultivated on plate count agar at 30 °C in aerobic conditions, lactic acid bacteria on MRS at 37 °C in anaerobic conditions, coliform on VRBL and VRBG at 37 °C in aerobic condition, yeasts and microscopic fungi on MEA at 25 °C under aerobic condition. Gram-positive, Gram-negative and yeasts isolates were identified with MALDI-TOF MS Biotyper. Totally, a number of 1175 isolates of G^-, G^+ and yeast were identified with score higher than 2 and moulds. *Escherichia coli* and *Stenotrophomonas maltophilia* were the most frequently identified species of Gram-negative and *Leuconostoc mesenteroides ssp. mesenteroides* and *Lactococcus lactis ssp. lactis* from Gram-positive bacteria. *Yarrowia lipolitica* and *Kluyveromyces lactis* were the most distributed yeasts. Lactic acid bacteria group was represented by *Lactobacillus, Lactococcus, Leuconostoc* and *Pediococcus.* The most abundant genera of lactic acid bacteria were *Lactobacillus* with 11 species. This study describes the indigenous microbiota of the traditional ewe's milk cheeses from Slovakia.

Keywords: isolation and identification of microorganisms; MALDI TOF MS Biotyper; Slovak ewe's cheese

INTRODUCTION

Slovak „Bryndza" is a natural white, gently spreadable, slightly moist fresh ripened cheese with curds and own texture, made in a traditional way from well-fermented ripened ewe's lump cheese.

A characteristic feature of the production of Slovak „Bryndza" is the crushing and grinding of mature ewe's or a mixture of ewe's and cow's lump cheese and their mixing with salt or specially prepared saline solution to achieve the required composition, which distinguishes this production from the production of other ewe's cheese produced outside Slovakia. Its characteristic sensory attributes are due to the natural microflora contained in raw ewe's milk and ewe's lump cheese and to the characteristic production method. The basic raw material for the production of Slovak „Bryndza" is ewe's lump cheese or a mixture of ewe's and cow's lump cheese, or a mixture of cured ewe's lump cheese and cow's lump cheese aged under specific conditions **(Commission Regulation No. 676/2008)**.

Microorganisms represent without doubt the largest group of living organisms in the world, with only a small fraction of microbial species which have been identified until now. They can be highly diverse in their biochemistry, physiology and nutritional modes. Most of them are reproducing swiftly and the significant plasticity of their genome allows them to easily adapt to changing environmental conditions, as well as perform a variety of essential ecosystem functions, on which food production depends on. According to **FAO (2009)**, the main functional groups for food processing are beneficial microorganisms (fermentation and probiotics). Microbial food cultures include bacterial food cultures, fungi and yeasts. These microorganisms determine the characteristics of the fermented food, e.g., acidity, flavour and texture, as well as health benefits that go beyond elementar nutrition **(Vogel et al., 2011)**.

The aim of our study was to isolate and identificate the microorganisms from Slovak ewe's cheese „Bryndza" obtained from different Slovak regions.

Scientific hypothesis

Slovak „Bryndza" is specific traditional food product with various microorganisms, which has positive and negative role of quality.

Hypothesis no. 1: There are a lot of different bacteria and yeast species presented in the traditional Slovak sheep cheese called „Bryndza".

Hypothesis no. 2: There are microscopic filamentous fungi presented in the traditional Slovak sheep cheese „Bryndza".

MATERIAL AND METHODOLOGY

There were 60 samples of Slovak ewe's cheese „Bryndza“ from east, middle and west part of Slovakia evaluated for microbiological quality in our study. All samples were obtained in May 2019. These samples were placed in sterile sample containers and transported on ice to the laboratory for microbiological investigations. Samples were kept in a refrigerator (4 ±1 °C) until the testing began. The primary dilution of the ewe's cheese was made for preparing the samples for testing: a 5 mL of sample material was added to 45 mL of 0.87 % sterile saline. Then the serial dilutions (10^{-2} to 10^{-4}) were done and a 100 μL of each dilution was plated out.

Determination of total bacterial count

Plate count agar (PCA, Sigma-Aldrich®, St. Louis, USA) for total microbial count enumeration was used. Inoculated plates were incubated at 30 °C for 24 – 48 h and then examined for the characteristics of bacterial colonies.

Isolation of coliform bacteria

The Violet red bile lactose agar (VRBGA, Sigma-Aldrich®, St. Louis, USA) for enumeration of coliforms bacteria was used. Inoculated plates were incubated at 37 °C for 24 – 48 h and then examined for the characteristics of typical colonies.

Isolation of enterococci

Enterococcus selective agar (ESA, Sigma-Aldrich®, St. Louis, USA) for enumeration of enterococci was used. Inoculated plates were incubated at 37 °C for 24 – 48 h and then examined for the characteristics of typical colonies.

Isolation of Lactic Acid Bacteria (LAB)

MRS (Main Rogose agar, Oxoid, UK), MSE (Mayeux, Sandine and Elliker in 1962, Oxoid, UK), and APT (All Purpose TWEEN® agar, Oxoid, UK) agars were used for enumeration of LAB including lactobacilli, leuconostocs and lactic acid streptococci as well as other microorganisms with high requirements for thiamine (Sigma-Aldrich®, St. Louis, USA). Inoculated agars were incubated at 30 °C for 72 h anaerobically and then the bacterial growth was evaluated.

Isolation of yeasts

Malt extract agar (Sigma-Aldrich®, St. Louis, USA) and acid base indicator bromocresol green (Sigma-Aldrich®, St. Louis, USA) (0.020 $g.L^{-1}$) were used for yeasts identification. Inoculated plates were incubated at 25 °C for 5 days aerobically and then the growth was evaluated.

Sample preparation and MALDI-TOF MS measurement

Prior to the identification, the bacterial and yeasts colonies were subcultured on TSA agar (Tryptone Soya Agar, Oxoid, UK) at 37 °C for 18 – 24 h. One colony of eight bacterial isolate was selected. Subsequently, the identification was performed using the Maldi TOF MS Biotyper as was described by **Kačániová et al. (2019)**. We identified totally 870 isolates with a score higher than 2 **(Kačániová et al., 2019)**.

Identification of microscopic fungi

Microscopic fungi were identified to species level according to the manuals of **Samson et al. (2002)**, **Samson and Frisvad (2004)**, **Pitt and Hocking (2009)**.

Statistical analysis

All experiments were carried out in triplicate and the results reported are the results of those replicate determinations with standard deviations.

RESULTS AND DISCUSSION

Different groups of microorganisms were isolated from the 60 ewe's cheese „Bryndza“ samples (Table 1). Total bacterial count in ewe's cheese ranged from 3.87 ±0.58 $CFU.g^{-1}$ from west Slovak producers to 4.32 ±0.17 $CFU.g^{-1}$ from middle Slovak producers. Generally, the coliform bacteria ranged from 3.46 ±0.26 $CFU.g^{-1}$ from east Slovak producers to 3.64 ±0.19 $CFU.g^{-1}$ for bryndza from middle Slovak producers. The number of lactic acid bacteria ranged from 3.14 ±0.09 $CFU.g^{-1}$ from east Slovak producers to 3.24 ±0.21 $CFU.g^{-1}$ in the bryndza cheeses from west Slovak producers. Table 2a and Table 2b showes isolated species of bacteria.

The eukaryotic microorganisms were represented largely by members of the genera of *Dipodascus* and *Kluyveromyces*, which were present at a level of 99 isolates and 60 isolates, and by other yeasts, which were present in *Candida* genera (Figure 3). The moulds were present generally at middle levels, with the most colonies of *Rhizopus* spp. With 21 isolates. All samples contained high numbers of lactic acid bacteria belonging to genera *Lactobacillus, Lactococcus* and *Leuconostoc*. In order to obtain a better view of the lactic acid bacteria isolates, the *Enterococcus, Lactobacillus, Lactococcus, Leuconostoc and Pediococcus* strains were identified by mass spectrometry assays. Representatives of the species *Leuconostoc mesenteroides* ssp. *mesenteroides* were isolated and identified in all bryndza cheese samples (Figure 2).

Different *Lactobacillus* species, such as *Lb. brevis*, *Lb. delbrueckii*, *Lb. fermentum, Lb. helveticus, Lb. harbinensis, Lb. jonsonii, Lb. paracasei* ssp. *paracasei, Lb. plantarum, Lb. paraplantarum, Lb. rhamnosus* and *Lb. suebicus*, were identified in the bryndza cheese samples from all producers (Figure 2). The most isolated species were *Lb. brevis, Lb. fermentum* and *Lb. plantarum.*

There were totally 1175 isolates identified by mass spectrometry include G^-, G^+ and microscopic filamentous fungi in our study. Together 199 isolates were (Figure 1) isolated and identified from G^- and most frequently species was *Escherichia coli*, 599 isolates from G^+ with most isolated species *Leuconostoc mesenteroides* ssp. *mesenteroides* (Figure 2) and 377 isolates of yeast and molds where the most frequently isolated species was *Yarrowia lipolitica* (Figure 3).

Table 1 Groups of microorganisms in ewe's cheese „Bryndza".

Microorganisms	Content CFU.g^{-1}		
	east	middle	west
Total bacterial count	4.05 ±0.45	4.32 ±0.17	3.87 ±0.58
Coliforms bacteria	3.64 ±0.19	3.60 ±0.21	3.46 ±0.26
Enterococci	2.77 ±0.23	2.71 ±0.17	2.67 ±0.29
Lactic acid bacteria	3.24 ±0.21	3.17 ±0.10	3.14 ±0.09
Yeats and molds	2.41 ±0.19	2.28 ±0.14	2.18 ±0.10

Figure 1 Gram negative bacteria isolated from ewe's cheese bryndza.

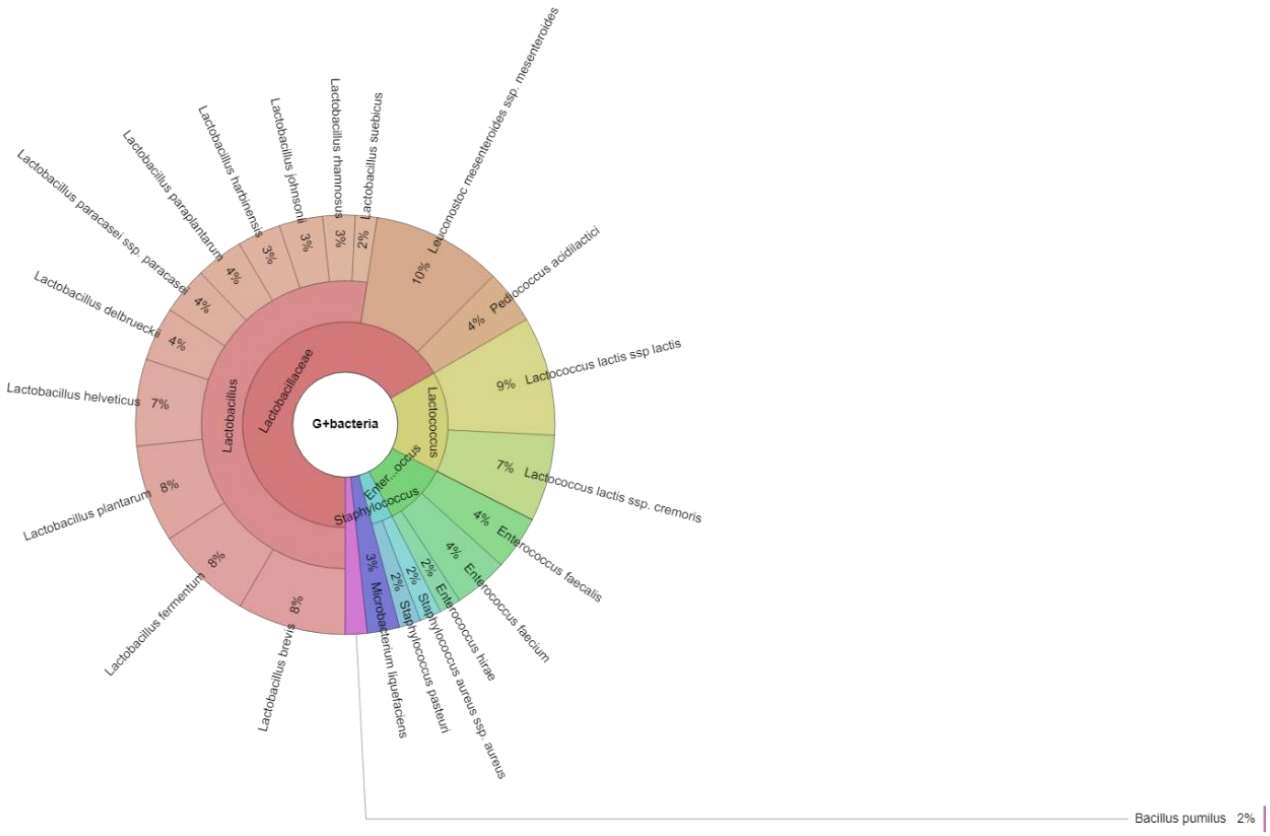

Figure 2 Gram positive bacteria isolated from ewe's cheese bryndza.

Figure 3 Microscopic filamentous fungi isolated from ewe's cheese bryndza.

The distinctive flavour of bryndza cheese produced in month May is apparently composed from compounds contained in ewes' milk and from the products of fermentation of the substrate by microflora. Principal volatile aroma-active compounds of May bryndza cheese have been characterized by **Sádecká et al. (2014)**.

Due to composition and activity of microflora is estimated to have a great impact on the flavour of bryndza cheese, several culture-based as well as culture-independent microbiological studies were carried out in this regard. Data from older culture based studies, which identified *Lactobacillus* spp., *Lactococcus* spp., *Streptococcus* spp., *Enterococcus* spp., *Kluyveromyces marxianus* and *Galactomyces geotrichum* as main components of the microflora of bryndza cheese **(Palo and Kalab, 1984; Görner and Valík, 2004; Görner, 1980)** were updated by a study of **Berta et al. (2009)**, in which a range of *Lactobacillus* spp. isolates were identified by 16S rDNA sequencing. Enterococci **(Jurkovič et al., 2006)**, staphylococci **(Mikulášová et al., 2014)** and fungal species **(Laurenčík et al., 2008)** were cultured and identified in bryndza cheese. Culture-independent studies **(Chebeňová-Turcovská et al., 2011; Pangallo et al., 2014)** provided information on the diversity of bacteria and fungi and its dynamics during the production of bryndza cheese. In the production of bryndza cheese, also interactions between lactic acid bacteria and *Galactomyces*/*Geotrichum* group **(Hudecová et al., 2011)** and competition between lactic acid bacteria and coagulase-positive staphylococci **(Medveďová and Valík, 2012)** were studied.

Although basic information on May bryndza cheese is available regarding microbiological composition as well as aroma-active compounds, most of the previous experiments were done on a limited geographical basis, sometimes with products of just one factory. In order to obtain a more reliable and representative view, this study aimed to gain data for the products from the entire territory of Slovakia that is relevant to bryndza production, i.e. specified mountainous regions of Slovakia **(Commission Regulation (EC) No. 676/2008)**. In Slovakia, the presence of Carpathian Mountains creates different climatic conditions that can have influence various characteristics of the produced bryndza cheese. These can relate, in particular, to the ewe's diet in terms of different plant species composition in the pasture and, therefore, to the quality of milk used for the production of bryndza **(Ostrovský et al., 2009)** and to different temperatures at which the lump cheese is produced, which can affect the microbial consortia in the beginning of the ripening process **(Görner and Valík, 2004)**.

CONCLUSION

The aim of our study was to evaluate the microbiological quality of Slovak ewe's cheese bryndza from producers of east, middle and west Slovakia. The number of isolated group of microorganisms was accurate for the traditional cheese produced in Slovakia. Totally 1175 isolates of bacteria with score more than 2 were identified with MALDI TOF MS Biotyper.

INFLUENCE OF REDUCTION ON ADHESIVE PROPERTIES

Igor Stadnyk, Volodymyr Piddubnyi, Svitlana Krsnozhon, Nataliia Antoshkova

ABSTRACT
An analytical analysis of the action of rolls on the medium and its behaviour at adhesion bonds with its surface are carried out. The methods and means of carrying out researches on determination of surface roughness are offered, and the experimental setting for determining the adhesion strength is developed. To reveal the essence and understanding of the general research execution, a number of hypotheses for the determination of adhesion are given and a generalized approach to the definition of adhesion is given. The physical nature of the influence of the roughness of the roller surface on the injection of the dies depends on the shape and angle of roughness, the application of mechanical forces, the degree of its previous dispersion (recipe) and its physical and mechanical properties. The nature of the contact interaction of the dough with the rough surface of the roller working organ in the injection nozzle of the fumigation machine is established. Violation of these mutual relations leads to the production of poor-quality products and a reduction in the efficiency of the machine. The contact area of the adhesive and the component forming work for overcoming the adhesion and deformation of the environment in determining the criteria influencing the process according to each particular period of the deformation stage are substantiated. The obtained data give an answer to a number of questions about the possibility of interaction of the surface of the working bodies from the environment. On the basis of their data, the actual change in the contact adhesion in the roller unit of the molding machine with a comparative analysis of existing ones with the newly designed design is considered. It is established that in order to provide a constant area of actual contact, which contributes to better adhesion, and, accordingly, the passage of a qualitative process of tightening, compression and pouring, the necessary condition is the consistency of the specified criteria. This means that the actual contact area $S_{f.к}$, varies from $S_{N.к}$ to S_c depending on the ratio of parameters.

INTRODUCTION
In food technologies, in the preparation of raw materials, the receipt of semi-finished products, finished products, their storage is important interaction product with various moving and stationary surfaces. Such interaction, as a rule, leads to the adhesion of the product to the surface of the working bodies, working chambers of technological equipment, as well as structural and technological materials etc. In technology, the phenomenon of sticking is called adhesion **(Zimon and Yevtushenko, 1985)**.Adhesion of the food masses is often undesirable. Oftentimes one has to face the phenomenon when the dough is sticking to the surface, and when it is removed, the part remains on the surface of the latter. This results in loss and deterioration of the semi-finished product and its appearance. Consequently, it negatively affects the efficiency of the use of equipment. The quality of the product, leads to increased costs of raw materials and energy resources, complicates the sanitary conditions of enterprises. In the previous part of our research, an example of the effect of adhesion is given. Effect of adhesion in the formation of bagels, drying on a molding machine, where the surface of roller working bodies is rough, has grooves, grooves. This is evidenced by the sticking of the dough to the surface of the roller working bodies of the molding device **(Stadnyk et al., 2018)**.With the wide introduction into food production of modern automated, integrated mechanized lines, when the processing speed of the non-Newtonian food masses has significantly increased and new building materials are widely introduced, there is always a need to study the strength of adhesion, modelling processes. Modelling of technological processes is directed to the separation zone, considering both the type and condition of the surface, and the structural and mechanical properties of the non-Newtonian food masses. Processes associated with the adhesion of structured food masses, such as dough, baking and flour confectionery products, are still poorly studied and especially difficult to model. This phenomenon was investigated by many inventors who revealed the essence and possible ways of decreasing adhesion, its determination with the help of theoretical and experimental studies and was substantiated by mathematical modelling. Therefore, in our opinion, to

reduce the negative impact of adhesion on technological processes can be by means of a comprehensive study of this phenomenon, i.e., based on the application of modern methods of simulation, analysis of processes in the contact area, the product -product.

ANALYSIS OF LATEST RESEARCHES

The adhesion of the elastic-plastic food masses is realized at the boundary between the two solids. Elastic-plastic bodies have abnormal viscosity, which varies depending on the shear stress, mass properties and other factors. The reason for the variability of viscosity is the peculiarities of the structure of elastic-plastic bodies. Adhesion as a superficial phenomenon arises at the boundary of the distribution of two phases of heterogeneous condensed bodies: the food masses – one phase, the contact surface - the second phase **(Moriarty et al., 2011)**. Superficial properties of the food masses, in particular, adhesion, depend on the bulk properties of the masses themselves. The latter determine the contact area of two bodies, which affects the amount of adhesion and its consequence, which characterizes the condition of the surface after removing the adherent mass. The separation of material from a solid contact surface may have adhesion (the boundary separates through the surface of the contact surface), cohesive (the fringe is contained in the product layer) and mixed **(Hoevar et al., 2014)**. Adhesion is due to various forces and connections by nature, they can be divided into two groups. The first group of forces is manifested in the convergence of two bodies and in the absence of contact between them, when there is a gap of a certain magnitude. The same forces act after the violation of the contact of dissimilar bodies and cannot exist in the absence of contact.As a result of the works under consideration **(Stadnyk et al., 2019)** it was established that the structural parameters of the rolls are directed to ensure the flow of the dough during its alignment and redistribution in the volume of its mass due to the smooth drag, transport and injection in the gap between them. Although the process of injection of medium (dough) with rollers at first glance seems simple, but the construction of its mathematical model and the search for the basic calculations of dependencies is quite complicated. Now there are a number of solutions for this problem, which are based on simplification of the actual process and do not consider the influence of the elastic-viscous and plastic structure of the dough and the action on it of the pressure fluctuations. Due to the fact that the pressure of the dough on the roller working bodies is transmitted on a normal basis, on the basis of the applied working pressure and the diagrams of its change over the length of the working chamber, one can determine the forces acting on them in the zones of power and pumping. **(Stadnyk et al., 2018)**, grain storage.Surface adhesion is considered to be a complex physical and chemical process that depends on surface properties such as topography, roughness, hydrophobicity, chemical composition and surface energy; the initial amount of the medium, its size, temperature and pH of the environment, etc. **(Hoevar et al., 2014; Whitehead and Verran, 2007; Merritt and Yuehuei, 2000)**. However, among many of the factors that influence the process of adhesion, researchers **(Whitehead and Verran, 2007; Merritt and Yuehuei, 2000)** believe that surface properties play a major role. As a result, three theories of microbial adhesion to the surface have been proposed: thermodynamic, DLVO (Deryaguin-Landau-Verwey-Overbeek) theory and the theory of extended XDLVO **(Hoevar et al., 2014; Whitehead and Verran, 2007)**.The thermodynamic theory is based on the fact that when the particles are attached to the surface there is a change in the total free energy of Gibbs (the energy, which is determined in the closed system). This energy is calculated by the equation of Lifshitz-van der Waals and the acidic interactions of Lewis **(Hoevar et al., 2014)**.

$$G_{ADN} = \Delta G_{LW} + \Delta G_{AB}$$

Where:

ΔG_{ADH} – change in the total free energy of Gibbs involved in adhesion; ΔG_{LW} – the change in the total free energy of Gibbs and the forces of Lifshitz-van der Waals; ΔG_{AB} – change of free energy of acidic main forces of Lewis.

The thermodynamic theory assumes that adhesion is always a reverse and distance-independent process. This theory does not determine the influence of surface charge and the concentration of electrolytes in the environment. It is believed that this theory is most accurate when working with uncharged surfaces or in the presence of a large number of electrolytes in the medium **(Hoevar et al., 2014)**. The theory of DLVO is based on the thermodynamic theory, and also suggests that adhesion is the sum of interphase energies. This theory believes that colloidal particles of a disperse system can easily unite with each other until contact of their liquid diffuse shells occurs.

$$U^{DLVO} = U^{LW} + U^{EL}$$

Where:

U^{DLVO} – full energy interactions; U^{LW} – the energy of the forces of Lifshitz-van der Waals; U^{EL} – electrostatic energy interactions.

The theory assumes that adhesion can be reciprocal and depends on distance. It is most accurate when electrostatic forces prevail, but it is limited in the case of ignoring the effect of polar interactions **(Hoevar et al., 2014)**. In order to more accurately model microbial adhesion, the theory of XDLVO, based on the thermodynamic and DLVO theory, was proposed. According to this model, it is assumed that the adhesion is the sum of the forces of Lifshitz-van der Waals, the electrostatic and free energy of the acid-base forces of Lewis.

$$G_{ADN} = \Delta G_{LW} + \Delta G_{AB}$$

Where:

U^{DLVO} – full energy interactions; U^{LW} – the energy of the forces of Lifshitz-van der Waals;U^{EL} – electrostatic energy interactions; U^{AB} – the energy of the acidic main forces of Lewis.

As in the case with the DLVO theory, the XDLVO model believes that adhesion can be reciprocal and depends on distance.However, researchers **(Hoevar et al., 2014; Whitehead and Verran, 2007)** believe that all three theoretical models, which aim to reveal the essence of adhesion to the surface, are designed for an ideal colloidal system.

Scientific hypothesis

In production conditions, adhesion is a much more complicated process and its attachment to the surface may occur in different ways. Therefore, in our view, the process of adhesion to the surface in practice often differs from the above described theories. This is due to the fact that the surfaces of solid materials are exposed to various contacting media, adsorb organic and inorganic substances, thus forming a conditioning layer, to which the attachment of the contact medium comes. In the future, under the action of the driving forces, the formed air conditioning layer changes the physical and chemical properties of the surface, and this affects the process of adhesion.

On the basis of the above, we consider that the adhesion of the medium to solid surfaces is a two-phase process, which consists of the initial inverse (physical) and the next irreversible (molecular or cellular) phase. Adhesion to the solid surface can also be passive or active, which depends on the driving forces and transport of cell media on the basis of gravity, diffusion, or hydrodynamic forces. In addition, the process of adhesion is influenced by the physical and chemical properties of the medium, phase composition and surface roughness.

Therefore, when studying adhesion, we pay attention to the surface roughness and the parameters of the topography. Thus, proceeding from this, the process of adhesion is closely related to the amplitude surface parameter (roughness) and its spatial changes, which are characterized by morphological features of the surface (topography). Therefore, the theory of attachment of the medium to the surface should consider mainly the physical and chemical aspects of the surface of materials, and to a lesser extent, pay attention to the morphological and physiological features of the medium.

MATERIAL AND METHODOLOGY

A dough with a moisture content of 33%, for high quality wheat flakes on pressed yeast, was prepared in an opaque manner with a fermentation time of 60 minutes at a temperature of 32 – 33 °C. The quality of the pressed yeast corresponds to the DSTU. Characteristics of wheat flour:

- mass fraction of moisture,% – 14.5;
- the content of raw gluten,% – 28;
- resistance gluten compression on the device IDK-1, per.pril. – 54;
- gluten stretch, cm – 14.

The study of the dough injection process was carried out on the molding machine B-54 of the confectionery factory (Ternopil). It is known from work **(Zimon and Yevtushenko**, **1985)** that the adhesion is determined by separating the medium from the surface, measuring the separation effort. In this effort, the adhesion resistance of the medium is calculated. Therefore, the adhesiveness of the Fvd (equal to the ratio of the fracture effort of the Fvd model to the area of the nominal contact Shk) depends on the size of the surface and adhesion, the conditions of contact and the separation of the dough. Adhesion was seen as a process that occurs in time when the surfaces of two heterogeneous bodies come into contact or are violated. For the quantity that quantitatively evaluates the adhesion, the work of the separation (strength) and the unstable process of filling the medium (dough) of the groove surface of the roll at the pressure of the previous loading Pk were used.

The problem that complicates the determination of adhesion strength is the establishment of the actual contact area. After all, the size of the area of actual contact is influenced by many factors: normal pressure, the nature of the contacting bodies, as well as external factors - temperature, tenseness, duration of the previous load, speed of growth separation effort. These factors have a different effect on the change in the actual contact area.

An analysis of existing methods of studying the adhesion properties of food products showed that all the methods considered have their advantages and disadvantages. In this regard, an experimental device was developed for the study of adhesion properties of the dough consisting of vessel 1 (Figure 1), plate 2, rod 3, cargoes 4, measuring vessel 5, capacity 6, flexible hose 7, valve 8, a cable 9, a pulley 10, a tripod 11, a guide 12, and a valve 13.

This installation worked as follows. A bowl of uniform dough was placed in the vessel 1, on top of which a wide plate 2 with a rigidly fixed rod 3 was installed. The previous loading was carried out by measuring loads 4 which were mounted on the plate 2. In a measuring vessel 5, a liquid from the container 6 was fed by means of a flexible hose 7 and thus created the separation effort that was transmitted to the plate 2 by means of a rope 9, which is one end attached to the rod 3, and the other to a measuring vessel 5. In the vessel 6, a constant level of liquid was maintained. The valve 8 made it possible to adjust the flow rate of the liquid to the measuring vessel 5 and thus adjust the rate of application of the force to the plate 2.

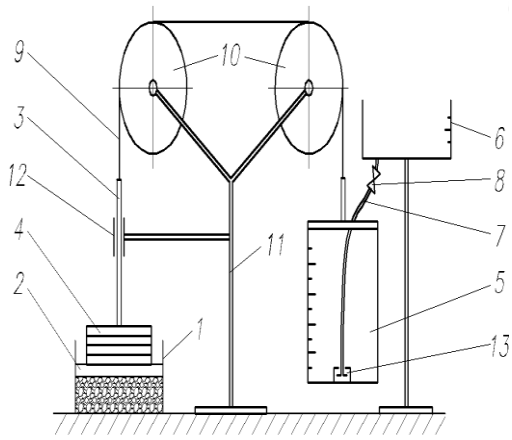

Figure 1 Scheme of the installation for the study of adhesion propertiesprotein dispersed phase:1 – a vessel; 2 – plate; 3 – stock; 4 – cargoes; 5 – measuring vessel; 6 – capacity; 7 – flexible hose; 8 – valve: 9 – cable: 10 – pulleys;11 – tripod; 12 – guiding; 13 – valve.

The change in the direction of the force by 180 ° was carried out with the help of pulleys 10 which are attached with the possibility of rotation around their axis on the tripod 11. As a previous load so and the separation effort acted at right angles to the plate 2.

This was provided by means of a guide 12 rigidly attached to the tripod 11. After the complete separation of the plate, the 2-meter vessel 5 moved down and the valve 13 blocked the feeds in the liquid from the vessel 6. The separation effort was determined through the volume of the liquid that was in the measuring vessel 5 after the plate was detached.

The developed experimental setup allowed to regulate parameters that influence the adhesion interactions: the pressure of the previous loading (0 – 10 kPa), the separation effort (0 – 100 N), the rate of growth of the separation effort (0.2 – 2 $N.s^{-1}$) and contact area

The quarrying of the experimental set-up was to determine the force to be applied to rod 3 to ensure that the plate 2 is detached from the bottom of the vessel 1 provided there is no layer of the protein disperse phase in vessel 1.

The dough was applied uniformly to the bottom of a rigid vessel with cylindrical walls in such a way that the height of the layer was 1.2 x 10^{-2} m. The area of the bottom of the vessel corresponded to the area of the plate and amounted to 7.8 x 10^{-3} m^2.

Adhesion strength was determined by substituting data obtained during the experiment into the following formula:

$$P_a = \frac{F - F_0}{S_k}$$

Where:

F_0 – separation effort in the absence of the test material in the vessel, H.

Methods of study of roughness of a surface

Experimental researches were carried out using modern technical and standard methods (determination of surface roughness of steel), microscopic (light and electron microscopy of the process of formation and degradation of dough residues), spectrophotometric (optical density (density), mathematical and theoretical modelling, statistical). Used plates of stainless corrosion-resistant nickel-chrome austenitic steel in the size of 30 × 30 mm and 5 mm thick, with roughness of the surface R_a = 2.687 ±0.014 microns, R_a = 0.95 ±0.092 microns, shown in Figure. 2. Their roughness corresponded to the surface of the roll.

The roughness of the surfaces of the stainless-steel plates was determined using a profiler of the mark 296. The profile of the profile (Figure 3) includes: a rack 3 for installing parts with a diamond measuring needle, a drive 1 for moving the sensor along the measured surface and an electronic unit 2 for control and calculation roughness of the surfaces. The measured part is mounted on the plate of the rack 3. If the part has a cylindrical shape, the prism 5 is installed on the stove plate and the measured part is mounted on the prism 5. The part is set so that the measured surface is perpendicular to the measuring plane. The nut 6 is designed to move the sensor 4 with actuator 1 along the guide rack 3 and install the diamond needle of the sensor 4 on the measured surface of the part.

R_a = (2.68±0.014) microns, R_a = (0.95±0.092) microns, R_a= (0.63±0.087) microns

Figure 2 The appearance of the stainless plates with different roughness: a- native appearance of the plates; B-appearance of plates using microinterferometer MII-4U4.2 (increase 1500 times).

Figure 3 Ploofilometer mark 296.

Electronic block 2 is executed in a desktop version. On the block front panel there are: a digital scoreboard for the measured Ra value; indicator of the working area; power button.

Statistical analysis

Considering the chaotic interaction of the dough during its displacement, where the change of interaction occurs between the broad-walled surface in the surface of the roll, the task planning experiment with the use of a full factor experiment of the second order is compiled. With two factors, the model of the experiment's function has the form:

$$y = f(X_1 X_2)$$

According to the results of the experiment, we obtain a regression equation of the second order.

$$Y = b_0 + b_1 x_1 + b_2 x_2 + b_{11} x_1^2 + b_{22} x_2^2 + b_{12} x_1 x_2$$

For experiments a plan with corresponding matrices of experiment planning with the number of experiments and boundaries of factor changes has been drawn up. The matrix is a list of options taken in this series of experiments. Independent variables were selected from the analysis of the nature of the effect on the change in the contact angle of the dough with the roll (forums number 5). As a parameter of optimization, the side a and the contact area of the broadened surface S are used respectively.

X_1 – side length **a**, mm;

X_2 – the contact area of the broad surface **S**, mm^2. Experiments were carried out on the basis of mathematical planning. Determining which factors influence the change in the angle of contact, we determine their level variations and the step of variation. The main factors and their variation equation are given in Table 1.

Output parameters were:

$У_1$ – change in the angle of interaction of the dough in height of its movement in the gap between the burrs. The displacement height of the test mass was recorded by the visual control method on a scale applied to the working roller;

$У_2$ – change the angle of interaction of the dough on its contact area on the roll surface. The weight of the test was fixed by the method of visual inspection according to the photographs.

Using the obtained data of the regression coefficients, we make a regression equation for $У_1$ and $У_2$

$$y_1 = -54.39 - 3a + 12.07S + +0.59a^2 + 0.21aS - 0.33S^2$$

$$y_2 = -17.43 + 0.8a + 3.13S + 0.11a^2 - 0.09aS - 9.9S^2$$

The analysis of the impact of the surface roughness of the roll confirms our opinion about the activity of adhesion at the injection stage and its dependence on the driving forces. From the graphical dependencies of Figure 5 – 8 it is quite clear about the influence of the parameters a and S on the process flow. Therefore, the change in the angle of interaction of the dough in its height of movement (Figure 5) depends significantly on X_2 – contact area and quite significantly depending on X_1 – the length of side a (the basis of latitude).

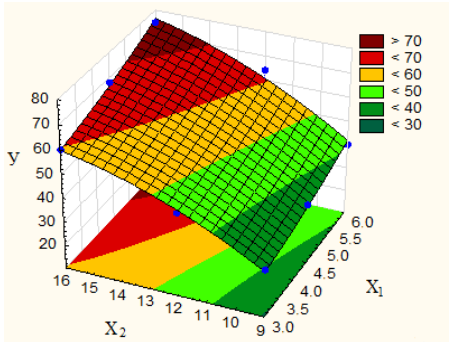

Figure5 Two-dimensional section of the surface of the response as a function.

The optimum values are within the range of 50 – 600 at the values a = 4.5 – 5.5 mm, S = 11 – 13.5 mm^2. To change the angle of interaction of the dough along its contact plane $У_2$ – the optimal values are at the corner 6 – 9^0 at values a = 5 – 6 mm, S = 10.5 – 12.5 mm^2.

Thus, the surface of the roll really creates conditions for the movement of the mass of the dough both on its surface and in the layers placed in the working chamber.

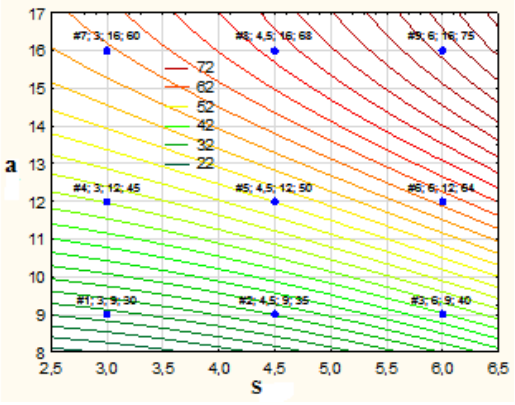

Figure6 Surface response $У_1$ = f (a, S).

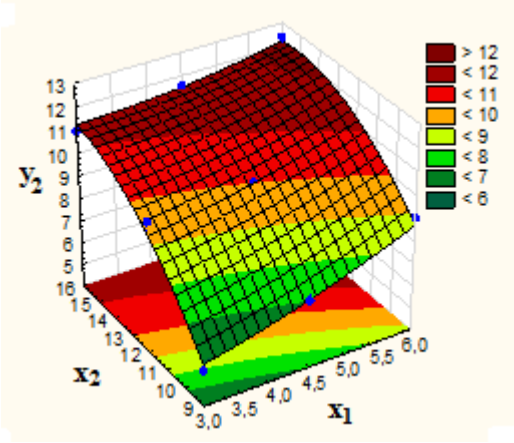

Figure 7 Two-dimensional section of the surface of the response as a function $У_2$ = f (a, S).

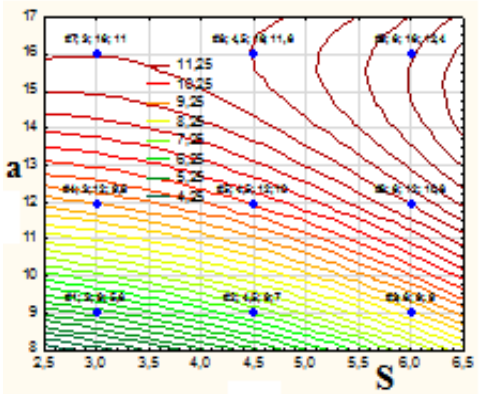

Figure 8 Surface response $У_2$ = f (a, S).

RESULTS AND DISCUSSION

The formed adhesion on the surface of the roll consists of an inhomogeneous structure, resulting in a gas concentration gradient, in particular, reducing the amount of oxygen from the periphery to the depth of the environment, pH gradients and temperature. Such gradients of functioning provide contact between the two bodies, resulting in phenotypic resistance to abrupt change in environmental factors. Data from the scientific literature **(Hoevar et al., 2014 Stadnyk et al., 2016; Gorbatov, 1979)** indicate that when studying adhesion, it is necessary to approach complexly and consider, along with roughness, the topography of the surface, as these quantities are interdependent. Consequently, the adhesion process is closely related to the amplitude parameters of the surface (roughness) and its spatial changes, which are characterized by morphological features of the surface (topography).

Studies on the effect of terrain and surface roughness on adhesion are not straightforward. Thus, according to **(Stadnyk et al., 2018; Nikolaev, 1976; Jullien et al., 2003)**, there is a correlation between surface roughness and adhesion, with the attachment of the medium to the surface increasing with increasing roughness. However, other studies indicate **(Kolari, 2003; Kukhtyn et al., 2017;Langsrud et al., 2016)** that there is practically no correlation bond between the roughness of the surface of the stainless steel and the roughness range of 0.01 to 3.3 μm. It has also been found that adhesion on surfaces with high roughness reduces the efficiency of heat transfer in heat exchangers by about 15% **(Kukhtyn et al., 2017)**.

Therefore, the conflicting data obtained by scientists regarding the effect of the surface roughness of stainless steel on the adhesion process are obviously related to the experiments under different conditions using different media, materials and methods of study. However, scientists have concluded that such elements of the surface topography as scratches, cracks, holes, protrusions, cracks play an important role in the adhesion process **(Kolari, 2003**; **Monds and O'Toole, 2009; Moons and Michiels, 2009; Zogaj et al., 2003)**.

The results of the analytical review and the conducted research and statistical modelling made it possible to approach the development of methods for determining the surface and adhesion strength by mathematical modelling. Based on the above and the data processing, two mathematical modelling approaches are proposed that can be used to determine the adhesion strength and strength.

Method of determining the wide surface of the roll

The results of the computational experiments allowed to investigate the effect of changing the angle of roughness of the roll surface on the interaction with the dough. From the studies it is clearly seen that the angle of roughness of the surface when interacting with the dough affects the adhesion properties. This approach allows us to determine rational design parameters that will contribute to the intensification of the dough injection process. Based on previous studies **(Stadnyk et al., 2019)**, when studying adhesion, it is necessary to approach the complex and consider, along with the roughness, the topography of the surface, since these values are interdependent. The surface

roughness refers to the two-dimensional surface of the material and is usually described as arithmetic mean roughness (Ra) and average square roughness (Rq). At the same time, the topography has three dimensional parameters and describes the elements of the shape of the surface. Under the strength of adhesion, adhesion must be understood as a function of factors such as separation speed, duration and pressure of the previous contact, flat contact, etc. It is necessary to distinguish between the strength of adhesion, which is measured in H (Newton), and the strength of adhesion – $N.m^{-1}$.

Interaction on the boundary of two phases, that is, the dough and the surface of the rolls, occurs from the first seconds of the molding machine. Therefore, the phenomenon of wetting the roller surface is related to the ratio of surface tensions (σ) of the adhesive and substrate. To achieve wetting on the surface of a well-adhesive roller, it must be ensured that the surface tension of the substrate is greater than the surface tension of the adhesive. This will accelerate the process as a whole with a corresponding reduction in energy costs.

The studies carried out by the authors found that the strength of the adhesion of the dough at speeds of its separation from the roller working body of the molding machine was not determined more than 1 $m.s^{-1}$. This is due, first of all, to the lack of simulation of the existing processes of formation, transport of the dough, which is mainly due to relatively small speeds of movement of the working bodies of the molding machine.

Power interaction of the medium with a roll occurs on its surfaces after the discrete injection of the mass of the test. Since the method of formation and the shape of the interaction profiles of the dough with the surface of the roll has a significant impact on the quality characteristics and the injection process, a number of comparative studies have been carried out to determine the rational roughness section of the roll.

To increase the force of adhesion between the viscous medium and the leading roller working body is possible by increasing the angle of coverage in accordance with the well-known law of Euler:

$$S_{nab} = S_{nag} e^{\alpha f}$$

Where:

S_{nab} and s_{nag} – respectively, tightening at the points of the runoff of the medium and its coincidence with a rough surface; α – the angle of coverage of the medium; f – coefficient of friction in a pair of materials.

The change in the angle of coverage of the medium is achieved due to the geometric orientation of the tightening and its injection. The problem of geometric synthesis of the system with an increase in the angle of coverage of the medium is solved on the basis of geometric bonds. Consider cases of power interaction, in which the line of vertices of roughness of a roll:- parallel to the vector of injection velocity $\upsilon_p$and the circular power R_{KB} (angle α = 0 °);

- not parallel to the velocity vector injection υr and circular power R_{KB} (angle α >0°).

The angle α depends on the lifting of roughness (Figure 6). Roll movement in the middle during its injection can be divided into 3 components:

- rectilinear horizontal in the direction from the axis of the roll to the inner surface of its body, due to centrifugal force Pvb;

- rotational horizontal in the direction of rotation of the roll due to the force of the knee P_{KB};

- straight vertical from the force of gravity on the dough layer of the dough that is above it $P_{TG.}$

Due to these movements, the friction forces (adhesion) appear on the upper and lower front roughness of the roller surface. The three components of the dice movement described above correspond to the coordinate axes of the XYZ Cartesian coordinate system (Figure 9). That is, the direction of the axis OX (vertical axis) coincides with the direction of gravity, $P_{TG.}$, OY (horizontal axis) with the direction of action of the centrifugal force P_{VB}, OZ (orthogonal) with directional velocity υ_{KB}, circular force P_{KB} and the forces of compression of the dough P_{CT}. With a steady state of work, we assume that the velocity of the circle υ_{KB} will be equal to the pumping speed υp ($\upsilon_{KB} = \upsilon_{н}$).

In the case of α = 0 °, the vertical coordinate plane XOY will be perpendicular to a plane passing through lines of roughness to its front surface. If α >0 °, then the angle between the above-mentioned planes will be 90 °±α.

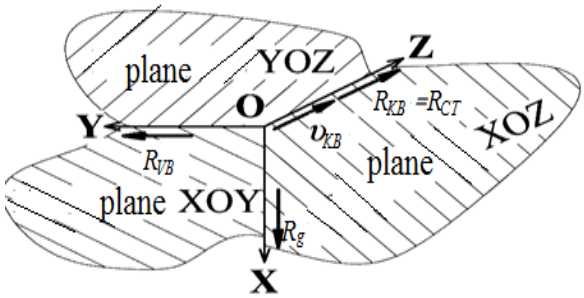

Figure 9 Coordinate system, which considered power interaction: R_{VB}– centrifugal force; Rg– gravity force; R_{KB} – the force acting on the dough; P_{CT} is a compressive force; υ_{KB}– circular speed.

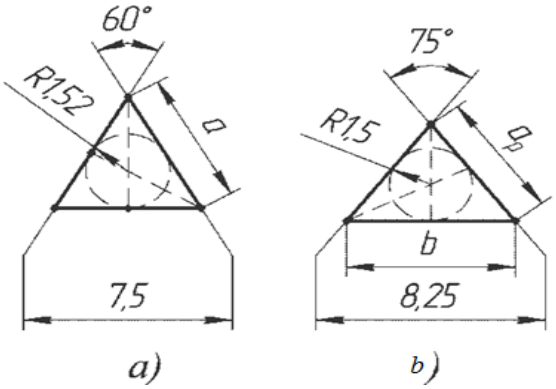

Figure 10 Cross-sections of roughness of different profiles with an area of 1.2 mm^2 each: a) triangular, equilateral; b) triangular, equidistant.

For comparison, two triangles were chosen (an equilateral triangle, an equilateral triangle with an angle at

the vertex of 75, cross-sections of roughness with an area of 1.2 mm^2 each (Figure 10).

For an equilateral triangle S, the length of a side is determined by the formula:

$$a = \sqrt{S\frac{\sqrt{3}}{4}}$$

For an isosceles triangle, the area (S) will be determined by the formula:

$$S = \frac{1}{2}a_p b sin\alpha \quad (4)$$

Where:
a – side of the triangle; b – the basis of the triangle; S – is the angle between the side and the base (for an isosceles triangle with an angle at the apex 75 ° α = 52.5 °).

We will define the projection theorem ***b***:

$$b = 2a_p cos\alpha \quad (5)$$

Substituting equation (5) into formula (4) and expressing ***a***, we obtain it:

$$a_p = \sqrt{\frac{S}{cos\alpha\ sin\alpha}}$$

Where:
S =1.2 mm^2 → *ap* = 0.498 mm, *b* = 0.606 mm.

Method of determining adhesion strength

At the moving surface of the rotary rollers, a general work is performed which consists of elastic forces and changes in the contact of the rolling dough: $A_z = A_{pr} + A_k$.

Work of elastic forces:

$$A_{pr} = S_{nk}(l_1 - l_0)$$

Specific work 1 kg of dough (in J) can be calculated by the formula:

$$A_{pr} = \frac{A_z}{m_{sr}\ 10^3}$$

Where: m_{sr} – average weight of dough between surfaces of rotating rolls, kg:

$$m_{Sr} = \frac{V}{v}$$

Where: υ – specific volume; V– camera volume.

The work that is spent on changing the contact of a moving layer of the medium with the surface of the working chamber and rollers to overcome the adhesion and deformation of the medium A_d, will be:

$$A_V = A_{ad} + A_d = F_V dx = F_{ad} dh + A_d dh$$

Where:
F_{ad}, A_d – the efforts of adhesion and deformation;
h – the thickness of the medium on the surface of the roll when the separation of its layer on the subsequent process -formation;
F_{vid} – the effort of separating a piece of medium from the surface of the roll.

Consider the components forming the work of the separation:

$$F_{ad} = \int_o^i frld = f_{ad} rl^2 \quad (6)$$

Deformation of the environment is determined:

$$F_d = \tau_0 \frac{V_v}{h} rl \quad (7)$$

Where:
V_v –the speed of separation of the medium from the surface of the roll under the action of external forces; τ_0 – tangential stresses; η – plastic viscosity of the medium; r – dough layer on roller; l – the length of contact of a part of the working body.

Given the length of the contact area, we obtain the expression:

$$F_d = \tau_0 \frac{V_v}{h}\ rl$$

Work determined by the separation effort is spent on overcoming adhesion F_{ad} and deformation of the medium, when exiting through a rectangular molding surface between rotating rolls F_{def}

$$F_V = F_{ad} + F_d \quad (8)$$

When studying the process of dough injection, one of its conditions was to change the gap between the rolls and the angular velocity of their rotation. Knowing the mass of the dough, the area of its contact with the surface of the mixing drum, with the help of the proposed method and computer symbolic mathematics, the strength of adhesion is determined.

Initial speeds are selected at three values of the crack (δ = 20 mm; δ = 25 mm; δ = 30 mm). Trajectory of the mass of the test for three cases in the car chamber: $v_0 = 0.18$ m.s^{-1}; $v_0 = 0.32$ m.s^{-1}; $v_0 = 0.4$ m.s^{-1}. On the dash movement there is an impedance which is expressed by the coefficient of resistance K. For the three clearances we make the equation of spline approximation:

$$v_0 = 0.18 ms^{-1}$$

$$K = 4.58x^2 - 3.25x + 2.7$$
$$v_0 = 0.32 ms^{-1}$$

$$K = 3.65x^2 - 2.9x + 2.69$$
$$v_0 = 0.4 ms^{-1}$$

$$K = 2.29x^2 - 2.26x + 2.73$$

Where:
v_0– speed of the dough movement at the output of the rollers, with different values of the gap;
K – factor of resistance.

The graph of the relationship between the coefficient of resistance K and the length of the dough movement at the output of the rollers (x) is shown in Figure 11.

Experimentally determining the value of length (x), substituting it into an approximation equation, one can determine the coefficient of resistance K, which is the sum:

$$K = K_{\Pi} + K_{ad}$$

Where:

K_n– component of the resistance coefficient considering the air resistance;

K_{ad}– part of adhesion.

The air resistance coefficient is 0.11.

Consequently, considering the trajectory of the dough movement at m.s^{-1} the most favourable (gap of 30 mm), we will substitute x = 0.3 into the approximation equation:

$$K = 2.29(0.3)^2 - 2.26 \cdot 0.3 + 2.73 = 2.26$$

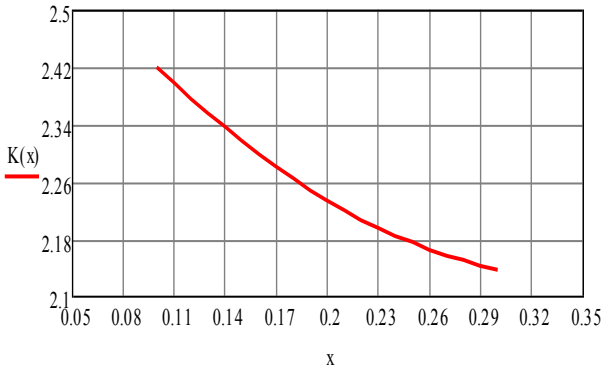

Figure11 Charts of functions K (x) for an initial speed of 0.18 m.s^{-1}.

We find the coefficient of adhesion, which in our case will be:

$$K_{ad} = K - K_n = 2.26 - 0.11 = 2.15\frac{Hc}{m}$$

In accordance with the chosen model of motion, we consider that due to adhesion, the strength of resistance appeared, directed against the movement of the mass of the test, equal to:

$$P_{on} = K_{ad}\frac{\partial x}{\partial t}$$

Since x-axis is chosen for calculations, then:

$$\frac{\partial x}{\partial t} = v_0 \cdot cos\alpha$$

Substituting this equation in (в), we obtain:

$$P_{on} = K_a v_0 cos\alpha$$

Knowing the magnitude $K_{ad}, v_{0,} cos\alpha$, we will define:

$$P_{on} = 2.15 \cdot 0.4 \cdot cos15^0 = 0.831H$$

Where:

$cos15$ – the angle between the surface of the roll and the detached moving dough during the injection process.

Area of the nominal contact

$$S = 2\pi R\frac{1}{8}(2b + \frac{2}{5}\text{R}) = 2\pi 0.11\frac{1}{8}\left(2.02 + \frac{2}{5}0.11\right) = 9.0343m^2 \quad (8)$$

Where:

R – roll radius;

b – roller width (Figure 12).

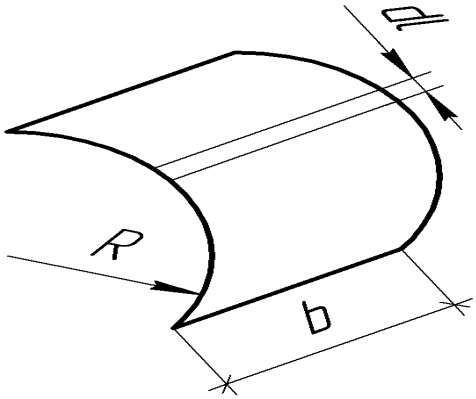

Figure 12 Scheme of Roll.

$$F_{ad} = \frac{P_{ad}}{S} = \frac{0.831H}{0.0343m^2} = 24.2\frac{H}{m^2}$$

considering relations (6) and (7) – (8), the separation effort will be in the form:

$$f_{ad} + \tau_0\frac{V_v}{h}F_V = S_{re} \cdot f_{ad} + \tau_0\frac{V_v}{h} \quad (9)$$

With these conditions, it is possible to determine the actual adhesion by the results of an adhesion test at insignificant discontinuation rates when Vv → 0.

These conditions are fully consistent with the processes taking place at the pumping stage. In addition, we know the actual contact area of the phases. Minimum actual contact area S_{nk}, formed by a contact of a dough with a roll surface, where α = 1. The maximum contact area is equal to the surface area of the roll (substrate) Sc (Figure 13).

The nominal contact area is easily determined by the geometry of the adhesive or substrate. The area of the substrate, considering the relief surface (depends on the frequency and type of its processing, Figure 13, type A) is known to us. Therefore, in the general form, the relief of the surface with the side a can be written by a double Fourier series:

$$Z = \sum_{m,n-1}^{\infty} a_{m,n} \cdot sin\frac{\pi mx}{a} \cdot cos\frac{\pi RY}{a} \quad (10)$$

Where:

Z – the value of the height of the inequalities;

a_{rs}- Fourier coefficients;

x, y – Cartesian coordinates;

m, n – Harmonic numbers.

The forces of adhesion in these cases are very small.

Expression (10) characterizes the profile of any surface. The element is selected on the surface of the areas :

$$ds = \sqrt{1} + (\frac{dz}{dx})^2 + \sqrt{1} + (\frac{dz}{dy})^2 dx \cdot dy$$

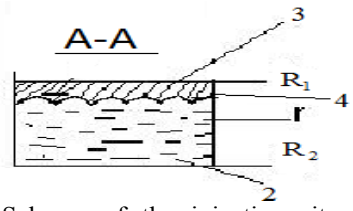

Figure13 Scheme of the injection site: 1–working chamber, 2–dough, 3–rolls; A-determination of the actual contact area of the roller working body and the dough: 2–adhesive (dough); 3 – substrate; 4 – surface of the substrate.

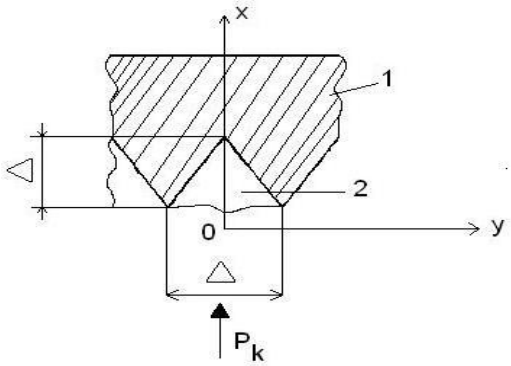

Figure14 Filling the cavity on the substrate surface 1 with adhesive 2.

Knowing the profile form, i.e. dz/dx and dz/dy, it is possible by means of integration to define Sc based on the topography of the surface. So, as the relief of the surface of the roller working body has grooves with the appropriate angle, the angle of the vertex between the groove protrusion γ = 60° at the top of the trapeze. In any arbitrarily selected slit, the relief has the form of an equilateral trapezoid (Figure 16). Then the length of the profile formed by the surface in 2 times will increase the length of the middle line of the profile. Accordingly, the surface area of the substrate will be 2 times greater than the nominal contact area.

In real conditions, the dough does not fully contact the surface of the roller working body. According to the work **(Nikolaev, 1976)**, the filling of the rough surface is proportional to the pressure and time of contact of the dough, as well as its viscosity:

$$\frac{h}{d} \sim \left(\frac{p_k t_k}{\mu}\right)^{\frac{1}{2}}$$

It can be assumed that the dough is in contact with a broad-walled surface at a contact pressure Pk. The width of the roll is characterized by the mean square value of the inequalities Rz. In this case, the cavity on the surface of the roll is filled with a dough. If the size of the macromolecules of the dough is much smaller than the slit of the surface, the law of the mechanics of continuous media propagates in the car's current and the two-dimensional flow motion passes.

In this case, the forces of inertia are small, and the forces of hydrostatic pressure, viscous friction and capillary are mutually balanced. In such conditions, to obtain the basic criteria for the similarity of the current, it is sufficient to consider the one-dimensional equation of the dough movement. In isothermal flow, when the values of the temperature of the dough and rolls are equal (this is evident from the experiments of **(Stadnyk et al., 2019)**, the equation of motion has the form:

$$Q = -\frac{\partial p}{\partial x} - \frac{1}{\rho} \cdot \frac{\partial \tau_{xy}}{\partial y} \qquad (11)$$

Where:
p – pressure;
x, y – Cartesian coordinates;
$\tau_{x,y}$– tangential tension;
ρ– density of the dough.

On the free surface of the dough, the conditions of continuity of the normal and the absence of tangential stresses are fulfilled.

We denote the radius of curvature of the adhesive on the surface of the substrate (Figure 14) Δ, then the condition of the continuity of normal stresses on the Laplace formula has the form:

$$\tau_x = \frac{\delta_{rn}}{\Delta} \qquad (12)$$

Where:
δ_{rn}– surface tension on the boundary adhesive - surface.

The rheological properties of the dough in the region of small deformation velocities, namely, when passing through the gap between rotating roller working bodies, is characterized by the Shvedov-Bingam equation **(Stadnyk et al., 2016; Believ, Egorenkov and Pleskachevsky, 1971)**,

$$\tau = \tau_0 \cdot sinj = \mu_{pl} \qquad (13)$$

Where:
τ_0– conditional yield curve;
μ_{pl} – plastic viscosity;
j – gradient of strain rate.

The tensile stress in the xx direction is determined accordingly

$$\tau_{xx} = 2B\frac{\partial v}{\partial x} \qquad (14)$$

Where:

$$B = \tau \cdot A - \mu_{pl}$$

A – the second invariant of the strain rate tensor, obtained for a one-dimensional flow from the ratio:

$$A = \frac{\partial v}{\partial x} \qquad (15)$$

Considering (13) – (15) and equation (11) and boundary conditions (12) can be written as:

$$\frac{\partial p}{\partial x} + \frac{\partial}{\partial y}\left(\tau_0 + \mu_{pl}\frac{\partial v}{\partial x}\right) = 0 \qquad (16)$$

$$2\left(\tau_0 + \mu_{PL} \cdot \frac{\partial V}{\partial x}\right) = \frac{\delta_{ab}}{\Delta} \qquad (17)$$

Replacing differentials with characteristic values

$$P \approx P_K; \text{У} - \Delta; \text{X} \approx \Delta; v \approx \frac{\Delta}{t}$$

we get dimensionless components:

$$N_1 = \frac{\delta_{AB} t_k}{\Delta \mu_{pl}}; N_2 = \frac{\tau_{0\cdot\cdot} t_k}{\mu_{pl}}; N_3 = \frac{p_k t_k}{\mu_{pl}} \qquad (18)$$

Figure 15 Photo of adhesion of the dough to the surface of the roll of a new design: 1 – roll with screw grooves; 2 – car body.

Criterion N_1, characterizes the ratio of forces of surface tension and viscous friction; N_2 analogue of Saint-Venant's criterion for conditions of non-stationary movement (flow); N_3 – takes into account the influence of contact pressure and viscous friction. Thus, completeness complements the grooves of the working body $S_{f.к}$ varies from $S_{N.к}$ to S_c depending on the ratio of the parameters of the criteria N_1, N_2, N_3. These criteria, as well as a number of others, affect the injection according to each particular period of the corresponding stage of the process. From the criterion equations, it is evident that the plastic viscosity of the dough is of great importance. At the first minutes of the process, the contacts of the medium with the surface of the roller working body pass through the basic principle of slow plastic deformation. With increased contact time with the contact pressure present, adhesion elasticity increases, mainly due to the plastic flow and is determined by the value of plastic viscosity. At the exit from the molding channel formed by the roll's criterion N_3 loses its meaning and there is a qualitative separation of the given mass of the test to the molding device. At the same time, there are two criteria N_1 and N_2 continue to affect the bulk of the dough that is on the roll, retaining its plastic properties and thereby ensuring the cleanliness of the surface (Figure 15).

CONCLUSION

To ensure a constant area of actual contact, which contributes to better adhesion and, accordingly, the passage of a qualitative process of tightening, compression and pouring, the necessary condition is the consistency of the criteria (18). This means that the actual contact area $S_{f.к}$, varies from $S_{N.к}$to S_c depending on the ratio of parameters. Therefore, to meet the requirements of the process, the gap between the rotary rolls is set at the appropriate distance to create a forming channel, which corresponds to theoretical and practical calculations. In such conditions, qualitative stages of the process in the injection site pass through large stresses of deformations. These conditions must last for a certain period of injection. Therefore, the effect of adhesion should be minimal. It is possible to change the forces of adhesive bonding only if the thickness of the dough layer is sufficiently small and in the separation from the surface of the shafts should be clean.

COMPARATIVE ASSESSMENT OF STORAGE STABILITY OF GINGER-GARLIC AND CHEMICAL PRESERVATION ON FRUIT JUICE BLENDS

Abiola Olaniran, Helen Abu, Ruth Afolabi, Charles Okolie, Akinyomade Owolabi, Oghenerobor Akpor

ABSTRACT
The study aimed at reduction of wastage of fruit, encourage production, consumption and preservation of fruit juice blends using garlic ginger filtrate with health benefits as biopreservative thus providing alternatives with biological advantage over chemical preservatives (ascorbic and benzoate acids) without altering the organoleptic and physicochemical properties of fruit juice blends. The study evaluated the potential of natural preservatives (ginger, garlic and ginger-garlic filtrates) in comparison with two conventional chemical preservatives (ascorbic and benzoate acids) for fruit juice blends preservation. The juice blend used was cashew, pineapple and watermelon. In terms of flavor and mouth feel, the order of preference of the juice were the preserved with 1% garlic-ginger > 1% ginger > 1% garlic > 1% ascorbic acid > and preserved with 1% sodium benzoate at ambient temperature. Maximum decrease in pH was observed in the juice sample that had no added preservative. Generally, all the fruit blends (preserved and unpreserved), with the exception of the one preserve with 1% ginger-garlic showed growth of bacteria after one week of storage. Juice blends preserved with the 1% ginger-garlic were most acceptable compared to other preservatives. The synergistic biopreservative ability observed with the ginger-garlic may be a preferable alternative to conventional preservatives.

Keywords: juice blends; ginger; garlic; stability; preservatives

INTRODUCTION
Juices are the extractable fluid contents of cells or tissues intended for direct consumption obtained by the mechanical process from sound, ripe fruits **(Naz, 2018)**. They are non-alcoholic liquid products with diverse degree of clarity and viscosity **(Sádecká et al., 2014)**. Fruit juices are rich in lycopene, ascorbic acid and citrulline that have been reported to have protection against cancer and cardiovascular disorders. The functionality of fruit juices have been attributed to their antioxidative properties **(Okwori et al., 2017)**. Water melon is a common staple fruit in the world consumed as a dessert, fruit salad or used fo garnishing drinks **(Mohammad, 2016)**. Cashew is a hard, drought-resistant, tropical tree, widely grown primarily for its nuts. Cashew apple, the pseudo-fruit, is fibrous, juicy and weighs approximately 8 times of the nut **(Afolayan et al., 2016)**. Much (90%) of the harvest is wasted after harvesting **(Igbinadolor et al., 2017)**. Because, cashew apple has a characteristic astringent taste with biting sensation on the tongue and throat, blending it with other fruits may lessen its astringency **(Rebouças et al., 2016)**. Raw pineapple juice is an excellent source of calcium, magnesium and manganese; however, pineapple mostly consumed around the world as canned products **(Kaddumukasa et al., 2017)**. The demand for pineapple and its juice rises continually most especially due to its health benefits **(Nwachukwu and Ezejiaku, 2014).** It is usually used for blend composition to obtain new flavors in drinks. Most juice if not refrigerated has a very short shelf life **(Okwori et al., 2017)**. Ginger is a spice with characteristic flavor due combination of zingerone, shogaols and gingerols and volatile oils. Fresh ginger is composed of 80.9% moisture, 23% protein, 0.9% fat, 1.2% minerals, 2.4% fibre and 12.3% carbohydrates **(Olaniran and Abiose, 2018)**. Ginger has antibacterial effect and exhibits antifungal activity and extended the shelf life for 8 weeks in tomato paste. Ginger powder has been compared with synthetic antimicrobial agents such as potassium sorbate and citric acid in smoked fish **(Oduah et al., 2015)**. Ginger is a commonly added to beverages for flavor. Garlic (*Allium sativum*) also regarded as Russian penicillin, stinky rose, *tafanuwa* in Hausa, *ayo-ishi* in Igbo and *ayu* in Yoruba **(Neeraj et al., 2014; Olaniran et al., 2019a)**. Garlic comprises of sulphur containing compounds, the fresh bulb contains allicin, alliin and volatile oil. Garlic has exhibited antibacterial activity against Gram positive and Gram-negative bacteria **(Olaniran et al., 2015)**. Fruit juice blends produced from different fruits combines basic nutrients present in these different fruits to provide a better quality juice nutritionally and organoleptically **(Eke-Ejiofor, 2016)**. The inhibition of microbial growth and activity of

microorganisms is one of the main purposes of the use of chemical preservatives such as benzoic, sorbic, lactic and acetic acid **(Piper, 2018)**. Benzoic acid has been used in different forms as preservative in foods because of its established antimicrobial properties against yeasts and molds. They can denature protein, inhibit enzymes and alter or destroy the cell walls or cell membranes **(Reut et al., 2004)**. Current reduction in consumption of chemically preserved foods is due to consumer's awareness of the health implication of consumption of synthetic preservatives **(Pongsavee, 2015)**. Replacing chemicals with natural preservatives (bio-preservatives) which have no side effects to the consumer is of interest. To provide alternatives with biological advantage over chemical preservatives without altering the organoleptic and physicochemical properties of fruit juice blends, the need to explore natural preservatives has been highlighted recently in scientific literature. In this regard therefore, the current study aimed to apply ginger-garlic mix; exploring their effectiveness as preservatives and assessing organoleptic acceptability of the new combination in fruit juice blends using cashew, pineapple and watermelon fruit for the storage study.

Scientific hypothesis

Biopreservatives are as effective as chemical preservatives in the preservation of fruit blends. The presence of biopreservatives in fruit blends can improved their organoleptic properties, when compare to chemical preservatives.

MATERIAL AND METHODOLOGY

Preparation of preservative filtrates

Garlic, ginger and ginger-garlic filtrates were used as preservatives in this study. For preparation of the filtrates, fresh ginger rhizomes and garlic cloves obtained from a local market in Kwara State, Nigeria. Prior to use, they were washed under running water, peeled and diced into cubes separately. The respective diced cubes (100 g) were blended with 100 mL of distilled water using a grinder (Marlex Appliances PVT, Mumbai, India) for 5 min and allowed to stay for 30 min. The suspensions were then filtered and the filtrates were poured into labelled clean bottles. Garlic-ginger mix was obtained by mixing equal volume of garlic and ginger filterate and homogenized for 60 s **(Olaniran et al., 2019b)**.

The preservatives used were 1% ginger filtrate, 1% garlic filtrate, 1% ginger-garlic, 1% ascorbic acid and 1% sodium benzoate**.**

Preparation of the juice blend

For preparation of the juice blend, pineapple, watermelon and cashew fruits were used. Three kilograms of each of the fresh, ripe fruits were respectively washed under running water, drained in colanders, peeled and diced into cubes. Each juice of the edible parts of the respective fruits was extracted separately using juice extractor (Imarflex IM-3180, Quezon City, Philippines).

Following extraction, the cashew, pineapple and watermelon (CPW) juice were mixed in ratio of 10:50:40 (v/v) respectively to obtain the blends which was homogenized for 10 sec. A glass jar of CPW juice, containing no preservative was maintained as positive control. Five other separate jars were engaged with five different pretreatments.

Sensory analysis

To estimate consumers' acceptability, the following sensory attributes were investigated: aroma, color, flavor, sweetness, mouth feel and overall impression. A nine-point structured hedonic scale test (9 = "extremely like"; 5 = "neither like nor dislike"; 1 = "extremely dislike") was used for the assessment of overall acceptance of the freshly prepared juice blend, with and without the respective preservatives.

For investigation, the samples were served in a sequential manner in cups containing 25 mL of the respective juice treatments and codified with three random digits. The sensory evaluation was conducted with 45 panelists (25 females and 20 males) comprising of students and staff of a university and aged between 18 and 50 years. The inclusion criteria in being selected as a panelist on condition of regular consumption of the juice blend. Approval was granted by the University research ethics boards (LUAC-0046B).

Determination of physical characteristics

pH was determined using a pH meter (Jenway model 6505). Before use, the pH meter was calibrated using standard buffers of 7.0, 4.0 and 9.2. After calibration, pH readings were read and documented only when equilibrium pH was reached.

Titratable acidity and specific gravity were determined as described in **AOAC (2010)**. For determination of total soluble solids, a refractometer (Hanna HI 96801) was used. Values were measured in % Brix as described elsewhere **(Makebe et al., 2017)**.

Microbiological enumeration

During the storage period, microbial analysis was carried out on a weekly basis for 5 weeks, using nutrient agar (Oxoid limited, UK), De Man, Rogosa and Sharpe agar for enumeration of lactic acid bacteria incubated at 37 °C for total bacterial and lactic acid bacteria count for 24 and 72 hours respectively and potato dextrose agar incubated at 28 °C for 3 days, for estimation of fungal count, using the standard pour-plating method **(APHA, 2015)**.

Statistical analysis

All data from sensory evaluation, variation in pH, titratable acidity, specific gravity and total soluble solid of the juice blend containing different preservatives during storage were analysed using analysis of variance (ANOVA) and differences in mean values were assessed using Duncan's multiple range test. A value of $p < 0.05$ was used to indicate statistical significance. Using Microsoft Excel (Microsoft Corporation, Redmond, WA, USA) means of the replicates were all calculated and separated.

RESULTS AND DISCUSSION

All samples were acceptable in terms of color, taste, flavor and texture. In terms of flavor and mouth feel, the order of preference of the juice were the preserved with 1% garlic-ginger > preserved with 1% ginger > preserved with 1% garlic > preserved with 1% ascorbic acid > and preserved with 1% sodium benzoate at ambient temperature of blends. Addition of preservatives enhanced the colour of the juice blends with the preserved with 1% ginger-garlic having the highest mean score of 8.88. There was no significant difference (p <0.05) in the sweetness of all the juice blends and the scores were in-between 8.77 to 8.94. Combination of ginger and garlic significantly (p <0.05) improved the mouth feel of the juice blends. In terms of overall impression, the most acceptable juice blend was the one preserved with 1% ginger-garlic (Table 1). In this the study all the juice blends that was garlic-ginger preserved was most acceptable and preferred. This observation may be due tempering of the pungent taste of garlic with pleasant scent of ginger resulting from mixing of equal volume of garlic and ginger filtrates. A similar observation has been reported by **Mancini et al. (2019)**. The least preference for the garlic preserved juice blend, as observed in this study may be due to the strong pungent taste of garlic compared to that of those with ginger due to its pleasant **(Mancini et al., 2019)**. In a study on the preservation of soymilk, **Borode (2017)** however reported low preference for garlic preserved soymilk.

In all the juice samples, pH was observed to show consistent decreases with period of storage. Maximum decrease in pH was observed in the juice sample that had no added preservative. At end of the five weeks storage period, pH decreases of 31.6, 25.1, 30.8, 30.9, 20.7 and 25.1% were observed in the juice samples without preservative, preserved with 1% ginger, 1% garlic, 1% garlic-ginger, 1% ascorbic acid and 1% sodium benzoate, respectively
(Table 2).

For the titratable acidity, consistent increases were observed in the juice sample throughout the period of storage. Increases of 90.9, 133, 240, 35.7, 200 and 80% were observed in juice samples the juice samples without preservative, preserved with 1% ginger, 1% garlic, 1% garlic-ginger, 1% ascorbic acid and 1% sodium benzoate, respectively (Table 3). The consistent decrease in pH with period of storage as reported in this study is indicated to be vital to retaining the quality of tartness to the product. Decrease in pH with period of storage has been also been reported by previous investigators **(Kaddumukasa et al., 2017; Olaniran et al., 2019b)**. It is opined that that low pH could enhance the stability of bioactive compounds during storage, thus extending shelf life **(Chia et al., 2012)**.

In the case of specific gravity, increases were observed at the end of the five weeks period of storage. However, only minute increases of 8.4, 4.5 and 6.0 were observed were observed in juice samples preserved with, preserved with 1% ginger, 1 % garlic and 1 % garlic-ginger, respectively. Remarkable increase of 44.7% in specific gravity was observed in the unpreserved juice sample (Table 4). The total soluble solids in the preserved juice blends were observed to show consistent decreases with time. This observation was irrespective of the preservative used. Highest increase (12.1%) in total solids was however observed in the unpreserved juice blend at the end of the five weeks storage period. At the end of storage, increases in total soluble solids of 6.3, 3.6, 5.5, 10.5 and 9.4% were observed for juice blends that were preserved with 1% ginger, 1% garlic, 1% garlic-ginger, 1% ascorbic acid and 1% sodium benzoate, respectively (Table 5). The stability documented in the study in the values of total soluble solids and specific gravity of preserved juice blends for weeks might be due to the presence of garlic, ginger, garlic-ginger filtrates, sodium benzoate and ascorbic acid added as preservatives. The preservatives slowed down the rate of fermentation of sugars present in the juices blends to water, carbon dioxide and ethyl alcohol at room temperature during storage **(Kaddumukasa et al., 2017)**. In this study, the concentration of total soluble solid in the juice blends showed consistent increases with period of storage. Increase in soluble solids is an indicator of the rate of deterioration. The minimal increase soluble solid level observed in the preserved juice during storage could be due to decrease in the rate of conversion of organic acid to sugar thus increasing the shelf life of the juice. Similar observations have been reported by earlier researchers in related studies **(Samad et al., 2019; Rapisarda et al., 2008)**. Generally, all the fruit blends (preserved and unpreserved), with the exception of the one preserve with 1% ginger-garlic showed growth of bacteria after one week of storage. Growth was only observed in the 1% ginger-garlic preserved juice from the third week of storage. At the end of the 5-week storage period, the bacterial count in the unpreserved juice was however remarkably higher than those of the preserved samples. The growth of lactic acid bacteria was observed in all the juice samples throughout the period of storage, except the 1% garlic and 1% ginger-garlic preserved samples where growth was observed only after 2 and 3 weeks of storage, respectively. For the total fungal counts, no growth was observed for the ginger-garlic preserved juice until after 5 weeks of storage. The 1% ginger and 1% garlic preserved juice showed growth after 2 weeks and 3 weeks of storage, respectively (Table 6). Combining the garlic-ginger as preservative in the study was the most effective during storage as microbial growth was greatly inhibited. This could be as result of a synergistic effect of ginger and garlic **(Juan et al., 2017)**. It is opined that the major challenge in spoilage of fresh juice is the stability of the pH, natural microflora; chemical composition fruit juice **(Ephrema et al., 2018)**. From the results from the study, addition of 1% garlic-ginger as preservative was effective in reduction of the microbial load and other physicochemical parameters. This may be due to the presence of essential oil from garlic and ginger, which are reported to have health promoting bioactive components offering consumers health benefits **(Aneja et al., 2014; Baskaran et al., 2010)**. Thus, if 1% garlic-ginger is incorporated into industrial production of cashew apple, pineapple and water melon juice blends; it has better potential replacement for the chemical preservative during storage.

Table 1 Sensory Evaluation of freshly prepared Cashew, pineapple and watermelon blends.

Attributes	CPW	CPW-GIN	CPW-GAR	CPWGG2	CPW-ASC	CPW-SBZ

Table 6 Microbial Counts of the Fruit Juice during Storage.

Samples	Storage period (weeks)				
	1	2	3	4	5
Total bacterial count (colony-forming units.mL^{-1})					
Unpreserved	80×10^{3}	25×10^{3}	43×10^{3}	30×10^{5}	10×10^{8}
Preserved 1% ginger	12×10^{3}	20×10^{3}	24×10^{3}	10×10^{4}	15×10^{5}
Preserved with 1% garlic	11×10^{3}	18×10^{3}	17×10^{3}	29×10^{3}	11×10^{4}
Preserved with 1% ginger-garlic	Nil	Nil	12×10^{3}	20×10^{3}	35×10^{3}
Preserved with 1% ascorbic acid	12×10^{3}	22×10^{3}	39×10^{3}	24×10^{3}	75×10^{5}
Preserved with 1% sodium benzoate	12×10^{3}	25×10^{3}	43×10^{3}	84×10^{4}	90×10^{5}
Lactic acid bacterial count (colony-forming units.mL^{-1})					
Unpreserved	36×10^{3}	39×10^{3}	54×10^{3}	25×10^{4}	25×10^{6}
Preserved 1% ginger	24×10^{2}	38×10^{2}	51×10^{2}	45×10^{3}	65×10^{3}
Preserved with 1% garlic	Nil	21×10^{2}	29×10^{2}	33×10^{2}	40×10^{3}
Preserved with 1% ginger-garlic	Nil	Nil	12×10^{2}	16×10^{2}	52×10^{2}
Preserved with 1% ascorbic acid	60×10^{2}	58×10^{2}	40×10^{3}	56×10^{3}	46×10^{4}
Preserved with 1% sodium benzoate	34×10^{2}	60×10^{2}	39×10^{3}	47×10^{3}	15×10^{4}
Total fungal count (spore-forming units.mL^{-1})					
Unpreserved	14×10^{3}	29×10^{3}	40×10^{3}	25×10^{5}	34×10^{6}
Preserved 1% ginger	Nil	15×10^{3}	33×10^{3}	42×10^{3}	15×10^{4}
Preserved with 1% garlic	Nil	Nil	25×10^{2}	10×10^{2}	60×10^{2}
Preserved with 1% ginger-garlic	Nil	Nil	Nil	Nil	11×10^{2}
Preserved with 1% ascorbic acid	10×10^{2}	31×10^{2}	46×10^{3}	30×10^{4}	35×10^{4}
Preserved with 1% sodium benzoate	15×10^{2}	43×10^{2}	20×10^{3}	18×10^{4}	30×10^{4}

With respect to sensory accetability, the fruit blend preseved with the 1% garlic-ginger blend was the most accepatble (p <0.05). In presence of the biopreseravtives, the phyicochemical patrameters of the fruit blend showed stability during storage.

The study concluded that ginger and garlic could be used as effective biopreservatives in fruit juice blends at a minimum concentration at 1% and recommended as potential replacement for the chemical preservative during storage juice blends from cashew water melon and pineapple. The outcome of this study may expand the utilization of ginger and garlic more often in fruit juice production, create more job opportunities and reduce seasonal losses and wastage of fruits like cashew.

CONCLUSION

From the findings of this study, the biopreservatives (1% ginger, 1% garlic and 1% garlic-ginger extracts) compared favourably with the chemical preservatives (1% sodium benzoate and ascobic acid) used for preservation of the cashew water melon and pineapple juice blend. In addition, the study revealed 1% garlic-ginger extract as the most effective biopreservatives of all the biopresevatives used.

INVESTIGATION OF ZERANOL IN BEEF OF UKRAINIAN PRODUCTION AND ITS REDUCTION WITH VARIOUS TECHNOLOGICAL PROCESSING

Mykola Kukhtyn, Volodymyr Salata, Ruslan Pelenyo, Volodymyr Selskyi, Yulia Horiuk, Nataliia Boltyk, Larisa Ulko, Volodymyr Dobrovolsky

ABSTRACT

Synthetic growth stimulants are widely used to get high productivity of animals. These preparations can accumulate in the meat and their residual quantities will adversely affect the health of consumers. The purpose of the work was to monitor the content of zeranol, growth stimulant of ruminants in beef which goes to meat processing enterprises of the Western region of Ukraine and to determine the effect of heat treatment on its quantity. It was found out that 29.8% of beef samples taken at meat processing enterprises contained a stimulant for the growth of ruminant zeranol. It was found that during the storage of beef samples frozen at a temperature of -18 °C with different content of zeranol there is a decrease in its number. The most intense process of destruction of zeranol occurred during the first month of storage, during this period of time the amount of zeranol is reduced by an average of 20%, regardless of the initial content. Within two months of storage of frozen beef, the content of zeranol decreases by 28.2 ±0.17%, and at the end of the sixth month its quantity decreases to 33.2 ±0.58%. It was also found that the dynamics of zeranol reducing in beef samples with large quantities (22.5 $\mu g.kg^{-1}$) and small (2.3 $\mu g.kg^{-1}$) were the same. It was set up that during 30 min of meat cooking there was a decrease in the content of zeranol 24.7 ±0.23% and 32.0 ±0.35% for 60 min, compared to its content in fresh meat. At the same time, when stored in the frozen state and subsequent cooking, the reduction of zeranol content in meat was 39.3 ±0.3%. Therefore, it is proposed to revise and amendments into the regulatory documents of Ukraine regarding the control and supervision of the presence of hormone (zeranol) residues in meat and meat products in order to prevent their sale and consumption by humans.

Keywords: beef; zeranol; frozen meat; synthetic growth promoters; meat temperature processing

INTRODUCTION

The meat industry is one of the main branches of agriculture, which provides the population with food rich in high protein. Currently, beef is an important part of the human diet, since meat has good taste, high nutritional levels and is also considered a dietary product **(Tonu, 2013; Salata et al., 2017)**. However, various synthetic hormonal growth promoters have become widely used for short periods of time in animal husbandry, in particular: zeranol, trenbolone acetate, diethylstilbestrol and others **(Galbraith, 2002; Brynes, 2005; Azza, Sania and Weam, 2015; Lykholat, Grigoryuk and Lykholat, 2016)**. Meat obtained from animals on the use of anabolics is characterized by a gentle consistency and lower fat content. However, according to many researches of many scientists **(Larrea and Chirinos, 2007; Jeong et al., 2010; Wang et al., 2013)**, excessive amounts of residues of hormonal preparation in meat and meat products adversely affect the health of consumers, causing various metabolic disorders and causing cancer. Therefore, in the countries of the European Union it is forbidden to use hormonal preparations – stimulants of growth of live weight of ruminants and it is regulated by directives **(EC, 1996a; EC, 1996b)**. At the same time in countries of Latin America and the USA the use of synthetic preparations in animal husbandry is allowed by national legislation **(CFR, 1999)**.

Our attention was drawn to the synthetic stimulator anabolic zeranol, known as α-zearalanol, it is a non-steroidal estrogen of the lactone group of resorbic acid and is used as an implant in the ear of cattle to increase muscle mass **(Leffers et al., 2001)**. Ukrainian legislation does not oblige the definition of this anabolic in beef at slaughterhouses and when implemented within the state. Therefore, researches on the presence of zeranol in the bovine muscle grown in Ukraine in domestic scientific publications are virtually none.

Therefore, conducting experimental researches on the monitoring of zeranol in beef at meat processing enterprises in Ukraine will allow to determine the real status of its circulation. Besides, based on the obtained information, it will be possible to propose appropriate amendments to the legislation of Ukraine on the safety of meat and meat products.

The purpose of the work was to monitor the content of zeranol, growth stimulant of ruminants in beef which goes to meat processing enterprises of the Western region of Ukraine and to determine the effect of heat treatment on its quantity.

Scientific hypothesis

The main hypothesis of the investigation is in the detected beef containing the synthetic anabolic stimulant zeranol, which goes to meat processing enterprises of the Western region of Ukraine and the possible use of meat processing that would reduce the amount of meat.

MATERIAL AND METHODOLOGY

Research on beef meat was conducted during years 2016 – 2018. Samples of beef meat were selected at the meat processing enterprises of the Western region of Ukraine to determine the amount of zeranol. Determination of zeranol in meat was performed using the test system for enzyme immunoassay RIDASCRIN® Zeranol (Art. No.:R3301) (manufactured by firm Art-Biopharm/R-Biopharm, Darmstadt, Germany) at the Stepan Gzhytskyj Lviv National University of Veterinary Medicine and Biotechnologies.

Statistical analysis

Statistical processing of the results was carried out using methods of variation statistics using the program Statistica 9.0 (StatSoft Inc., USA). Non-parametric methods of research were used (Wilcoxon-Mann-Whitney test). The arithmetic mean (x) and the standard error of mean (SE) were determined. The difference between the comparable values was considered to be significant for $p < 0.05$.

RESULTS AND DISCUSSION

The results of the searches of the content of zeranol in fresh beef are shown in Figure 1. From Figure 1 it can be seen that, on average, 30% of beef samples taken from meat at processing enterprises in the Western region of Ukraine contained a stimulant for the growth of ruminant zeranols. The number of negative samples without zeranol content was 70.2 ±2.1%. The detected amount of zeranol in meat was different (Figure 2). The highest number of samples – 35.7% with the content of zeranol was found in the smallest range from 1 to 5 $\mu g.kg^{-1}$. The number of samples with zeranol content from 5.1 to 10.0 $\mu g.kg^{-1}$ was found in 28.6%. A significant number of samples – 21.5% contained zeranol at high concentrations from 10.1 to 15.0 $\mu g.kg^{-1}$ and 14.2% of the investigated samples had its content greater than 15.1 $\mu g.kg^{-1}$.

Thus, the conducted searches have established the fact of receipts at processing plants of the Western region of Ukraine of beef containing the prohibited in the European Union countries the stimulant of growth of live mass of ruminants – zeranol.

Considering that when consuming food products containing residues of hormonal preparation, there is a violation of metabolism in humans we conducted research of the influence of different technological processes of temperature meat processing on reducing of zeranol content. In Figure 3 the results of the research are presented of changes in the content of zeranol in beef during its storage in the frozen state at a temperature of -18 °C.

The results of the research indicate that there is no complete reduction in the content of zeranol in meat during the six-month refrigerated storage. However, we note the same dynamics of zeranol reducing in beef samples, which contained both large and small amounts. The most intense process of destruction of zeranol occurred during the first month of storage. During this period of time, the amount of zeranol is decreased by an average of 20% in all samples, regardless of initial content. During the two-month term of storage of frozen beef, the content of zeranol was decreased by 28.2 ±0.17%, compared to the initial amount in fresh meat. Next storage of beef for three months did not cause a significant decrease in the content of zeranol and at the end of the sixth month their number was decreased by 33.2 ±0.58%.

Analogical results of the research on the dynamics of changes in zeranol in beef were obtained using the freezing temperature of meat -25 °C and -30 °C. However, when storing meat containing zeranol in the cooled state at +2 to +4 °C and frozen for -2 to -3 °C for 20 days, no decrease in the amount of zeranol was observed.

Thus, obtained scientific data indicate that the storage of meat in the frozen state has a positive effect on the dynamics of reducing the content of zeranol. This process is particularly active within two months of the start of storage.

In Figure 4 results of researches are given of the influence of the cooking process on the dynamics of changes in zeranol in beef. Installed that the process of cooking also affects to reduce the content of zeranol in beef. After 30 minutes of meat cooking, the amount of zeranol in all samples was decreased by 24.7 ±0.23% and over the next 30 minutes to 32.0 ±0.35%, compared to its content in fresh meat. Further heat processing up to 120 minutes did not cause a significant decrease in the zeranol content compared to the 60 minutes of cooking process.

Consequently, during cooking, about 30% of the zeranol from the meat to the broth is destroyed or transferred, which is almost the same amount as in the frozen storage process.

Changes in the content of zeranol in meat were also examined after 6 months of storage in the frozen state and subsequent cooking for 60 min (Figure 5). After freezing, the decrease in the amount of zeranol was found to be 33.2 ±0.58%, and the subsequent meat cooking process led to a slight reduction of the zeranol content to 6.1 ±0.2%. Therefore, in general, after the freezing process and further meat cooking process, the amount of zeranol is reduced by 39.3 ±0.3%.

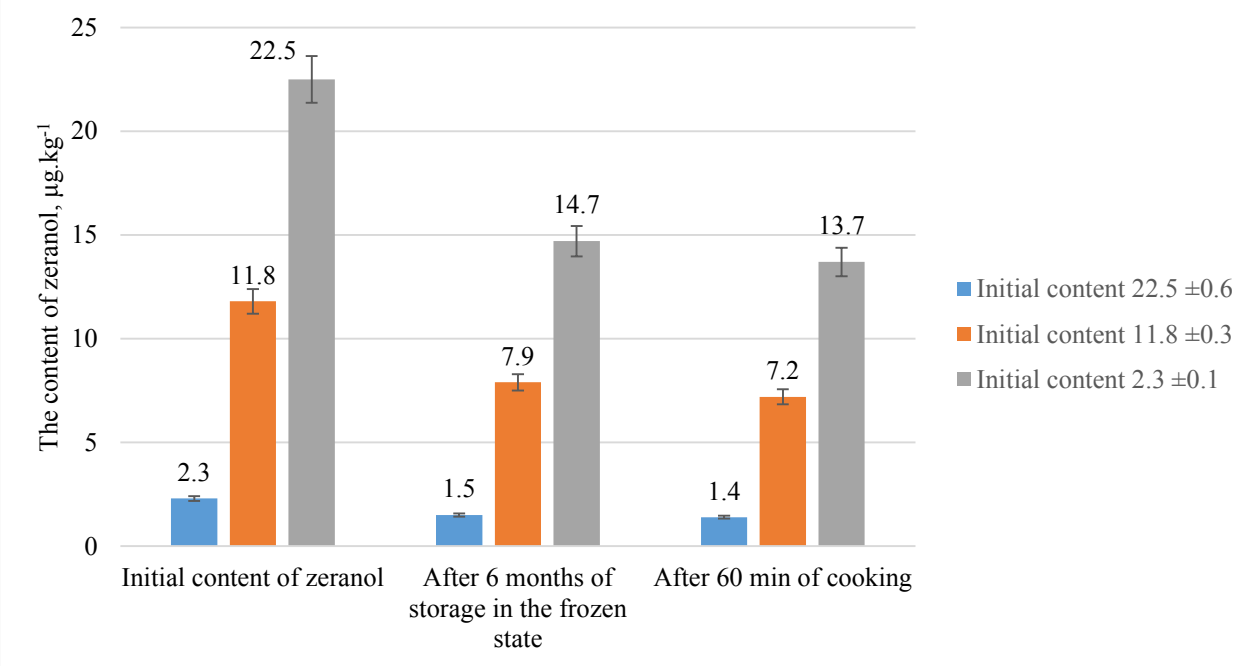

Figure 5 The intensity of the process of reducing zeranol in beef after 6 months of storage and 60 min of cooking

Meat and meat products are essential components of the human diet, so first of all they must be safe in biological, chemical and physical terms. It is currently widely used in the world to increase the growth of live weight of animals and improve the use of feed anabolic hormonal preparations of synthetic production **(Galbraith, 2002; Brynes, 2005; Azza, Sania and Weam, 2015; Lykholat, Grigoryuk and Lykholat, 2016)**. However, in violation of the fattening technology, these preparations can accumulate in the products of slaughter, and their residual quantities adversely affect the health of consumers **(Larrea and Chirinos, 2007; Jeong et al., 2010; Wang et al., 2013)**. Synthetic anabolic stimulator – zeranol is banned in the European Union for use in veterinary medicine because of its adverse influence on humans. At the same time in the USA this preparation is allowed and its amount in ruminant muscles is allowed up to 2 $\mu g.kg^{-1}$ and 10 $\mu g.kg^{-1}$ in liver **(CFR, 1999)**. In Ukraine, regulatory and legal documents do not regulate the definition of this anabolic in domestic beef and imported abroad.

Our research has found that 29.8% of beef samples taken at meat processing enterprises in the Western region of Ukraine contained a stimulant for the growth of ruminant

zeranol. In addition, a significant number of samples – 35.7% contained zeranol at high concentrations greater than 10 μg.kg^{-1}. Our researches are consistent with the results of scientists from other European countries **(Borazan et al., 2007; Salata, et al., 2017)**, who reported the detection of zeranol in 100% of the investigated meat samples and meat products. Consequently, conducted research have found that there is an income for the processing of beef, which contains the hormone to stimulate the growth of live weight – zeranol. Therefore, we consider it necessary to revise and making changes in the regulatory and legal documents of Ukraine on the control and supervision of the presence of residues of hormone preparations (zeranol) in meat and meat products in order to prevent their sale and consumption by humans. In addition, at the present time, due to the large number of food supplies from different countries, it is impossible to guarantee the safety of meat in terms of residues of animal growth stimulants **(Gladij and Sychevs'kyj, 2018)**. Therefore, when importing beef in Ukraine, it is necessary to control it for the presence of residual quantities of zeranol.

Considering the fact of receipts for beef processing with high content of zeranol, we conducted a research to determine the influence of different types of heat treatment and storage of beef on the quantitative content of zeranol. It has been established that storage of beef in chilled and frozen state for 20 days does not affect the content of zeranol. At the same time, it was found that the storage of beef samples in the frozen state at a temperature of -18 °C with different content of zeranol decreases its amount. Thus, the most intense process of destruction of zeranol occurred during the first month of storage, during this period of time the amount of zeranol was decreased by an average of 20%, regardless of the initial content. During the two-month term of storage of frozen beef, the content of zeranol was decreased by 28.2 ±0.17%, and at the end of the sixth month its amount was decreased to 33.2 ±0.58%. It was also found out that the dynamics of zeranol reducing in beef samples with large quantities (22.5 μg.kg^{-1}) and small (2.3 μg.kg^{-1}) were the same. Therefore, conducted researches have given us reason to affirm that the storage of meat in the frozen state has a positive influence on changes in the content of zeranol, that is, it significantly reduces its amount. With the small content of zeranol in meat, it can be reduced to the limit of 2 μg.kg^{-1} in the US. In addition, it was found out that during 30 min of cooking meat there is a decrease in the content of zeranol by 24.7 ±0.23%, and for 60 min by 32.0 ±0.35%, compared with its content in fresh meat. Further heat processing did not cause a significant decrease in the content of zeranol. At the same time, when stored in the frozen state and subsequent cooking, the reduction of zeranol content in meat was 39.3 ±0.3%. In researches **(Braekevelt et al., 2011)** it was also found a decrease in the amount of estrogen hormones in beef by 25 – 30% after its two-hour cooking. Moreover, the researchers found that in the non-fat beef, the process of disintegration of hormonal preparations was less and ranged from 5 to 20%. Thus, cooking reduces the content of anabiolics in meat, but in the presence of high concentrations, this process is not effective enough to produce a safe product.

CONCLUSION

In summary, it can be noted that the revealed fact of earnings to the processing of beef containing zeran in high concentrations, therefore, we consider it necessary to carry out a selective control and selection of beef at meat processing enterprises in order to establish safety indicators, namely the content of zeranol. To reduce the number of detected samples, the meat must be frozen at -18 °C and stored for at least two months and then subjected to heat processing (cooking). However, if significant concentrations of zeranol (greater than 2 μg.kg^{-1}) are found, such meat is prohibited. Consequently, the planned monitoring will allow the monitoring and analysis of the situation of beef zeranol in Ukraine.

TECHNICAL EFFICIENCY AND FACTORS AFFECTING RICE PRODUCTION IN TIDAL LOWLANDS OF SOUTH SUMATRA PROVINCE INDONESIA

Khairul Fahmi Purba, Muhammad Yazid, Mery Hasmeda, Dessy Adriani, Meitry Firdha Tafarini

ABSTRACT
Rice has been the staple food for most Indonesians, so the rice consumption in Indonesia is considerably high. Rice is cultivated in many agroecosystems, including tidal lowlands. Some tidal lowlands are considered suitable for rice cultivation. Therefore, tidal lowlands may support food security in Indonesia. However, productivity remains a problem in which inputs are not used efficiently. This study aims to determine the technical efficiency and identify factors affecting rice production in tidal lowlands of South Sumatra, one of main rice barns in Indonesia. A survey was conducted by interviewing 93 farmers in Telang Rejo Village. A data envelopment analysis (DEA) with output-oriented and variable returns to scale (VRS) approach was applied to measure technical efficiency score from each farm observed. An ordinary least square (OLS) regression with a Cobb-Douglass production function approach was employed to analyse the factors affecting rice production in tidal lowlands of South Sumatra, Indonesia. The results showed that majority of rice farms in the tidal lowlands of South Sumatra Indonesia were inefficient. There were 44 rice farms (47.31%) that were efficient, 5 rice farms (5.38%) that were inefficient under increasing returns to scale and 44 rice farms (47.31%) that were inefficient under decreasing returns to scale. The inputs, such as nitrogen, phosphorus, and potassium fertilisers, herbicides, insecticides and fungicides had positive significant influences on rice production in the tidal lowlands of South Sumatra, Indonesia.

Keywords: technical efficiency; rice production; tidal lowlands; data envelopment analysis; ordinary least square

INTRODUCTION
Rice is a staple food and livelihood platform for Asian countries, such as Vietnam, Indonesia, Pakistan and others **(Roy, Chan and Rainis, 2014; Roy, Chan and Xenarios, 2016; Al-Mashadani and Mahmood, 2019)** Rice is still an income source for rural society in Indonesia. Therefore, it has a strategic position. Moreover, Rice also contributes to 9.5% of the Gross Domestic Product of Indonesia **(Adriani and Wildayana, 2015; Central Bureau of Statistics of Indonesia, 2019)**. According to **Government regulation #12 of 2012** concerning food, the Indonesian government is obligated to guarantee availability, affordability, and fulfilment of food consumption for all Indonesians. However, the consumption rate of rice is very high in Indonesia. The rice consumption of Indonesia achieved approximately 29.13 million tons or 111.58 kg per capita per year **(Central Bureau of Statistics of Indonesia, 2017)**. A population rate increase caused rice consumption to also increase. At the same time, a high land conversion causes unstable rice production for fulfilling rice consumption in Indonesia. This means that the government must take an appropriate decision or policy for solving those problems.

One of the solutions taken by government is the development of agriculture in the suboptimal lands of Indonesia. One of the suboptimal lands in Indonesia is tidal lowland. Tidal lowland is reclaimed swamp land and occurs between the land and the sea. Therefore, tidal lowland depends on the changing tides. Tidal lowland has potential to support food security in Indonesia. One of the available tidal lowlands of Indonesia is in South Sumatra Province. Based on data, the total of tidal lowland area is 266,674 hectares in South Sumatra. A large number of tidal lowlands in South Sumatra are in Banyuasin Regency. Based on the report of statistics, the total of tidal lowlands in Banyuasin is 161,917 hectares **(Central Bureau of Statistics of Banyuasin Regency, 2018)**. Due to the available total area of tidal lowland is being large, it is expected become a food barn or food growing area or rice production centre of Indonesia. On the other hand, tidal lowland is still not reclaimed in large amounts because of peat in tidal lowlands. Therefore, Many tidal lowlands may not be utilised **(Susanto, 2003)**.

One of locations for tidal lowlands is in Telang Rejo Village, Delta Telang I, South Sumatra Province of Indonesia. This location is a reclamation project in the

1970s involving the transmigration program from Java Island to Sumatra Island **(Scholz, 1980; Wildayana, Adriani and Armanto, 2017; Wildayana and Armanto, 2018)**. Telang Rejo Village has type A tidal lowlands. The type A is a tidal lowlands suitable for rice cultivation **(Imanudin and Armanto, 2012)**, it forms by tidal lowlands that are overflowed both large and small tides at all times **(Irwandi, 2015)**.

Besides the good potential of tidal lowlands, the constraints and threats exist, such as the rice productivity of tidal lowlands still being low. The rice productivity of tidal lowlands is approximately 4.10 to 4.43 tons per hectare. Whereas, the average rice productivity is 8 tons per hectare **(Wildayana and Armanto, 2019)**. This difference between actual and expected production was caused by inefficient use of input **(Majumder et al., 2016)**. The other problems of rice cultivation in tidal lowlands are soil acidity, nutrient deficiency, salinity and pyrite (Fe_2S) content **(Armanto, et al., 2013; Armanto, 2014; Wildayana and Armanto, 2018)**. Furthermore, the water is unsuitable for the crop needs for rice cultivation in tidal lowlands agriculture **(Yazid et al., 2015)**. There is no technological recommendation based location, such as fertiliser, variety of rice, land clearing and management, and also water management **(Oemar, 2003)**. These factors are causes of inefficient use of agricultural inputs to rice production in tidal lowland agriculture.

Studies regarding the technical efficiency of rice production become important for estimating the efficiency level of rice production in tidal lowlands agriculture. Technical efficiency refers to achieving a total of potential output though s combination of total of available input **(Iráizoz, Rapún, and Zabaleta, 2003)**. If a business or enterprise can improve output by input use optimization, the business is efficient **(Coelli et al., 2005)**. Some studies regarding the technical efficiency of rice production in Indonesia have been conducted **(Erwidodo, 1990; Squires and Tabor, 1991; Trewin et al., 1995)**. Even through there have been many studies regarding the efficiency of rice production in Indonesia, there are only a little of them discussing the efficiency of rice production in tidal lowlands of South Sumatra in particular. These previous studies investigated phenomena on Java Island with technical irrigated land agroecosystem. On the other hand, this study investigates the case of Sumatra Island with its suboptimal land agroecosystem, which is tidal lowlands. Therefore, this study is very important to be conducted.

Scientific hypotheses

There were two hypotheses in this study:

1. 70% of rice farms in tidal lowlands of South Sumatra Indonesia are efficient in constant returns to scale condition
2. Land area, seed, fertilizer of N, P, and K fertilisers herbicides, insecticides, fungicides and labour significantly affect rice production in tidal lowlands of South Sumatra Indonesia

MATERIAL AND METHODOLOGY

Location

This study was conducted in Telang Rejo Village, Banyuasin Regency, South Sumatra Province of Indonesia. There are some considerations in choosing the location.

1. This location has tidal lowlands of type A, and this location is suitable for rice cultivation.
2. This location is well known as food barn and production centre of tidal lowland rice for Banyuasin Regency.
3. This location is the largest village in tidal lowland agriculture of South Sumatera.
4. Telang Rejo is one of the transmigration project villages in the 1970s. The tidal lowlands in Telang Rejo was reclaimed by government to transmigrants from Java Island to Sumatra Island.
5. The Water management system was built by the agency of public work through grants from the government. The map of study site is in Figure 1.

Data Collection

Data was obtained by interviewing 93 farmers in Telang Rejo. Therefore, there were 93 decision making units (DMUs). They were selected randomly. This study used a questionnaire as a tool of research. This study was assisted by five master degree students as enumerators. The variables used in this study consisted one dependent variable (Y) and nine independent variables (X). The dependent variable was the rice production of tidal lowlands **(Coelli et al., 2005)**. The independent variables were land area **(Thanh Nguyen, Hoang and Seo, 2012)**, seeds **(Duangbootsee and Myers, 2014)**, chemical fertilisers which are N, P and K **(Hoang and Alauddin, 2012; Hoang and Nguyen, 2013; Jansen et al., 2006)**, pesticides and labour **(Rios and Shively, 2005; (Duangbootsee and Myers, 2014)**.

Technical Efficiency

Efficiency is the ratio between output and input. If the ratio is high, the efficiency score will be high. The efficiency score is between 0 to 1. It can be defined mathematically $0 \leq TE \leq 1$. Efficiency score can be obtained by **(Arnade, 1994)**:

$$Efficiency = \frac{\sum_k u_k y_{k,j}}{\sum_i v_i x_{i,j}}$$

Where :
y = output
x = input
u, v = average weight
i,j,k = 1,2,3,...n

Data Envelopment Analysis (DEA)

Data envelopment analysis (DEA) is a method to estimate efficiency with linear programming nonparametric approach **(Charnes, Cooper and Rhodes 1978; Charnes, Cooper and Rhodes, 1979)** DEA identifies the best frontier solution involving all observation of decision making units (DMUs). Therefore, it is called an envelope model. The DEA model also can be applied to estimate efficiency or performance in some sectors such as hospital **(Gholami, Higón and Emrouznejad, 2015; Khushalani and Ozcan, 2017)**,

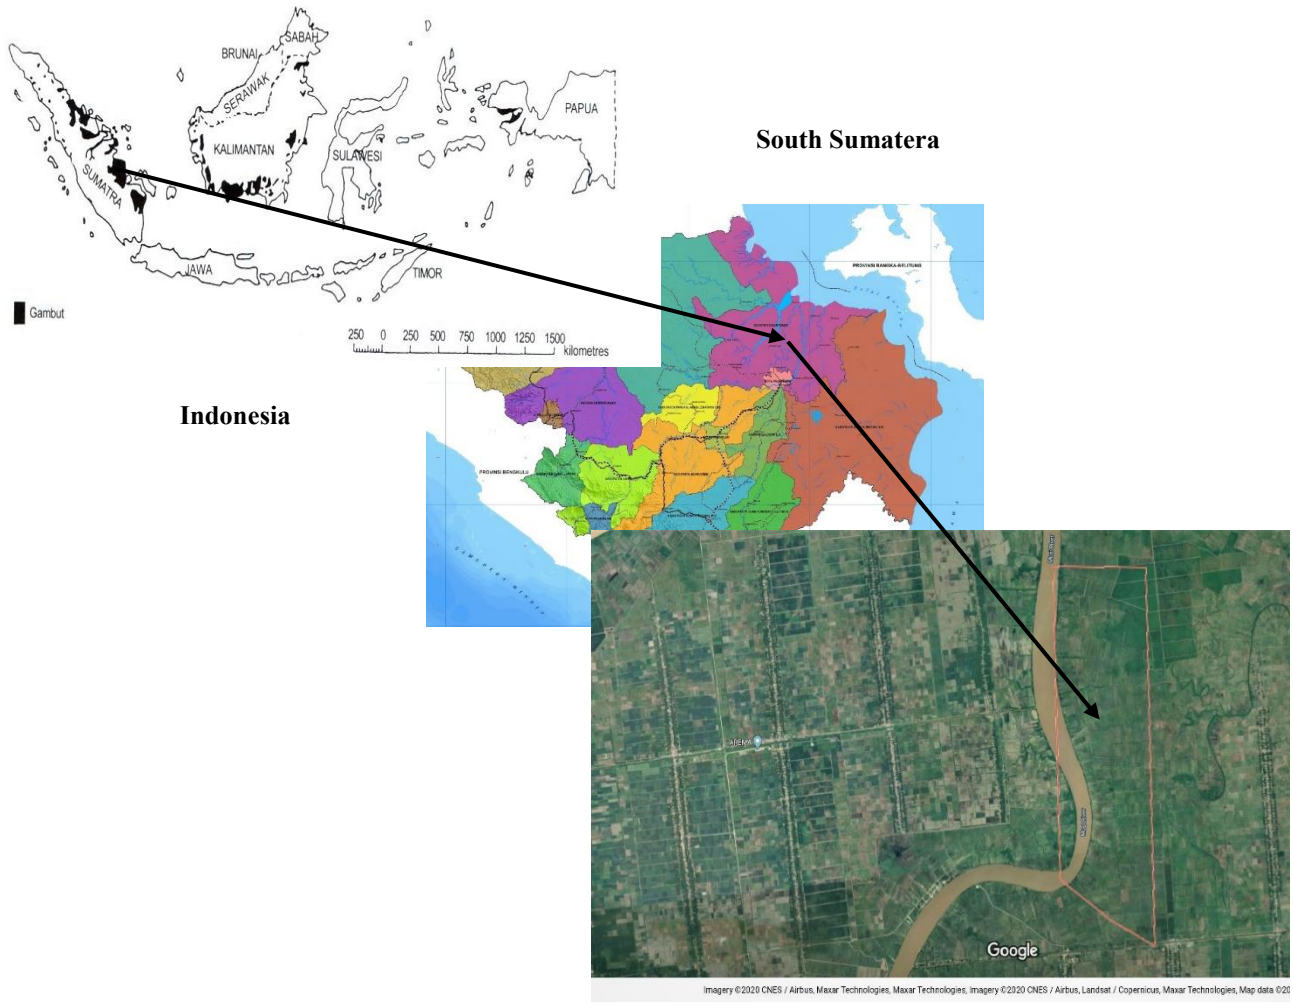

Figure 1 Location of study.

school **(Fatimah and Mahmudah, 2017)**, construction **(Hu and Liu, 2016)**, banking **(Wanke and Barros, 2014; Avkiran, 2015)**, port operation **(Rajasekar and Deo, 2014; Nguyen et al., 2016)**, industry and manufacture **(Kotey and O'Donnell, 2002)**, agriculture **(Haji, 2007; Guzman et al., 2009; Mardani and Salarpour, 2015)** and among others.

DEA has also been applied widely to estimate farm and agricultural performance worldwide **(Kočišová, 2015; Wang et al., 2017, Wang et al., 2018; Adeyonu et al., 2019)**. DEA has been used as a tool for decision making in a businesses, organisations, and governments as well. DEA has some advantages. It can be applied simultaneously by multiple inputs and ouputs. Without the need to previously determine weights. Furthermore, DEA does not need a functional form and specific production function such as input-output relationship.

DEA is divided by 2 orientations. The first is oriented input. It minimises input to achieve a potential output level. The second one is oriented output. It maximises output bundle while keeping the input level constant. Both of them minimise input and maximise output for achieving efficiency, DEA model oriented input focuses on operational and managerial problems while DEA model oriented output is in regards to planning and strategy **(Cullinane, Song and Wang, 2005)**.

The asssumptions of the DEA model are constant retun to scale (CRS) and variable returns to scale (VRS). These assumptions affect the envelope frontier. CRS is difined as a proportion of input addition equaling proportion of output addition. VRS is defined as production technology showing increasing, constant or decreasing returns to scale. The VRS assumption is appropriate for agriculture study because agricultural production may occur in 3 situations which are increasing, constant or decreasing returns to scale.

The DEA model in this study applied oriented output. The model can defined as **(Färe, Grosskopf and Lovell, 1985; Ali and Seiford, 1993; Färe et al., 2017; O'Donnell, 2018)**:

$$Max\ \theta i \qquad (1)$$

Subject to:

$$u_{jm} \leq \sum_{j=1}^{j} z_j u_{jm} \qquad (2)$$

Where:

θ = output efficiency of DMU's being estimated by DEA

u_{jm} = amount of output m produced by DMU j

z_j = intensity variable for DMU j

j,m = 1,2,3...n

The model obtained is a CCR or CRS model. To transform the model to be VRS or BCC Model, this constraint below should be add in the model.

$$\sum_j \lambda_j = 1 \qquad (3)$$

A DEA model with oriented output and VRS approach estimates technical efficiency though measuring potential output by 93 farmers or DMUs. The level of input (λ) is kept constant so that it obtains three stages of production, namely increasing, constant or decreasing returns to scale.

Ordinary Least Square (OLS)

The use of OLS has been widely applied by many scholars. OLS is amethod to identify the factors affecting agricultural production. OLS is also used as a second phase analysis of the DEA. According to **Banker, Natarjan and Zhang (2019)** the application of the combination between DEA and OLS is better than the Simar-Wilson model in measuring productivity at the second stage. The application of OLS is also more consistent when combined with DEA in second stage **(Simar and Wilson, 2007)**. The OLS equation used in this study is the Cobb-Douglass production function equation. We can define it as :

$$Y = f(X1, X2, X3 \ldots Xn) \qquad (4)$$

$$Y = \beta 0 X1^{\beta 1} X2^{\beta 2} X3^{\beta 3} \ldots Xn^{\beta} \qquad (5)$$

The estimation of the above OLS equation was transformed by natural logarithm (Ln). It was created to obtain the equation or model easier to interpret **(Koutsoyiannis, 2001)**.

$$LnY = Ln\beta_0 + \beta_1 LnX_1 + \beta_2 LnX_2 + \beta_3 LnX_3 \ldots \beta_n LnXn \qquad (6)$$

Where:

Y	= Production
$\beta 0$	= Intercept
$\beta_1, \beta_2, \beta_3 \ldots \beta n$	= Parameter
$X_1, X_2, X_3 \ldots Xn$	= Input
n	= 1,2,3....n

Statistical analysis

The software used for data analysis in the study was the Data Envelopment Analysis Program (DEAP) software version 2.1. The software was developed by Tim Coelli from the Centre of Efficiency and Productivity Analysis (CEPA) in the University of Queensland, Australia. In addition, the Statistical Package for Social Science (SPSS) version 23 was also used for OLS analysis. The *p*-values used in OLS analysis were $p < 0.01$; 0.05 and 0.10

RESULTS AND DISCUSSION

Characteristics of farmers

Based on Table 1, farmers were in productive age group. The majority of farmers aged 40 – 49 years. The household size was 2 people for the majority. A small percentage of respondents were elderly and whose wife or husband has passed away lived alone. These respondents normally had children who were married and lived nearby. A low percentage of respondents had two or more children. These respondents normally are middle aged with children who are still young and unmarried. However, the education of farmers is still relatively low. The length of education only 4 to 7 years, which is equivalent to primary school. The majority of farmers had 11 – 20 years of farming experience. This was because farmers in Telang Rejo Village are the second and third generation of transmigrants of the transmigration project from Java Island to Sumatra Island in the 1970s. The land status of farmers in Telang Rejo Village was mainly private ownership. This is because at the beginning of the transmigration program each household was given 2 hectares of reclaimed tidal lowlands by the government **(Arsyad, Saidi and Enrizal, 2014)**.

Table 2 showed agricultural input uses and output produced in tidal lowlands of Telang Rejo Village. According to The Ministry of Agriculture of Indonesia (2007) the uses of N, P and K fertilisers are 200 $kg.ha^{-1}$, 75 $kg.ha^{-1}$ and 50 $kg.ha^{-1}$ resepectively . In fact, the uses of N, P and K fertilisers in tidal lowlands were higher than the recommendation. This could be a threat for sustainability and environmental integrity in tidal lowlands with theses surpluses.

Characteristic of Tidal Lowlands

Tidal lowlands contain pyrite and peat. Pyrite was formed when the tidal lowlands were flowed by sea water in dry season. It will be dangerous to rice when it was oxidized. Furthermore, peat was cause of soil acidity **(Shamshuddin et al., 2004; Nurita and Ar-Riza, 2014)**.

The tidal lowlands' problem are pH, nutrient deficiency, high content of Fe and Al and uncontrolled water **(Purnomo et al., 2005)**. Water management in tidal lowlands was different with irrigation system. The government had built some primary and secondary canals with the sliding gate and flap gate. In the rice farm, The intensive shallow canals were conducted which function to wash acidic and toxic substances from the field **(Widjaja-Adi, Ratmini and Swastika, 1997)**. However, the maintenance of the canals need to consider because some gates were broken **(Ar-Riza and Alkasuma, 2008)**.

Identification of efficient and inefficient rice farms in tidal lowland

A total of 93 farms were used for each efficiency score using the DEA method. The result of DEA showed that most of the tidal lowlands rice farms in Telang Rejo Village were inefficient. There were only 44 (47.31%) efficient rice farms that were in constant returns to scale condition, while there were 49 inefficient farms. Where 44 (47.31%) of those in decreasing returns to scale condition and 5 (5.38%) that were in in increasing returns to scale condition. Figure 2 is presented to show the results of the DEA.

There were 44 rice farms that had decreasing returns to scale caused by the excesses of input use. Therefore, to achieve efficiency the input uses need to be reduced. The purpose of reducing input use on the farms for the law of diminishing returns has not occurred. Whereas the farms with increasing returns to scale (five rice farms) should increase the input uses to achieve efficiency because it is still possible for them to increase production. The finding of a study stated that rice farms in Vietnam operated with less than the optimal scale **(Linh, 2012)**. The result supported this study.

Table 1 Descriptive statistics of farmers in Telang Rejo Village (n = 93).

Characteristics	Frequency	Percentage (%)
Age (year)		
20 – 29	12	12.90
30 – 39	23	24.73
40 – 49	36	38.71
50 – 59	18	19.35
60 – 69	4	4.30
Household size (individual)		
1	20	21.51
2	34	36.56
3	30	32.26
4	8	8.60
5	1	1.08
Education (year)		
0 – 3	3	3.23
4 – 7	52	55.91
8 – 11	17	18.28
12 – 15	20	21.51
≥16	1	1.08
Farming experience (year)		
0 – 10	18	19.35
11 – 20	38	40.86
21 – 30	18	19.35
31 – 40	18	19.35
41 – 50	1	1.08
Land Status		
Renter	4	4.30
Owner	80	86.02
Renter and Owner	9	9.68

Table 2 Descriptive statistics of input and ouput (n=93)

Variable	Mean	Std. Deviation	Min.	Max.
Production (kg.ha^{-1})	6,602.15	142.66	3,000.00	10,000.00
Land area cultivated (ha)	4.83	3.52	0.50	20.00
Seeds (kg.ha^{-1})	86.40	18.71	50.00	120.00
N fertiliser (kg.ha^{-1})	329.57	1.61	50.00	650.00
P fertiliser (kg.ha^{-1})	223.66	1.14	50,00	500.00
K fertiliser (kg.ha^{-1})	195.16	1.09	50.00	400.00
Herbicide (L.ha^{-1})	6.90	3.59	2.00	20.00
Insekticide (L.ha^{-1})	6.41	3.83	1.00	17.00
Fungicide (L.ha^{-1})	5.99	3.22	1.00	17.00
Labour (day.ha^{-1})	3.78	3.36	1.00	14.00

Farm performance can also be divided based on the efficiency score. **Jalilov et al. (2019)** divided 3 performance using efficiency scores based on: 1) the best performance which has an efficiency score between 0.90 to 1.00 or 90% to 100%. Farming in this category was called efficient farming 2) good performance, or farming that has an efficiency score of 0.80 to 0.89 or 80% to 89% also included in the efficient category, while for 3) poor performance is farming that has efficiency score under 0.79 or 79%. Farming with this score is categorised as inefficient.

Based on this grouping, there were 68 (73.12%) farms that had efficiency scores from 90% to 100%. Then, there were 17 (18.28%) farms that had efficiency scores between 80% and 89%. Meanwhile, 8 (8.60%) farms had score of less than 79%. Figure 3 was given to show the categorisation

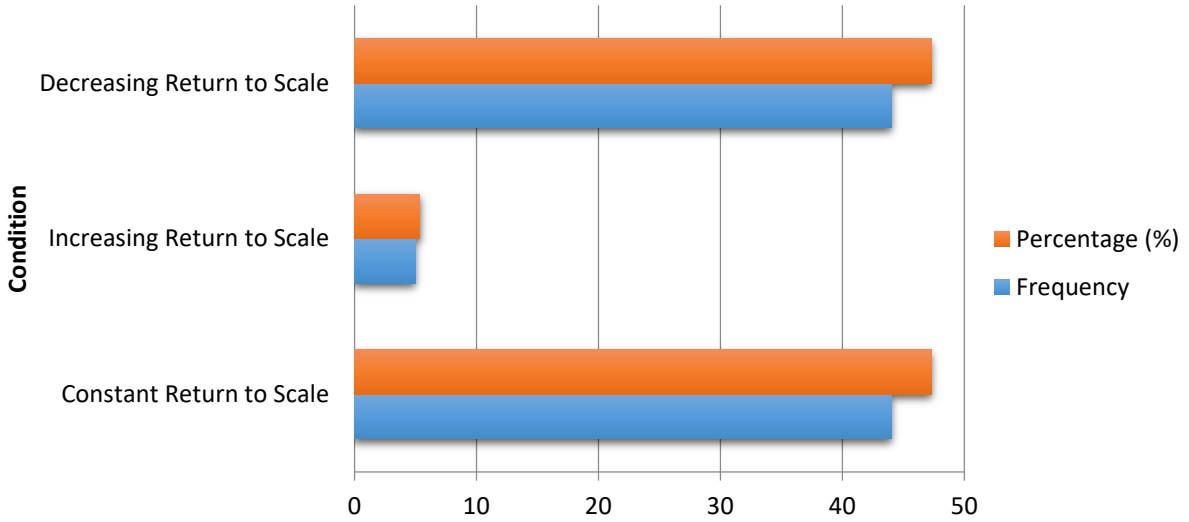

Figure 2 Distribution of farming based on returns to scale condition.

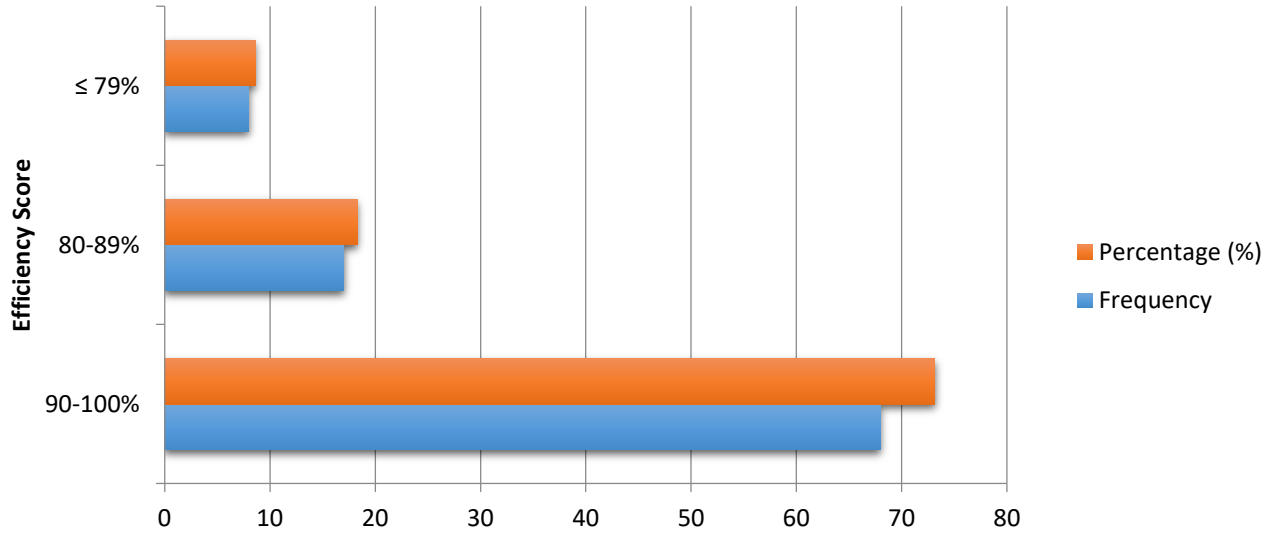

Figure 3 Categorisation of rice farming performance based on efficiency scores.

of rice farming performance based on efficiency scores. This finding is same like a study in Turkey. The average efficiency score of rice production in Marmara region was 92%. It means performance of rice farming in Turkey was the best performance **(Tipi et al., 2009)**.

The poorly performing farms occurred due to the input use not being optimal. The achievement of actual total production was not in accordance with the expected total production. It was further determined that poorly

performing farms were on decreasing returns to scale. The well performing farms with efficiency scores of 80% to 89% had worked on optimal input use. Furthermore, the best performing farms with efficiency scores of 90% to 100% had been on the efficiency frontier **(Jalilov et al., 2019)**.

Factors affecting rice production in tidal lowlands

This study applied an OLS analysis as the second stage analysis of DEA. The classic assumption test (data normality, heteroscedasticity and multicollinearity) was applied in OLS model. It was applied to obtain a free errors OLS model. In addition to obtain factors affecting rice production in tidal lowlands, OLS can also obtain an equation of the Cobb-Douglass production function for rice production in tidal lowland. The production functions obtained from OLS analysis were:

$$Y=127938130X1^{0.023}X2^{0.030}X3^{0.049}X4^{0.072}X5^{0.057}X6^{0.097}X7^{0.039}X8^{0.082}X9^{0.003} \quad (7)$$

Where:

Y = Tidal lowland rice production (kg.ha^{-1})
X1 = Land area cultivated (ha)
X2 = Seed (kg.ha^{-1})
X3 = N fertiliser (kg.ha^{-1})
X4 = P fertiliser (kg.ha^{-1})
X5 = K fertiliser (kg.ha^{-1})
X6 = Herbicide (L.ha^{-1})
X7 = Insecticide (L.ha^{-1})
X8 = Fungicide (L.ha^{-1})
X9 = Labour (day.ha^{-1})

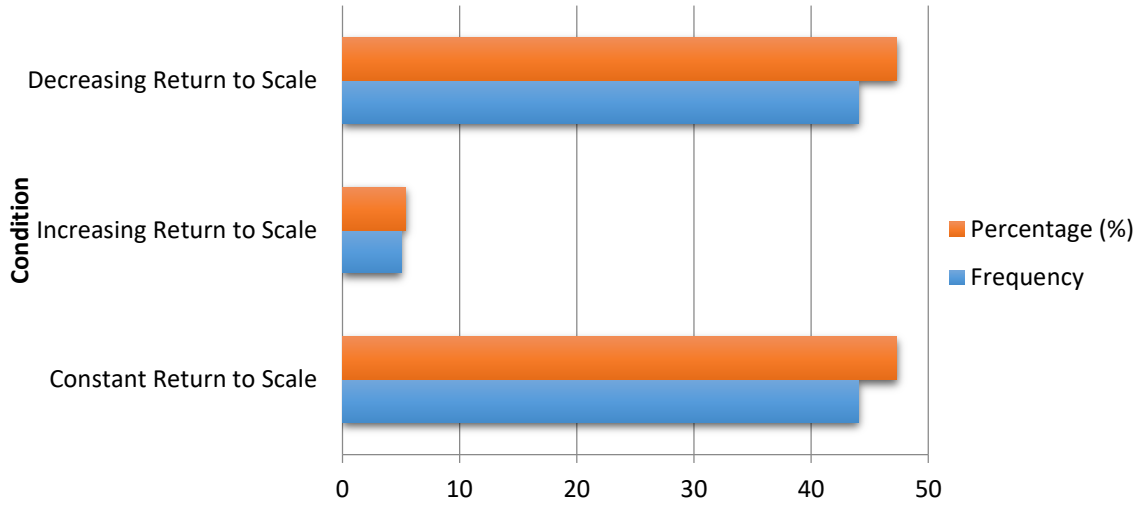

Figure 2 Distribution of farming based on returns to scale condition.

Labour (X9)	0.003	0.022	0.135	0.893

Note: F-stat = 30.682; R-Square = 0.769; Adjusted R-Square = 0.744; * Significant at p <0.01; ** Significant at p <0.05; *** Significant at p <0.10.

Based on the OLS analysis (Table 3), it was found that herbicides had a positive significant influence on rice production in tidal lowlands (p <0.01), and P fertiliser and fungicides had a positive significant influence on rice production in tidal lowlands (p <0.05).

Furthermore, N Fertiliser , K Fertiliser and insecticides also had a significant influence on rice production in tidal lowlands (p <0.10). The findings supported a study by **Piya, Kiminami and Yagi (2012)**. The result of study stated that chemical fertilizer, pesticide and fungicide were positive and statistically significant to rice production in Nepal. Furthermore, pesticide and herbicide also affected rice production in Sri Lanka **(Gedara et al., 2012)**. Meanwhile, the land area cultivated, seeds and labour did not significantly influence rice production in tidal lowlands. A study stated that farm size did not affect rice production in Nigeria **(Ahmaedu and Alufohai, 2012)**. Many the land used by farmers in Telang Rejo Village were fragmented. The impact of fragmented land was that farmers had difficulty in managing rice farms. This was caused by the scattered distribution of land. Therefore, the management of rice farms in tidal lowland became ineffective. This case began when many farmers took a credit or loan from a wealthier farmer or *toke*. The land became a guarantee in this loan system. It was an informal credit with high interest. The interest applied by the *toke* is approximately 30% – 40% per year in a term of one to five years. The informal credit is absolutely not profitable for farmers in tidal lowland area. The loan system had terms and conditions as agreement between farmer and the *toke*. The farmers were not allowed to cultivate rice in their lands until they were able to pay their loan during the repayment period. The farmers who were not able to pay the loan according to agreement had to give their land to the *toke*. This situation created rich farmers with large land areas and poor farmers with small land area, so there was significant inequality among the farmers in tidal lowlands.

Seed did not significantly affect rice production in tidal lowlands. The use of seeds was very high in the rice farms of tidal lowlands. This finding was supported by **Dhungana, Nuthall and Nartea (2004)** and **Linn and Maenhout (2019)** . They stated that use of seed was very high in rice farming in Nepal and Myanmar. The use of excess seeds caused many farms to be in decreasing returns to scale condition. The use of excess seeds was mostly encouraged by cultivating system in tidal lowland. *Tabela* is well-known seedling system by farmers. In fact, the optimal use of seeds was 20 kg to 30 kg per hectare

with seeding. *Tabe*la is abbreviation from three words (*Tebar Benih Langsung*) in Bahasa Indonesia. *Tabela* was done by spreading seed out directly to land without first seeding. When *tabela* was applied, seeds would flow out with water. Therefore, seeds were useless. *Tabela* is often known as *sonor*. *Tabela* was followed by burning land in land preparation **(Wildayana, Armanto and Junedi, 2017)**. This cultivation system was a local wisdom for tidal lowland farmers in Telang Rejo Village. The cultivation system made spacing of crops irregular, and caused the rice production of tidal lowlands to be low. Furthermore, the varieties used by farmers are ciherang, IR 42 or others. That was developed by farmers with technology limitations. In addition, it is possibly not water stress tolerant variety. One of the problems in tidal lowlands is a need for water because tidal lowlands depend on tides. Therefore, a water stress tolerant variety is needed by farmers in tidal lowland agriculture to increase rice production. Inpara-3 is a suitable variety to tidal lowlands **(Saidi et al., 2014)**. However, the farmers do not adopt it yet.

Labour was also a factor that did not affect rice production in tidal lowlands. The available labour force in tidal lowland agriculture is very low. In fact, many transmigrant farmers sold their land and farms given by the government to return to their homeland on Java Island. Then, many farmers migrated to find other work in the capital city of South Sumatra Province (Palembang). It occurred along cultivation season. Therefore, a large labour force for agriculture and farming in Telang Rejo Village was not available. Moreover, some farmers changed their jobs from agricultural jobs to non-agricultural jobs. The majority of them worked in construction in the capital city of South Sumatra Province or became workers on an engine boat in the Musi River. Musi River is the longest river of South Sumatra. It is also used as transportation like Mekong River in Vietnam. The case of labour migration also occurred in China. The available labour for agricultural jobs has decreased significantly **(Peng, Tang and Zou, 2009)**. It will be a challenges of rice production. The other cause was agricultural mechanisation. Many farmers used machines for land preparation, harvesting and other activities.

CONCLUSION

This paper concluded that rice production on tidal lowlands was inefficient. Only 47.31% of rice farming was efficient. They were in constant returns to scale. Meanwhile, 5.38% of rice farming was inefficient under increasing returns to scale and 47.31% of rice farming was inefficient under decreasing returns to scale. The factors affecting rice production in tidal lowlands were N, P, and K fertiliser, herbicides, insecticides and fungicides. In terms of policy implications, the need for rice varieties tolerant to tidal lowlands, use of organic fertilizer such as livestock dung, compost and others to achieve sustainability of tidal lowlands, seed nursery training by agricultural extension and also policies regarding the use of agricultural inputs, including doses and the other factors, so that rice production in tidal lowlands can be improved to achieve efficiency and food security in Indonesia.

NUTRITIONAL AND BIOLOGICAL VALUE OF PORK OBTAINED FROM ANIMALS FED WITH LYSINE AND METHIONINE

Ivan Gorlov, Marina Slozhenkina, Alexander Mosolov, Vladimir Baranikov, Dmitry Nikolaev, Alexander Chernyak, Bogdan Sherstyuk, Olga Krotova

ABSTRACT
The article presents material on the effect of the amino acids lysine and methionine in pig diets. Studies have been carried out to increase the live weight of animals, depending on the content of these amino acids in the diet when fattening up to 100 and 120 kg. Presented research results obtained during testing in certified and accredited laboratories. When growing gilts to live weight from 30 to 50 kg, a deficiency in the level of lysine was found, which reaches up to 29.6%, and methionine with cystine up to 23.1%. When growing animals from 81 to 120 kg of live weight, the lysine deficiency is 14.9%, and methionine with cystine is 8,8%. This necessitated balancing the diet of animals to the required level of amino acid content. The most effective on the growth and development of animals, as well as on indicators of pork quality, was the introduction of feed lysine in combination with methionine in pig diets.

Keywords: lysine; methionine with cystine; gilts; live weight; rations

INTRODUCTION
At present, the pig-breeding industry in the Russian Federation is developing quite dynamically and domestic pork production reaches more than 95% of the volume consumed, which provides the population of the country per person 26 kg of this type of product. However, in countries of world pork exporters in the USA, England, Germany, Canada, Denmark, Italy, Spain, more than 100 kg of meat is produced per person. Therefore, in Russia there is a need to further increase the production of pig meat, including not only through the use of breeding and genetic innovations, but also to improve animal breeding by improving the quality of feeding rations **(Mysik, 2008; Strekozov and Chinarov, 2012)**. Full and balanced nutrition of pigs in all nutrients is the key not only to a steady increase in meat productivity of animals, but also their reproductive qualities, as well as physiological development at all stages of growth **(Kukushkin and Filatov, 2011; Belous et al., 2018; Kulintsev, 2011; Nikonkov et al., 2015; Kumar et al., 2012; Smith et al., 1999)**.

The aim of the research was to study the effect of diets with a low protein level in pig diets, which is typical for the southern regions of our country, on the physiological parameters of animals, as well as on fattening and meat qualities of young animals.

Scientific hypothesis
Supplementation of lysine and methionine in pig diet will increase production of pork. In connection with the foregoing, it is advisable to conduct research aimed at studying the effect of the introduction of the amino acids lysine and methionine with cystine on the physiological development of animals, growth, development of young pigs, as well as on increasing production of pork.

MATERIAL AND METHODOLOGY
The studies were conducted at the Lenin collective farm breeding farm in the Surovikinsky district of the Volgograd region in the period from 2017 to 2019. For testing, 3 groups of purebred gilts of large white breed, 16 animals each, obtained as a result of the second farrow, were selected. Gilts were selected according to the principle of analogue pairs, considering gender, age, and physiological state. For the experiment, the feeding process was divided into three periods. The first period is from 30 to 50 kg of live weight; the second period is from 51 – 80 kg and the third period are from 81 to 120 kg of live weight. Control slaughter of experimental animals was carried out when 100 and 120 kg of live weight were achieved.

The animals were grown according to the zootechnical standarts adopted in Russia. According to the recommendations of the all-russian institute of animal

husbandry, the balance sheet experience was divided into preparatory and main periods. The preparatory period was carried out for 21 days, animals of all experimental groups received the main diet. The study of the balance of the diets of feeding experimental animals was carried out on the basis of the analysis of the actual diet by the content of protein, lysine, methionine with cystine in it at the Volgograd Regional Veterinary Laboratory, a comprehensive analytical laboratory of the State Scientific Research Institute of Nuclear Medicine and Pediatrics, and Volgograd. The analysis of the chemical composition of feed and animal metabolic products was carried out according to generally accepted methods of zootechnical analysis **(Alikaev et al., 1967; Zlebedev and Usovich, 1976)**. In all experimental groups, animals were fed using concentrated feeds (concentrate type of feeding). The first group received the main diet, while the content of digestible protein fluctuated in weighted periods of 119 g, 106 g and 98 g, respectively. To adjust the balance of diets for essential amino acids, they were carried out using a mixture of peas and meat and bone meal, and the lack of carotene in the diet was ensured by the introduction of alfalfa flour. Gilts of the second and third groups received the main diet. At the same time, animals of the second group to compensate for the lack of lysine received feed lysine, which was prepared according to GOST R 56913-2016, and in the third group, the lack of lysine and methionine was compensated by feed lysine with the addition of methionine. Additionally, chalk and sodium chloride were added to the diets of animals of all experimental groups to provide them with calcium, sodium and chlorine. General economic rations for the periods of experiment consisted of 98.2 concentrated feed and 1.8% roughage in the first period; in the second period - concentrated feed – by 98.6% and roughage – by 1.4%, in the third period – concentrated feed – by 98.6% and roughage – by 1.4%. The analysis of the content in the meat samples of experimental animals was studied on the basis of data obtained on an amino acid analyzer model (L-8800, "Hitachi", Ltd). The content of amino acids and minerals is shown in Figure 1.

Analyzing the data presented in Figure 1, we can draw the following conclusion: in the first period of the experiment, the deficiency of the diets of experimental gilts for digestible protein is 19.0%, lysine – 34.9%, methionine with cystine – 37,8%; for the second period – by 14.4; 29.6; 23.1%, respectively; in the third period, there was a deficiency in the amino acid lysine – 14.9%, methionine with cystine – 8.8%. The experimental gilts were kept separately in groups, feeding was carried out twice. The necessary amino acids (in dry form) were introduced into the feed mixture stepwise after thorough mixing in the diets of experimental gilts. A study of the growth and development of gilts was established on the basis of taking into account the monthly increase in live weight. Before the control slaughter of the experimental animals, weighing was carried out after 24 hours of fasting. Assessment of meat productivity of animal carcasses was studied in accordance with the "All-Russian Institute of animal Husbandry Methodological Recommendations for the assessment of meat productivity, quality of meat and subcutaneous fat of pigs". Sampling of the longest muscle of the back and adipose tissue was

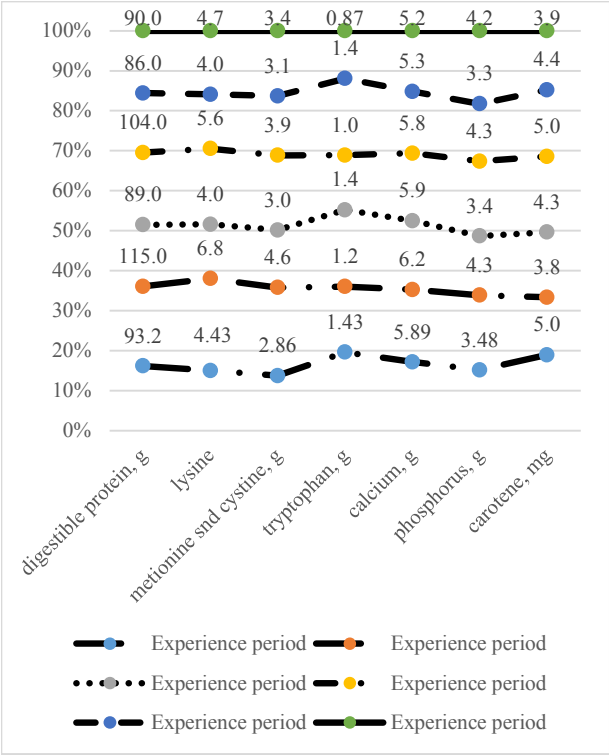

Figure 1 Diets of experimental animals.

carried out at a level between the 9th and 12th thoracic vertebrae, after cooling at a temperature of 2 – 4 °C in the refrigerator for 24 hours.

In order to more fully evaluate the meat qualities of experimental gilts after 24-hour exposure, the right half carcasses were deboned. At the same time, the weight of the ham, the ratio of meat, fat and bones, the area of the "muscle eye", determined on the cross section of the longest muscle of the back between the last pectoral and first lumbar vertebrae, were evaluated. Tasting evaluation of the broth and meat obtained from experimental animals was evaluated on the basis of organoleptic evaluation according to GOST 9959-91 "Meat products. General conditions for organoleptic assessment".

Statistic analysis

The data obtained during the experiments were processed using mathematical methods of variation statistics using the Microsof Excel software and Statistika 6 developer: StatSoft, USA. In the course of our work, we used the Student-Fisher method. For to assess the effect of lysine and methionine content in animal diets during different periods of their growth. The first threshold of reliability of the obtained data is designated as ($p \geq 0.95$); the second ($p \geq 0.99$); the third ($p \geq 0.999$), and if the results are not reliable, then ($p \leq 0.95$).

RESULTS AND DISCUSSION

The results of the dynamics of the live weight of experimental gilts are presented in Table 1. As we can see from the data in Table 1, animals of the 1st group were superior to analogues from groups 2 and 3 in live weight at 4, 5 and 6 months by 6.21 ($p \geq 0.95$) and 2.22%; 5.62 ($p \geq 0.95$) and 2.65% and 6,41 ($p \geq 0.95$) and 1.19%, respectively. However, when fattening up to 100 kg of live weight, the highest weight was achieved in group 2, which

is 0.60 and 0.20% higher in comparison with groups 1 and 3. Upon reaching 120 kg, the highest weight was observed in animals of the 3rd group, which is 0.33 and 0.83% more, respectively, in comparison with the 1st and 2nd groups. Based on the results of monthly weighings, the average daily gain in live weight was calculated, the data are presented in Figure 2.

As we can see from the data of Figure 2 and Figure 3, despite the fact that the average daily gain in live weight in animals of groups 2 and 3 at 5 months of age when reaching 100 and 120 kg of live weight was lower than in analogues of group 1 – by 97 and 40 g; 37 and 27 g and 28 and 13 g, the age of reaching 100 and 120 kg was less when reaching 100 kg of live weight by 9 and 5 days, when reaching 120 kg, animals of the 2nd group exceeded the analogues of the 1st group by 11 days, and analogues of 3 groups spent less by 24 days. It should be noted that the balance of plant general rations allows to significantly ($p \geq 0.95$) reduce feed costs (Figure 4). From the presented Figure 4 it can be seen that in animals of groups 2 and 3, when fattening up to 100 kg, the absolute increase in live weight increased in comparison with the analogues of group 1 by 1.5 kg, or 2.1% and 0.8 kg, or 1.13 %, feed costs increased by 0.39 units, or 8.99% ($p \geq 0.95$) and 0.13 units, or 3.04%. The results obtained allow us to conclude that the use of the amino acids lysine and methionine in general diets can help to reduce the cost of feed per unit of growth and this helps to save feed, and also helps to increase the efficiency of pork production. As a result of the control slaughter of the experimental animals, we studied the meat qualities of the experimental young animals, which are presented in Table 2. The presented results in Table 2 indicate that the qualitative indicators were at the same level and did not have significant differences ($p \leq 0.95$). It is worth noting that when fattening up to 100 kg in meat of gilts of group 3, the meat yield was higher in comparison with groups 1 and 2 by 0.5 and 0.8%, and the protein-quality indicator (BPC) i.e. the ratio of the essential amino acid tryptophan to the essential amino acid oxyproline is 0.02 and 0.08% higher in animal meat. According to the area of the muscle eye, the meat of animals of the 1st group is the best indicator, which is higher than in the 2nd and 3rd groups by 0.5 and 0.4 cm^2.

In addition, we analyzed the amino acid scores of pork obtained from experimental gilts. For comparison, three samples were taken from half carcasses of groups 1, 2, and 3. For a comparative assessment, the content of the most deficient amino acids of tryptophan, methionine + cystine and lysine was studied in meat.

By comparing the reference protein recommended by the FAO/WHO with experimental data, the following results were obtained: 1.29 $g.100g^{-1}$ of protein was contained in meat obtained from tryptophan group 1 animals; methionine + cystine – 3.58 $g.100g^{-1}$ protein; lysine – 5.31 $g.100g^{-1}$ protein, which is less in comparison with analogues of groups 2 and 3 in tryptophan – by 3.9 and 7.7%; methionine + cystine – by 2.2 and 2.8%; lysine – by 1.9 and 6.0%, respectively.

The studies presented showed that in the meat of animals of group 1, the amino acid rate was the smallest and amounted to 96.9%, and in the meat of animals of groups 2 and 3 – 103.8 and 105.6%. In order to establish the nutritional value of pork obtained during research, an organoleptic assessment of broths was carried out on a 5-point scale with the participation of 15 tasters. Based on the appearance of the meat broths, the tasters determined that the broth prepared from pork of the 1st group scored the highest score – 5.49.

Assessing the appearance of meat broths, experts found that the broth obtained from the meat of gilts of the experimental group I scored the highest score – 5.49. At the same time, it was inferior in terms of aroma, taste, richness and overall rating, the broth of group 3 received the highest scores. The second place was established during the tasting of the broth of group 2 (Table 3).

Tasters found that in terms of appearance, aroma, taste, texture, juiciness and overall rating, the best results among the studied groups were boiled meat of gilts of group I. The second place, according to the general assessment, was obtained by the meat of gilts of the 3rd group. In **Smith (1999)**, it is noted that increasing the content of amino acids, including metinin and cystine, in the diets of pigs affects not only the improvement of digestibility of nutrients, but also the energy value of the diet.

Table 1 Dynamics of live weight of experimental gilts, kg (n = 16).

Group	Live weight					
	when fattening	at the age of months			when removing from fattening kg	
		4	5	6	100	120
1	29.7 ±0.40	45.1 ±0.95*	64.1 ±1.22*	84.2 ±1.55*	99.8 ±3.18	119.9 ±3.28

Aroma	4.61	4.64	4.68
Taste	4.53	4.66	4.73
Richness	4.47	4.55	4.66
Overall raiting	4.78	4.81	4.88

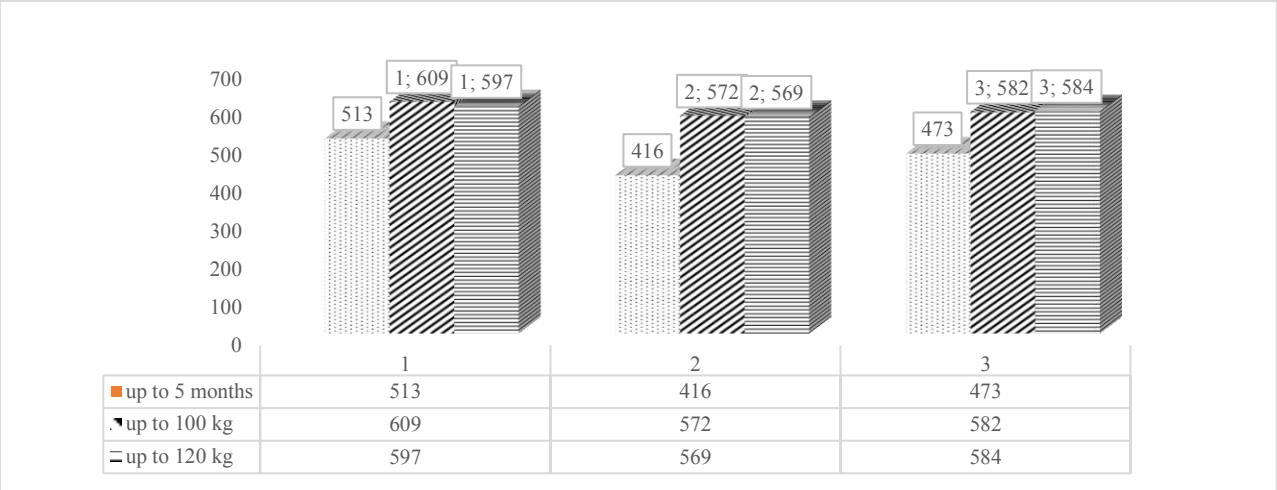

Figure 2 The average daily gain in live weight of experimental guinea pigs (g).

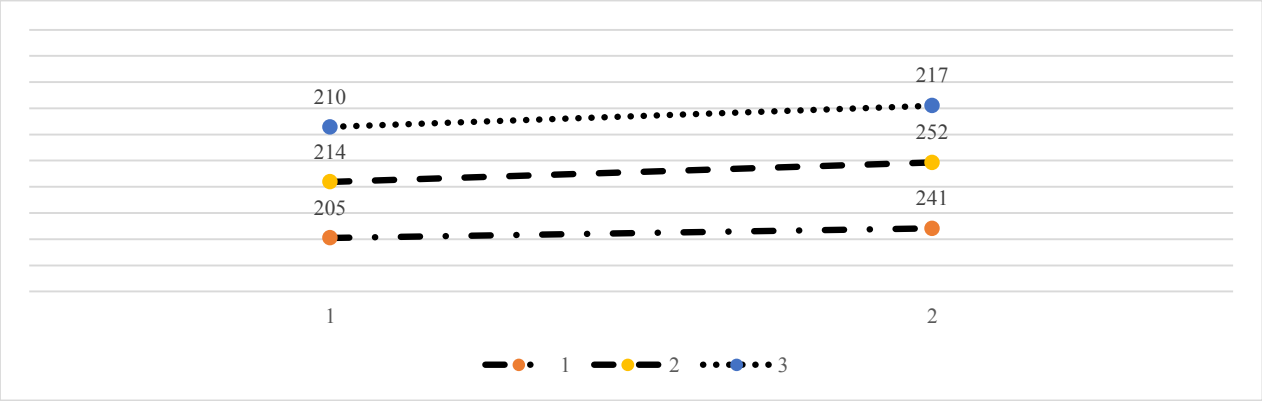

Figure 3 Age of achievement of live weight of 100 and 120 kg, days.

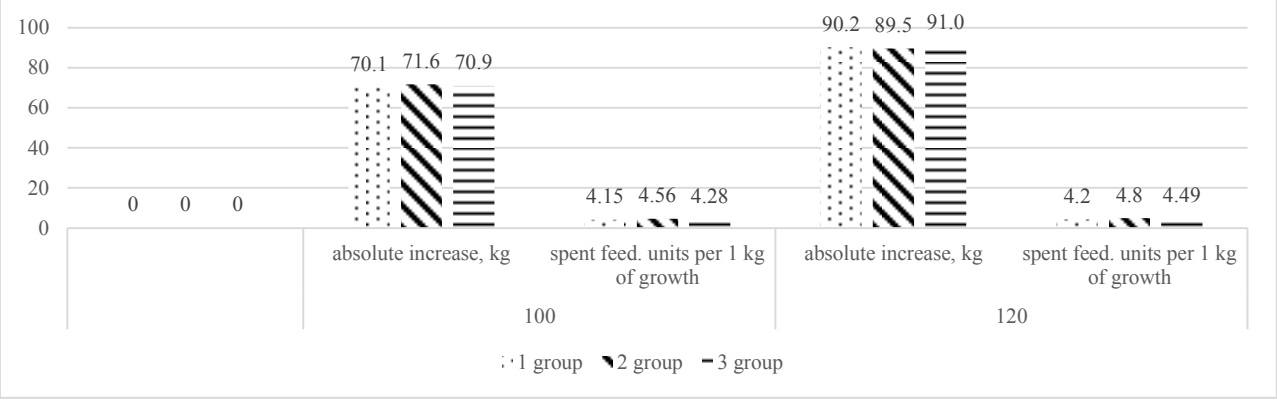

Figure 4 Feed costs and absolute increase in live weight depending on the period from the feed.

The lack of lysine is completely eliminated when introduced into the pre-start feed of piglets 2 – 4 months of age with 20% of its addition. When granulating feed for pigs, it is necessary to take into account the temperature regime, it should not exceed 50 °C since at a higher temperature there is a connection of sugar with amino acids **(Shkatov, 2013)**.

The data obtained by us in the experiment are consistent with earlier works of **(Alikaev et al., 1967; Komlatsky, 2012; Zimina, 2012; Sazonov, 2013; Sanchez, 2012)** in which there is a high efficiency from the use of various components of the diet for its better digestibility, including the use of lysine in combination with methionine.

Today, the world pays great attention to the production of environmentally friendly food, including animal origin. In this regard, studies aimed at studying the increase in pork production due to the introduction of environmentally safe feed additives based on amino acids are very relevant **(Komlatsky, 2012)**.

However, in the work of **Varley (2012)** it is noted that with the modern development of the pig industry, it is impossible to abandon the use of atibiotics in some cases. It is especially important to use feed antibiotics in various feed disorders to control the health of animals and reduce the impact of pathogenic microflora.

A number of Russian and foreign researchers note that for the growing organism of pigs, it is necessary to use an increased level of amino acids in the diets of feeding, including methionine and lysine. This contributes to a significant increase in metabolic processes in their body, which significantly increases the living mass in comparison with analogues that did not receive these amino acids **(Ryadchikov et al., 2000; Ryadchikov et al., 2010; Omarov, 2007, Omarov et al., 2010; Ettle, et al., 2004; Moreira et al., 2004; Stein et al., 2007, Main et al., 2008, Niyazov N.S.-A., et al., 2019)**.

Cheryukanov, 2013 notes that reducing the level of raw protein in the diets of pigs in the growing period from 17.2 to 12.5%, and in the first period of fattening from 15.0 to 11.5% and the second period of fattening from 13.0 to 10.5% is possible if the diets are balanced with synthetic amino acids lysine, threonine and methionine in an amount 24-37% higher in comparison with detailed standards of the all-Russian Institute of animal Husbandry. This contributes not only to the normalization of the level of elemental composition of the blood, but also has a positive effect on the growth of meat productivity. Thus, the live weight of pigs increased by 18.6 and 14.3%, and in the second period of fattening – by 16.5 and 14.33%, than in the control group. This is consistent with the results obtained in our experiments.

Thus, justifying all of the above, we can conclude that the study and justification of the use of synthetic amino acids lysine and methionine in pig feeding will contribute to the development of diets aimed at increasing the productivity of animals. These developments will not only increase the productivity of animals, but can also be used in the development of technologies for obtaining safe food products of animal origin.

CONCLUSION

As a result of the experimental work, it was found that the lack of amino acids such as lysine and methionine in pig diets adversely affects the productivity of animals. It has been experimentally proved that when fattening pigs to 100 and 120 kg of live weight, it is necessary to maintain the amino acid content at the optimal level due to the introduction of synthetic amino acids, which provides an increase in live weight gain and a decrease in the age of removal from fattening. An increase in the content of a balanced amount of amino acids in the diet contributed to an improvement in the balanced composition of their meat. Thus, no significant differences ($p \leq 0.95$) were found in the nutritional value of the resulting meat.

THE COMPARISON OF HPLC AND SPECTROPHOTOMETRIC METHOD FOR CHOLESTEROL DETERMINATION

Lukáš Kolarič, Peter Šimko

ABSTRACT

The present study was carried out to compare two different analytical methods (HPLC and spectrophotometric) for determination of cholesterol content in milk while cholesterol in food is important not only for the nutritional value setting of foods but also due to the validation of a fast, reliable and economical method for studying the possible mechanism of its reduction. Spectrophotometric determination of cholesterol content was based on the Liebermann-Burchard (LB) reaction among cholesterol, ethyl acetate, acetic anhydride, plus concentrated H_2SO_4 and measuring absorbance of formed color at 625 nm. HPLC method was performed by column chromatography on reverse phase C_{18} with DAD detection at 205 nm. The methods were applied to the milk sample. The achieved LOD and LOQ for HPLC were 2.13 $mg.kg^{-1}$ and 6.45 $mg.kg^{-1}$, respectively, while for spectrophotometric method were 12.55 and 38.04 $mg.kg^{-1}$. The difference between cholesterol content determined by both methods was statistically insignificant at p <0.05. Therefore, it can be concluded that both methods are suitable for determination of cholesterol content in milk, however, HPLC method exhibited higher sensitivity and lower limits of detection or quantification, respectively.

Keywords: cholesterol; HPLC; spectrophotometry; analysis; milk

INTRODUCTION

Cholesterol is a key compound in most biological systems. It is an essential compound in cellular membrane functions of animals and the precursor of important endogenous substances. In humans, cholesterol is obtained from two sources: endogenous synthesis and exogenous ingestion from food **(Ramalho, Casal and Oliveira, 2011)**.

From a nutritional point of view, cholesterol is not found in significant amounts in plant sources, is mostly present in foods of animal origin, namely cheese, egg, beef, pork, poultry, fish, and shrimp. High levels of low-density lipoprotein cholesterol are a major cardiovascular risk factor. Once dietary cholesterol intake is increasing, the plasma cholesterol levels rise and consequently increases the risk of cardiovascular diseases and atherosclerosis **(Albuquerque et al., 2016)**.

Multiple methods have been developed for cholesterol levels determination. According to **Li et al. (2019)** the methods can be divided into three major categories: 1. classical chemical methods based on the Abell-Kendall protocol, 2. fluorometric and colorimetric enzymatic assays, and 3. analytical instrumental approaches. Cholesterol determination procedures in foods usually involve lipid extraction, separation of cholesterol from interfering components or liberation of cholesterol into the free form, and measurement of isolated cholesterol. A mixture of polar and nonpolar solvents has been suggested to give better cholesterol extraction from food materials because cholesterol in these samples is usually bound by many other biological compounds such as lipoproteins, proteins, and phospholipids, and a multiple extraction approach was thought to be more suitable to remove membrane cholesterol **(Dinh et al., 2011)**. Gas and liquid chromatography are the most suitable methods for cholesterol determination, due to their ability to separate and quantify this compound from other similar ones **(Albuquerque et al., 2016)**. The foremost colorimetric test for the identification of cholesterol is probably the Liebermann-Burchard (LB) reaction, which was first described in 1885 **(Xiong, Wilson and Pang, 2007)**. It includes saponification of cholesterol ester with alcoholic potassium hydroxide, extraction of hydrolyzed cholesterol with hexane followed by evaporation of the solvent, and finally color development with acetic anhydride and concentrated sulfuric acid. However, its use is not accepted for routine tests nowadays since highly corrosive reagents are used **(Li et al., 2019)**. High-performance liquid chromatography (HPLC) has the main advantage of being carried out at relatively low temperatures, thus preventing cholesterol oxidation **(Ramalho, Casal and Oliveira, 2011; Albuquerque et al., 2016)**. In spite of some

drawbacks, such as elevated volumes of solvents and limits of detection and quantification, sample preparation is simple and required a small number of steps (saponification and the choice of extraction solvents are needed for adequate separation and quantification of analytes by HPLC) **(Bauer et al., 2014)**.

Scientific hypothesis

Both HPLC and spectrophotometric method could be acceptable for the determination of cholesterol content in milk.

MATERIAL AND METHODOLOGY

All reagents and standards were of analytical grade. Cholesterol standard was from Sigma-Aldrich with a purity ≥99%. Potassium hydroxide (KOH), concentrated sulfuric acid (H_2SO_4), and acetic anhydride were purchased from Mikrochem (Pezinok, Slovakia). Ethyl acetate, n-hexane, and sodium sulphate anhydrous were purchased from Centralchem s.r.o. (Bratislava, Slovakia). Methanol, HPLC grade was purchased from Fisher Chemical (Loughborough, UK). The cow´s milk (3.5% fat, Tatranská mliekareň a.s., Kežmarok, Slovakia) was bought in a local market.

Sample preparation

HPLC analysis

The samples were prepared according to the modified method of **Borkovcová et al. (2009)**. To the 5.0 g of the sample methanolic solution of KOH (1 mol.L^{-1}) was added and refluxed for 30 min. After cooling, 10 mL of n-hexane and 5 mL of deionized water were added and intensively shaken in a separating funnel. The organic layer was separated into the beaker with 2.0 g of sodium sulphate. The water layer was further washing 2 more times. The hexane solution was evaporated, and the residue was dissolved in 3 mL of ethyl acetate. The solution was filtered using syringe filters with PVDF membrane and particle size 0.45 μm (Agilent Captiva, USA). The prepared solution was directly analyzed by HPLC chromatograph. The calibration curve was performed using seven standard concentrations. A stock solution of cholesterol (1 mg.mL^{-1}) was diluted in methanol to prepare calibration standards at 25, 40, 50, 75, 100, 300, and 350 μg.mL^{-1}.

Spectrophotometric determination

The samples for spectrophotometric determination of cholesterol were prepared similarly to HPLC analysis. The LB color reagent was prepared according to the modified method of **Xiong et al. (2007)**. Ethyl acetate (75 mL), acetic anhydride (60 mL), and concentrated H_2SO_4 (12 mL) were pipetted to the volumetric flask at 0 °C, stirring for 10 min, and storage in the fridge for 3 hours. To the prepared LB reagent 1 mL sample solution was added. After 5 min the absorbance value was recorded at 625 nm for 20 min. The concentration of cholesterol in the sample was calculated from the calibration curve, which was performed using calibration standards. The calibration standards were prepared by dilution of cholesterol in ethyl acetate at 0.1 to 1 mg.

Instrument and chromatographic conditions

HPLC

Chromatography analysis was performed using an Agilent Technologies 1260 infinity system (USA) equipped with a vacuum degasser, a quarterly pump, an autosampler, and the UV-DAD detector. Cholesterol was detected at UV wavelength of 205 nm. Isocratic elution was performed at a flow rate of 1.2 mL.min^{-1} using the mobile phase consisted of water/methanol 5:95 (v/v). The injection volume was 10 μL and the temperature was set at 35 °C. As a stationary phase, a Poroshell 120 EC-C18 column (4.6 x 50 mm, 2.7 μm particle size) was used with the guard column Poroshell 120 EC-C18 (4.6 x 5 mm, 2.7 μm particle size). The results were recorded using the OpenLab CDS software, ChemStation Edition for LC and LC/MS systems (product version A.01.08.108).

Spectrophotometric determination

Spectrophotometric determination was performed using a spectrophotometer Cary 300 UV-Vis (Agilent Technologies, USA). The detection wavelength was 625 nm. The results were determined with Cary WinUV software (software version 4.20(468).

Statistical analysis

Results are expressed as mean ±standard deviation or as percentage. Statistical analysis was performed using Microsoft Exel version 2010. The data were subjected to the Student´s test and the values were considered significantly different when $p < 0.05$.

To obtain validation parameters, the linearity, limit of detection (LOD), limit of quantification (LOQ), accuracy, precision, and selectivity were determined. The linearity was evaluated according to the correlation coefficient by Pearson (R^2) for linear regression. The LOD and LOQ were calculated considering the signal-to-noise ratio accepted for each limit and the parameters estimated for the analytical curve, according to equations 1 and 2:

$$LOD = 3.3 \times \frac{s}{S} \quad (1)$$

$$LOQ = 10 \times \frac{s}{S} \quad (2)$$

Where s is the estimate of the standard deviation of the equation's linear coefficient, and S is the angular coefficient of the analytical curve **(Bauer et al., 2014)**.

The precision was assessed by the Horrat test, which is the ratio of the method standard deviation and the Horwitz relative standard deviation (equation 3):

$$RSD_{Horwitz} = 2^{(1-0.5logC)} \quad (3)$$

Where C is the analyte concentration in mass percentage **(Ribeiro and Brandäo, 2017)**.

The accuracy was evaluated by recovery studies at one standard concentration level of cholesterol (1 mg.mL^{-1}). Recoveries were evaluated by adding to milk sample aliquots standard solutions of the analytes. After the quantification of the analytes in the fortified samples and in the control, the recovery percentage (% REC) was calculated according to equation 4 **(Bauer et al., 2014)**:

$$\%REC = \left(\frac{Obtained\ conc. - Control\ conc.}{Expected\ conc.}\right) \times 100 \quad (4)$$

Selectivity was evaluated by using the spectra provided by the DAD detector by comparison of the peaks present in the chromatograms of the products with those peaks in the chromatograms of the standards, as described by **Bauer et al. (2014)**.

In order to evaluate the conformity of the results obtained by HPLC and spectrophotometric determination, Moore´s test was used according to **Eckschlager, Horsák and Kodejš (1980)**. The test is applicable if $n_A \neq n_B$ and the range of R_A and R_B is used as a measure of variance. Conformity is tested according to Moore´s criterion (U). Moore´s criterion is calculated according to the equation 5:

$$U = \frac{|\overline{x_A} - \bar{x}_B|}{R_A + R_B} \quad (5)$$

Where x_A is an average value obtained from the first method, x_B is the average value obtained from the second method, and R_A, R_B are the values of variance. The calculated U is compared with the critical value U_α. If $U \geq U_\alpha$, the difference is statistically significant at $p < 0.05$. If $U < U_\alpha$, the difference is not significant and we accept the null hypothesis about the consistency of the results **(Eckschlager, Horsák and Kodejš, 1980)**.

RESULTS AND DISCUSSION

Optimization of the spectrophotometric determination and chromatographic conditions

In color-based methods, the application of the LB reaction is usually the key step after the extraction procedure **(Dinh et al., 2011)**. Cholesterol in the presence of concentrated sulphuric acid and acetic anhydride is oxidized to a conjugated pentaene known as cholestapolyene carbonium ion and this undergoes further reaction to form cholestahexaene sulphonic acid, with a wavelength of absorption of 410 nm **(Adu et al., 2019)**. The LB reaction depends, however, on various factors, such as temperature, time, proportions of reactant, wavelength or exposure of light as described by **Kenny (1952)** or **Essaka (2007)**. Firstly, our study thus investigated the kinetics of LB reaction. We monitored the dependence between the time of reaction and the absorbance of the solution. The results are shown in Figure 1. The absorbance maximum at 625 nm is stable for 20 to 30 min and there is little difference in the measured absorbances. With the increasing time, the absorbance maximum is moving to higher wavelength values (665 to 670 nm), where is also stable. However, a longer time interval is less suitable regarding total analysis time. From the Student´s test, it was observed that the difference between the absorbance values at 625 nm in 20 and 30 min was not significant at $p < 0.05$. The spectrophotometric measurement was thus optimized regarding these results. **Atinafu and Bedemo (2011)** used quite a similar wavelength (640 nm) for the determination of cholesterol in some commercial edible oils. According to **Burke et al. (1974)**, a 30 min reaction time is optimum for spectrophotometric measurement. According to **Kim and Goldberg (1969)**, maximum color development occurs after 15 – 18 min incubation at 30 °C. The other important factor, which has to be considered, is the stability of LB color reagent. **Kim and Goldberg (1969)** stated that the LB reagent is not unstable and it need not be used within a few hours. According to these authors, the reagent is stable for 6 months when stored at 4 °C. On the other hand, some authors using the LB reagent, which was prepared freshly **(Sperry and Brand, 1943; Xiong et al., 2007; Adu et al., 2019)**. Firstly, the stability of LB reagent was measured after 7 hours. After this time the new calibration standards curve was recorded. Based on the Student´s test the differences were statistically insignificant at $p < 0.05$. Statistically insignificant differences were also noticed after 24 and 48 hours. From the results, it was thus obvious that LB color reagent is stable. The reaction is also influenced by the stability of cholesterol solution. The difference between the results obtained with the freshly prepared cholesterol solution and after 21 days was statistically significant at $p < 0.05$ thus the solution was not stable, and the use of freshly prepared solution is recommended.

Because of the slight polarity caused by the hydroxyl group, either normal-phase (NP) or reversed-phase (RP) HPLC can be used for the analysis of cholesterol **(Dinh et al., 2011)**. In our study, we worked with non-polar C_{18} stationary phase and polar mobile phase.

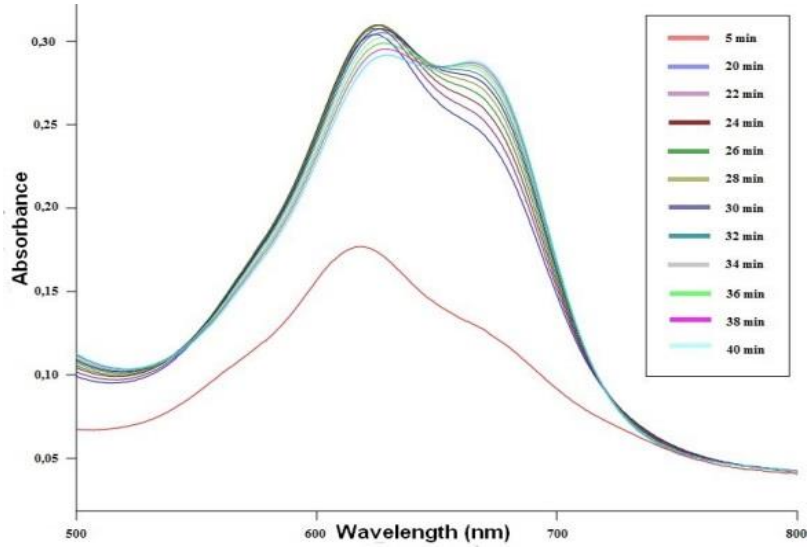

Figure 1 Absorbance spectrum of Liebermann-Burchard reaction.

In literature, there is described a lot of different types of mobile phase composition. For example, **Borkovcová et al. (2009)** used water with methanol 5:95, **Oh, Shin and Chang (2001)** acetonitrile: methanol: isopropanol 7:3:1 or **Bauer et al. (2014)** acetonitrile with isopropanol 95:5. In this work, several mobile phases were tested but the best results were obtained using deionized water with methanol (5:95, v/v). The same conditions were described by **Borkovcová et al. (2009)**. After the optimization procedure, the retention time of cholesterol peak was 5.2 min. The absorbance spectrum (Figure 2) showed that the maximum is obtained at 201 nm, but to avoid the interferences caused by impurities, we used the absorption at 205 nm, because the differences were not statistically significant $p < 0.05$.

Sample analysis and validation

The sample saponification and extraction of cholesterol to non-polar solvent were crucial steps for the analysis of this compound in milk by both methods. The saponification of the lipids has the primordial objectives of removing acylglycerols from the extract of the lipids and hydrolyzing the esters of cholesterol. The reaction can be done after the extraction of the lipids, or by direct saponification **(Bauer et al. 2014)**. These authors also suggested that direct saponification is preferably due to a significantly lower quantity of solvents and shorter preparation time. In our work, we thus used direct saponification followed by the extraction. According to **Ahn et al. (2012)**, three important factors must be considered when selecting a cholesterol extraction solvent: a high solubility of cholesterol, a low efficiency for fat extraction, and hydrophilicity. The most widely used solvents are n-hexane or toluene. Especially hexane has some advantages, such as it is less toxic than other solvents and does not form emulsions as toluene does **(Fletouris et al., 1998)**. The extraction with hexane was performed three times due to increased efficiency, as described **Oh, Shin and Chang (2001)**. Based on these authors, the chromatogram of method, which used hexane as the extraction solvent, had an excellent baseline and no interference was detected. The efficiency of extraction with hexane is also influenced by the presence of water **(Fletouris et al., 1998)**. Therefore, a small amount of water was added to the extraction solvent. The water was then removed by the filtration through anhydrous sodium sulphate. Almost the same steps were also described by **Borkovcová et al. (2009)**.

Based on these modified methods the cholesterol content in milk was analyzed by both techniques. By HPLC the mean content of cholesterol in milk was determined on 92.78 ±9.57 $mg.kg^{-1}$ and by spectrophotometric determination on 84.57 ±10.95 $mg.kg^{-1}$. The 3D record of cholesterol peak in the milk sample is showed in Figure 3.

Ramalho, Casal and Oliveira (2011) determined the mean content of cholesterol in commercial milk samples on 11.6 ±0.2 $mg.100\ mL^{-1}$ by HPLC. According to **Faye et al. (2015)**, the mean values of cholesterol in cow milk are 8.51 ±9.07 $mg.100\ g^{-1}$, which is close to our results.

From the results of **Manzi, Di Costanzo and Mattera (2013)**, the average cholesterol content in Italian cow´s milk is 12.8 ±0.4 $mg.100\ g^{-1}$. Thus, on average, the cholesterol content of whole milk is 12 $mg.100\ g^{-1}$. The variations of values can be attributed to variations in the processing of the milk as well as to differences in the animal breeds, individual characteristics, and intervals between milking, lactation phase, the composition of the animal´s diet, etc. **(Bauer et al., 2014)**.

To obtain the validation parameters, the linearity of both methods was performed by the calibration curves. The linearity is the ability of a method to demonstrate that its results are directly proportional to the concentration of the analyte in the sample, within the linear working range **(Ribeiro and Brandäo, 2017)**. In spectrophotometric determination, the linear range was obtained in the range of cholesterol content 0.1 to 1 mg with the correlation coefficient of 0.9992. In HPLC the linear range was achieved at the cholesterol concentrations at 25 to 350 $mg.L^{-1}$ with the correlation coefficient at 0.9999. This result agrees with **Albuquerque et al. (2016)**, where the linearity was obtained over the range of 0.07-0.4 $mg.mL^{-1}$. The obtained LOD and LOQ for HPLC were 2.13 $mg.kg^{-1}$ and 6.45 $mg.kg^{-1}$, respectively, while for the spectrophotometric method were 12.55 and 38.04 $mg.kg^{-1}$. Thus, from the results, it can be stated that HPLC has better sensitivity than spectrophotometric determination. The almost similar values of LOD and LOQ are reported by **Ahn et al. (2012)** with LOD 2.27 $mg.kg^{-1}$ and LOQ 7.56 $mg.kg^{-1}$. The other important validation parameters are accuracy and precision.

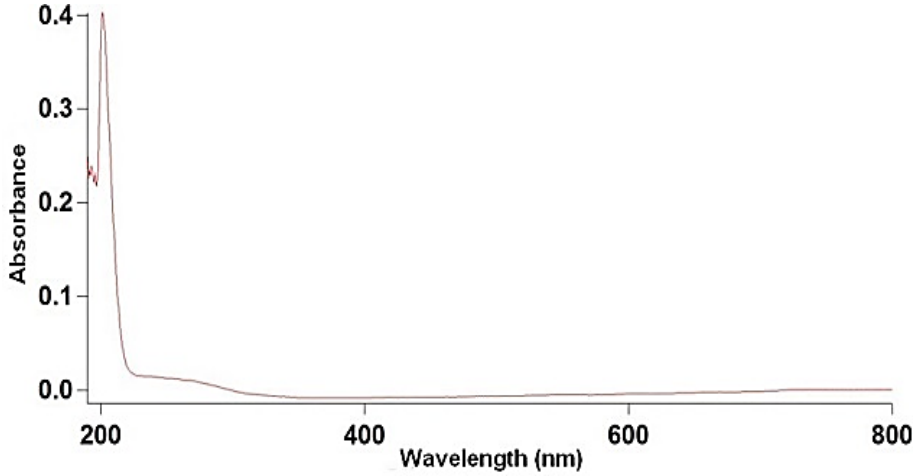

Figure 2 Absorbance spectrum of cholesterol in methanol obtained by UV-VIS spectrophotometer.

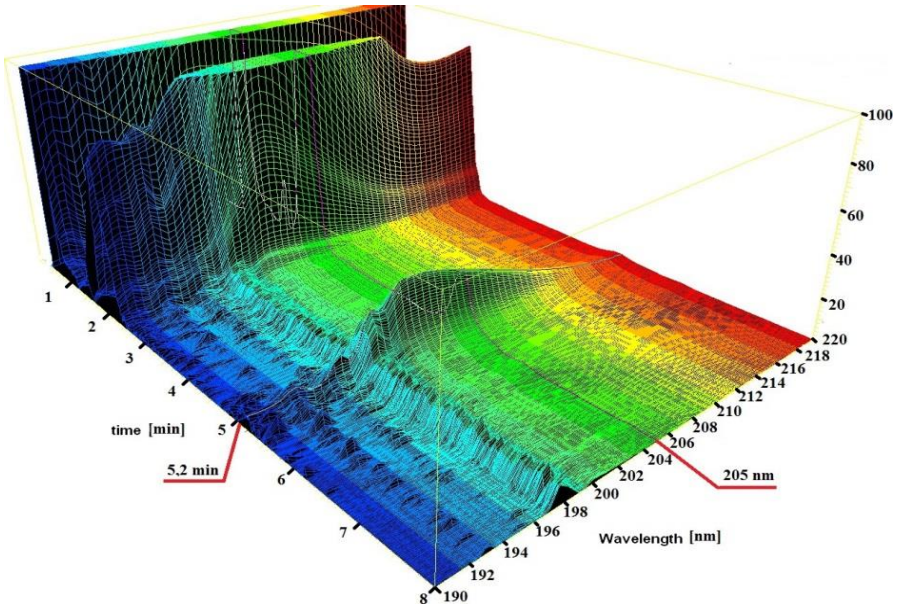

Figure 3 The 3D record of cholesterol peak in milk sample.

Table 1 Comparison of the results obtained from the analysis of cholesterol content in milk by HPLC (Method A) and spectrophotometric determination (Method B).

	Method A[a]	**Method B[b]**
Cholesterol content (mg.kg^{-1} ±SD)	92.78 ±9.57	84.57 ±10.95
LOD (mg.kg^{-1})	2.13	12.55
LOQ (mg.kg^{-1})	6.45	38.04
Recoveries (%)	91.05	85.34
Horrat	1.3	1.45
Slope of calibration curve (b)	433	0.558
Correlation coefficient (R^2)	0.9999	0.9992

Note: [a]n = 6, [b]n = 3, LOD – limit of detection, LOQ – limit of quantification.

The precision refers to the degree of agreement among repeated measurements. Precision is approved when Horrat parameter is less or equal 2 **(Ribeiro and Brandäo, 2017)**. Both methods showed good precision with Horrat value less than 2. Accuracy was obtained by the standard addition method at one concentration level of cholesterol. The recoveries were 85.34% and 91.05% for spectrophotometric determination and HPLC, respectively. Analyte recoveries close to 100% are ideal, but smaller values are admitted if the precision is good **(Bauer et al., 2014)**, and in this case, it is proved by the Horrat values. The selectivity of chromatographic method was proven by the adequate separation of cholesterol with good resolution of the peaks and without co-elution of other compounds in the sample.

The comparison of the propose methods

The comparison of the results obtained from the analysis of cholesterol content in milk by HPLC and spectrophotometric determination is shown in Table 1. For the testing of conformity of the results obtained from both methods, Moore´s test was used according to **Eckschlager, Horsák and Kodejš (1980)**. Based on Moore´s test, the difference between cholesterol content in milk by HPLC and spectrophotometric determination is statistically insignificant at p <0.05 and the null hypothesis of consistency of results is accepted. The resulting mean cholesterol contents in milk determined by these two methods are thus relatively identical. The results showed an 8.8% difference. The cholesterol level in milk can be thus determined by either HPLC or spectrophotometric method. The same conclusion is described by **Essaka (2007)**. Based on his research, the agreement of the values obtained by HPLC and LB reaction with a 16% difference showed that the proposed method was indeed reliable.

As seen from validation parametres, HPLC has some advantages over spectrophotometry. Firstly, LOD and LOQ values are lower thus HPLC is more sensitive. Better sensitivity of HPLC can be seen also from the slope of the calibration curve, where the value is much higher than in spectrophotometric determination. The recoveries were lower in spectrophotometric determination, which can be caused by the different approaches in sample preparation. After saponification and extraction, the sample before spectrophotometry must be reacted with LB reagent, which could lower the recovery. Besides that, the color stability, the issue of temperature dependency, and the turbidity of the final color-developed solution have made colorimetric methods subject to significant concern regarding accuracy **(Dinh et al., 2011)**. According to **Osman and Chin (2006)** HPLC was considered as the method of choice for

cholesterol determination with the lowest LOD and LOQ compare to spectrophotometry and gas chromatography. The performance of spectrophotometer was better than gas chromatography in terms of reproducibility.

CONCLUSION

This study was focused on the comparison of HPLC and spectrophotometric determination of cholesterol content in milk. From the results, the following conclusions can be postulated:

1. The spectrophotometric determination is influenced by the stability and absorbance characteristics of LB reagent.
2. The results obtained from HPLC and spectrophotometric determination differed only in 8.8% thus both methods are suitable for analysis of cholesterol in milk products.
3. HPLC analysis has some advantages over spectrophotometry, mainly higher sensitivity and lower LOD and LOQ values, which makes it more favorable in cholesterol determination in milk.

PARAMETERS OF ANTIOXIDANT ACTIVITY OF *GALEGA OFFICINALIS* L. AND *GALEGA ORIENTALIS* LAM. (*FABACEAE* LINDL.) PLANT RAW MATERIAL

Olena Vergun, Oksana Shymanska, Dzhamal Rakhmetov, Olga Grygorieva, Eva Ivanišová, Jan Brindza

ABSTRACT

The plant raw material of *Galega officinalis* L. (goat's rue) and *Galega orientalis* Lam. (fodder galega) investigated in this study. These species are known as fodder crops with high productivity of green mass and as medicine plants. The current study was aimed to evaluate an accumulation in dry raw of selected plants the total content of phenolic acids (TPA) and flavonoids (TFC) as compounds with antioxidant activity (AA) by spectrophotometric method. AA by DPPH-method and phosphomolybdenum method (reducing power (RP)) was measured. Study of ethanolic extracts of *G. officinalis* showed accumulation of TPA in different organs in range from 3.65 to 15.17 mg.g^{-1} caffeic acid equivalent (CAE) and TFC from 10.08 to 65.75 mg.g^{-1} quercetin equivalent (QE), AA by DPPH-method from 6.02 to 8.45 mg.g^{-1} Trolox equivalent (TE) and RP of extracts by phosphomolybdenum method from 86.56 to 288.15 mg TE.g^{-1}. In extracts of *G. orientalis* was identified TPA from 3.52 to 18.52 mg CAE.g^{-1} and TFC from 6.09 to 46.72 mg QE.g^{-1}, antioxidant activity by DPPH-method from 6.80 to 8.48 mg TE.g^{-1} and antioxidant capacity by phosphomolybdenum method from 52.52 to 188.51 mg TE.g^{-1}. It was established that less concentration of studied compounds found in the stems for both species. It should be noted that the content of phenolic acids in the leaves was decreased and flavonoids in stems increased during vegetation for both species. Content of phenolic acids in the generative organs and flavonoids in the leaves decreased in raw of *G. orientalis* during vegetation. Pearson's correlation analysis demonstrated very strong relations between TFC and AA by DPPH, TPA and RP, TFC and RP for *G. officinalis* extracts. Very strong correlation in the extracts of *G. orientalis* found between TFC and RP, TPA and RP. Obtained results can be used in the further biochemical and pharmacological study.

Keywords: *Galega officinalis*; *Galega orientalis*; antioxidant activity; flavonoids; phenolic acids

INTRODUCTION

Study of the antioxidant activity and compounds that cause it very widespread and actually in modern biological science **(Carocho and Ferreira, 2013; Kumar, Sharma and Vasudeva, 2017)**. Plant raw material of medicinal **(Adámková, Kouřimská and Kadlecová, 2015; Vergun et al., 2019b)**, food **(Frusciante et al., 2007; Mendelová et al., 2016)**, forage **(Sang et al., 2014; Petrović et al., 2016; Vergun et al., 2018)**, fruit **(Ivanišová et al., 2017; Horčinová Sedláčková et al., 2018; Brindza et al., 2019)** and other plant groups and their products are a valuable source of antioxidant compounds of different nature. Leguminous plants (*Fabaceae* Lindl.) are a perspective group of crops, which ecological and economic function is important in agriculture. It is one of the most important plant families in the production of food for humans and livestock, as well as in the production of industrial products. These crops have provided interesting as forage grasses with high productivity and play an important role as N fixators **(Peiretti, 2009; Teleută et al., 2015)**. Plants from the *Fabaceae* family are of interest in relation to biologically active compounds, especially individuals, in different organs **(Danilčenko et al., 2017)**.

Among economically important leguminous plants can be highlight goat's rue (*Galega officinalis* L.) and fodder galega (*Galega orientalis* Lam.). Plants of species of *Galega* L. are valuable perennial and productive crops with the protein-rich chemical composition of plant raw material **(Baležentienė, 2008)**. They widespread in natural flora and are characterized by high productivity of seeds **(Tkacheva, Vinogradova and Pavlova, 2011)**. Results obtained by **Peiretti (2009)** showed that *G. officinalis* has the potential for large-scale ensiling if plants are harvested at the budding stage or during regrowth. These species cultivated as medicinal plants due to the biochemical composition of plant raw material and as garden plants **(Baležentienė and Spruogis, 2011; Kumar et al., 2012)**. As reported **Kiselova et al. (2006)**, plants of *G. officinalis*

use in traditional phytotherapy due to hypoglycemic and diuretic properties. Also, the hypoglycemic and weight-reducing ability of this species was described in some reports **(Lemus et al., 1999; Hasani-Ranjbar et al., 2009; Shojaee et al., 2015)**.

As described in some reports, plants of *G. officinalis* use in traditional phytotherapy due to hypoglycemic, diuretic properties, and weight-reducing ability **(Modak et al., 2007; Hasani-Ranjbar et al., 2009; Shojaee et al., 2015)**. These plants as a source of metformin use to treat diabetes and use in the pharmacology **(Umashanker and Shruti, 2011; Khodadidi, 2016; Abhati-Evari et al., 2017; Luka, Adoga and Istifanus, 2017)**. Leaves of *G. officinalis* are a source of bioactive secondary metabolites **(Pehlivan Karakas, Sahin and Türker, 2016a)**.

Biochemical composition of *Galega* species raw is ascorbic acid, carotene, soluble sugars, lipids, protein, ash, alkaloids, macroelements, etc. **(Symanowicz and Kalembasa, 2012; Vergun, Shymanska and Rakhmetov, 2012; Shymanska et al., 2017)**. Also, the phytochemicals screening revealed that in aqueous, methanolic, ethanolic and acetone extracts were found flavonoids, tannins, cardiac glycosides, triterpenoids, and steroids. Methanolic extracts of goat's rue significantly improved the lipid profile in a clinical study **(Peirs et al., 2006; Luka, Adoga and Istifanus, 2017)**. As pointed out **Pehlivan Karakas, Yildirim and Türker (2012)**, different extracts of *G. officinalis* showed broad-spectrum activity against both gram-positive and gram-negative bacteria. Moreover, different extracts of goat's rue exhibited cytotoxic, anti-inflammatory and antioxidant activity **(Pehlivan Karakas et al., 2016b)**.

As reported by **Meripõld et al. (2017)**, the first cut of *G. orientalis* advisable to use as a bioenergy crop and the second cut as forage. Also, fodder galega was the object of allelopathic study. Experimental evidence obtained by **Baležentienė (2009)** and **Baležentienė and Kusta (2011)** suggests that shoots of fodder galega are the main source of its allelochemicals, especially at flowering stage. As emphasizes **Ignat, Volf and Popa (2011)**, the main group of biochemical compounds among allelochemicals is phenolic compounds. According to **Symanowicz et al. (2015)**, nitrogen fertilization significantly increased the dry matter yield of fodder galega.

Investigations of oxidative properties of *Galega* species indicated that plant raw material is the source of antioxidants with different natures **(Maslennikov, Chupakhina and Skrypnik, 2014; Shymanska et al., 2018a; Shymanska et al., 2018b)**. Also, high antioxidant activity found in the seed extracts **(Vergun et al., 2019a)**.

Nonetheless, it is necessary to carry out a study with plants of a genus of *Galega* as a source of important biologically active compounds. The aim of this study was to determine the peculiarities of accumulation of compounds with phenolic nature that can detect the antioxidant status of investigated plants as important crops.

Scientific hypothesis

Comparative assessment of the accumulation of phenolic compounds and determination of the antioxidant activity of two species of *Galega* L. genus during vegetation.

MATERIAL AND METHODOLOGY

Conditions of plant growing

The plants were grown in 2017 – 2018 at the experimental fields of the M. M. Gryshko National Botanical Garden of the NAS of Ukraine in the Kyiv city (50°24′55″N, 30°33′45″E).

Biological material

Observation on plants was conducted in the experimental collection of the Cultural Flora Department of M. M. Gryshko National Botanical Garden of the NAS of Ukraine (Figure 1). Plant raw material of two species – *Galega officinalis* and *G. orientalis* were collected in the stages according to Biologische Bundesanstalt, Bundessortenamt and Chemische Industrie (BBCH) coding system **(Meier, 2018)**. According to the BBCH scale, plant samples were taken at the phenological growth stages described for faba bean (*Vicia faba* L.). Four principal growth stages were assigned: leaf development (19 – nine or more leaves infolded), inflorescence emergence (50 – flower buds present, still enclosed by leaves), flowering (65 – full flowering: flowers open on 5 racemes per plant), and ripening (80 – beginning of ripening: seed green, filling pod cavity). For chemical analyses plant raw material was dried at 35 °C for three days **(Müller and Heindl, 2006)**. After this, the samples were milled in the powder condition. All biochemical analyses were done in the Slovak University of Agriculture

Figure 1 *Galega officinalis* L. and *Galega orientalis* Lam. in the stage of flowering.

in Nitra (Slovak Republic).

Sample preparation

For planned analyses, 0.2 g of milling fraction was extracted with 20 mL of 80% ethanol for 24 hours. After centrifugation at 4000 g with Rotofix 32 A (Hettich, Germany) for 20 min, the supernatant was used for measurement (phenolic acids, flavonoids, antioxidant activity by DPPH-method and reducing power of extracts).

Total phenolic acid content (TPAC)

The content of phenolic acids was determined using **Farmakopea Polska (1999)**. 0.5 mL of sample extract was mixed with 0.5 mL of 0.5 M hydrochloric acid, 0.5 mL Arnova reagent, 0.5 mL of 1 M sodium hydroxide (w/v) and 0.5 mL of distilled water. Absorbance at 490 nm was measured using the spectrophotometer Jenway (6405 UV/VIS, England). Caffeic acid 1 – 200 mg L^{-1} (R^2 = 0.999) was used as a standard. The results were expressed in mg.g^{-1} caffeic acid equivalents (CAE).

Total content of flavonoids (TFC)

Analise was conducted according to the procedure which was described by **Shafii et al. (2017)**. 0.5 mL of sample extract was mixed with 0.1 mL of 10% (w/v) ethanolic solution of aluminium chloride, 0.1 mL of 1 M sodium acetate and 4.3 mL of distilled water. After 30 min. in darkness the absorbance at 415 nm was measured using the spectrophotometer 6405 UV/VIS (Jenway, England). Quercetin 0.01 – 0.5 mg L^{-1} (R^2 = 0.997) was used as the standard and the results were expressed in mg.g^{-1} quercetin equivalents (QE).

Antioxidant activity (AA)

Radical scavenging activity of samples was measured using 2,2-diphenyl-1-picrylhydrazyl (DPPH) according to **Sánchéz-Moreno, Larrauri and Saura-Calixto (1999)** with slight modification. The ethanol extract (1 mL) was mixed with 4 mL of DPPH solution (0.025 g of radical in 100 mL of ethanol). The absorbance of the sample extract was determined using the spectrophotometer Jenway (6405 UV/VIS, England) at 515 nm. Trolox (6-hydroxy-2,5,7,8-tetramethylchroman-2-carboxylic acid) 10 – 100 mg L^{-1} (R^2 = 0.983) was used as a standard and the results were expressed in mg.g^{-1} Trolox equivalents (TE).

Reducing power of extracts

Reducing power of extracts was determined by the phosphomolybdenum method of **Prieto, Pineda and Aguilar (1999)** with slight modifications. The mixture of 1 mL of sample, 2.8 mL of monopotassium phosphate (0.1 M), 6 mL of sulfuric acid (1 M), 0.4 mL of ammonium heptamolybdate (0.1 M) and 0.8 mL of distilled water was incubated at 90 °C for 120 min, then rapidly cooled and detected by monitoring absorbance at 700 nm using the spectrophotometer Jenway (6405 UV/VIS, England). Trolox 10 – 1000 mg L^{-1} (R^2 = 0.998) was used as the standard and the results were expressed in mg.g^{-1} TE.

Statistical analysis

The statistically treated data are given in tables as the arithmetical mean values and their standard errors. Data were submitted ANOVA and differences between means compared through the Tukey-Kramer test (α = 0.05). Correlation analysis was performed using Pearson's criterion.

RESULTS AND DISCUSSION

Antioxidant compounds common nowadays play an important role in protecting factors that explain reducing the risk of different chronic diseases and belong to various classes of biochemical compounds. Phenolic compounds are widespread secondary metabolites in plant extracts, and it possesses various biological activities such as antioxidant, anticarcinogenic, antimicrobial, antiallergic, antimutagenic, anti-inflammatory etc. **(Tatiya et al., 2011; Najafabad Morabbi and Jamei, 2014)**. In addition, they play an important role in plant resistance **(Kulbat, 2016)**. The antioxidant compounds are the natural defense system to protect the plants from abiotic and biotic stresses such as salinity and drought. They play a key role in defense mechanisms against the free radicals which cause the deleterious effect to plant organisms **(Govindaraj et al., 2017)**. A high level of antioxidant agents in medicinal plants can be proposed as an effective therapeutic approach **(Saeed, Khan and Shabbir, 2012)**.

Phytonutrients found in different parts of plants are powerful antioxidants, especially compounds with phenolic nature. Polyphenol compounds from many legumes can be represented by different compounds such as phenolic acids (gallic, ellagic), hydrolyzable tannins **(Akbarirad et al., 2016)**. In some studies, flavonoids indicated as the main components responsible for antioxidant capacity **(Zhang et al., 2012)**. It is a large group of secondary metabolites, which play a variety of significant functions in plants. They play a role as signal molecules, phytoalexins, detoxifying agents, as UV-filters, pollinator attractants etc. **(Samanta, Das and Das, 2011)**. Moreover, as summed up by **Asif (2015)**, flavonoids exhibit a wide spectrum of biological activity such as antioxidant, antibacterial, antiviral, anti-inflammatory, anti-allergic, anti-thrombotic.

Antioxidant activity of plant extracts can be measured by different methods. Free radical scavenging activity by DPPH method is a simple assay for antioxidant activity evaluation **(Marinova and Batchvarov, 2011; Tatiya et al., 2011; Shekhar and Anju, 2014)**. DPPH radical shows the reduction capability by the decrease in absorbance induced by investigated plant extract. In our study reducing power of plant extracts measured with Trolox as standard while its can be, for example, ascorbic acid **(Tatiya et al., 2011)**.

In Table 1 and Table 2 are shown data of accumulation of total phenolic acids and total flavonoids content in vegetative and generative organs of *G. officinalis* and *G. orientalis* during vegetation. Polyphenol compounds can form several hydrogen bonds and even ionic bonds with most proteins. They modulate the activity of many proteins, involving enzymes, ion channels, etc. As a consequence, many polyphenols are pharmacologically active, being among antioxidants, anti-inflammatory, antibacterial, antifungal, and antiviral **(Wink, 2013)**.

Maslennikov, Chupakhina and Skrypnik (2014) reported that *G. officinalis* leaves contain 3.6 mg GAE.g^{-1} of polyphenol compounds. According to **Tusevski et al. (2014)**, this parameter for *G. officinalis* plants was 32.53 mg GAE.g^{-1}. **Pehlivan Karakas, Sahin and Türker (2016a)** obtained twenty phenolics compounds from methanolic leaves extracts of *G. officinalis*. The total phenolic content, in this case, was 36.69 mg.g^{-1} of dry extract. According to **Sałata and Gruszecki (2010)**, roots and leaves in vegetative stages of plants contained considerably more phenolic acids than the beginning of the flowering period, while in leaf nodes more polyphenolic compounds were marked during flowering than at the vegetative stage. Total phenolic acids in plant raw material of investigated *G. officinalis* plants were in the range from 3.65 to 15.17 mg CAE.g^{-1} depending on the phase of growth (Table 1).

Flavonoids belong to derivates of simple phenols, and their synthesis increases at the stress conditions due to microbial infections, injury, deficiency of nutrients, changing of temperature, etc. **(Kulbat, 2016)**. Flavonoids are biologically active compounds that possess the ability to capture radicals and play a significant role in agriculture and pharmaceutical chemistry as anti-hyperglycemic, anti-cancerous, anti-allergic, anti-viral, immune-stimulating activity **(Sulaiman et al., 2013; Marella, 2017)**.

The level of flavonoid accumulation in raw of *G. officinalis* during vegetation was in the range from 10.08 to 67.75 mg QE.g^{-1}. The study of **Tusevski et al. (2014)** resulted that the concentration of flavonoids in this plant was 8.95 ±0.13 mg CAE.g^{-1}.

As shown in Table 2 phenolic acid content of *G. orientalis* plant raw material ranged from 3.52 to 18.52 mg CAE.g^{-1} during vegetation. The concentration of flavonoids ranged from 6.09 to 46.72 mg QE.g^{-1}. According to **Baležentienė (2009)** report, the highest total content of phenols was determined at the budding stage which was characterized as the most intensive growth period of the plant shoot.

Also, it should be noted that minimal content of phenolic acids and flavonoids in the plant raw material of both investigated species during vegetation was identified in stems. Obtained data showed that higher accumulation of investigated biochemical parameters was different for two species. So, flavonoids content for *G. officinalis* were maximal in inflorescences and phenolic acids – in leaves (inflorescence emergence stage). For *G. orientalis* total content of phenolic acids and flavonoids was maximal in leaves (inflorescence emergence stage).

There are a great number of methods for the determination of antioxidant capacity based on different principles. One of them is the DPPH method that is rapid, simple, and accurate **(Marinova and Batchvarov, 2011; Pisoschi et al., 2016)**. The method is based on the scavenging of DPPH through the addition of a radical species or antioxidant that decolorizes the radical solution **(Saeed, Khan and Shabbir, 2012)**. Trolox Equivalent Antioxidant Capacity assay is widely used to evaluate the antioxidant property of investigated products **(Kumar, Sharma and Vasudeva, 2017)**. Figure 2 demonstrates the antioxidant capacity by DPPH-method of plant raw material of *Galega* species during vegetation.

We found that the antioxidant activity of investigated ethanol extracts of *G. officinalis* was in the range from 6.02 to 8.45 mg TE.g^{-1}. For *G. orientalis* extracts this parameter ranged from 6.80 to 8.48 mg TE.g^{-1}.

Also, the antioxidant capacity can be illustrated by the reducing power of investigated extracts as an important indicator. According to some studies, there is some connection between antioxidant activity and reducing power **(Zhang et al., 2012)**. In our experiment extracts analyzed spectrophotometrically through the phosphomolybdenum method, based on the reduction of Mo (VI) to Mo (V) **(Kumar, Sharma and Vasudeva, 2017; Saeed, Khan and Shabbir, 2012; Ravishankar, Kiranmayi and Prasad, 2018)**. The present study demonstrated that ethanol extracts of *G. officinalis* and *G. orientalis* had antioxidant activity during vegetation ranged between 86.56 – 288.15 and 52.52 – 188.51 mg TE.g^{-1}, respectively (Figure 3).

Correlation analysis was used to explore the relationships between the polyphenols, phenolic, flavonoids compounds and antioxidant capacities (by DPPH and phosphomolybdenum methods) measured for all plant extracts of *Galega officinalis* and *Galega orientalis* (Table 3, Table 4). The results of this study have demonstrated that investigated antioxidant components in two species of *Galega* L. had a correlation between different parameters of an experiment during vegetation. In the period of inflorescence emergence we found a very strong correlation between TPA and TF for both *G. officinalis* and *G. orientalis* (0.985 and 0.950 respectively). Very strong correlation found between AA by DPPH and RP of extracts for *G. officinalis*. The relation between TPA accumulation and RP and TFC and RP was moderate for *G. officinalis* (0.433 and 0.583 respectively). For *G. orientalis* in this period between TPA and RP was strong relation (0.750) and between TFC and RP very strong (0.919). In the period of flowering indicated that very strong correlation found for both species between TFC and RP. Dramatically strong correlation detected between TFC and AA by DPPH (0.999) for *G. officinalis* in this stage. However, in this case for *G. orientalis* found a very weak correlation (0.033). Also, very strong relations found between TPA, TFC and RP for *G. officinalis* (0.924 and 0.851 respectively). In this case values of coefficient of correlation were 0.670 (strong) and 0.953 (very strong) for *G. orientalis*. Different values found for two species regarding the relation between AA by DPPH and RP (very strong for *G. officinalis* and weak for *G. orientalis*).

Table 1 The total content of phenolic acids and flavonoids in plant raw material of *Galega officinalis* L. during vegetation.

Phase of growing	Organ of plant	Total phenolic acids, mg CAE.g^{-1}	Total flavonoid content, mg QE.g^{-1}
Leaf development	aerial part	14.13 ±0.89 ^{a}	44.27 ±2.97 ^{b}
Inflorescence	leaves	15.17 ±0.12 ^{a}	55.61 ±0.75 ^{a}
emergence	stems	6.47 ±0.20 ^{c}	10.08 ±0.94 ^{ef}
	buds	12.44 ±0.07 ^{b}	48.91 ±1.14 ^{b}
Flowering	leaves	11.62 ±0.25 ^{b}	44.91 ±1.12 ^{b}
	stems	3.65 ±0.24 ^{c}	13.18 ±0.86 ^{e}
	inflorescences	7.70 ±0.48 ^{c}	67.75 ±5.05 ^{a}
Ripening	leaves	10.15 ±0.28 ^{b}	32.24 ±0.29 ^{c}
	stems	9.62 ±0.19 ^{b}	24.78 ±0.57 ^{d}
	fruits	5.89 ±0.29 ^{c}	16.86 ±0.55 ^{e}

Note: Means in columns followed by different letters are different at p = 0.05; each value represents the mean of three independent experiments (±SD); GAE – gallic acid equivalents; CAE – caffeic acid equivalents; QE – quercetin equivalents.

Table 2 The total content of phenolic acids and flavonoids in plant raw material of *Galega orientalis* Lam. during vegetation.

Phase of growing	Organ of plant	Total phenolic acids mg CAE.g^{-1}	Total flavonoid content mg QE.g^{-1}
Leaf development	aerial part	16.73 ±0.52 ^{a}	38.79 ±0.83 ^{b}
Inflorescence	leaves	18.52 ±1.64 ^{a}	46.72 ±0.26 ^{a}
emergence	stems	4.37 ±0.19 ^{d}	6.09 ±0.67 ^{e}

RP	0.880*	0.959	-0.669*

Note: Significant according to the t-test (p <0.05).

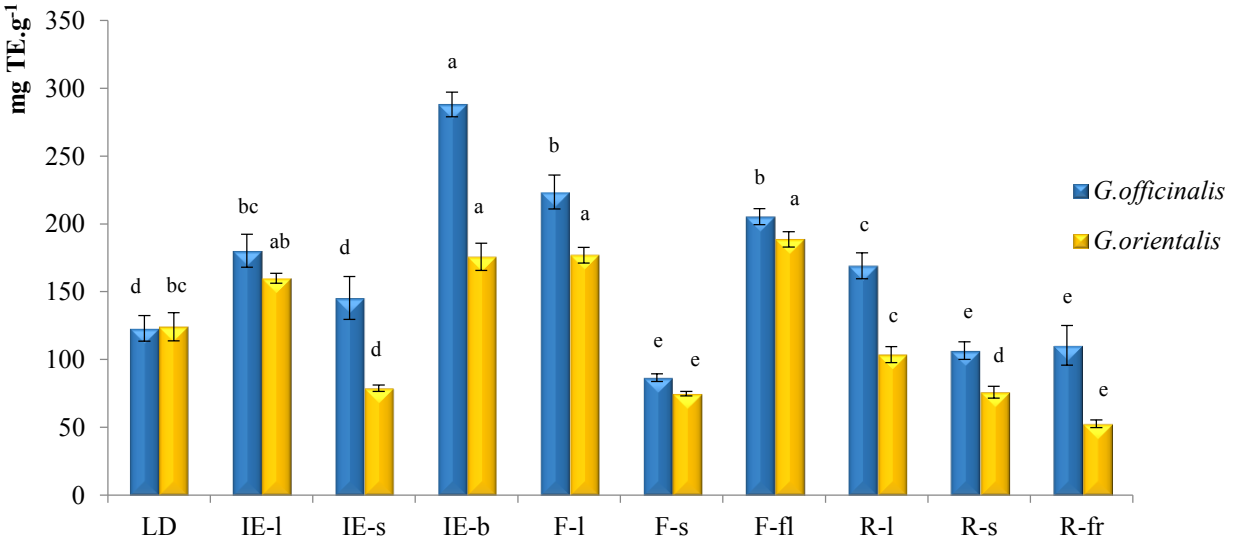

Figure 4 The reducing power of ethanol extracts of *Galega officinalis* L. and *G. orientalis* Lam. during vegetation. Note: LD – leaf development; IE-l – inflorescence emergence, leaves; IE-s – inflorescence emergence, stems; IE-b – inflorescence emergence, buds; F-l – flowering stage, leaves; F-s – flowering stage, stems; F-fl – flowering stage, inflorescences; R-l – ripening, leaves; R-s – ripening, stems; R-fr – ripening, fruits; means in columns followed by different letters are different at p = 0.05; each value represents the mean of three independent. experiments (±SD).

At the period of ripening determined the very strong correlation between TPA and TFC, TFC and RP for both investigated species. Correlation between TPA and RP was moderate for *G. officinalis* (0.551) and very strong for *G. orientalis* (0.880). It should be noted that for both species was found a negative correlation between TPA and AA by DPPH, TFC and AA by DPPH, and between AA by DPPH and RP. The direction of correlation between antioxidant components depends on them nature, thus, different types of phenolics possess different antioxidant activity **(Vamanu et al., 2011)**.

According to previous studies, it should be noted that phenolic extracts exhibited different antioxidant activity that depends on their structure **(Tatiya et al., 2011)**. The study of relationships between phenolic compounds and antioxidant activity demonstrated a significant correlation **(Li, Wu and Huang, 2009)**. Some results, also, not confirmed correlations between the content of phenolic compounds and antioxidant activity **(Vamanu et al., 2011)**. Moreover, according to **Vamanu et al. (2011)**, reducing power and antioxidant activity correlated with extract concentration. In some cases, there wasn't found relationship between phenolic compounds content and antioxidant activity.

CONCLUSION

Based on the results obtained in this study concluded that two investigated species of *Galega* L. as medicine and forage cultures characterized by plant raw material with high antioxidant activity. The maximal content of phenolic acids for both investigated species was found in the leaves in the period at the inflorescence emergence, flavonoids in inflorescences at the flowering stage for *G. officinalis* and in the leaves at the inflorescence emergence period for *G. orientalis*. The least content of phenolic acids and flavonoids identified in the stems of both investigated species. Ethanolic extracts of stems of *G. officinalis* and *G. orientalis* plants exhibited the most antioxidant activity at the ripening stage by DPPH-method. Reducing power of ethanol extracts was higher for *G. officinalis* in the buds, for *G. orientalis* in the inflorescences. Pearson's correlation analysis (at $p < 0.05$) showed very strong values of coefficient of variation between TFC and AA by DPPH (0.999), TPA and RP (0.924), TFC and RP (0.828) for *G. officinalis* depending on the stage of growth. The highest correlation found in extracts of *G. orientalis* between TFC and RP at every investigated stage (0.919, 0.953, and 0.959), between TPA and RP (0.880). Obtained results demonstrated that two investigated species of *Galega* are a good source of antioxidant compounds with polyphenol nature such as phenolic acids and flavonoids. These data can provide further information about an accumulation of flavonoids and phenolic acids in *Galega* spp. raw that possess antioxidant activity and also can be used in pharmacological investigations.

COMPARISON OF THE PHYSICO-CHEMICAL MEAT QUALITY OF THE BREEDS MANGALITSA AND LARGE WHITE WITH REGARD TO THE SLAUGHTER WEIGHT

Ivan Imrich, Eva Mlyneková, Juraj Mlynek, Marko Halo, Tomáš Kanka

ABSTRACT

The aim of this study was to compare the quality of *musculus longissimus dorsi* in the breeds of Mangalitsa and Large White with regard to the slaughter weight. Large White (LW) breed and White Mangalitsa (Ma) breed were used in the experiment. The system of housing and feeding was the same in both of the monitored breeds. The pigs were fed with the same feeding mixture *ad libitum.* According to the slaughter weight, the pigs were divided into three groups: up to 100 kg, 101 – 110 kg and over 110 kg. The breed Ma had a significantly lower drip loss than the breed LW. Evaluating the color of the meat, the LW breed has showed significantly higher L* (lightness, white ±black) and lower a* (redness, red ± green) values than the Ma breed. Within the chemical meat composition, the Ma breed had a significantly higher water content in MLD compared to the LW breed. Generally, there were no major differences in the meat quality between the Mangalitsa and Large White breeds. Finally it can be concluded that the breed Mangalitsa showed more favorable values of the physico-chemical indicators. Comparing the quality of the meat with regard to the slaughter weight, there were no large differences between individual weight groups. A higher slaughter weight has positively influenced mainly the color of the meat, as pigs weighing more than 110 kg achieved a significantly lower value of L* and a higher value of a* in comparison to pigs of the lower weight. As a positive effect of a higher slaughter weight can be considered its effect on the protein content in the meat, as pigs weighing over 100 kg have a significantly higher protein content in the meat than pigs weighing below 100 kg.

Keywords: Large White; Mangalitsa; pork quality; slaughter weight

INTRODUCTION

Pork quality has become a primary focus for producers, researchers, packers, processors, retailers, and ultimately, consumers **(Newcom et al., 2004)**. In the last few years, consumers and the meat industry have emphasized the descending quality of the pig meat offered, such as a high frequency of pale, soft and exudative (PSE) fault expressed by a high drip loss and low water-holding capacity, unacceptable taste of pork, and a low content of the intramuscular fat **(Florowski et al., 2006)**. The meat quality is evaluated according to the quality parameters, such as the pH, color, or the intramuscular fat content. Meat color is one of the main quality properties, which influences consumer's acceptance, but also reflects the quality of meat **(Alonso et al., 2009)**. Moreover, the meat classification based on the pH and color directly in the cutting plant could help to separate the low-quality meat **(Bednářová et al. 2014)**. There are many factors that influence the final quality of meat, e.g. animal nutrition, transportation, handling and stunning, but it is well-known that the breed itself can affect the pork quality **(Gil et al., 2008; Pascual et al., 2007; Šimek et al., 2004)**.

Meat and the meat products from the autochthonous pigs are highly appreciated by consumers because of their high sensory quality **(Živković et al., 2012)**. A high amount of the intramuscular fat, great concentrations of the heme pigments and high levels of unsaturated fatty acids have been highlighted as some of the most relevant quality aspects in the muscles of the autochthonous pig breeds **(Stanišić et al., 2015)**.

The slaughter weight is considered an important factor determining the economic profitability of the pork production. Some disadvantages caused by the increased slaughter weight are related to the reduced pig performance, feed conversion efficiency, and excessive fat thickness **(Serrano et al., 2008)**. From the point of view of the meat quality, the slaughter weight has shown some effects on the meat color, since the darker and redder colors were found in the pork meat at increasing the slaughter weight **(Ellis et al., 1996; Latorre et al., 2004)**.

Additionally, the intramuscular fat content was found to increase with the increased slaughter weight from 100 to 130 kg **(Weatherup et al., 1998)**. However, the slaughter weight has not shown any effects on the total protein, salt-soluble protein, and instrumental colors or marbling scores **(Serrano et al., 2008; Sutton et al., 1997)**.

Considering the fact that quality of pork may be significantly influenced by a genotype, but also by the weight at slaughter, the aim of this study was to evaluate the physico-chemical parameters of pork of the Mangalitsa and Large White breeds with regard to the slaughter weight.

Scientific hypothesis

We have assumed that the Mangalitsa breed meat will have better physico - chemical parameters compared to the Large White breed and that a higher slaughter weight will have a positive impact on the meat quality indicators.

MATERIAL AND METHODOLOGY

Biological material

In the experiment, a total of 20 pigs were analysed, 12 pigs of the breed Large White (LW) and 8 pigs of the breed White Mangalitsa (Ma). The pigs were bred on the pig farm in the village of Žirany (Slovakia).

Feeding and rearing conditions

The housing and feeding systems were the same for both breeds. The pigs were bred under the intensive breeding conditions, while they were housed in groups so as to comply with the requirements for the minimum housing area according to Government Regulation (SR) no. 735/2002 Coll., laying down the minimum standards for the protection of pigs **(NCSR, 2002)**. There was a concrete floor in the pens, covered with the wheat straw. The temperature in the stables was kept at 18 – 20 °C. The air exchange in the stables was realized by a vacuum ventilation system. Water and feed intake in both breeds was *ad libitum.* Feeding of the pigs was provided by the automatic feeders designed for a dry compound feed, which was granulated in order to reduce dustiness. Nipple drinkers were used for watering. The nutritional composition of the used commercial feed mixture was as follows: crude protein 164.63 $g.kg^{-1}$, crude fat 36.25 $g.kg^{-1}$, crude fiber 48.89 $g.kg^{-1}$, ash 39.69 $g.kg^{-1}$, nitrogen free extract 710.53 $g.kg^{-1}$, metabolisable energy 13.10 $MJ.kg^{-1}$ (the data represent the proportion of individual components in the dry matter of the analyzed feed).

Sampling

After reaching the slaughter weight, the pigs were transported to the Experimental Center of Livestock at the Department of Animal Husbandry of the Slovak University of Agriculture in Nitra, where they were killed and subsequently analyzed. The slaughter was realized according to Government Regulation (SR) no. 432/2012 of the Coll. Of the Slovak Republic, establishing the protection of animals during the slaughter **(NCSR, 2012)**. The meat quality parameters were evaluated in the longest back muscle MLD (*musculus longissimus dorsi*) at the level of the last thoracic vertebra in the right carcass half.

Analysis of the physical indicators

The values of pH 45 minutes (pH_{45}) and 24 hours (pH_{24}) *post mortem* were measured by the pH meter HI99161 (Hanna Instruments, Romania) in the units $-\log_{10}[H^+]$. The electric conductivity was determined 45 minutes (EC_{45}) and 24 hours (EC_{24}) *post mortem* by using the instrument Quality Meter (Tecpro, Germany) in the unit $mS.cm^{-1}$. The drip losses in MLT were measured from 24 to 48 h *post mortem* by the method according to **Honikel (1998)**. The meat color was measured in MLD 24 hours *post mortem* by using the spectrophotometer CM-2600d with the CIE Lab space and illuminate D65 (Konica Minolta, Japan). **Commission Internationale de l'Eclairage (1975)** determined the following color coordinates: L* (lightness, white ± black), a* (redness, red ± green) and b* (yellowness, yellow ± blue). The values were recorded from the average of three random readings across the muscle surface.

Analysis of the chemical indicators

The basic chemical parameters were determined from a homogenized muscle sample *musculus longissimus dorsi* by the FT IR method (FourierTransform InfraRed) using the Nicolet 6700 device (Thermo Scientific, USA). The content of water (%), protein (%), intramuscular fat - IMF (%) and cholesterol ($mg.100g^{-1}$) were determined in the meat sample.

Statistical analysis

Statistical analysis of the obtained results was performed in the **IBM (2011)** SPSS Statistics 20 Program (IBM corp., New York). The Univariate Analysis of Variance (UNIANOVA) was used to assess the effect of genotype and the slaughter weight on the monitored meat quality parameters, with testing the contrasts by means of the Scheffe test at the level of significance $p < 0.05$. The analysis was performed according to the following model equation:

$$Y_{ijk} = \mu + B_i + SW_j + e_{ijk}$$

where Y_{ijk} is an indicator of the meat quality, μ is the overall mean, B_i is the fixed effect (n = 2; Mangalitsa, Large White), SW_j is the fixed effect slaughter weight (n = 3; SW up to 100 kg, SW from 101 to 110 kg, SW over 110 kg), e_{ijk} is the random error. The Pearson correlation coefficient was used to calculate the correlation dependencies between the selected monitored indicators.

RESULTS AND DISCUSSION

Comparison of the physical meat quality indicators in MLD of the slaughtered pigs is shown in the Table 1. Analysis of the physical indicators has shown that the breed and the live weight have any effect on pH_{45}, pH_{24}, EC_{45}, EC_{24}, and the color range b*. Mangalitsa achieved higher pH_{45} values (6.26 ±0.20) compared to Large White (6.12 ±0.22). Similarly, **Lípová et al. (2019)** and **Tomović et al. (2016)** found out that Mangalitsa achieved higher pH_{45} values than its crossbreeds and the Large White breed. The highest pH_{45} values were reached by the pigs with a live weight over 110 kg (6.32 ±0.32).

Table 1 Comparison of the physical meat quality indicators *m. longissimus dorsi.*

Parameter	Breed (B)		Slaughter weight (SW)			Significance		
	Ma (n = 12)	LW (n = 8)	to 100 kg (n = 4)	101 – 110 kg (n = 12)	over 110 kg (n = 4)	B	SW	R^2

Note: Ma: Mangalitsa, LW: Large White, n.s.: not significant, *: p <0.05, **: p <0.01, ***: p <0.001, different letters in the same row indicate significant differences among the mean values (p <0.05), R^2: coefficient of determination.

24 hours after slaughter, the pH_{24} values dropped to 5.63 ±0.07 in Mangalitsa and to 5.69 ±0.12 in Large White. Similar pH_{24} values were found in MLD in the breed Ma (5.69 ±0.07) and in the hybrids of Ma x LW (5.68 ±0.11) by **Lípová et al. (2019)**. **Alonso et al. (2009)** found the pH_{24} values of various commercial hybrids at the level of 5.70 - 5.74. Contrary to these findings, **Stanišić et al. (2015)** found higher MLD muscle acidification 24 hours *post mortem* in Mangalitsa at the level of 5.47 ±0.07 and in Landrace at the level of 5.47 ±0.10. In accordance with the results of our study, **Ba et al. (2019)** did not detect any significant differences in pH_{24} values in relation to the pig weight.

Electric conductivity, 45 minutes after slaughter (EC_{45}), was recorded in the breed Ma (3.50 ±0.34 $mS.cm^{-1}$) and LW (3.38 ±0.32 $mS.cm^{-1}$). After 24 hours, there was a significant increase in the electric conductivity (EC_{24}) to 11.32 ±3.10 $mS.cm^{-1}$ for Ma and 11.08 ±5.07 $mS.cm^{-1}$ for LW. Lower EC_{24} values in the breed Ma (9.31 ±1.91 $mS.cm^{-1}$) and the crossbreeds Ma x LW (10.86 ±2.25 $mS.cm^{-1}$) were found by **Lípová et al. (2019)**. In the commercial hybrids, **Mörlein et al. (2007)** found in the study the value EC_{24} at the level 6.24 ±2.32 $mS.cm^{-1}$. In assessing the meat quality deviations, the EC_{24} values at the level of 7 $mS.cm^{-1}$ and 9 $mS.cm^{-1}$, respectively, were used as the criterion for the PSE meat (pale, soft, exudative). It follows from the above that some individuals of both monitored breeds have shown deteriorated meat quality in this indicator. In terms of comparing pigs by their live weight, the EC_{24} values were decreasing with the weight gain.

In the drip loss indicator, the Ma breed (7.57 ±0.88%) had a significantly lower drip loss (p <0.05) than the LW breed (10.13 ±2.72%). No significant differences were found within the weight groups and the confidence of estimation was 35% (R^2 = 0.35). **Lípová et al. (2019)** found similar drip loss values for the Ma breed (7.15 ±2.99%) and the higher ones for the Ma x LW hybrid (8.22 ±2.78%). **Mörlein et al. (2007)** and **Fischer et al. (2000)** found out that the smallest drip loss was reported by the crossbreeds that contained the breed Duroc.

Color is considered an important indicator of the pork quality, as it is one of the most important characteristics affecting consumers´ ratings of meat **(Valous et al., 2010)**. The analysis of the L* values has shown that both the breed (p <0.001) and the live weight (p <0.01) had a significant effect on the meat lightness, with a confidence estimate of 85 (R^2 = 0.85). The LW breed had a lot lighter meat than the Ma breed (58.75 ±1.85 vs. 51.71 ±2.84) and the pigs weighing over 110 kg had significantly darker meat than the lower weight pigs (p <0.05). The a* indicator, representing the meat redness, has also shown a significant effect of the breed (p <0.001) and the live weight (p <0.001), the reliability of the estimate was at 87% (R^2 = 0.87). Meat of the Ma breed was redder compared to the LW breed (3.52 ±1.96 vs. 0.59 ±0.65) and the pigs weighing over 110 kg had significantly redder meat compared to the lower weight pig groups (p <0.05). Neither the breed nor live weight had a significant effect on the indicator b*, which represents the yellowness of the meat. Several authors have found out, when comparing the meat color of the Ma breed with other breeds, respectively with the hybrids of the mangalitsa breed, that the meat of the Ma breed is darker and redder, which is in accordance with our results **(Lípová et al., 2019; Tomović et al., 2016; Tomović et al., 2014)**. **Ba et al. (2019)** comparing the meat color depending on the slaughter weight of the pigs found any significant differences in the meat lightness (L*). In the a* and b* indicators pigs with a higher slaughter weight (120 kg) had significantly redder and yellower meat than the pigs weighing 100 kg. Similarly, **Latorre et al. (2004)** found a higher a* value in MLD of the pigs killed at a higher weight (132 kg) compared to the pigs that were killed at a lower weight (116 kg). Contrary to our results, **Correa et al. (2006)** and **Serrano et al. (2008)** found no significant differences in the meat color depending on the weight of the slaughter pigs.

The basic chemical composition and cholesterol content are shown in the Table 2. The Ma breed had a significantly higher water content in MLD (p <0.05) compared to the LW breed (70.42 ±0.41% vs. 69.22 ±1.51%). However, the slaughter weight have any effect on this indicator and the reliability of the estimate was at the level of 31% (R^2 = 0.31). In contrast, the genotype (n.s.) have any influence on the the protein content of MLD, but the slaughter weight (p <0.05), with a confidence estimate of 53% (R^2 = 0.53). Pigs weighing up to 100 kg had a significantly lower protein content in meat (24.32 ±0.01%) than the pigs of higher weight. The weight categories 101 – 110 kg and over 110 kg had similar

Table 2 Basic chemical composition of the meat and cholesterol content in *m. longissimus dorsi*.

Parameter	Breed (B)		Slaughter weight (SW)			Significance		
	Ma (n = 12)	LW (n = 8)	to 100 kg (n = 4)	101 – 110 kg (n = 12)	over 110 kg (n = 4)	B	SW	R^2
	Mean ± SD	*Mean ± SD*	*Mean ± SD*	*Mean ± SD*	*Mean ± SD*			
Water	70.42 ±0.41	69.22 ±1.51	70.23 ±0.59	69.72 ±1.42	70.29 ±0.18	*	n.s.	0.31
Protein	24.64 ±0.35	25.02 ±0.27	24.32 ±0.01[a]	24.92 ±0.31[b]	24.87 ±0.37[b]	n.s.	*	0.53
IMF	1.34 ±0.38	0.98 ±0.24	1.56 ±0.20	1.07 ±0.40	1.22 ±0.03	n.s.	n.s.	0.35
Cholesterol	44.17 ±5.77	40.00 ±2.14	47.50 ±0.58	40.50 ±5.45	43.50 ±0.58	n.s.	n.s.	0.33

Note: Ma: Mangalitsa, LW: Large White, IMT: intramuscular fat, n.s.: not significant, *: p <0.05, different letters in the same row indicate significant differences among the mean values (p <0.05), R^2: coefficient of determination.

protein content in MLD (24.92 ±0.31% and 24.87 ±0.37%).

The opposite tendency of the slaughter weight influence on the protein content was found by **Ba et al. (2019)** and **Raj et al. (2010)**, who recorded a significantly lower protein content in the pigs of the greater weight (110 – 130 kg) than in the pigs of the lower weight (90 – 110 kg). The differences between breeds were not conclusive (Ma: 24.64 ±0.35%, LW: 25.02 ±0.27%). **Parunović et al. (2013)** found a higher proportion of water in MLD of the Swedish Landrace (72.70%, p <0.001) than in the Swallow-bellied Mangalitsa breeds 64.30% and the White mangalitsa 62.70%, while the difference in water content among the mangalitsa breeds was not significant. **Kim et al. (2016)** found the water content in MLD for the Berkshire breed at the level of 75%. **Holló et al. (2003)** found that different slaughter weight had no effect on the water content of the MLD muscle of the Mangalitsa breed. The water content was 68.80 ±2.01% in the pigs weighing 91.64 ±2.41 kg and 68.96 ±2.60%, in those with the weight of 114.14 ±7.70 kg, which is comparable to our results.

Regarding the protein content in MLD, the differences between the breeds were not significant (Ma: 24.64 ±0.35%, LW: 25.02 ±0.27%). Contrary to our results, several authors found a lower protein content in the Mangalitsa breed, ranging from 19.50% to 21.83% **(Tomović et al., 2016; Stanišić et al., 2015; Parunović et al. 2013; Holló et al., 2003)**. Vice versa, **Lípová et al. (2019)** found a similar protein content in Mangalitsa (24.15 ±0.66%). Also, in the meat breeds and crossbreeds, there are not clear results of protein content in MLD. **Tomović et al. (2016)** found a protein content of 21.82 ± 0.12% in the Large White breed, **Parunović et al. (2013)** in the Swedish Landrace 22.10%, **Ruusunen et al. (2012)** in various breeds in Scandinavia 21.8 to 22.9%, **Kameník, Saláková and Kašpar (2018)** in the Danish-Norwegian breed Topigs 24.40%, **Stanišić et al. (2015)** in Landrace 23.43 ±1.71%.

An important indicator which affects the taste properties of meat is the content of the intramuscular fat (IMF). According to **Fortin, Robertson and Tong (2005)**, the optimal IMF content in meat is 1.5 to 2.5%. The Ma breed had a higher IMF content (1.34 ±0.38%) compared to the LW breed (0.98 ±0.24%), but this difference was not statistically significant. Similarly, no significant differences were observed among groups with different slaughter weights. The IMF content was relatively low in both breeds compared to other authors, e.g. as far as the Ma breed is concerned**, Ender et al. (2002)** found the IMF content 9.00%, **Holló et al. (2003)** 8.38%, **Stanišić et al. (2015)** 6.40%. **Matoušek et al. (2016)** and **Nevrkla et al. (2017)** found the IMF content of the Czech autochthonous breed Prestice Black-pied pig at the level of 2.47% up to 2.89%. **Tomović et al. (2016)** found the IMF content at the level of 2.56% in the Large White breed.

Neither the breed nor the different slaughter weight had any effect on the cholesterol content in MLD. However, the Ma breed had by 4 mg.100g^{-1} of cholesterol in the meat more than the LW breed (44.17 ±5.77 mg.100g^{-1} vs.

Table 3 Correlation coefficients of the physico-chemical indicators *m. longissimus dorsi* in relation to slaughter weight and the IMF content.

	Slaughter weight	IMF
pH_1	0.304	0.086
pH_2	- 0.008	- 0.031
EC_1	0.160	- 0.038
EC_2	- 0.265	0.416
Drip loss	- 0.104	- 0.283
CIE L*	- 0.449*	- 0.282
CIE a*	0.598**	- 0.061
CIE b*	0.222	- 0.481*
Water	0.054	0.524*
Protein	0.356	- 0.506*
IMF	- 0.164	1
Cholesterol	- 0.159	0.813**

Note: IMT: intramuscular fat, *: p <0.05, **: p <0.01.

40.00 ±2.14 mg.100g^{-1}). Comparable values of the cholesterol content in MLD were also found by **Lípová et al. (2019)** in the Ma breed (43.01 mg.100g^{-1}) and the hybrids Ma x LW (38.91 mg.100g^{-1}).

Pârvu et al. (2012) have reported a similar cholesterol content in the Ma breed (41.64 mg.100g^{-1}), but they had a significantly higher cholesterol content of 61.24 mg.100g^{-1} in the LW breed. In contrast to our findings, other authors have reported higher cholesterol levels in MLD in the Ma breed, ranging from 61.14 to 62.90 mg.100g^{-1} **(Parunović et al., 2013; Petrović et al., 2010)**.

Table 3 shows the correlation coefficients of the physico-chemical indicators in relation to slaughter weight and the IMF content. The slaughter weight positively correlated with the indicator a* (p <0.01, r = 0.598) and negatively with the indicator L* (p <0.05, r = -0.449). It follows from the above that the pig meat is darker and redder with the increase of the slaughter weight. **Ba et al. (2019)** have stated that increase of the slaughter weight is associated with the redder and yellower meat. In terms of the physico-chemical indicators, the IMF content correlated negatively with the indicator b* (p <0.05, r = -0.481). In contrast, **Ba et al. (2019)** found a positive relationship between the value b* and the fat content (r = 0.652, p <0.05). Within the chemical meat composition, the IMF content correlated positively with water (p <0.05, r = 0.524) and cholesterol (p <0.01, r = 0.813) and negatively with the protein content (p <0.05, r = -0.506). Contrary to our results, several authors have found a negative relationship between the IMF content and water in the MLD muscle **(Tomović et al., 2014; Vranic et al., 2015; Lípová et al., 2019)**.

CONCLUSION

There were no major differences in the meat quality between the Mangalitsa and Large White breeds. Nevertheless, we can conclude that the breed Mangalitsa has showed more favorable values of the physico-chemical indicators, as it has achieved a significantly lower drip loss (7.57% vs. 10.13%, p <0.05), a lower value of L* (51.71 vs. 58.75, p <0.001) and a higher value of a* (3.52 vs. 0.59, p <0.001). That means that meat of the Mangalitsa breed had a better water holding capacity, was darker and redder in comparison to the Large White breed. Similarly, when comparing the quality of the meat with regard to the slaughter weight, there were no large differences between individual weight groups. However, a higher slaughter weight has positively influenced mainly the color of the meat, as pigs weighing more than 110 kg achieved a significantly lower value of L* (p <0.01) and a higher value of a* (p <0.001) in comparison to pigs of the lower weight. As a positive effect of a higher slaughter weight its effect on the protein content in the meat can be considered, as pigs weighing over 100 kg had a significantly higher protein content in the meat than pigs weighing below 100 kg (p <0.05).

RESEARCH ON MILK HOMOGENIZATION IN THE STREAM HOMOGENIZER WITH SEPARATE CREAM FEEDING

Kyrylo Samoichuk, Dmytro Zhuravel, Olga Viunyk, Dmytro Milko, Andrii Bondar, Yuriy Sukhenko, Vladyslav Sukhenko, Leonora Adamchuk, Sergey Denisenko

ABSTRACT

Homogenization, which is used in the technological schemes of production of most dairy products, is the most energy-intensive of the processes of mechanical processing of milk. One promising way to increase the energy efficiency of homogenization is to use separate homogenization and to use a little-researched stream homogenizer with separate cream feeding. The principle of its action is to pre-divide milk into cream and skim milk, and feed the fat phase with a thin stream into the stream of skim milk. This creates the conditions for achieving the high value of the Weber criterion – the main factor in the dispersion of milk fat. The purpose of these researches is to conduct experimental studies and determine the energy consumption and quality of homogenization of milk after treatment in a stream homogenizer. To achieve this goal, a designed experimental setup was used. The dispersive indices of the milk emulsion were determined by computer analysis of micrographs of milk samples obtained with an optical microscope and a digital camera using Microsoft Office Excel and Microsoft Visual Studio C # software using the OpenCV Sharp library. As a result of experimental studies, the critical value of the Weber criterion for homogenization of milk was determined, which is 28. The regularities of dispersion of milk fat in a stream homogenizer with separate feeding of the fat phase have been established. It is determined that the milk treatment in the experimental homogenizer allows us to achieve an emulsion with an average size of fat globules of about 0.8 μm (at the level of valve homogenizers). The value of the homogenization coefficient is obtained for the disruption of the fat globule in the conditions: subject to a single effect on the emulsion, without the influence of vibration and cavitation. This homogenization coefficient equals 3300 $m^{3/2}.s^{-1}$.

Keywords: milk; homogenization; homogenizer; stream homogenizers with separate cream feeding

INTRODUCTION

Today, the vast majority of milk as raw materials for the production of drinking milk, cream and other types of dairy products is homogenized **(Rayner and Dejmek, 2015)**. The main advantages of products manufactured using homogenization: providing uniformity of color, taste, fat content; improving the consistency, increasing the intensity of the white color, increasing the stability during storage, reducing the settling of fat and creating a fuller taste of the product.

But homogenization is one of the most energy-consuming processes in the vast majority of technological schemes for dairy production. The specific energy consumption of the most commonly used valve homogenizers reaches 8 $kW.h.t^{-1}$ and is the largest of the milk processing equipment **(Yong, Islam and Hasan, 2017a; Ashokkumar, Rink and Shestakov, 2011)**.

As a result of attempts to solve the existing disadvantages of homogenization, scientists have developed a wide range of homogenizers, such as valve, pulsation, vacuum, stream, ultrasonic, rotary, etc. However, none of them combines a high degree of grinding milk fat globules (such as valves) with low energy consumption **(Narvhus, Abrahamsen and Østlie, 2007; Yong, Islam and Hasan, 2017b)**.

The main reason for such problems is the lack of a unified theory and mechanism of dispersion of the fine-phase phase of fat emulsions and difficulties in obtaining experimental visual data of the process of disruption of fat particles of microscopic size.

Recent visual data on the process of fat phase dispersion in valve homogenizers confirm the validity of the turbulent viscous theory according to which the disruption occurs as a result of the destabilization of Kelvin – Helmholtz and Rayleigh – Taylor **(Håkansson et al., 2011; Håkansson et al., 2010; Innings and Trägårdh, 2005; Loitsyansky, 2003)**. Despite the significant differences between these hypotheses, they are common to create hydrodynamic

conditions in the fracture zone that contribute to the increase of the relative velocity of the emulsion phases. That is, the universal criterion for deformation and disruption of the fat globule is the Weber criterion (We), the main reason for dispersion being the difference in velocity between the fat globule and the surrounding plasma (relative velocity of phases or velocity of sliding of the fat globule) **(Håkansson et al., 2013)**.

The simplest and most obvious way to create a sliding fat globule is to separate milk fat from whole milk and feed it with a thin stream or film into the product's high-velocity stream of skim milk. This method is the basis for the construction of a stream homogenizer with separate cream feeding (SHSCF), in which the milk cream is fed by a thin stream perpendicular to the flow of skim milk (Figure 1) **(Deinychenko, Samoichuk and Kovalyov, 2016)**.

Additional intensification of the process of homogenization in such devices is due to the concentration of the supplied energy on the fatty phase of the emulsion using separate homogenization. Preliminary separation of milk into cream and skim milk and treatment of only the fat phase, which results in the reduction of the volume of the emulsion being processed, which leads to the proportional reduction of energy consumption **(Dhankhar, 2014; Samoichuk and Kovalyov, 2015)**.

Due to the selection of structural-technological and mode parameters it is possible to combine the normalization of milk fat content with the operation of homogenization.

Therefore, the purpose of the study is to determine the prospects of using a stream homogenizer with separate cream feeding for milk processing by experimentally determining the quality of homogenization and energy consumption.

Scientific hypothesis

The scientific hypothesis is the ability to solve the problem of high energy consumption for homogenization of milk by using a stream homogenizer with separate cream feeding. In such a homogenizer, when the fat fraction is fed into the stream of skim milk, a high difference of phase velocities is created between the dispersed and dispersive phases of the emulsion, which makes it possible to achieve higher values of the Weber criterion than in other types of homogenizers.

MATERIAL AND METHODOLOGY

Experimental equipment

For the experimental research of the SHSCF, an installation was developed, the scheme of which is presented in Figure 2 **(Samoichuk and Kovalyov, 2011; Samoichuk and Kovalyov, 2013)**.

Skim milk goes through the pipeline from the container 2 through the pump 1 into the homogenization chamber 4. From the tank for cream 12, with the pump 7 through the channel 11, the fat phase is supplied to the central zone of the homogenization chamber in the stream of skim milk, where the process of dispersion takes place.

To increase the flow of skim milk in the homogenization chamber, stream guides 5 made of stainless steel were installed, which are secured by hinges 10 and have adjustable rods to adjust the distance between the guides. The housing of the homogenization chamber is made of organic glass for process monitoring. A gauge 3 is required to control the fluid pressure values. In the container 2 there is an opening for draining the residues of the product. The finished product is poured into the container 8.

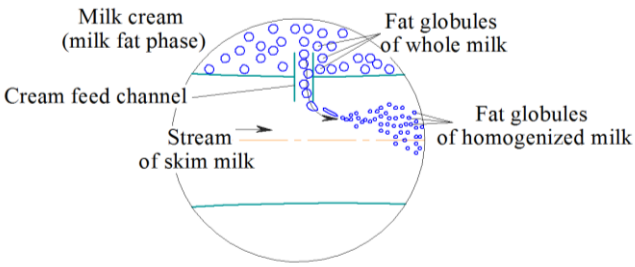

Figure 1 Scheme of homogenization in a stream apparatus with separate cream feeding.

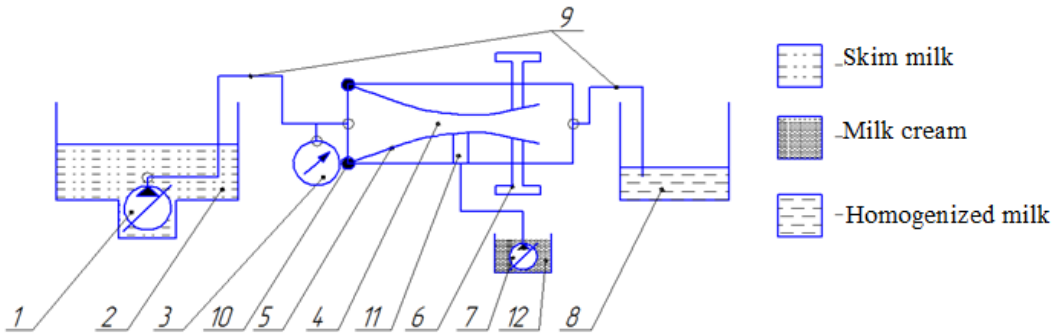

Figure 2 Scheme of the laboratory unit of the SHSCF. Note: 1 – rotor type pump; 2 – container for skim milk; 3 – pressure gauge; 4 – homogenization chamber; 5 – guides; 6 – adjusting rods; 7 – pump of supply of the fat phase; 8 – container for receiving the finished product; 9 – pipelines; 10 – hinges; 11– feed cream channel; 12 – tank for cream.

Prior to submission to the SHSCF, the milk is divided into skim milk and cream. Skimmed milk is fed under pressure at a certain rate, which increases in the central area of the device due to the narrowing of the flow, the value of which can be adjusted by rods. In the place of greatest narrowing, cream is supplied through a thin channel which diameter is 0.6 – 0.8 mm **(Samoichuk and Kovalyov, 2013; Samoichuk, Kovalyov and Sultanova, 2015)**. The channel of such a small diameter creates minimal flow resistance and allows the flow of cream with a thin stream. By varying the flow velocity in the cream feed zone, the distance from the end of the cream feed channel to the edge of the narrowing channel and the cream supply it is possible to investigate their effect on the quality and energy consumption of the milk fat dispersion process.

Figure 3 presents a general view of the laboratory unit for studying SHSCF.

In the central part of the chamber 3 (Figure 3), at the place of maximum narrowing, radial channels for feeding the fat phase are made.

Thus, thin streams of cream are fed into the high-velocity stream of skim milk, which creates the conditions for high-efficiency dispersion of milk fat – a high difference in velocity of phases (velocity of sliding the fat globule relative to the dispersion medium), which by Weber's criterion is the main parameter of the disruption of fat globules of milk.

The main parameter that determines the dispersion of the milk emulsion after treatment in SHSCF (Figure 4) is the relative velocity of the dispersed and dispersive phases, which is most influenced by the velocity of skim milk stream υ_{sm}, the velocity of the flow of cream υ_c, the diameter of the feed channel of cream d_c and its fat content F_c.

For the experimental studies, whole milk was used **(DSTU 8553:2015)**. Density 1027 – 1023 kg.m^{-3}, fat content 2.5 – 4.4%.

Note: 1 – electric motor; 2 – container for skim milk; 3 – homogenization chamber; 4 – throttle valve; 5 – pressure gauge; 6 – cream feed channel; 7 – control unit for the cream feed pump; 8 – electric starter of the main engine; 9 – tank for cream; 10 – pump for feeding cream; 11 – skim milk feed pump.

The average diameter of the fat globules of the emulsion (d), which should be provided as a result of homogenization, is 0.8 – 1.2 μm, which is sufficient for modern technological processes of milk processing.

The temperature of homogenization of milk was provided within the range of 60 – 65 °C. Numerous studies show that this temperature is optimal for the dispersion process. The minimum surface tension of the fat globule and the viscosity of the milk is ensured, the fat fractions go into the liquid state and no undesirable changes of properties occur under the action of high temperature **(Ion-Titapiccolo, Alexander and Corredig, 2013)**.

Statistical analysis

The dispersive indices of the milk emulsion were determined by computer analysis of micrographs of milk samples obtained with an optical microscope and a digital camera Mustek Wcam 300 (resolution 640 x 480). Each experiment was repeated 3 times. From each experiment, 3 samples were selected and 2 dilutions were prepared from each sample. 6 characteristic microscope field of view photos were selected from each dilution. Thus, 36 microscope fields of view were analyzed to determine statistical characteristics of milk.

The method of analysis of geometric characteristics of fat globules based on digital image analysis technologies was used to analyze the obtained micrographs.

The number of fat globules in the microscope field of view and their diameter were determined in the process of calculations. The average diameter of the fat globule was determined by the statistical method of power average (arithmetic mean).

For this purpose, the software module has been developed that is implemented in Microsoft Visual Studio 2013 based on C # using the OpenCV Sharp library set 4.2.0. The exported numerical data and the calculation of the sample statistics were performed in Microsoft Office Excel 2013. McBrain VA 318 electric wattmeter (Volga region plant of power equipment, Russia) was used to record power.

RESULTS AND DISCUSSION

Determination of the influence of the velocity of skim milk and the distance between the guides on the dispersion of milk emulsion

The main influential factor in the dispersion of the fat phase in the SHSCF is the rate of flow of skim milk, the change of which was varied by the supply of skim milk Q_{sm}. The results of the experimental studies and their comparison with the theoretical ones by the formula **(Samoichuk and Kovalyov, 2013; Samoichuk, 2018)** are shown in Figure 5.

As shown by the obtained data, the change in the distance between the guides (the area of intersection of the working chamber) has virtually no effect on the dispersion of the milk emulsion, which is consistent with the results of theoretical studies **(Samoichuk and Kovalyov, 2013; Samoichuk, 2018)**.

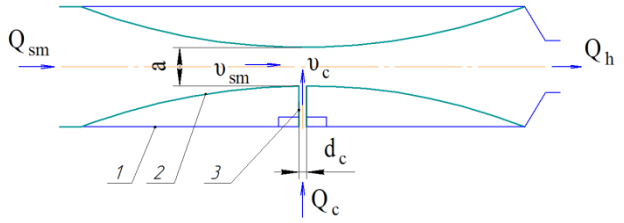

Figure 4 Calculation scheme of SHSCF. Note: 1 – chamber of stream homogenizer of milk; 2 – guides for the formation of a stream of skim milk; 3 – cream feed channel; a – distance between the guides; Q_{sm}, Q_c, Q_h – supply of skim milk, cream and productivity of SHSCF, $m^3.s^{-1}$.

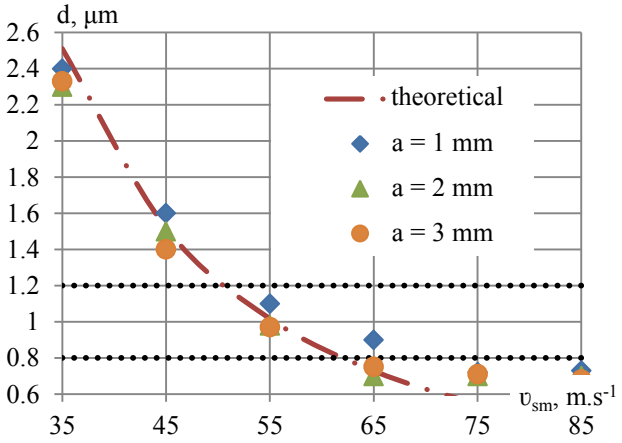

Figure 5 The dependence of the average diameter of fat globules d on the distance between the guides of SHSCF a and the velocity of skim milk υ_{sm} at d_c = 0.7 mm, υ_c = 80 $m.s^{-1}$, F_c = 30%.

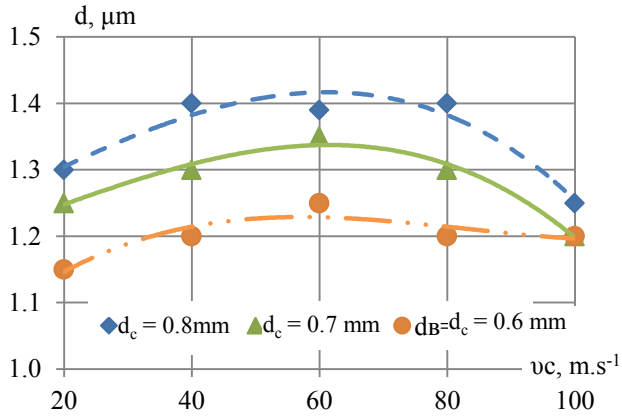

Figure 7 Dependence of the average diameter of the fat globules ***d*** on the velocity υ_c and the diameter of the feed channel of dairy cream d_c SHSCF (at υ_{sm} = 60 $m.s^{-1}$).

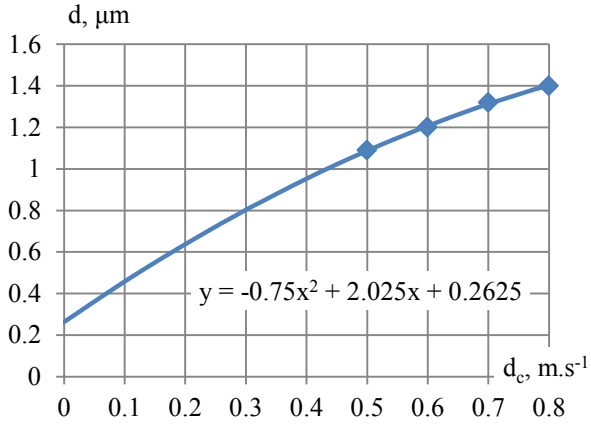

Figure 8 Prediction of the average size of fat globules of milk d for d_c <0.5 mm.

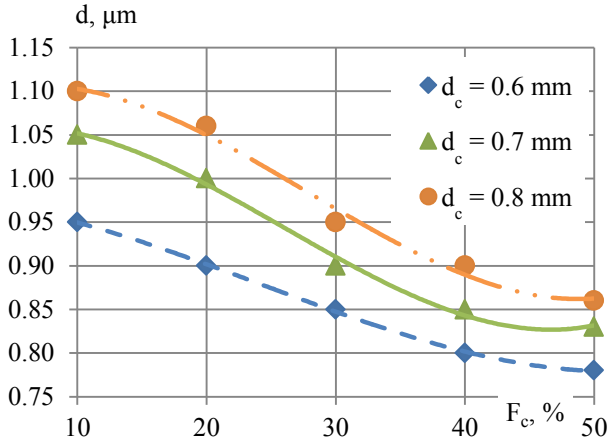

Figure 9 The dependence of the average diameter of the fat globules d on the diameter of the feed channel d_c SHSCF and cream fat F_c (at υ_{sm} = 80 $m.s^{-1}$).

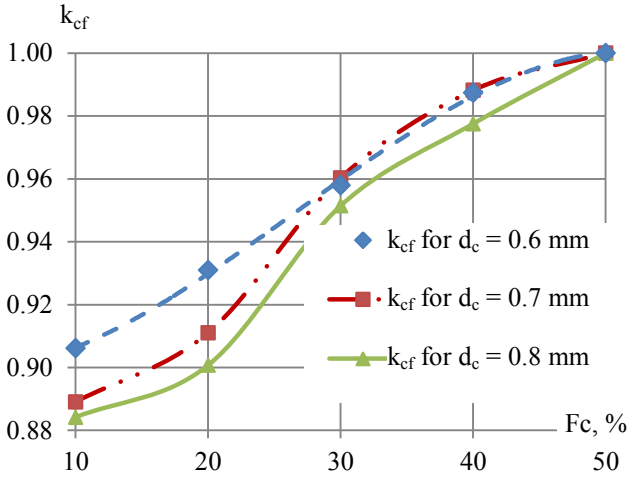

Figure 10 The dependence of the fat coefficient of cream for SHSCF k_{cf} on the fat content F_c, % (at υ_{sm} = 80 m.s^{-1}).

The slight increase in the size of the fat globules at a = 1 mm (by 2 – 5%) is explained by the increase in the Reynolds coefficient and the fluid turbulence. Increasing turbulence can be the cause of inefficient power dissipation, which is consistent with the results of the stream apparatus study **(Abiev, 2000)**. For SHSCF, the main factor in the disruption of fat globules is the sliding velocity of the fat globules, which increases as the flow rate of skim milk increases. To obtain an average size of fat globules of 0.8 μm, it is necessary to provide a skim milk velocity of 60 – 65 m.s^{-1}.

The experimental data are in good agreement with the theoretical data at critical Weber number We_k = 130, coefficient of SHSCF **(Samoichuk, 2018)** k_c = 0.7 in the range of 35 <υ_{sm} <70. However, the true critical Weber number can only be calculated after the experimental determination of the stream dispersion coefficient.

At a velocity of more than 70 m.s^{-1}, the dispersion is hardly increased. Similar is the graph of the dependence of the dispersion on the pressure for the valve **(Rovinsky, 1994; Loncin and Merson, 1979)**, pulsation homogenization with a vibrating rotor **(Samoichuk et al., 2016)** and flow-stream **(Samoichuk, 2018)** homogenization, which testifies to the similarity of the mechanisms of dispersion of fat globules in them.

Determination of effect of stream dispersion coefficient on average size of fat globules in milk

The use of higher fat cream increases the dispersion of the homogenized emulsion (Figure 6). This is due to the increase in the velocity of sliding fat globules of cream due to the decrease in the amount of plasma fed together with the cream. The dashed line shows the relationship between the size of the fat globules and the velocity of the cream in the disruption of the fat globules similar to the valve homogenization according to the formula by N. V. Baranovsky **(Rovinsky, 1994)**. If $\boldsymbol{v_c}$ >80 – 100 m.s^{-1}, the valve dispersion is the dominant principle of dispersion – the value of dispersion is close to that calculated by Baranovsky's formula.

In the range of 40 <$\boldsymbol{v_c}$ <80, the sizes of fat globules are maximal, and at $\boldsymbol{v_c}$ <30 m.s^{-1} they are reduced by 6 – 10% **(Samoichuk, 2018)**. The decrease in dispersion at the velocity of the stream of cream more than 30 m.s^{-1} can be explained by the presence of a steady stream of cream, which is destroyed only at the chamber wall which is opposite to the location of the channel of the cream. In this zone, the velocity of the skim milk stream is minimal, which results in lower values of the flow rate of fat globules.

If you do not take into account the dispersion of the type of valve homogenization, which is energy inefficient (in the range of 20 <$\boldsymbol{v_c}$ <80 m.s^{-1}), the highest degree of homogenization in SHSCF can be achieved at $\boldsymbol{v_c}$ <20 m.s^{-1}. By predicting with Excel spreadsheet tools at $\boldsymbol{v_c}$ <5 – 10 m.s^{-1}, the coefficient of influence of the flow velocity of the cream, SHSCF has a maximum value k_υ = 1.At 40 <$\boldsymbol{v_c}$ <80 k_υ =0.75 – 0.80, and at 20 <$\boldsymbol{v_c}$ <40 k_υ = 0.8 – 0.85.

Reducing the diameter of the cream channel leads to a decrease in the size of fat globules of milk (Figure 7).

This is due to the decrease in the central zone of the cream stream with a reduced flow rate of fat globules. Reducing the diameter of the channels from 0.8 to 0.6 mm leads to an increase in the dispersion by 8 – 10%. It is logical to assume that the maximum flow rate can be obtained by entering only one fat globule into the stream of skim milk. The maximum value of the coefficient of influence of the diameter of the channel of the fat phase will be at $\boldsymbol{d_c} = \boldsymbol{d}$. But testing this assumption in practice is difficult. The prediction made by Microsoft Excel (Figure 8) shows that at $\boldsymbol{d_c} = \boldsymbol{d}$ the average size of fat globules is 0.26 microns, therefore the coefficient of cream feed channel diameter k_{cd} = 1 at $\boldsymbol{d_c}$ = 0.26 mm.

Then the formula for the definition of k_{cd} looks like

$$k_{cd} = \sqrt{\frac{0.26}{2.025d_c - 0.75{d_c}^2 + 0.2625}}. \qquad (1)$$

Example: at d_c = 0.6 mm k_{cd} = 0.46; at $d_в$ = 0.7 mm k_{cd} = 0.44; at $d_в$ = 0.8 mm k_{cd} = 0.43.

The graph of the dependence of the dispersion of the emulsion on the fat content of the cream (Figure 9) indicates a decrease in the rate of decrease in the size of fat globules with increasing fat content of cream **(Samoichuk, 2018)**.

When the fat content of the cream is more than 40%, the dispersion of the emulsion is almost not reduced. The predicted minimum dispersion of milk is reached at F_c = 45 – 55%, where the coefficient k_{cf} = 1. For other values of the fat content of cream k_{cf} of the SHSCF are shown in the graph (Figure 10). In the range of F_c >30%, the values of the fat coefficient of stream dispersion do not differ for different d_c. At F_c <30% a significant effect is caused by the high turbulence of the flow and the mechanisms of disruption associated with the disruption of turbulent vortices, thus values of k_{cf} for d_c = 0.8 mm increase by 2 – 4% compared with d_c = 0.6 mm.

Therefore, to increase the degree of dispersion it is necessary to reduce the diameter of the feed channel of cream, use cream with a fat content of 30 – 50% and provide a feed rate of cream less than 30 – 40 m.s^{-1} or more than 80 – 100 m.s^{-1}.

Thus, for the data shown in Figure 6, the coefficient of stream dispersion will be equal (at k_{cd} = 0.44; k_υ = 0.75; k_{cf} = 0.96) k_c = 0.44 × 0.75 × 0.96 = 0.32.

The critical Weber number corresponding to the experimental data is $We_k = 28$. Compared to opposite-flow stream homogenization ($We_k^c = 500$ **(Samoichuk, 2008)**), this value is much smaller. But a direct comparison of these values is incorrect due to the use of the modified Weber criterion for opposite-flow stream homogenization – that is such We_k, where instead of the velocity of the sliding of the fat globule, the flow rate of the milk emulsion is used.

According to the obtained data of the critical value of the Weber criterion and **(Samoichuk, 2018; Samoichuk et al., 2019)**, the homogenization coefficient for SHSCF will be

$$K_h = \sqrt{\frac{28\ x\ 0.024\ x\ 0.1}{8\ x\ 980}\sqrt[3]{\frac{6}{3.14}}} = 3.300\ x\ 10^{-6}\ \mathrm{m^{3/2}.s^{-1}}.$$

The importance of the obtained results is that this value is obtained for the disruption of the fat globule in "pure" conditions: subject to a single effect on the emulsion, without the influence of vibration and cavitation. Therefore, the value of K_h is the largest among other types of homogenizers. For example, for the valve homogenizer, high turbulence and cavitation have a significant effect on the dispersion of milk fat, leading to a reduction in K_h to 1100×10^{-6} $m^{3/2}.s^{-1}$. For the pulsation homogenizer multiple treatments leads to a reduction in Kh to 225×10^{-6} $m^{3/2}.s^{-1}$ **(Deynichenko et al., 2018; Samoichuk, 2018; Samoichuk et al., 2019)**. For the pulsation homogenizer with a vibrating rotor, the influence of resonant phenomena, as well as the developed turbulence and cavitation in the gap between the rotor and the stator leads to a minimum $K_h = 68 \times 10^{-6}$ $m^{3/2}.s^{-1}$ **(Samoichuk et al., 2019)**.

CONCLUSION

Experimental studies of the dispersion of milk fat in SHSCF and the experimental determination of the stream dispersion index allowed us to determine the critical value of the Weber criterion for the disruption of the fat globule of milk in the milk plasma stream, which is 28. The value of the homogenization coefficient has been determined for the disruption of the fat globule under the condition of a single effect on the emulsion, without the influence of vibration and cavitation: $K_h = 3300 \times 10^{-6}$ $m^{3/2}.s^{-1}$.

On the basis of experimental studies of the patterns of dispersion of milk fat in SHSCF, it is established that to obtain an average size of fat globules of 0.8 μm it is necessary to provide a velocity of skim milk of 60 – 65 $m.s^{-1}$, to use cream, with a fat content of 40 – 45%, to ensure the velocity of the flow of cream 20 – 40 $m.s^{-1}$ and the diameter of the cream feed channel of 0.9 – 1.0 mm.

COMPARISON OF HEAT-STABLE PEPTIDES USING A MULTIPLE-REACTION MONITORING METHOD TO IDENTIFY BEEF MUSCLE TISSUE

Daniil Khvostov, Natalya Vostrikova, Irina Chernukha

ABSTRACT

Nowadays, proteomics is widely used as an analytical control method. A new method for determining animal tissue species-specificity based on a combination of two effective methods of food analysis, liquid chromatography (LC) and mass spectrometry (MS), was used in this work. Using this approach, it became possible to detect peptides. This work presents a comparison of species-specific, heat-stable peptides for the identification of beef. The objects of the study were native and boiled model mixtures containing beef with concentrations of 8% (w/w) and 16% (w/w). Pork was also added to the recipe to control for false-positive results. A high-performance liquid chromatography technique with mass spectrometric detection (LC-MS/MS) was used. Analysis of finished samples takes 25 minutes and is adapted to detect marker peptides. From the processing of the obtained data, three beef marker peptides were identified that were accepted as the best candidates. Two peptide prototypes, NDMAAQYK and YLEFISDAIIHVLHAK from the myoglobin protein and SNVSDAVAQSAR from the triosephosphate isomerase protein, were selected as potential biomarkers. For all samples, the signal-to-noise ratio (S/N) was set above 10. Temperature was not found to affect the structure and detection of marker peptides in samples with a muscle tissue concentration of 8% (w/w) at p <0.05. This approach is universally applicable for comparing biomarkers of other types of meat and to identify the most suitable candidates.

Keywords: biomarker; LC-MS/MS; prototype peptides; meat authentication; heat-stable peptide

INTRODUCTION

Over the past 15 years, extensive research has been conducted around the world on the study of protein substances in raw meat and meat products, both native and those formed in the process of various technological treatments.

A classic quantification method in proteomics is the use of an isotopic tag, the modification of which has more than 40 species **(Kopylov and Zgoda, 2007)**. There are also techniques that do not use isotopic labels **(Kopylov, Zgoda and Archakov, 2009)**. The sensitivity of protein determination compared with gel electrophoresis increases by several orders of magnitude. More recently, the complexity of the study of phosphorylated proteins has been overcome. Various post-translational modifications of proteins with high sensitivity and specificity are studied by the Selected Reaction Monitoring (SRM) method **(Zav'yalova, et al., 2014)**. Recently, a method of identifying species-specific molecular markers in the field of food analysis has gained strength, based on a combination of two methods, high-performance liquid chromatography (HPLC) and mass spectrometry (MS), used to detect peptides. Using this method, up to 0.5% (w/w) chicken meat was found in meat mixtures **(Sentandreu et al., 2010)**. In more recent studies, in boiled meat products, up to 1.0% (w/w) impurities of beef, pork, chicken, duck and goose were detected **(Montowska and Fornal, 2017)**. Heat treatment products were analysed using marker peptides derived from myosin 1 and 2 light chains. It is very important to determine the limit of detection (LOD) of the method. Using this criterion, one can compare various methods aimed at determining muscle tissue. Indicators of 0.5% and below were set for meat products. As an example, the established quantification limit for buffalo and sheep meat was up to 0.48% (w/w) meat **(Naveena et al., 2017)**. The good thermal stability of the peptides was demonstrated by the authors to identify horse and pork markers a lower limit of 0.24% **(Von Bargen, Brockmeyer and Humpf, 2014)**.

Scientific hypothesis

Using the S/N criterion, it is proposed that peptide markers be compared for the authenticity of raw meat and heat-treated meat. The aim of this work was to establish the best candidates for the species-specificity of beef. The selected biomarkers will be used for a highly specific and reliable method of multivariate identification and quantification of the proportion of muscle tissue.

MATERIAL AND METHODOLOGY

Model mixtures of minced muscle tissue were prepared in accordance with standard industrial procedures. A set of samples with a given recipe was prepared (Table 1). Beef muscle tissue content was 8% (w/w) and 16% (w/w). The calculation of muscle tissue content was carried out according to BEFFE (bindegewebseiweißfreies Fleischeiweiß − meat proteins that do not contain connective tissue) **(Leitsätze für Fleisch und Fleischerzeugnisse, 2016)**. Samples of minced meat mixtures were placed in a collagen shell and cooked to a core temperature of 72 °C.

Reagents and solvents

All reagents used were of U.S.P. purity or higher. All solvents, including water, were used with the LC-MS label.

Protein extraction

A 100.0 ±0.1 mg portion of each sample was weighed on an analytical balance (CP224S, Sartorius, Germany). A 1000 µL volume of denaturing buffer (6 M guanidine chloride) was added to the sample and ground in a mortar until completely dissolved. Samples of homogenized muscle tissue (MagNA Lyser, Roche Applied Science, Germany) were centrifuged at 10,000 rpm for 15 minutes at 4 °C (5430 R, Eppendorf, Germany) and 10 µL of sample was transferred to a 1.5 mL tube (for subsequent hydrolysis).

Protein digestion

Disulphide bridges were restored by adding 2 µL of dithiothreitol (0.5 M in water) and incubating the samples at 37 °C for 60 minutes (Thermomixer comfort, Eppendorf, Germany). Then, sulfhydryl groups were alkylated by adding 5 µL of iodoacetamide (0.5 M in water) and incubating them in the dark for 30 min at room temperature. Ultrafiltration at 13,000 rpm for 15 minutes at 4 °C using bicarbonate buffer was used to eliminate salts and denaturing agents. Protein content was measured by using a Quant-it protein analysis kit (Thermo Fisher Scientific, USA) with a Qubit fluorometer (Thermo Fisher Scientific, USA) according to the manufacturer's instructions. Trypsin digestion was carried out by using an enzyme-to-substrate ratio of 1:50 and incubating the reaction for 16 hours at 37 °C. Enzymatic hydrolysis was stopped by adding 1 µL of formic acid. Samples were stored at -20 °C and thawed before analysis.

LC-MS/MS analysis

For chromatographic analysis, a ZORBAX Eclipse Plus C18 column with a fast HD resolution of 2.7 µm (50 × 2.1 mm; Agilent Technologies, Santa Clara, California, USA) was used. Separation was performed by using an Agilent 1260 Infinity HPLC system (USA). The flow rate was set at 0.4 $mL.min^{-1}$, the column temperature was 30 °C, and the sample temperature was 19 °C; eluent A was water with 0.1% (v/v) formic acid, and eluent B was acetonitrile with 0.1% (v/v) formic acid. Gradient elution was performed as follows parameters: 0 min 95% A, 0 – 10 min from 95% A to 40% A, 10 – 15 min from 40% A to 0% A, 15 – 20 min 0% A, 20 – 21 min from 0% A to 95% A, 21 – 25 min 95% A (total analysis time 25 min). The injection volume was 10 µL for all types of samples.

Peptides were detected by using a three-quadrupole mass spectrometer (6410, Agilent Technologies, Santa Clara, California, USA) **(Khvostov et al., 2019)**.

Statistical analysis

STATISTICA 10.0 software was used in this study for statistical analysis. Significant differences were verified by using two-way analysis of variance (ANOVA), $p < 0.05$. Data were extracted from bioprograms in Microsoft Excel (USA).

RESULTS AND DISCUSSION

In this work, we used the **Skyline program (2019)**, capable of theoretically cleaving proteins and listing the SRM for each peptide (Table 2). Protein analysis was performed by using biomodelling. If it is necessary to process complete protein sequences during analysis of LC-MS/MS data, it is possible to use software such as Spectrum Mill (Agilent Technologies, Santa Clara, CA, USA) **(Sarah et al., 2016; Fornal and Montowska, 2019; Montowska and Fornal, 2017; Montowska and Fornal, 2019)**, Protein Lynx Global Server (Waters) **(Naveena et al., 2017)**, Peaks Studio software (Bioinformatics Solutions, Waterloo, ON, Canada) **(Prandi et al., 2017; Prandi et al., 2019)** and MASCOT (Matrix Science, Boston, MA, USA) **(Sentandreu et al., 2010; Naveena et al., 2017; Ruiz Orduna et al., 2015; Ruiz Orduna et al., 2017; Fornal and Montowska, 2019; Montowska and Fornal, 2017; Montowska and Fornal, 2019)**. In our work with the search for parameters for biomarkers on a mass spectrometer, the Skyline program proved to be the best. This is the best choice in the presence of a previously studied peptide sequence for develop of MRM methods. Most often, three transitions were selected. Only y-ions were used. The transition from parent ion (*m/z)* to product ions (*m/z)* occurred from a smaller to a larger one (*m/z)*.

Note: * Only the peptide sequence provided from the review article by **Stachniuk et al. (2019)**. The MRM transitions and Collision energy metrics were selected anew.

Peptides presented in a recent review **(Stachniuk et al., 2019)** were selected for comparison of potential biomarkers. Previously submitted peptides by us were analysed **(Khvostov et al., 2019; Kulikovskii et al., 2019)**. One of the criteria for marker specificity is the presence of a sequence of more than six amino acids **(Watson et al., 2015)**. This peptide length provides the species specificity of muscle protein. We decided to use the S/N indicator as the criterion for the comparison of heat-stable peptides.

Chromatograms of SRM peptide markers are shown in Figure 1a and Figure 1b. The four most intense peptides with a signal value of (50−250)*10^3 cps are presented in Figure 1a. The remaining peptides in the intensity range of (10 - 50)*10^3 cps are indicated in Figure 1b. The chromatogram data were obtained in a sample with a beef concentration of 16% (w/w), subjected to thermal treatment.

The S/N results for a sample of minced meat with 16% beef (w/w) after heat treatment are shown in Table 3.

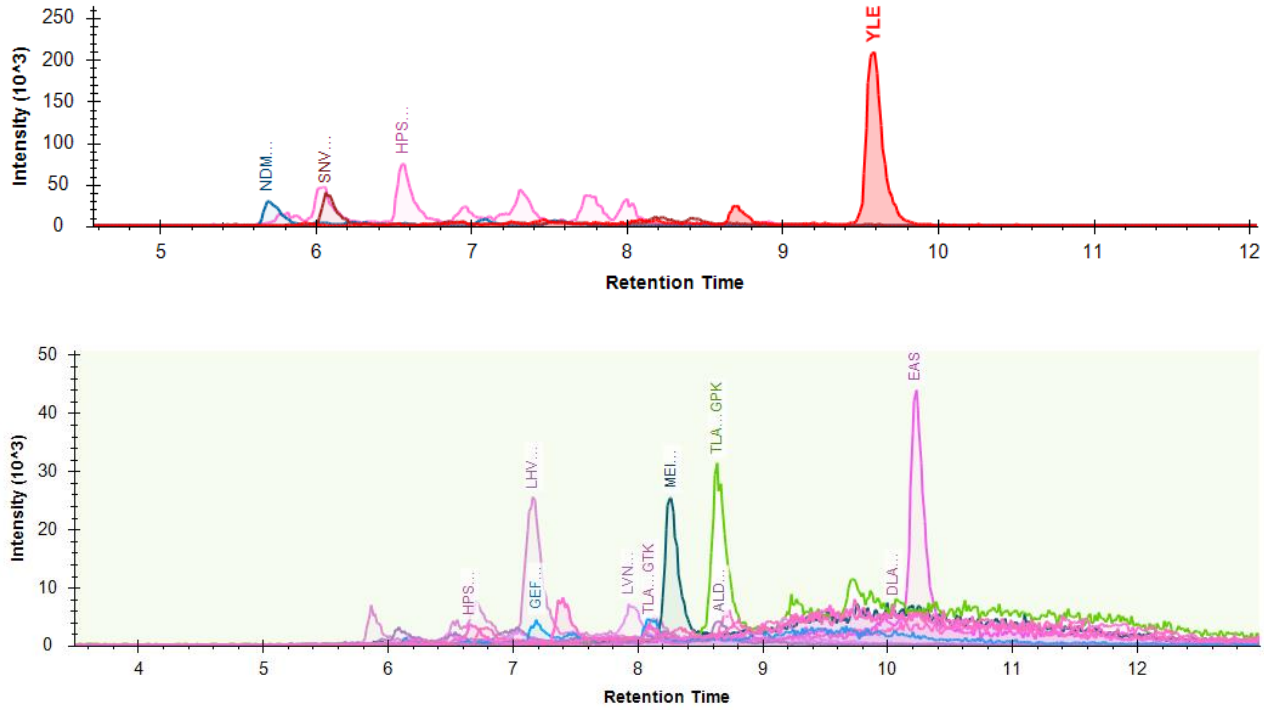

Figure 1 Chromatograms of selected biomarkers responsible for the identification of beef muscle tissue: major peptides (a) and minor peptides (b). Heat-treated mixture with 16% (w/w) beef.

The peptides are arranged in descending order of S/N. The data show that S/N is the highest for the peptide sequences NDMAAQYK **(Kulikovskii et al., 2019)** and YLEFISDAIIHVLHAK **(Khvostov et al., 2019)**, which are myoglobin derivatives. Since beef contains a high level of myoglobin, we obtained the largest number of myoglobin peptide derivatives. The S/N ratio is above 10 for both raw and heat-treated samples. For the peptide HPSDFGADAQAAMSK **(Claydon et al., 2015; Li et al., 2018; Khvostov et al., 2019)**, an additional MRM search was performed. Two parent ions, 766.8 (m/z) and 511.6 (m/z), were used. The most significant was ion 511.6 (m/z). The MRM intensity for this mass increased by 40% ±7.4 compared with ion 766.8 (m/z).

Samples were frozen and re-thawed. We evaluated the effect of one freeze/thaw cycle in digested samples on the intensity of the HPSDFGADAQAAMSK peptide in all mixtures. For samples subjected to and without heat treatment, S/N did not change. It was found that one freeze/thaw cycle did not affect the concentration of meat in mixture 1. If the beef content was less than 10% (w/w), the intensity decreased to 52.4 ±15.2. For peptides ALDLDSNC [+57.0] K **(Wang et al., 2018)**, DLADEVALVDVMEDK, and GEFQLLLDALDK **(Li et al., 2018)**, cross-contamination was recorded in a blank sample (no beef) (mixture 3) (Figure 2).

Many peptides did not meet the criterion of S/N >3.

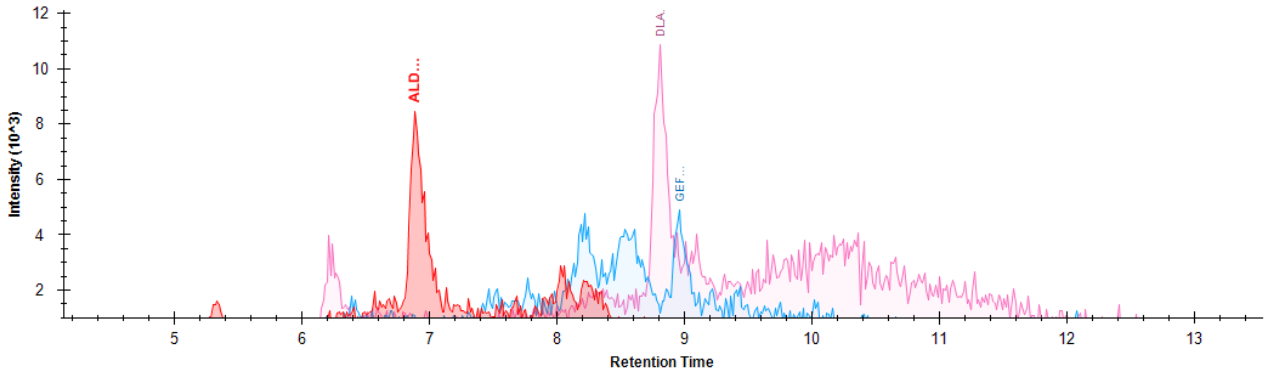

Figure 2 Peptides ALDLDSNC, DLADEVALVDVMEDK and GEFQLLLDALDK identified in samples not containing beef (mixture 3).

Table 3 Comparison of peptide markers with respect to signal-to-noise characteristics for two concentrations of beef muscle tissue and two cooking modes (without and with heat treatment).

Myosin-2	TLAFLFSGTPTGDSEASGGTK	5.00 ±0.84	4.35 ±0.43	4.49 ±0.45	1.87 ±0.21
L-Lactate dehydrogenase A chain	DLADEVALVDVMEDK	0.2 ±0.12	1.36 ±0.13	0.58 ±0.13	0.51 ±0.35

Peptides representing from myosin proteins, such as MEIDDLASNVETISK **(Montowska and Fornal, 2019)** TLALLFSGPASGEAEGGPK **(Claydon et al., 2015; Fornal and Montowska, 2019; Montowska and Fornal, 2019)** were sensitive to heat-treated products with 16% muscle tissue (w/w). At lower concentrations, S/N approached 2 – 3. It was not possible to identify the DLADEVALVDVMEDK peptide **(Li et al., 2018)** in all types of samples. The S/N index for all samples was no greater than 1. A one-way analysis of variance (ANOVA) found an insignificant effect of temperature on the intensity of marker peptides at a concentration of 8% (w/w). In previous studies by **Kulikovskii et al. (2019)** and **Khvostov et al. (2019)**, we established a limit of detection (LOD) of 0.29% for the NDMAAQYK peptides and 0.93% for the SNVSDAVAQSAR peptide. From the analysis of species-specific marker peptides, three peptides for determining muscle tissue in beef were selected, taking into account the following factors: high prevalence in muscle tissues (>50 cps), good S/N ratio at low concentrations (S\N >10), high specificity and the presence of trypsin-specific cleavage sites at both ends of the protein chain.

Two-way analysis of variance does not reveal differences in the assessment of the criterion for the influence of heat treatment of mixtures at a concentration of 8% beef, confirmed by statistical calculation of p (<0.71), which is higher than the significance level of alpha (0.05).

CONCLUSION

The developed methodology allowed us to simultaneously identify and compare up to 13 beef peptide biomarker. Using the S/N criterion, it was possible to compare peptide markers for the authenticity of raw meat and heat-treated meat. Considered successful candidates whose signal-to-noise ratio was higher than 3.

From the analysis of species-specific marker peptides, three peptides for determining muscle tissue in beef were finally determined: NDMAAQYK and YLEFISDAIIHVLHAK from myoglobin and

SNVSDAVAQSAR from triosephosphate isomerase protein. For samples with two concentration levels and under cooking conditions at 100 °C, the S/N ratio was set above 10. This approach is universal. It is suitable for comparing meat biomarkers of other animal species. It will be able to identify the most suitable candidates. Selected peptide markers can be used to construct regression curves with good linearity, allowing a quantitative assessment of the types of meat present. The selected peptides can be used effectively to distinguish between accidental contamination (technologically unavoidable impurity) and deliberate falsification.

The developed methodology can aid in the study of the effect of meat protein on meat quality and functional characteristics, as well as the safety of finished meat products.

RESEARCH OF QUALITY INDICATORS IN PROTEIN-BLUEBERRY CONCENTRATES

Olena Grek, Tetiana Pshenychna, Alla Tymchuk, Oleksandr Savchenko, Olena Ochkolyas

ABSTRACT

The effect of blueberry coagulant in the form of specially processed blueberry paste on the building-up process of protein-blueberry concentrates has been considered in the article and the change in their physical-chemical indicators during storage has been determined. A study of blueberry coagulant application in the amount of up to 12% provides the effective running to process of thermo acid coagulation of milk proteins with a maximum clot yield (excluding limiting factors – organoleptic indicators and active acidity). It has been found that with an increase in the amount of blueberry paste adding from 2% to 10%, the yield of protein-blueberry concentrates increases from 5% to 40%, and the moisture mass fraction in clots decreases, on the contrary, from 73.4% to 67.1%. Other quality indicators of protein-blueberry concentrates were recorded: active acidity (from 5.0 pH at the beginning to 4.7 pH at the end of the storage life), and the water-retaining capacity at the level of (75.44 ±0.5%). Based on chromatographic studies, the degree of polyphenolic compounds transition (including anthocyanins) to protein-blueberry concentrates at the level of 52.26% has been determined by the calculation method and analyzed compared with control sample (blueberry paste) and colored whey. Based on the researches, protein-blueberry concentrates obtained by thermo acid coagulation of milk proteins are suggested to be used as basis in the cheese products recipes.

Keywords: coagulant; coagulation; concentrate; milk; protein

INTRODUCTION

Full use of all milk protein components during its processing is a condition for increasing the efficiency of obtaining concentrates. There are different methods of milk proteins coagulation: acid, acid rennet, rennet, thermo acid and thermo calcium. The most common methods include acid and rennet coagulation – the basics in the production of fermented milk product **(Bittante, Penasa and Cecchinato, 2012)**. According to the authors **(Kalmykova, 2013; Dabija and Sion, 2012)**, the production of protein products by acid milk coagulation is a popular and common practice. Enzymatic coagulation lasts until 10 hours. There is a need for the use of capacitive equipment. The technology of producing products by thermo acid coagulation of milk proteins involves less time, production space and equipment, but has several disadvantages **(Lyalin and Fedotov, 2009; Bittante, 2011)**. However, the degree of protein extraction during thermo acid coagulation is up to 95 – 97%, while for acid coagulation about 90%, and for rennet – 85% **(Osintsev et al., 2013; Ostroumova et al., 2009)**.

There is a problem of losing valuable proteins with whey in the production of milk protein clots. The use of various technological methods for the conversion of whey proteins to concentrate is actual. This approach will not only increase the yield, but also increase the biological value of the clots **(Abeykoon et al., 2016)**.

Complex precipitation of milk proteins can be achieved by thermo acid coagulation with various coagulants: acid whey (higher 150 °T) or food acids (hydrochloric, acetic, lactic, less often citric) **(Chinprahast, Subhimaros and Pattorn, 2015)**. Without limiting the foregoing, another task for the dairy industry is to increase the dairy products production with a high content of biologically active substances – using berry raw materials.

One of the qualitative characteristics of raw berry is acidity. Blueberries are different of variety and high content of organic acids at the level of (1.25 – 2.3 %). Organic acids at (93 – 95 %) represented by citric, malic, and in smaller quantities succinic, salicylic, and phosphoric **(Simakhina, 2018)**.

The biochemical composition of blueberries indicates not only high nutritional value, but also the pharmacological properties of this crop. It is expected that the therapeutic effect of blueberries is largely due to the content of phenolic compounds in it **(Vikul and Khomich, 2011)**. Berries have radioprotective properties, contribute to the neutralization of radionuclides in the body **(Van Breda, Briedé and de Kok, 2019)**.

For mitigate seasonal fluctuations in the use of berries in the dairy products production, including for coagulation, it

is advisable to attract raw materials, which are stable during storage. Because berries are products that quickly deteriorate, there is a need in their preservation to regulate biochemical processes **(Korotkiy, Korotkaya and Ibragimova, 2010)**.

A modern method of conservation is the processing of raw berry using cavitation devices and those that operate in the mode of developed turbulence **(Pakhomova, Dashkovsky and Stoyanova, 2012)**. Technologies of various homogenized berry pastes (blueberry, blackcurrant, lingonberry, etc.) of long-term storage with increased biological value have been deveped by using hydrodynamic cavitation processing of berry raw materials **(Bessarab et al., 2014)**.

Sterile pastes are industrially produced from blueberries with stable indicators, which excludes the introduction of extraneous microflora and, as a result, the production of a product safe by microbiological parameters during the storage period. Specially processed blueberry paste has an active acidity at 3.0 pH and the following chemical composition: dry soluble substances – 11.0%, polyphenols 457 mg.100g^{-1}, sugars – 7.92%, fiber – 1.57%, pectin – 0.27%.

Known technologies where berry raw materials are used as a filler in the production of cheese products, as well as a coagulant for the acid coagulation of milk proteins **(Shchetinin, Koltyugina and Kosynkina, 2011; Shchetinin et al., 2010)**. The development of milk-based products with berry raw materials is actual for using the functional and technological properties of berries and optimizing the composition of products in matter of vitamins and minerals. The use of berries as natural coagulants for thermo acid coagulation with the protein-berry concentrates production – the basis for cheese products, has not been enough investigated. The use of colored products as the basis for different dairy products will provide appropriate quality indicators with the exception of food colors and artificial flavorings, which corresponds to the concept of a healthy diet.

Scientific hypothesis

Scientific hypothesis is formulated, which is based on the assumption that it is possible to use blueberries as a coagulant, which will provide a clot yield, a natural color and the corresponding physicochemical parameters of the concentrates.

The aim of the work is to study the quality indicators of protein-blueberry concentrates obtained by thermo acid coagulation of milk proteins using blueberries in the form of a specially treated paste as a coagulant.

MATERIAL AND METHODOLOGY

The object of research is the quality indicators of protein-blueberry concentrates (PBC) obtained by thermo acid coagulation of milk proteins using blueberry paste as a coagulant.

Subjects of research – whole milk, blueberry paste (TU 10.8-2789021380-001 2012), yield, organoleptic, physical-chemical indicators (moisture mass fraction, active acidity, water-retaining capacity, polyphenol compounds content) of protein-blueberry concentrates.

The technology of protein-blueberry concentrates provides for thermo acid coagulation of milk proteins using berry raw materials as a coagulant according to the classical condition – coagulation temperature (93 – 95 °C) with duration of 5 min. To obtain a control sample (milk-protein concentrate), acid whey with titratable acidity of 160 °T in the amount of 8 – 10% of milk mass was used **(Grek and Skorchenko, 2009)**. The complex effect on milk proteins of high temperatures and acid reagents leads to the most complete coagulation of them. The coagulation process was established visually by the intensive formation of protein flakes and whey excretion. The obtained protein-blueberry concentrates were formed and self-pressed duration of (30 ±2 min). Pressing was carried out to a moisture mass fraction of 65 – 75%, depending on the further use of PBC for the manufacture of various cheese products.

In order to modify the method of thermo acid coagulation and rationalize the dose of blueberry coagulant (pH 2.6 ±0.2), a range from 2% to 12% with a variation step of 2% has determined. That particular amount in a different extent changed the active acidity in the mixture to ensure a balanced isoelectric state of milk proteins at a pH level (4.1 – 4.5) in the entire volume and led to their active coagulation **(Grek, Onopriichuk and Pshenychna, 2017)**. The products of this technological operation are protein-blueberry concentrates and the colored whey with a touch of blueberry coagulant added.

The yield (mass) of protein-blueberry concentrates was calculated by the gravimetric method based on the mass obtained from 4 dm^3 of milk and converted in percentage terms **(Pytel et al., 2017)**.

The active acidity was determined potentiometrically on Sartorius PB-20 universal pH meter **(Pytel et al., 2016)**.

The moisture mass fraction was investigated by the accelerated method on a KVARTS-21M-33 moisture meter and by the thermogravimetric method on an ADS series laboratory electronic moisture meter, manufactured by AXIS (Poland).

The water-retaining capacity (WRC) of protein-blueberry concentrates was determined by the Grau-Hamm method by A. A. Alekseev modification based on the determination of the water amount that is released from the product by light pressing, which is absorbed by filter paper **(Grek et al., 2015)**.

The polyphenol composition of protein-blueberry concentrates was determined by high-performance liquid chromatography using the spectrophotometer of Prominence LC-20 Shimadzu system (Japan). The substances identification in the extracts was determined by comparing the retention time and spectral characteristics of the investigated substances with similar characteristics of the standards in accordance with the method of polyphenols identification **(Mlček et al., 2019)**. Chromatography was performed at a wave-length of 225, 255, 286 and 350 nm **(Khodakov and Makarenko, 2010; Huang et al., 2012; Giovanelli and Buratti, 2009)**.

The titratable acidity of concentrates was determined according to **GOST 3624-92** and measured in degrees Turner (ºT). Turner degrees mean the amount of alkali solution milliliters of 0.1 mol.dm^{-3} that spent on neutralization of 5 g concentrate **(Grek et al., 2015)**.

Statistical analysis

The studies were repeated three times and processed mathematically using Microsoft Excel 2007 to provide accuracy of the obtained results.

RESULTS AND DISCUSSION

The obtained concentrates are a polydisperse colloidal system in which whey is the dispersion medium and milk proteins and dry substances of the blueberry coagulant are the dispersed phase. The yield and change in the moisture mass fraction of protein-blueberry concentrates depending on the amount of blueberry coagulant is shown in Figue 1.

The obtained yield results of the concentrates were corrected depending on the amount of dry substance of added blueberry coagulant. The research results (Figure 1) showed that under the same conditions of the thermo acid coagulation process with an increase in the amount of blueberry paste adding from 2% to 12%, the yield of PBC increases from 5% to 42%. The moisture mass fraction in PBC decreases, on the contrary, from 73.4% to 66.0%. Generally, the process is characterized by an increase in the transition degree of casein and the maximum amount of whey proteins into concentrates.

It has been established that with the addition of 12% blueberry coagulant, the yield of PBC increased by 2% compared with a sample containing 10% coagulant. The difference was in a margin of error, and the concentrate was characterized by too pronounced (berry) organoleptic indicators. Accordingly, for the further studies, the amount of blueberry coagulant has been selected at a level from 2% to 10%.

The next step of research was the study of changes in active acidity and water-retaining capacity of protein-blueberry concentrates for 72 hours at a temperature of (4 ±2 °C). The results are presented in the diagrams in Figure 2 and Figure 3.

Research has shown, that the active acidity of protein-blueberry concentrates depends on the pH of the blueberry coagulant and the amount of it added. So, the CBF sample, which was obtained by thermo acid coagulation of milk proteins with a blueberry coagulant in the amount of 10% (PBC10), has the lowest active pH value of 5.0 pH at the beginning and 4.7 pH at the end of the storage life. For control sample and all other PBC samples, the decrease in active acidity took place at (0.15 – 0.23 pH). This makes it possible to assert that the use of different amounts of blueberry coagulant for the production of PBC almost does not affect on this indicator of concentrates during storage. Similar results were reported by several authors **(Perreault et al., 2017).**

The more amount of blueberry coagulant (10%) used in thermo acid coagulation of milk proteins, the lower value of the water-retaining capacity in model samples of protein-blueberry concentrates – 71.36 ±0.5%. With a decrease in the amount of blueberry coagulant from 10% to 2%, the WRC of PBC increases to 8.14%. The average value of the water-retaining capacity of the obtained concentrates is (75.44 ±0.5%). During storage, a sharp decrease of the water-retaining capacity in all PBC is observed, and in the end the WRC ranged from 43.82% to 56.75%, which is on average 14% higher than in the control sample.

The dynamics of moisture evaporation from model samples on an Axis electronic moisture meter has determined to study the effect of blueberry coagulant on the qualitative and quantitative moisture state in concentrates. PBC sample obtained by thermo acid coagulation of milk proteins with a blueberry coagulant in amount of 6 ± 1% and a milk-protein concentrate obtained by classical technology were used for research **(Ondrušíková et al., 2019)**. The dynamics of moisture evaporation from concentrates is presented in Figure 4.

According to the measurement results, the main part of the moisture (free) has removed from the milk-protein concentrate (control) sample faster – in 18.0 ±0.5 min, and from protein-blueberry concentrate – more slowly and the indicator was within 21 ±0.5 min. There are differences in the speed of processes. During thermo acid coagulation, irreversible whey protein precipitation reactions occur with the loss of native properties, which is accompanied by the unfolding of the polypeptide chain of the protein molecule **(Donato and Guyomarc'h, 2009)**. As a result of such chain transformations and destruction of the tertiary and secondary structures, hydrophobic groups are "released" on the surface of the protein molecule. In this case, whey protein loses its solubility, aggregates and precipitates. It is likely that the interaction of milk proteins with carbohydrates of blueberry coagulant leads to the formation of additional complexes, which differ by the presence of strong bonds between pectins, dietary fiber and plasma proteins **(Chevalier et. al., 2019; Jakobek, 2015; Han et. al., 2011)**. So blueberries are carriers of vitamins, including vitamin C (14.1 – 26.4 mg.100g^{-1}), pectin substances (0.32 – 0.45%), phenolic substances (339 – 364 mg.100g^{-1})major mineral – and trace elements and other substances indispensable for the normal functioning of the body, with the ability to improve the consumer properties of products **(Toshev, Chaplinsky and Vakhitov, 2012; Li et. al., 2017)**. From a practical perspective, that is how you can justify using blueberry paste for thermo acid coagulation of milk proteins to bind free moisture and prevent syneresis.

PBC (presented in Figure 5) were characterized by the presence of the natural violet color inherent in blueberries, which contain anthocyanins, it was appropriate to study the degree of coloring substances transition to concentrates **(Mendelová et al., 2013)**. Coloring substances of raw berry are low molecular phenolic compounds, relate to bioflavonoids, in particular anthocyanins, which in plants are in the form of glycosides **(Medvecký et al., 2015).** It is known that the complex of blueberry phenolic compounds is represented by chlorogenic acid, kempferol and quercetin glycosides; free, condensed catechins and proanthocyanidins **(Aly, Maraei and El-Leel, 2019)**. The blueberry anthocyanin complex is determined by the set of main components: 3-glycosides and 3-rutinoside of dolphinidin and cyanidine, which is unchanged for berries of all varieties with black color **(Goldina, Safronova and Gaidul, 2015)**. In addition, the berries contain flavones, flavonols, catechins, hydroxycinnamic acids, which determine the natural violet color of the product **(Le Pham, 2020)**. The use of colored PBC as a basis for cheese products will ensure the exclusion of food grade dyes and artificial flavorings **(Slozhenkina et al., 2019)**.

Figure 5 Protein-blueberry concentrates obtained by thermo-acid coagulation of milk proteins by berry coagulant. Note: The amount of milk proteins by berry coagulant, %: a) 2; b) 6; c) 10.

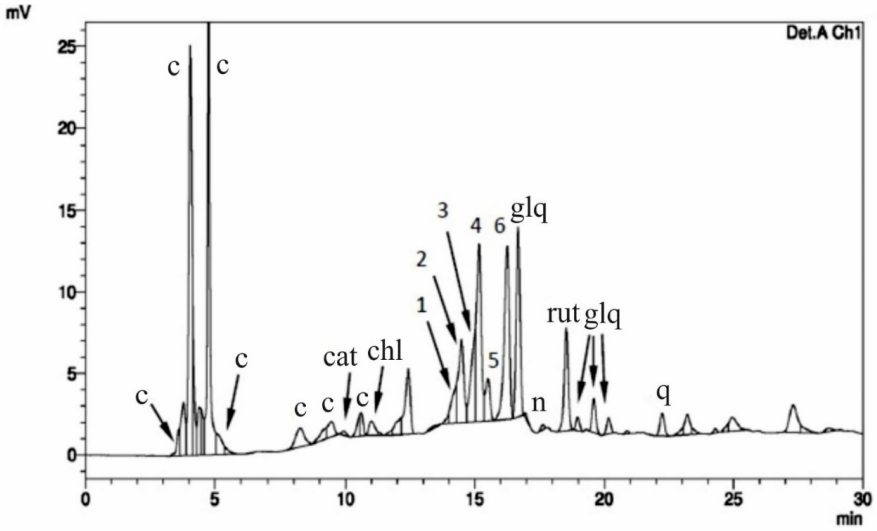

Figure 6 Chromatogram of protein-blueberry concentrates at 255 nm. Note: c – catechins, cat – catechin, chl – chlorogenic acid, n – naringin, rut – rutin, glq – quercetin glycosides, q – quercetin, 1 – delphinidin-galactoside, 2 – delphinidin-glucoside, 3 – cyanidin-galactoside, 4 – delphinide-arabinoside, 5 – cyanidin-glucoside, 6 – petunidine-galactoside + cyanidine-arabinoside + petunidine-glucoside + peonidin-galactoside.

The polyphenolic composition of blueberry paste (control sample), protein-blueberry concentrates and colored whey have been analyzed to determine the degree of coloring compounds transition. The chromatogram of protein-blueberry concentrates is presented in Figure 6.

Research results were analyzed in comparison with the control sample and the degree of their transition to separation products has been determined. The content of polyphenolic substances in protein-blueberry concentrates and colored whey is 281.10 and 146.19 mg.100g^{-1}, respectively. For comparison, the content of polyphenols in blackcurrant paste was on average 457 mg.100g^{-1}. The degree of polyphenolic compounds transition to PBC is 61.51% of their total number. About 31.99% of polyphenolic compounds, including anthocyanins, stay in colored whey. This effect is due to the weight loss correlation of the concentrate during technological operations, such as pressing and forming **(Cipolat-Gotet, et al., 2018)**.

Research results are fully sufficient to develop the technology of protein-berry concentrates obtained by thermo acid coagulation of milk proteins with a blueberry coagulant and subsequent use in the recipes of cheese products.

CONCLUSION

The quality indicators of protein-blueberry concentrates depending on the amount of blueberry paste added during the process of thermo-acid deposition of milk proteins have been studied. It has been found that with an increase in the amount of blueberry paste adding from 2% to 10%, the yield of protein-blueberry concentrates increases from 5% to 40%, and the moisture mass fraction in clots decreases, on the contrary, from 73.4% to 67.1%. Changes occur due to the complex coagulation and transition of milk proteins into a clot, as well as the hydrocarbon components of blueberry paste. This leads to the formation of additional complexes with tightly bound free moisture. The active acidity of protein-blueberry concentrates was in the range of 5.0 – 5.25 pH at the beginning of the storage life and decreased by (0.15 – 0.23 pH) for 72 hours. The average value of the water-retaining capacity of the obtained concentrates is (75.44 ±0.5%).

The degree of polyphenolic compounds transition (including anthocyanins) from berry raw materials in PBC at the level of 61.51% was determined by high performance liquid chromatography. About 31.99% of polyphenolic compounds, including anthocyanins, stay in colored whey of their total amount in blueberry paste.

Protein-blueberry concentrates can be used in the recipes of cheese products with a regulated moisture mass fraction, active acidity, water-retaining capacity and natural color.

MASTITIS PATHOGENS AND SOMATIC CELL COUNT IN EWES MILK

Kristína Tvarožková, Vladimír Tančin, Michal Uhrinčať, Lukáš Hleba, Lucia Mačuhová

ABSTRACT

The aim of this study was to determine the occurrence of pathogens in selected group of ewes and the relationship between somatic cell count (SCC) and the presence of pathogens. The experiment was carried out on a dairy farm, where predominantly breed was a Tsigai. Sampling was carried out in monthly intervals as part of the milk recording test day from February to July 2019. A total of 303 ewes were included in the survey, during the milk recording test day. The ewes with SCC $\geq 1000 \times 10^3$ cells.mL^{-1} were selected for further sampling at half udder level. Based on SCC the ewes were divided into five groups: $<200 \times 10^3$; $\geq 200 < 400 \times 10^3$; $\geq 400 < 600 \times 10^3$; $\geq 600 < 1000 \times 10^3$; $\geq 1000 \times 10^3$ cells.mL^{-1}. The first group of SCC contained 33.9% of milk samples, the second 14.1% of samples, the third 5.7% of samples, the fourth 6.2% and the fifth 40.1% of samples. The most common pathogens were coagulase negative staphylococci (CNS). The most frequent CNS was *Staphylococcus (S.) simulans* (24.4%). *S. aureus* was identified in 5.3% of bacteriological positive samples. Almost 70% of ewes with bacteriological positive samples were repeated identified the presence of pathogens during tested period. SCC $\geq 500 \times 10^3$ cells.mL^{-1} were detected in 92.5% bacteriological positive milk samples. The presence of pathogens increased SCC in milk ($p < 0.001$) as compared to samples free of pathogens. In conclusion, the SCC $\geq 500 \times 10^3$ cells.mL^{-1} could be important for detection of subclinical mastitis at half udder level in dairy ewes.

Keywords: ewes; mastitis; somatic cell count; SCC; pathogens

INTRODUCTION

Mastitis is big healthy, economic and welfare problem in dairy animals. The main cause of increase SCC in milk of ewes is intramammary infection **(Souza et al., 2012)**. Thus, SCC in milk can be used as indicator for diagnostic of subclinical mastitis **(Tvarožková et al., 2019; Olechnowicz and Jaskowski, 2005; Leitner, Silanikove and Merin, 2008; Zigo et al., 2019)**. However, the physiological level of SCC in ewe's milk is still under discussion despite the researches. The results of researches point to the need to set a limit for physiological level of SCC in raw ewe's milk in relation to mastitis **(Persson et al., 2017)**. Our preliminary results also support that high SCC are caused by presence of pathogens **(Uhrinčať et al., 2019)**. CNS are the most common pathogens isolated from milk samples of ewes **(Holko et al., 2019; Zigo et al., 2014; Zafalon et al., 2018)**.

Scientific hypothesis

The hypothesis of this article is that high SCC in milk is caused by presence of mastitis pathogens. The aim of this study was the evaluation of occurrence of pathogens in milk of ewes and the possible relation of pathogens with SCC.

MATERIAL AND METHODOLOGY

The experiment was carried out on farm with Tsigai ewes as dominantly kept breed, together with Lacaune and Improved Valachian (303 dairy ewes in farm). The ewes were on pasture during the day and received concentrates in amounts of 200 g per day during milking.

The milk sampling was performed once a month during morning milking as a part of regular milk recording test day from February to July 2019 (February, March, May, June, July). SCC was determined using a Somacount 150 (Bentley Czech, USA). The ewes with SCC $\geq 1000 \times 10^3$ cells.mL^{-1} at any time during the regular sampling period were selected for further sampling at half udder level three days later. All these ewes were sampled again always on third day after further regular recording test days during whole lactation period even if they had low SCC at regular sampling. The milk samples were collected at half udder level and analysed on SCC and presence of pathogens. Thus 95 ewes (407 milk samples) without symptoms of clinical mastitis were selected into study.

For the bacteriological cultivation and the presence of pathogens the milk samples were colltableected by discarding first squirts of milk and subsequently cleaning of the teat end with 70% alcohol and approximately 5 mL of milk from each udder halves was taken in sterile tube.

The inoculum of each sample of milk was inoculated onto blood agar (Oxoid LTD, Hamshire, UK). All plates were incubated aerobically at 37 °C and evaluated after 24 hours. The all plates were re-evaluated after another 24 hours incubation. Colonies were identified on basis of cells morphology, Gram staining, type of hemolysis, the activities of catalase (3% H_2O_2, Merck, Darmstadt, Germany) esculin hydrolysis and cytochrome oxidase C (Bactident Oxidase, Merck). Presumptive *Staphylococcus aureus* were detected with the clumping factor test (DiaMondiaL Staph Plus Kit, Germany). Esculin positive streptococci were cultivated on modified Rambach agar to identification *Streptococcus uberis* or *Enterococcus* sp. according to **Watts, Salmon and Yancey (1993)**. Lancefield serotyping (DiaMondiaL Strept Kit, Germany) was used to characterize esculin negative streptococci. The species of gram-negative rods were identified used by MALDI-TOF MS (Bruker Daltonics, Bremen, Germany). Contagious pathogens (*Staphylococcus aureus, Streptococcus agalactiae*) were classified as positive if one or more colony-forming unit (CFU) were found. Other pathogens were classified as positive if at least five CFU were found. Samples were classified as contaminated if three and more pathogens were isolated from one milk samples and growth of contagious pathogens were not identified.

The identification to species level by applying MALDI-TOF MS (Bruker Daltonics, Bremen, Germany). Briefly, fresh colony material was spotted by direct transfer method on to MALDI-TOF MS target plate, allowed to dry at room temperature and overlaid with 1 µL of matrix solution (saturated solution α-cyano-4-hydrosy-cinnamic acid in 50% acetonitrile and 2.5% trifluoroacetic acid) and allowed to dry at room temperature. Before the matrix solution was added 1 µL of 70% formic acid to the bacterial spot and allowed to dry for direct transfer-formic acid method. A loopful of bacterial colony was suspended in 300 µL distilled water and 900 µL ethanol was added for the protein extraction. The supernatant was discarded after centrifugation of cell suspension at 17,000 × g for 2 min. The centrifugation was repeated and the remaining ethanol was discarded. After dried the pellet was resuspended in 5 to 50 µL formic acid-water (70:30) in depending on the size of pellet and an equal volume of acetonitrile was added finally. 1 µL of the supernatant was transferred to the MALDI-TOF MS target plate after centrifugation at 17,000 × g for 2 min and allowed to dry before applying 1 µL of matrix solution. The MALDI Biotyper software version 2.0 (Bruker Daltonics) was used for bacterial identification.

Statistical analysis

Samples on the basis of SCC at half udder level were divided into following five SCC groups for evalutation of the distribution of milk samples: first $<200 \times 10^3$ cells.mL^{-1}; second $\geq 200 < 400 \times 10^3$ cells.mL^{-1}; third $\geq 400 < 600 \times 10^3$ cells.mL^{-1}; fourth $\geq 600 < 1000 \times 10^3$ cells.mL^{-1}; fifth $\geq 1000 \times 10^3$ cells.mL^{-1} (Using Excel, Microsoft, USA). The distribution of samples according SCC group was done by Microsoft Excel. Somatic cell score was used for statistical evaluation (SCS) and SCS was calculated according formula:

$$SCS = LOG_2 (SCC/100000) + 3$$

For statistical evaluation the data were divided according month of sampling where five groups of samples were created: Feburary, March, May, Juni and July. The samples also were divided into 9 pathogens group differed by presence of pathogens (1st group – major (*S. aureus, Str. agalactiae*), 2nd – minor (environmental pathogens other than CNS), 3rd – *S. simulans*, 4th – *S. schleiferi*, 5th – *S. caprae*, 6th – *S. epidermidis*, 7th – *S. chromogenes*, 8th – other CNS. Control group (9th group) consists from samples free of pathogens. Obtained data were processed by Microsoft Excel program and statistically evaluated by SAS/ 8.2 (2002). The model was tested by using Fisher's F-test. Differences between the levels of the effects were tested by Scheffe's multiple range test for studied trait. Data are presented as LSmeans ± standard error for evaluation of somatic cells the following model was used:

$$y = X\beta + Zu + e$$

y – was the measurements for somatic cell counts
β – the fixed effects of months, pathogens
e – random error, assuming $e \sim N(0, I\,\delta^2_e)$
X, Z – incidence matrices for fixed effects and random cow effect, resp.

RESULTS AND DISCUSSION

When evaluating the entire observation period tested ewes on udder half level the first group of SCC contained 33.9% of samples, the second 14.1% of samples, the third 5.7% of samples, the fourth 6.2% and the fifth 40.1% of samples (Figure 1). In our previous works we presented higher percentage (from 58.9% to 71.8%) of ewes in group $<200 \times 10^3$ cells.mL^{-1} under usual test day sampling for determination of physiological levels of SCC in healthy udder **(Tančin et al., 2017a; Tvarožková et al., 2018)**. The proposed physiological threshold of SCC for diagnosis of mastitis in Sarda sheep was determined by **Caboni et al. (2017)** at 265×10^3 cells.mL^{-1}. **Zafalon et al. (2016)** detected the value of SCC $>400 \times 10^3$ cells.mL^{-1} for diagnose of subclinical mastitis in flocks. Earlier proposed value of SCC for the diagnosis of mastitis was 500×10^3 cells.mL^{-1} **(Nunes et al., 2008)**. Low percentage of samples in group $<200 \times 10^3$ cells.mL^{-1} in present work could be explained by sampling schedule, where these samples were colected from the ewes with high SCC at udder level three days before. Thus some health problems of udder should be expected as it is presented later in article by cultivation of milk sample on pathogens presence. In ewes with SCC above 400×10^3 cells.mL^{-1} three or more months during lactation there were 5.6 to 7.5-fold higher probability of a subclinical mastitis in compared with ewes with SCC below above limit **(Spanu et al., 2011)**. **Berthelot et al. (2006)** reported 15% occurrence of subclinical mastitis if SCC in flock was over 650×10^3 cells.mL^{-1}.

Figure 1 Frequency of distribution of milk samples in SCC groups.

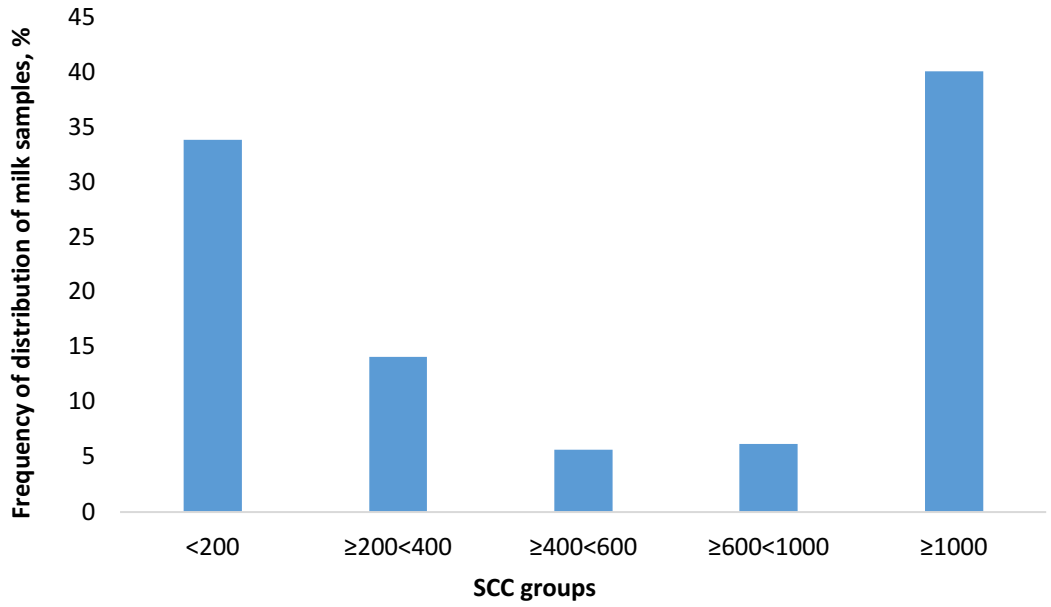

Table 1 The occurrence of pathogens in months of observation.

Pathogen	February	March	May	Jun	July
Enterococcus faecalis	2	1	3	-	-
Micrococcus luteus	-	-	-	-	1
S. aureus	1	2	4	1	-
S. capitis	1	2	-	-	-
S. caprae	2	3	2	1	20
S. cohni	-	-	-	-	1
S. epidermidis	3	7	3	3	5
S. felis	-	-	1	-	-
S. haemolyticus	1	-	-	-	-
S. chromogenes	5	4	1	-	-
S. lentus	-	-	-	-	1
S. piscifermentans	-	-	-	4	-
S. sciuri	1	-	-	-	-
S. schleiferi	-	-	8	21	-
S. simulans	7	6	15	3	2
S. warneri	-	-	1	-	-
Str. pluranimalium	1	1	-	-	-

Total 407 examined milk samples tested on presence of mastitis pathogens were as negative classified 63.1% of milk samples, out of these samples 75.9% had SCC below 500 × 10^3 cells.mL^{-1}. 36.1% of samples were classified as bacteriological positive and 0.7% of milk samples were classified as contaminated. Only 7.5% of bacteriological positive samples had SCC below 500 × 10^3 cells.mL^{-1}. Two pathogens were identified in 2.7% of bacteriological positive samples. In 67.9% of ewes with bacteriological positive samples there were repeated detected the presence of pathogens during tested period. Thus pathogens could persist in udder throughout whole lactation. Also up to 21.1% from these ewes had infected both udder halves pathogens repeatedly.

Important group of samples are those in fifth group – with very high SCC (Figure 1). In fifth SCC group there were almost 80% bacteriological positive samples, which indicated the reason of high SCC. Also even 92.5% bacteriological positive samples had SCC ≥500 × 10^3 cells.mL^{-1}. We detected significant lower SCS in milk of ewes without (4.03 ±0.12) than with the presence of any pathogens (p <0.001). There was no effect of different pathogens on SCS which ranged from 6.68 ±0.41 to 8.11 ±0.63. Also no effect of month of sampling on SCS was found out. Different pathogens could differently influence SCC **(Abu Baker Idriss et al., 2013; Bagnicka et al., 2011)**. **Kiossis et al. (2007)** used level of SCC of ≥500 × 10^3 cells.mL^{-1} and bacteriological positive milk samples for the diagnose of subclinical mastitis. Significantly higher SCC in bacteriological positive samples as compared with bacteriological negative samples found out **Ozenc et al. (2011)** in their study. **Świderek et al. (2016)** reported that milk samples without bacteria had the lowest average SCC. Also, **Persson et al. (2017)** detected significantly higher SCC for udder halves with intramammary infection compared to udder halves without bacterial findings.

From major pathogens only *S. aureus* was identified in 5.3% of bacteriological positive samples (Table 1). Other contagious pathogens were not found out in tested group of ewes. Low frequency of contagious pathogens in milk was also presented in our previous work **(Tančin et al. 2017b; Holko et al. 2018)** or abroad works **(Ergűn et al. 2009; Kern et al. 2013)**. **Zigo et al. (2011)** detected *S. aureus* in 9.3% of positive samples. **Moroni et al. (2007)** isolated *S. aureus* in 8.4% of infected milk samples. *S. aureus* was determined in 6.2% of subclinical mastitis cases **(Queiroga, 2017)**. The most frequent pathogens isolated from the milk samples were CNS. Also high occurrence of CNS was reported in study **Zigo et al. (2014)** and **Vasileiou et al. (2018)**. The most frequent CNS was *S. simulans* (24.6%) followed by *S. schleiferi* (21.6%), *S. caprae* (20.9%) (Table 1). From CNS found in farm had the highest occurrence *S. epidermidis* (36.3%) and *S. caprae* (21.3%) **(Pilipčincová et al., 2010)**. **Rahman et al. (2016)** showed that the most dominant CNS were *S. epidermidis*, *S. xylosus* and *S. chromogenes*. **Vasil' et al. (2018)** investigated that the most frequent CNS were *S. epidermidis* (24.3%), *S. schleiferi* (16.6%) and *S. chromogenes* (15.3%). *Enterococcus faecalis* and *Streptococcus (Str.) pluranimalium* was determined also (Table 1). **Zigo et al. (2017)** determined the incidence of *Enterococcus faecalis* in 6.1% of positive samples. **Grazia Puggioni et al. (2019)** detected 29.4% the occurrence of *Enterococcus faecalis* in their study.

CONCLUSION

CNS were the most common group of pathogens in milk followed by increased SCC in milk. *Staphylococcus (S.) simulans* (24.4%) was the most frequent CNS in milk samples. From contagious pathogens was identified *S. aureus* in 5.3% of bacteriological positive samples. The presence of mastitis pathogens during tested period were repeated detected in 67.9% of ewes with bacteriological positive samples. 92.5% bacteriological positive milk samples had SCC ≥500 × 10^3 cells.mL^{-1}. The high SCC ≥500 × 10^3 cells.mL^{-1} and bacteriological positive milk samples from udder halves may be useful criterion for detection of subclinical mastitis and poosible use for selecting ewes for dry treatment or culling.

EFFECT OF THERMAL STABILIZATION ON PHYSICO-CHEMICAL PARAMETERS AND FUNCTIONAL PROPERTIES OF WHEAT BRAN

Michaela Lauková, Jolana Karovičová, Lucia Minarovičová, Zlatica Kohajdová

ABSTRACT
The food industry also focuses on the use of by-products from food processing. Wheat bran is a valuable by-product of the wheat milling process, which is rich in dietary fiber. In addition to nutritional value, dietary fiber has a functional potential in the production of novel foods. Pre-treatment of the dietary fiber using different methods can change its functional properties. The objective of this study was to evaluate the effect of stabilization process on physico-chemical parameters and functional properties of wheat bran. Wheat bran from two wheat variety was treated using microwave and hot air heating. It was observed that wheat bran included more than 45% of total dietary fiber. Results suggested that treatment of bran using both method increased total dietary fiber content. Thermal treatment process decreased the anti-nutritional agent in bran samples. Phytic acid content diminishing of 44% and 49% was observed in microwave treated bran samples. Moreover, treatment of bran using a hot air heating improved the hydration properties (water holding, water retention and swelling capacity), while oil holding capacity was not significantly altered. Treatment decreased the antioxidant activity of treated bran samples. It was observed that thermal treatment modified the color parameters of bran (lightness, yellowness and hue angle decreased and redness and Chroma increased).

Keywords: wheat bran; thermal treatment; functional property, phytic acid; retention capacity

INTRODUCTION
With growing interest in health-promoting functional foods, the demand for natural bioactive additives has increased and the exploration for new sources is ongoing. The food processing industry in most countries generates large quantities of byproducts every year, which are frequently abandoned as wastes. However, many of these byproducts are dietary, functional, and potentially novel sources of nutrition. Of the many materials obtained, dietary fibers are particularly promising ingredients that has attracted considerable interest over the past few decades. The reason for this is their significant availability in most food byproducts, low costs, and positive effects for the prevention and treatment of a diverse range of diseases **(Han et al., 2017)**.

Dietary fiber is the edible part of plants or analogous carbohydrates; it consists of polysaccharides that are resistant to digestion and absorption in the human small intestine with complete or partial fermentation in the large intestine. Total dietary fiber (TDF) is the sum of insoluble (IDF) and soluble dietary fiber (SDF) **(Lebesi and Tzia, 2011)**. The soluble and insoluble nature of dietary fibres involves differences in their technological functionality and physiological effects. SDFs are characterised by their capacity to increase viscosity, and to reduce the glycemic response and plasma cholesterol. IDFs are characterised by their porosity, their low density and by their ability to increase faecal bulk and decrease intestinal transit **(Elleuch et al., 2011)**. Compared with the IDF, SDF has superior beneficial properties for human health. In the natural plant cell walls, IDF accounts for a large proportion, while the proportion of SDF is very low. Thus, finding the appropriate method to convert more IDFs into SDFs is extremely important **(Gan et al., 2020)**. Thermal steps like roasting, steaming, cooking under forced air or microwave radiation usually have little impact on the chemical composition, but some effects on the processing properties could be observed **(Prückler et al., 2014)**.

There are various sources of dietary fiber. The most common source in bakery products is cereal bran, especially wheat bran **(Almeida, Chang and Steel, 2010)**. Thus, using wheat bran with high TDF content, fiber enrichment objectives can be achieved by means of small amounts of bran. The incorporation of lower levels of bran means a less negative impact on the finished product quality **(Ellouze-Ghorbel et al., 2010)**. Nutritionally, bran fractions produced by milling are rich in fibre, minerals, vitamin B6, thiamine, folate and vitamin E and some phytochemicals, in particular antioxidants such as phenolic compounds. However, bioavailability is affected by the

food matrix as well as processing conditions. Bran is used in the production of brown and wholemeal flours, hence retaining some of the valuable nutritional components that are depleted when these fractions are further removed in the refinement of white flour **(Stevenson et al., 2012)**. Wheat bran is therefore composed of pericarp, seed coats, and aleurone layer with some attached remnants of endosperm. Considerable amounts of wheat bran are produced annually that are mostly used in animal feeding. Due to the presence of the aleurone layer, wheat bran constitutes, however, a potential source of micronutrients that could be better valorized in human nutrition **(Antoine et al., 2003)**. The physiological effects of wheat bran can be split into nutritional effects (from the nutrients present), mechanical effects (mainly on the gastrointestinal tract, due to the fibre content) and antioxidant effects (arising from the phytonutrients present such as phenolic acid and alkylresorcinols) **(Stevenson et al., 2012)**.

Scientific hypothesis

This work evaluated the effect of different treatment process (hot air heating and microwave heating) on the physico-chemical parameters and functional properties of treated wheat bran.

MATERIAL AND METHODOLOGY

Material

Wheat bran from the variety PS Bertold (BB) and PS 215 (WB) were observed from Research and Breeding Station, Vígľaš Pstruša, Slovakia and Research Institute of Plant Production Piešťany, Slovakia. Wheat bran samples were treated using hot-air and microwave heating acording to method described by **Lauková et al. (2019)**.

Chemical composition

Chemical composition of wheat bran included determination of: moisture (AACC Method 44-19.01), ash (AACC Method 08-01.01), protein (AACC Method 46-13.01) and crude fat (AACC Method 30-25.01) **(AACC, 2000)**.

TDF, IDF and SDF content was determined by enzymatic-gravimetric method **(AOAC, 2003)**.

Phytic acid content was measured using colorimetric method according to **McKie and McCleary (2016)**.

Antioxidant activity of wheat bran was determined according to the method of **Cai et al. (2014)** by measuring free radical 2,2-diphenyl-1-picrylhydrazyl (DPPH) scavenging capacity. Wheat bran (0.1 g) was extracted with 1 cm^3 of pure methanol at 25 °C for 2 h with continuous shaking under a dark environment and centrifuged at 1,200 × g for 10 min. The extract (0.05 cm^3) was reacted with 1 cm^3 of 0.1 mM DPPH solution at 25 °C for 30 min, and absorbance was measured at 517 nm. Antioxidant activity was calculated as percent discoloration of DPPH = $[1 – (A_1/A_0)] \times 100$, where A_1 is the absorbance of wheat bran extract at the end of the reaction (t = 30 min) and A_0 is the absorbance of the pure methanol control at the beginning of the reaction (t = 0). The data were reported as percentage of discoloration.

Functional properties

Swelling capacity, water absorption and water retention capacity were determined according to method described by **Lauková et al. (2018)**. Oil holding capacity was evaluated using method presented by **Mora et al. (2013)**.

Solvent retention capacity (SRC) tests were performed according to the method from authors **Xiao et al. (2006)** using 5% lactic acid, 5% sodium carbonate, 50% sucrose, and distilled water. Sample (5g) was added into a 50 cm^3 centrifuge tube with a screw cap. Then 25.0 cm^3 of an appropriate solvent was added and the mixture was vortexed vigorously to suspend the flour for 5 sec. The mixture was allowed to set and swell for 20 min and was vortexed for 5 s each at 5, 10, 15, and 20 min. After centrifugation at 1,000 x g for 15 min (not including time to achieve speed), the supernatant was decanted and the tube was drained at a 90° angle for 10 min on a paper towel. Finally, SRC value (14% mb) was calculated for each solvent as:

$$SRC\ (\%) = \left(\frac{gel\ weight - flour\ weight}{flour\ weight}\right) \times 100$$

Color of wheat bran

The color parameters *L* (lightness), *a* (redness/greenness), and *b* (yellowness/blueness) of the samples were measured by spectrophotometer Cary 300 UV-Vis (Agilent Technologies, Santa Clara, USA) with DRA-CA-30I sphere accessory. The spectrophotometer was calibrated with a white calibration tile. The Cary WinUV software with "Color" application was used for recalculation the Chroma (*C*) and hue angle (*H*). Color coordinates were determined five times per bran sample.

Statistical analysis

All determinations were carried out in triplicate unless otherwise state. The results were expressed as mean ± standard deviation. The significant differences between mean values of raw and treated bran were establish using a Student`s test at $p < 0.05$. The XLSTAT statistic software was used for data evaluation.

RESULTS AND DISCUSSION

Chemical composition

Composition of wheat bran is purely based on the variety, cultivation conditions and the methods employed for its separation, which determines the amount of starch attached to the aleurone layer after the separation **(Babu et al., 2018)**. Chemical composition of treated and raw wheat bran is summarized in Table 1. Results presented that moisture content of bran decreased after thermal treatment, which was caused by loss of water as a result of heating **(Dong et al., 2019)**. Furthermore, it was observed that treatment of wheat bran using microwave and hot air heating had no significant effect on ash and fat content.

Wheat bran contains more than 15% high quality proteins, but most of them are enclosed within a matrix of cell wall polysaccharides and so they are poorly digested. Wheat bran proteins have also been explored as a source of amino acids and bioactive peptides or as inhibitors of enzymes of industrial interest **(Balandrán-Quintana, Mercado-Ruiz and Mendoza-Wilson, 2015)**. From the

results concluded that protein content of raw bran varies from 15.46% (WB) to 15.92% (BB). These results were in agreement with those obtained by **Ferreira, Chang and Steel (2011)** (15.30%) and **Noort et al. (2010)** (15.90%). After microwave treatment, the protein content increased up to 16.56% (WB) and 17.20% (BB).

Wheat bran appears as an important dietary fiber source **(Ferreira, Chang and Steel, 2011)**. It was observed, that TDF content of raw bran samples were 46.35 and 45.99%, indicating bran as good source of dietary fiber. Similar TDF content in wheat bran was found by **Ma, Lee and Baik (2018)** (46.50%) and **Ferreira, Chang and Steel (2011)** (46.30%). Furthermore, IDF and SDF content of raw BB, 44.93% and 1.42%, respectively, were higher compared to raw WB (44.62 and 1.37%). Thermal treatments can change their physico-chemical properties of dietary fiber by altering the ratio between soluble and insoluble fiber (SDF/IDF), TDF content **(Ozyurt and Ötles, 2016)**. It can be concluded, that treatment of bran using both methods had significant effect on TDF and IDF. The results suggested that hot air treatment resulted in higher fiber content compared to microwave treated bran. Moreover, hot air treatment significantly increased the SDF content. In general, the changes in the dietary fiber composition during thermal processing may be partly attributed to the redistribution of the insoluble and soluble components of dietary fiber, and partly to the formation of resistant starch. An increased temperature breaks week bonds between polysaccharide chains and split glycosidic linkages in the polysaccharides **(Căprită, Căprită and Hărmănescu, 2012)**. Increase in total fiber can be also attributed to the formation of fiber-protein complexes that are resistant to heating and are quantified as dietary fiber **(Dhingra et al., 2012)**.

Bran also contains phytic acid which is the major phosphorus storage component and comprises 80% of total phosphorus in cereal grains **(Aktas-Akyildiz et al., 2017)**. The presence of phytate has been considered as an anti-nutrient in humans because of its effect on the bioavailability of iron, magnesium, zinc and calcium. While the mechanism is not entirely understood, it is suggested that phytic acid binds strongly with these mineral cations to form phytate-mineral complexes, changing their solubility, functionality absorption and digestibility. Consequently, the complex cannot be absorbed or easily hydrolysed by the human body and so there is an adverse effect on bioavailability of minerals **(Stevenson et al., 2012)**. The phytic acid content (Figure 1) in raw WB samples was higher (51.9 $mg.g^{-1}$) than in raw BB (40.4 $mg.g^{-1}$). These values are in agreement of those reported by **Noort et al. (2010)** (47.9 $mg.g^{-1}$) in wheat bran. It can be stated that thermal treatment significantly decreased phytic acid content in both bran variety. After microwave treatment, the phytic acid content was significantly reduced to 22.6 $mg.g^{-1}$ (BB) and 26.4 $mg.g^{-1}$ (WB). Recently, **Mosharraf, Kadivar and Shahedi (2009)**, and **Zhao, Guo and Zhu (2017)** also described a decrease in phytic acid content in treated wheat bran after steeping in acetate buffer and fermentation.

The antioxidant activity of wheat bran measured using DPPH is illustrated in Figure 2. The results showed that antioxidant activity of raw wheat bran was 24.84% and 28.85% for BB and WB, respectively. Both values were higher than those reported by **Verma, Hucl and Chibbar (2008)** (12.5 – 20.1%) in bran from 51 wheat cultivars. On the other hand, **Cai et al. (2014)** observed higher antioxidant activity (29.2 – 53.6%) in bran from American and Korean wheat varieties. Microwave and hot air heating of bran decreased its antioxidant activity. The lowest antioxidant activity values were recorded after hot air heating of bran samples (23.11 and 23.64% for BB and WB).

Functional properties

The technological interest and physiological effects of dietary fibre are related to their functional properties. The hydration properties of dietary fibres determine their optimal usage levels in foods because a desirable texture should be retained **(Yaich et al., 2015).** Wheat bran is rich in polysaccharides which can bind water on a molecular level through formation of hydrogen bridges. These mechanisms contribute to water uptake by bran in the case of unconstrained hydration. Alternatively, when bran is exposed to an external stress, only the water strongly bound in nanopores or through hydrogen bonds will govern water retention **(Hemdane et al., 2016)**. Functional properties of untreated and treated wheat bran are summarized in Table 2.

WHC is related to the porous matrix structure formed by polysaccharide chains which can hold large amounts of water through hydrogen bonding **(Du, Zhu and Xu, 2014)**. The WHC of raw bran samples were 2.46 $g.g^{-1}$ (BB) and 2.57 $g.g^{-1}$ (WB), which was similar to those described by **Cai et al. (2014)** (2.04 – 2.51 $g.g^{-1}$). From the results concluded that thermal tretment of bran resulted in increased WHC values. Moreover, hot air treated bran had higher WHC than microwave treated bran. The high WHC of modified bran suggested that this material could be used as a functional ingredient to avoid syneresis and to modify the viscosity and texture of formulated products in addition to reducing calories by the total or partial substitution of high-energy ingredients **(Grigelmo-Miguel, Gorinstein and Martín-Belloso, 1999)**. **Yan, Ye and Chen (2015)** demonstrated higher WHC value of bran after extrusion.

WRC is one of the major key parameter which has been studied in functional food. Most significant changes that happen during baking i.e. gelatinization of starch, denaturation of protein, flavor and color formation are due to water contents **(Khan et al., 2018)**. WRC is related to the content of insoluble dietary fiber and the intact cell structure of bran **(Zhao, Guo and Zhu, 2017)**. Raw BB bran had lower WRC value (1.74 $g.g^{-1}$) compared to WRC value of raw WB bran (2.16 $g.g^{-1}$). This WRC values are in agreement with result (2.18 $g.g^{-1}$) presented by **Ma, Lee and Baik (2018)**. After hot air treatment the WRC significantly increased up to 2.38 and 2.63 $g.g^{-1}$ for BB and WB, respectively.

SC indicates how much the fiber matrix swells as water is absorbed, including loosely associated water. It is a consequence of the macromolecule relaxation during hydration, which leads to an increment in the occupied volume by the fiber product. The greater capacity to swell is the most desirable parameter for the physiological functionality of DF **(Lebesi and Tzia, 2012)**. The SC of raw bran was higher (4.21 and 4.40 $cm^3.g^{-1}$) than obtained **Mora et al. (2013)** (2.92 $cm^3.g^{-1}$) for wheat bran. From the results concluded that thermal treatment significantly increased the SC of wheat bran. The highest SC (5.66 and 5.75 $cm^3.g^{-1}$) was recorded after microwave treating of bran. The increase in SC might be attributed to a rise in the amount of short chains and the surface area of DF induced by thermal processing **(Dong et al., 2019)**.

OAC is the capability of dietary fiber to adsorb fat. During food processing, the reduction of cholesterol level in blood is linked with higher value of OAC **(Khan et al., 2018)**. Oil absorption of cereal derivatives, e.g., wheat bran, is related mainly to the surface properties of the bran particles but may also be related to the overall charge density and to the hydrophilic nature of the constituents **(Elleuch et al., 2011)**. It was observed that OAC of raw BB bran was higher (1.33 $g.g^{-1}$) than WB bran (1.49 $g.g^{-1}$). These values were lower compared to values observed by **Mora et al. (2013)** for wheat bran (2.18 $g.g^{-1}$). Authors **Ma and Mu (2016)** describe that low OAC values might be due to the absence or limited presence of lignin. The results showed that treatment of bran using both methods had no significant effect on OAC values.

The SRC method has been conceived to produce a combined pattern of the four SRC values to establish a practical flour quality/functionality profile. It is clear that fibre functionality in food formulations derived from its interaction and spatial arrangement within the biopolymers system **(Rosell, Santos and Collar, 2009)**. Wheat bran is increasingly added to mostly cereal-based food products (bread, cookies, breakfast cereals, pasta, snacks, cakes, and more) **(Hemdane et al., 2016)**. For this reason the selected SRC of wheat bran samples and the effect of bran treatment were also evaluated. The SRC values are summarized in Table 2. Generally, lactic acid SRC is associated with glutenin characteristics, sodium carbonate SRC is related to levels of damaged starch, and sucrose SRC with pentosan characteristics **(Rosell, Santos and Collar, 2009)**. The results showed that thermal treated bran had significantly higher lactic acid and sucrose SRC compared to raw bran. The highest values of lactic acid SRC were observed after hot air heating (174.44 and 198.11% for BB and WB, respectively). Furthermore, the

results revealed that microwave treated WB bran had the highest sucrose SRC (224.56%). On the other hand, the sodium carbonate SRC decreased after thermal treatment process up to 163.25% (hot air heated WB).

Color parameters

Color is an important visual quality (attribute) of food products **(Ferreira, Chang and Steel, 2011)**. The color attributes of raw and treated bran are summarized in Table 3. The lightness values of raw bran (63.33 and 65.84 for BB and WB, respectively) were similar to results described by **Onipe, Beswa and Jideani (2017)**. Results showed that thermal treatment of bran samples decreased the lightness value of bran. Moreover, the lowest lightness values (58.60 and 59.87 for WB and BB, respectively) were recorded after hot air heating. It was also observed that after treatment of bran using both methods the redness of bran increased, while yellowness of bran decreased. Chroma (*C*), considered the quantitative attribute of colorfulness, is used to determine the degree of difference of a hue in comparison to a grey color with the same lightness **(Minarovičová et al., 2019)**. The results suggested that treated bran using both methods had higher *C* value compared to raw bran samples. The higher the *C* value, the higher is the color intensity of samples perceived by humans **(Minarovičová et al., 2019)**.

CONCLUSION

Wheat bran is the main source of dietary fiber in bakery products. The results showed that microwave and hot air heating altered the soluble and insoluble dietary fiber content. Hot air treatment significantly increased the total dietary fiber content up to 49.74%. The loss of phytic acid content was more than 44 % after microwave heating. The thermal treatment modified the functional properties of wheat bran, which are important in food processing. Wheat bran treated using hot air had higher water absorption and water retention capacity compared to wheat bran treated using microwave heating. Hot air heating significantly altered the color parameters of treated bran. From this study resulted that treatment of wheat bran using hot air heating significantly improved the wheat bran functional and physico-chemical properties.

NEW TRENDS AND INNOVATIVE APPROACHES IN PERSONNEL MANAGEMENT OF FOOD BUSINESSES IN SLOVAKIA

Zuzana Lušňáková, Silvia Lenčéšová, Mária Šajbidorová, Veronika Hrdá, Boris Rumanko

ABSTRACT
New practices and changes are appearing in personnel management in the same way as they occur in other areas of management. New trends, which have various ways of implementation, emerge, along with its impact on employees, managers and businesses. Employees are an important part of each business and therefore, it is important to have right people in right places. The objective of the paper is to find out how food businesses working in Slovakia are implementing an innovative approach to the personnel management. The research actively included 453 food businesses from all Slovakia. We decided to do research into these businesses because they are household names in the field of production of domestic food products. Production of high-quality domestic food products is considered important not only for people´s nutrition and availability of quality domestic products but also due to sustainability of the employment rate in this field, development and recruitment of professional, qualified and engaged employees. The statistical relations and correlations between variables were performed by Cronbach alpha, Spearman test, Kruskal-Walis test using programs EXCEL and SAS Enterprise Guide 7.1. We found out that food businesses in Slovakia had already started to implement innovative approaches to the personnel management, but there are still significant reserves and shortcomings. The positive aspect is that food business managers have understood importance of personnel management innovation because nowadays, their main task to find, recruit, select and retain a prospective employee.

Keywords: innovation; news trends; personnel management; food businesses

INTRODUCTION
Personnel management focuses on all the activities connected with a person in a working process. The most important functions are as follows: planning of human resources, recruitment and selection of employees, hiring and adaptation, development and education, evaluation and remuneration, communication and motivation of employees. The main goal of the human resource management is to procure employees that are necessary for occupying job vacancies within an organisation.

The global aim of the management of human resources is to achieve a competitive advantage through strategic distribution of capable and dedicated to the organization employees by using an integrated system of cultural personnel procedures **(Šajbidorová, Lušňáková and Dobišová, 2016)**. The first key to organisation´s success is *„to perceive the value and significance of employees and human resources and to understand that people represent the greatest asset of an organisation and its management decides whether an organisation will succeed or not"* **(Wroblovská, 2016)**. Human resources have become a core of each single business.

Current practice on human resource management refers to what human resource managers and line managers usually do **(Juríčková, Kapsdorferová and Kadlečíková, 2018)**. The attention is nowadays paid to the need for strategic and systematic human resource management application which creates an added value within an organisation through effective and efficient use of human resources. In this regard, various new approaches have emerged, for example, human capital management, enhancing loyalty, talent management, ability oriented management, electronic human resource management, creating systems focused on high performance, work performance management or performance-based remuneration. A modern approach to human resource management relates to deployment of employees within a company, where the primary working profile of workers, their work orientation and preferences are of the highest importance. The tasks to which an employee has dispositions and duties are adapted accordingly. This practice leads to optimum use of work ability and an employee manages to contribute to fulfilment of company goals while boosting work effectiveness **(Měrtlová, 2015)**.

Employee recruitment procedures aims to collect a sufficient number of adequate candidates for a job vacancy from whom, by adequate selection methods, an organisation selects the most appropriate candidate or candidates to occupy the work position. The basic decision is which segment of the labour market we focus on and what means of communication we select **(Frischmann and Žufan, 2017)**.

Recruitment of employees is an activity which ensures that job vacancies within a company attract a sufficient number of adequate applicants herefor, with adequate costs and in adequate time (on time) **(Koubek, 2015)**. During recruitment of employees, we might face "conflict of interests", of both, an employer, who needs to satisfy certain requirements and an applicant, who seeks new employment. On the other side, there might company employees who want to change their current work environment in the company. The study by **Diesel and Scheepers (2019)** gives human resource management insight into strategically directing leadership recruitment and development towards creating an organisational climate to enhance ambidexterity.

Present trends in employees´ recruitment developed back in 2004, when there was a significant technological shift in the area of the Internet communication and the era, called web development, started while hard website content was being replaced by shared content. **Blštáková et al. (2015)** wrote some methods, which actually show the highest usage potential, and as such has been proved to many companies:

- job recruiting websites of a company,
- professional webs,
- social sites,
- direct and indirect addressing of candidates.

Managers and leaders are provided with an opportunity to communicate across the market via social sites and therefore search for new employees. The biggest professional social site LinkedIn is mostly used by human resource managers when searching for professionals**.** Direct addressing of selected individuals is usually the last phase from the set of other methods, such as references of current employees, cooperation with educational institutions, etc. **(Koubek, 2015)**. Due to complexity of this method, new companies dealing with headhunting are slowly emerging and other businesses can hire such companies for searching for their prospective employees. The headhunting method can be demanding especially for leaders.

Employees´ selection can be placed between recruitment and hiring of employees. The objective of employees´ selection is to make the analysis and sort out applicants for a specific work position, compare them with requirements and demands of an organisation, and select the best possible applicant for a job vacancy.

The employees´ selection process is specific because a human resource manager has to sort out the best possible candidate from the given list of applications, the one who would best fulfil specific working criteria. At the same time, it entails personal as well as professional characteristics of applicants as well as their qualification potential and flexibility **(Mužík and Krpálek, 2017)**. An assessment centre belongs to the most frequently used methods within employees´ selection – it is a systematic selection tool, evaluating abilities of an applicant for a work position by comparing their knowledge, abilities, skills with requirements for their performance regarding a specific work position. This type of employees´ selection is mainly performed when occupying top management positions **(Vetráková and Bočincová, 2013)**. Nowadays, traditional work interviews have been moved to informal environment, e.g. lunch and it provides a unique view of candidate´s character. To make companies test the skills of candidates in a standardised way, they use for example 3D simulation of work environment in the virtual reality. New trends in employees´ selection and technology development has promoted creation of so-called video-recruitment.

In general, selection of employees via the Internet is seen more effective in contrast to offline methods. Considering the higher number of applicants, it provides the managers with the access to various applicants. It covers a shorter recruitment period and helps to cut overall recruitment costs **(Christiansen, et al., 2017)**. Talented people from abroad are often recruited via video-interviews.

Employees´ selection through information – communication technologies is likely to boost effectiveness and influence, cuts costs or increases the capacity in the selection process of the most appropriate candidate. In general, digital or online recruitment and the upcoming selection can help to reach a wider potential as well as promote the life cycle of selection **(Zeuch, 2016)**.

Within employees´ selection one cannot omit more and more active use of diagnostic methods, evaluating personal characteristics of applicants for work position and having a significant influence on performance and work effectiveness **(Evangelu, 2008)**.

Scientific hypothesis

In order to evaluate the level of active work in food businesses operating in Slovakia and implementation of new trends within personnel management, we have stated and, based on the analysis in question, verified the following research assumptions:

Searching and recruitment of employees:

A1: We assume, that companies deliberately pay attention to planning process of selection and employees´ recruitment.

A2: We assume, that companies, which deliberately plan the process of searching and recruiting of employees in companies, consequently prepare and carry out selection of employees.

Selection of employees:

A3: We assume that companies which deliberately prepare and carry out selection of employees, consequently accept principles of diversity of applicants within their selection.

A4: We assume, that companies, which deliberately prepare and carry out selection of employees, apply innovative methods of employees´ selection (assessment centre, chat bots, video interviews, diagnostic methods).

MATERIAL AND METHODOLOGY

Today´s concept of human resource management has started to evolve in order to form the core of the whole management. This new approach has helped to enhance significance of a human being as a key to organisation´s

success. Human resource management no longer contains only strategic aspects but focuses on external factors of formation and placement of people within an organisation as well, e.g. population development, labour market, value orientation and social conditions.

The aim of the paper is to assess implementation of these innovative approaches within specific areas of personnel management in food businesses across Slovakia.

Primary research was focused on activities within personnel management in food businesses working in Slovakia. Based on the data available on the website of the Statistical Office of the Slovak Republic, in the first quarter of 2019 there were 587 988 economic subjects in Slovakia. Out of which 4434 subjects were working, according to the statistical classification of economic activities SK NACE, in the sector of CA „Food, beverages and tobacco production. Even though the given number represents only 0.75% share of all the economic subjects, food businesses in Slovakia are an important part of national economy and they significantly influence production of domestic foodstuffs and beverages and at the same time they provide work positions for population.

A questionnaire called „New trends in human resource management in food businesses" was created based on elaborated theoretical results. The first part consisted of identification questions such as a company size, legal form, capital share of the company and the region of Slovakia in which the company operates. Each area contained several questions and thanks to specific statements we found out whether a specific activity within human resources is performed by the companies. We also searched how new trend in individual parts of business are implemented. Positive, rather positive, neutral, rather negative or negative attitude to question was expressed on a five-level Likert scale.

The questionnaire was, within the pilot research in February 2019, tested on a sample of 20 companies in the Nitra region. After little modification, the final research was done from March to April 2019, the questionnaire was provided by a phone call arrangement or e-mail arrangement to 470 food businesses operating in Slovakia. The respondents who answered the questions were mostly the managers from human resource departments. In case that the organisation did not have a specific department for human resources, the questionnaire was filled in by the manager or the owner, responsible for this area. By the beginning of May 2019 we received electronic or a printed version of 453 filled questionnaires ready for use, elaboration and evaluation.

The research included 70 big, 125 middle, 148 small and 110 micro companies. From the organisational-legal business form point of view we focused exclusively on companies which are incorporated (160) or limited (293) because there are various businesses with different legal forms in Slovakia to control assumptions we wanted to ensure representativeness of a selection file as for the organisational-legal business forms.The research included 379 exclusively Slovak businesses, 35 exclusively foreign businesses and 39 businesses with a combined capital share. As for the territorial point of view, there were food businesses from all the eight regions of Slovakia.

The questionnaire´s answers were elaborated and classified which enabled consequent verification of the given research assumptions by selected mathematical-statistical methods and formulation of suggestions and recommendation for the practice.

Except for the questionnaire, we carried out managed structured interviews in selected food businesses from February to March, providing us with entrance to the issue of human resources and enabled us with quality analysis of the given issue from another point of view, even though the answers of the respondents can be considered as partially subjective.

Nevertheless, we used the method of monitoring, findings of which served as a contribution within discussion, formulation of suggestions and conclusions.

Statistical analysis

Processing the data, obtained by the questionnaire, was done through table processor MS EXCEL 2016. The data was evaluated through statistical software SAS Enterprise Guide 7.1.

The consistency of a selection file was found by Cronbach alpha coefficient. Cronbach alpha coefficient belongs to widely used methods of scale reliability evaluation and represents level of the internal consistency. If Cronbach alpha coefficient reaches values of 0.7 and more, it represents sufficient internal scale consistency **(Benda-Prokeinová, 2014)**.

From the data obtained from the questionnaire, where respondents had a possibility to express the level of approval or disapproval with the statement on a five-level Likert scale, we found the characteristics of a position. According to **Prokeinová (2010)**, through application of basic descriptive characteristics we gain values of modus and averages of individual respondents´ preferences.

In the next part of the research we applied correlation analysis. Correlation analysis represents, according to **Benda-Prokeinová (2014)**, statistical approach which describes a relationship between numeral variables. The more the absolute value of correlation coefficient reaches one, the stronger the dependence and vice versa, the more it reaches zero, the weaker the dependence.

For testing statistical hypothesis resulting from research assumptions, mathematical-statistical methods – non parametrical test were applied: Kruskal-Wallis test and Spearman coefficient. We searched for differences in answers of the questionnaire based on specific identification symbols, dependence between two variables, as well as the power of this dependence **(Markechová, Stehlíková and Tirpáková, 2011; Rimarčík, 2007)**.

Except for the questionnaire, we realized managed structured interviews in selected food businesses from February to March, providing us with the entrance to the issue of human resources and enabled us with quality analysis of the given issue from a different point of view, even though the answers of the respondents can be considered as partially subjective. Nevertheless, we used the method of observation, findings of which were a contribution for a discussion, formulation of suggestions and recommendations and making conclusions.

RESULTS AND DISCUSSION

Employees are an important part of each company, therefore it is important to have right people in right

places. To have a reliable and responsible employee is not easy, as labour market is currently facing a lack of qualified personnel and is also recording a limited amount of work offers. Nowadays, companies have to attract a potential employee, not vice versa. People have the opportunity to select from various work offers, they are interested in what an employer can offer them. An organisation needs to have a good reputation, a right strategy, organisation culture and quality system of motivation and remuneration of employees.

Searching and recruitment of employees

To find and obtain the most appropriate candidate to occupy work place is not an easy task. Present-day labour market is marked with globalization, ongoing technological progress and occupational competitiveness results in talent fight. Potential of an employee, thus level of their abilities and skills, becomes inevitable part of every society´s prosperity.

Situation on the labour market is, from the employers´ point of view, demanding, as a number of free work positions still surpasses number of unemployed. To hire a new employee is becoming more and more difficult and costly. Therefore, many companies start to realize, that it is more effective to keep those working in the companies.

Searching and recruiting best candidates for a position is an activity, which contains identification and searching adequate work sources, informing about vacant work positions in an organisation, providing these vacant work positions, in negotiation with candidates, in receiving adequate information about candidates and in organisation and administrative arrangement of all these activities.

In the 1st round of questions of the questionnaire, respondents expressed the level of their approval or disapproval on a five scale range within three statements regarding searching and recruitment of potential employees:

-Process of searching and recruitment of employees in company is planned and we pay target attention to it.
-Within searching and recruitment of employees we use even innovative forms and ways.
-Within searching and recruitment of employees we apply even active searching of „talents“ or „headhunting“(„hunting for brains“).

In two questions, the respondents selected more alternatives and could select one or more answers:

Searching and recruitment of employees is realized traditionally by:

-personnel agencies,
-cooperation with educational institutions,
-recommendations of employees,
-advertisement in media,
-Profesia.sk,
-other.

Searching and recruitment of employees is realized by new forms:

-Facebook,
-LinkedIn,
-Twitter,
-Instagram,
-others.

For more comprehensive interpretation of research results we selected characteristics of average and modus, which can be used within questions with the possibility of answers on a five scale range. In the first round there were three such questions and their average and most common answers are showed in the Figure 1.

The bar graph represents average answers of respondents (data is shown in the basis of the graph) and the line graph shows the most common answers of respondents (data is shown above the graph).

Statement „Process of searching and recruitment of employees in a company is planned and we pay a target attention to it“ is approved by the most of the respondents because 67.77% respondents answered either partially or absolutely agree with this statement. Only 4.19% of companies expressed that they absolutely disagree with the statement. An average answer was 3.98 regarding the answer „I partially agree“ and the most selected value was 5, representing absolute approval.

An average answer of the representatives of food businesses within the statement „Within searching and recruitment of employees we use even innovative forms and ways“ reached 2.97, representing answer I rather agree than disagree and at the same time modus represented the same value. From the overall number of companies only 15.23% absolutely agreed with this statement and 18.10% absolutely disagreed with the statement.

The statement „Within searching and recruitment of employees we apply even active searching for talents or headhunting (hunting for managers)“ reached absolute disapproval of 43.7% companies. Absolute approval was expressed by 9.27% and partial approval was expressed by 8.6% companies. An average value selected was 2.2, representing possibility „I partially disagree“ and the most frequently selected value was „I absolutely disagree“ (1).

Except for the questions where respondents had a possibility to express level of approval or disapproval with the statement, there were, within the first round, „searching and recruitment of employees“ included two questions with more possibilities of answers, from which the respondents could select one or more answers. As the results of the research show, 53.8% companies within searching and recruitment of employees by traditional methods, they rely on recommendations of their employees. Some more than 40% of companies use advertising in media and portal www.profesia.sk. Personnel agencies are used by 20.5% of companies and using Office of Labour, Social Affairs and Family is used by 5% of companies for searching for employees.

If companies implement even innovative ways and possibilities of searching and recruitment of employees, 67.4% of them use social network of Facebook, 13.6% Instagram and 9.8% LinkedIn. Almost 20% of the representatives stated that their company does not use any innovative forms and ways of searching and recruitment of employees.

In the next step, using SAS Enterprise Guide 7.1, we realized Kruskal-Wallis test, to find out whether there are statistically significant differences among the answers of companies according to their size, legal form of business, capital participation of business or region, in which the company operates.

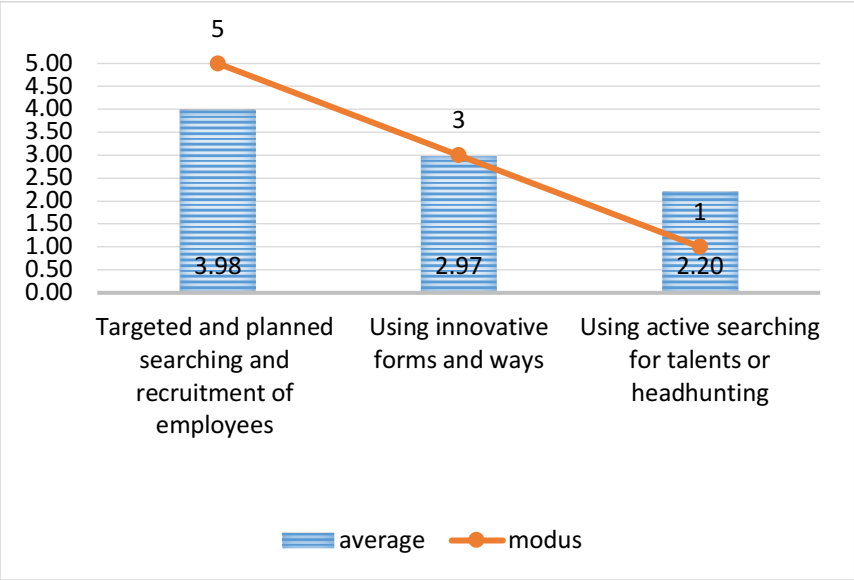

Figure 1 Characteristics of postion evaluating searching and recruitment of employees.

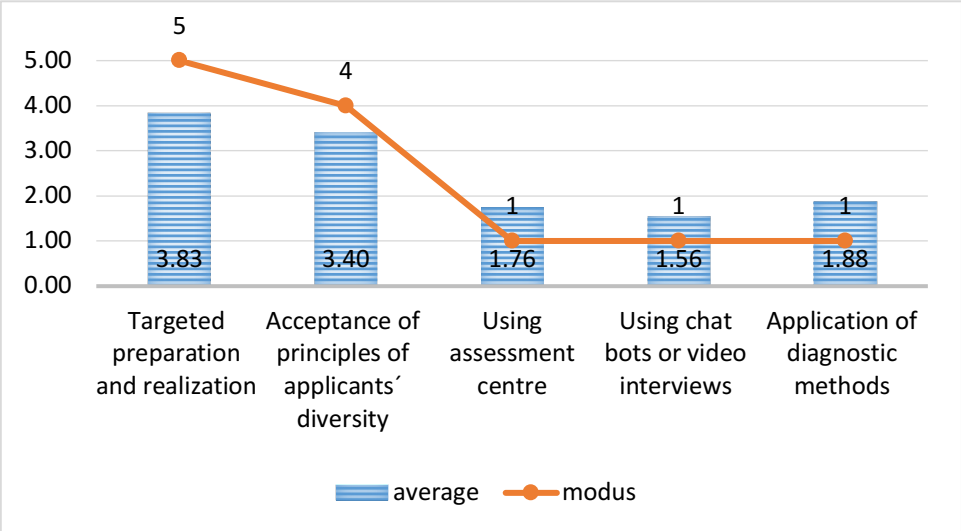

Figure 2 Characteristics of the position evaluating employees´ selection.

Table 1 Results of Kruskal-Wallis test – searching and recruitment of employees.

	Values of Kruskal-Wallis test according to			
	Company size	**Legal form of business**	**Capital participation of the company**	**Region**
Targeted and planned searching and recruitment of employees	<0.0001**	0.6876	<0.0001**	0.1637
Using innovative forms and ways	0.0025**	0.1494	<0.0001**	0.2089
Using active searching talents or headhunting	<0.0001**	0.0562	<0.0001**	0.0494*

Note: * statistically significant differences on the level of significance 0.05. ** highly statistically significant differences on the level of significance 0.01.

The results of Kruskal-Wallis test are shown in the Table 1. Values marked as „*“ represent statistically significant differences on the significance level 0.05 and values marked as „**“ represent highly statistically significant differences on a significance level 0.01.

In case of targeted and planned searching and recruitment of employees, we can see that within the company size and capital participation of the company, the value of Kruskal-Wallis test was lower than 0.0001. Thus, there are statistically significant differences in the answers pf companies based on their size as well as capital participation of companies. Legal form of business and region, in which the company operates, does not have an influence on targeted and planned searching and recruitment of employees and vice versa – size of a company and capital participation does have an influence on it.

Based on Kruskal-Wallis test, we can state that size of a company and its capital participation has influence on using innovative forms and ways of searching and recruitment of employees. We can state that legal form of business sand region in which the company operates, do not influence using innovative forms and ways within searching and recruitment of employees.

Application of active searching of talents or headhunting within searching and recruitment of employees is not influenced only by legal form of business. Thus, there is no difference in whether the company is incorporated or limited, from the statistical point of view there are no differences in answers of these companies. However, in case of the region, in which the company operates, there are statistically significant differences on a significance level of 0.05. We can state, that size of company, capital participation and the region in which the company operates have influence on application of active searching of talents or headhunting.

To find out the power of dependence among individual questions from the questionnaire of the research, we used SAS Enterprise Guide 7.1 values of Spearman correlation coefficient for combination of questions. Values marked with “**” mean, that they are highly statistically significant at the level of significance 0.01.

As the first, we found out power of dependence among the questions of the first round. The values can be seen in Table 2. The highest correlation reaches value of 0.36598 and consequently is marked as „**“ meaning that it is highly statistically significant. Based on the interpretation of correlation coefficients according to **De Vaus (2002)**, this statistical dependence between the third and the fifth question, is middle to significant. We can state, that there is middle to significant positive dependence between using innovative forms and ways of searching and recruitment of employees and application of active searching of talents or headhunting. The remaining two correlations are highly statistically significant as well but represent low or middle dependence.

Except dependences among questions of the first round we were interested in dependences among questions of the first and the second round. Values of Spearman correlation coefficient are given in the Table 3. Values marked with “**” mean, that they are highly statistically significant at the level of significance Alpha = 0.01. Values marked with “*” mean, that they are statistically significant at the level of significance Alpha = 0.05. The highest dependence can be seen between the questions 1 and 6, where the value found, was 0.47605 which is highly statistically significant and represents middle to significant dependence. We can state, that between planned searching and recruitment of employees and targeted preparation and detailed realization of selection of employees, there is middle to significant dependence.

Selection of employees

The main objective of the employees´ selection is to perform analysis and sort out applicants for specific position, compare them with the requirements and requests of the organisation, and to select the applicant who would be the best choice for the organisation.

Within the employees´ selection we can use an approach characteristic for modern human resource management, consisting of the fact that it pays more attention to whether the applicants fulfil conditions of specific position as well as requirements of organisation as a whole. These requirements include even ability to work more effectively as a member of a team. These characteristics are needed to be taken into account in case that an applicant is a member of the TOP management of the organisation, or if their position is in production.

Within the second round of questions of the questionnaire, regarding employees´ selection, and application of new trends within selection, the respondents expressed level of approval or disapproval with the following statements:

-Employees´ selection is prepared and realized in a detail.
-Within employees´ selection we accept principles of applicants´ diversity.
-Employees´ selection is done by assessment centre.
-Within employees´ selection we use chat bots or video interviews.
-Within employees´ selection we apply even diagnostic methods (such as personal cards packet, table of requested work, motivation table, creative pattern, brain teasers, etc.).

Average answers and the most common answers of companies´ representatives are shown in the Figure 2. The bar graph represents average answers of respondents (data is given in the basis of the graph) and the line graph shows the most common answers of the respondents (data is given above the graph).

The most common value selected, expressing respondent´s answer to the statement „Employees´ selection is prepared and realized in a detail“ was value „5“ „I absolutely agree“. This value was selected by 37.5% of managers. The value „4“ „I partially agree“ was selected by 28.03% companies, representing together 65.53%. Average selected value was 3.83. It represents answer „I partially agree“. Only 5.73% of the respondents absolutely disapproved of this statement. Average value of approval with the statement „Within employees´ selection we accept principles of applicants´ diversity“ was 3.40. This one is between the answers 3 and 4, closer to 3 expressing the answer „I rather agree than disagree“. The most common answer reached the value of 4, so 30.63% companies „partially agree“ with the statement. Absolute approval was expressed by 19.20% companies. Together,

the value represents 49.83% of companies, which partially or absolutely agreed with the statement.

Statement „Employees´ selection is done by assessment centre“ was absolutely approved by only 19.20%. Up to 58.28% of the respondents absolutely disapproved of this statement, representing the most common answers at the same time. Partial agreement was expressed by 20.75% of the respondents, representing together 79.03% of the companies, which partially or absolutely do not use assessment centre within employees´ selection. Average answer had a value of 1.76 – closest to the answer „I partially disagree“.

The average value selected within statement „Within employees selection we use chat bots or video interviews“ was value of 1.56. It ranks among the answers „I absolutely disagree“ „I partially disagree“ (values 1 and 2). The most common answer was „I absolutely disagree“, that was the answer of 73.51% of the respondents. 3.09% of the respondents absolutely agreed and 5.96% agreed partially. Together, only 6.05% agreed partially or absolutely.

The most common answer to the statement „Within employees´ selection we apply even diagnostic methods (such as personal cards packet, table of requested work, motivation table, creative pattern, brain teasers, etc.“ was, same like within the previous two answers, „I absolutely disagree“, stated by 55.85% of the representatives of companies. Average answer was 1.88 of the value. 18.32% of the companies expressed that the „partially disagree“. Only 4.41% of the companies absolutely approved and 8.83% partially agreed.

With the aim to find out, whether there are statistically significant differences between the answers of the respondents of the companies according to the size, legal form of business, capital participation of the company or region, in which the company operates, we performed, same as before, Kruskal-Wallis test. The results of the test are shown in Table 4. The values marked as „*“ represent statistically significant differences on the significance level 0.05 and values marked as „**“ represent highly statistically significant differences on the significance level of $\alpha = 0.01$.

Based on the realised Kruskal-Wallis test, we can state that size of company and capital participation have significant influence on targeted preparation and detailed realization of employees´ selection, as their value is lower than 0.0001 and we can confirm highly statistically significant differences. The region, where the company operates has influence on targeted preparation and detailed realization of employees´ selection. The value 0.0107 represents statistically significant differences in the answers of respondents. Legal form of business in this case does not have statistically significant influence.

In case of acceptance of diversity principles, from table it is clear that within size of company, legal form of business as well as capital participation, the value is lower than 0.0001, which proves the existence of highly statistically significant differences. As for the region, in which the company operates, the value is 0.0327, representing statistically significant differences. Based on our findings we can state that, all four factors have influence on acceptance of applicants´ diversity principles within selection of employees.

Table 4 shows that using assessment centre within employees´ selection is influenced by all the factors (size of company, legal form of business, capital participation of company and region in which the company operates), because within all four the result of Kruskal-Wallis test is smaller than 0.01. There are highly statistically significant differences in answers of companies on significance level 0.01.

In case of using chat bots or video interviews there are highly statistically significant differences within size of company and capital participation of company. We can state that legal form of business and region where the company operates, do not have influence, and on the contrary, size of company and capital participation of company have a significant influence on using chat bots or video interviews within employees´ selection.

Application of diagnostic methods within employees´ selection is significantly influenced by one identification symbol. Within all the factors there is a value lower than 0.01. Thus, in every case, there are highly statistically significant differences in the answers of the respondents.

Within the topic of „employees´ selection“, identification symbols of companies show significant influence on respondents´ answers.

Another research continued by finding values of Spearman correlation coefficient in order to find out the power of dependence among the questions of the second round.

Relationship among questions of the first and the second round was already solved and it is given above within the issue of „Searching and recruitment of employees“.

Values, showed by relationship among questions of the second round, are in Table 5. Values marked with “**” mean, that they are highly statistically significant at the level of significance 0.01. The highest value in the table expressing dependence, has a value of 0.52563 and at the same time it is highly statistically significant. It represents significant to very strong dependence between using assessment centre and at the same time using chat bots or video interviews within selection of employees.

The second highest correlation has a value of 0.44927, it is highly statistically significant and it ranks among questions 9 and 10. It represents middle to significant dependence between using chat bots or video interviews and applying diagnostic methods within employees´ selection. In the table there are other two correlations which are from then category of middle to significant, they are grey colour and they both are highly statistically significant. From the rest of the correlations there are four highly statistically significant, they represent low to middle dependence and two of them are not statistically significant. All the correlations in Table 5 belong to positive correlations.

Verification of the given research assumptions

Within the sub-chapter „Material and methods“ we formulated research assumptions. Based on realized analysis and mathematical – statistical methods they were verified and the results are as follows:

Table 2 Values of Spearman correlation coefficient for questions of the firs round.

	Question 1	Question 3	Question 5
Question 1	1.00000	0.29455**	0.19779**
Question 3	0.29455**	1.00000	0.36598**
Question 5	0.19779**	0.36598**	1.00000

Note: ** highly statistically significant on the level of significance 0.01.

Table 3 Values of Spearman correlation coefficient for questions from the first and the second round.

	Question 6	Question 7	Question 8	Question 9	Question 10
Question 1	**0.47605****	0.26992**	0.10504*	0.00987	0.13867**
Question 3	0.25829**	0.23726**	0.29350**	0.23360**	0.22435**
Question 5	0.18453**	0.21970**	0.44102**	0.40921**	0.41106**

Note: * statistically significant on the level of significance 0.05. ** highly statistically significant on the level of significance 0.01.

Table 4 Results of Kruskal-Wallis test – employees´selection.

	Values of Kruskal-Wallis test according to			
	Size of company	Legal form of business	Capital participation of company	Region
Preparation and detailed realization	<0.0001**	0.4431	<0.0001**	0.0107*
Acceptance of principles of applicants´ diversity	<0.0001**	<0.0001**	<0.0001**	0.0327*
Using assessment centre	<0.0001**	0.0023**	<0.0001**	<0.0001**
Using chat bots or video interviews	0.0051**	0.1798	0.0004**	0.2183
Application of diagnostic methods	<0.0001**	0.0040**	<0.0001**	0.0008**

Note: * statistically significant differences on the level of significance 0.05. ** highly statistically significant differences on the level of significance 0.01.

Table 5 Values of Spearman correlation coefficient for questions of the second round.

	Question 6	Question 7	Question 8	Question 9	Question 10
Question 6	1.00000	0.37320**	0.18601**	0.06095	0.16014**
Question 7	0.37320**	1.00000	0.15239**	0.05211	0.16284**
Question 8	0.18601**	0.15239**	1.00000	**0.52563****	0.41664**
Question 9	0.06095	0.05211	**0.52563****	1.00000	0.44927**
Question 10	0.16014**	0.16284**	0.41664**	0.44927**	1.00000

Note: ** highly statistically significant at the level of significance 0.01.

Searching and recruitment of employees

A1: We assume that companies deliberately pay attention to planning process of searching and recruitment of employees.

The first research assumption was accepted. Based on characteristics of the position of answers we state that two thirds of respondents partially or absolutely agreed with the statement about planning process of searching and recruitment of employees of company.

A2: We assume that companies which plan the process of searching and recruitment of employees in company, plan and realize selection of employees as well.

The second significant assumption was accepted based on values of Spearman correlation coefficient which proved positive dependence between the target planned process of searching and recruitment of employees and of detailed preparation and realization of employees selection, of providing possibilities of their improvement, of providing possibilities for their development and education and at the same time perceiving communication as an important attribute of cooperation in the company and outside. The strongest dependence among the three given above was proved between planning process of searching and recruitment of employees and detailed preparation and realization of employees´ selection.

Employees´ selection

A3: We assume that companies, which deliberately prepare and realize employees´ selection, at the same time accept applicants´ diversity principles within their selection.

The third research assumption was accepted. If companies deliberately prepare and realize process of employees´ selection, they try to accept and follow applicants´ diversity principles.

A4: We assume that companies that deliberately prepare and realize employees´ selection, apply innovative methods of employees´ selection (assessment centre, chat bots, video interviews, diagnostic methods).

The fourth research assumption was not accepted. We suppose that those companies which prepare and realize employees´ selection, will, within this kind of activity use innovative methods. We found out only very low dependence between preparation and realization of employees´ selection by using assessment centre as well as applying diagnostic methods. In case of using chat bots and video interviews there was no statistically significant influence found. Based on literature sources we assumed that assessment centre is very used method within process of employees´ selection. Based on our findings we can therefore state that between preparation and realization of employees´ selection and using assessment centre there is above mentioned positive dependence.

The process of economic growth greatly depends on the qualification and use of human resources, of the creative, dynamic capacity of the human factor in the unfolding of economic life **(Lušňáková et al, 2018)**. According to **Armstrong and Taylor (2015)**, intention of human resources is to ensure that organisation has employees who are necessary to fulfil the entrepreneurial goals. Therefore, the objective is to ensure competitive advantages of organisation through recruitment, stabilization and development of employees. The diversity of jobs and lack of candidates force the employers to find creative ways to recruit new employees **(Briscariu, 2019)**.

Among the human resources processes, recruitment has been considered to be one of the most important ones. Many theories nowadays emphasize the importance of recruitment practices in the welfare of an organisation, stressing that its impact is crucial even in the business financial performance **(Vejsiu, 2019)**. Process of employees´ recruitment should start with planning, establishing number and time span of the necessity to occupy vacant positions. Then it leads to time span of addressing applicants from the external and internal labour market. The advantage of internal searching is the acquaintance of employees, support for flexibility and internal mobility reflected in career development, stabilization, and improvement of work ethics **(Lawrel and Boudreau, 2009)**. As for our research, food businesses in Slovakia which were included into research of using new trends in human resource management, they expressed their effort to plan human resources in company, however some of the addressed representatives of companies did not know exactly how to define what human resource management includes. Especially representatives of domestic micro and small companies (mostly owners) explained that because of exceeded bureaucracy and duties, they have no time left for systematic work with human resources.

In spite of the fact that the analysed food businesses in Slovakia plan the process of searching and recruitment of employees and they pay attention to it, the representatives´ standpoint was neutral as for using innovative forms and ways of searching and recruitment of employees. The new ways include e-recruitment, which utilizes available computer network services, especially web sites and e-mail **(Šikýř, 2014)**. The Internet offers employers additional options for communicating with potential job seekers, such as creating and developing social networks (Facebook, LinkedIn, Myspace, and Google+), and virtual communities of users with common interests. Social networks enable job seekers to publish their professional and personal profiles and give employers the opportunity to reach out to suitable job candidates in their enterprise **(Vetráková et al., 2018)**. Companies within searching and recruitment of employees very occasionally apply active searching for talents or headhunting. This condition should therefore be changed. The reason is given by **Grenčíková (2015)** and she writes that quality work force is becoming a competitive advantage. It is an advantage especially for employers who offer interesting work conditions. The author did not mean financial evaluation but relationship between the employer and employees. According to **Lenčéšová et al. (2018)** it is complicated for the companies in Slovakia to find and obtain talented employees or professionals. This issue is not only connected with small and medium sized companies.

Social media serves as a mediator for the effect of external knowledge flows on firm innovativeness when firms attach high importance to modern HRM practices. Taken together, the findings of **de Zubielqui, Fryges and Jones (2019)** underscore the importance of modem HRM practices to enable knowledge inflows via social media to influence innovativeness.

Food businesses in Slovakia, according to our findings, prepare and realize employees´ selection. They, anyway, had neutral standpoint to acceptance of applicants´ diversity principles within their selection. **Horváthová, Bláha and Čopíková (2016)** on the other hand, write about necessity to manage cultural work forces and take into account individual and group differences in needs, in work styles and various aspirations. It is important to take steps for everybody to be satisfied, to provide ethic approach of all the employees, which is based on equality principle and we all have the same rights and deal equally with everyone regardless the sexual orientation, religion, race, political ideals and various beliefs.

The area of employees´ selection, according **Bělohlávek (2017)**, includes the main methods of interview, assessment centre and various types of tests on working ability. The selected companies within employees´ selection only occasionally use assessment centre, chat bots, video interviews and other innovative methods. **Lisá (2019)** states, that ability to predict, is very limited, during testing traditional curriculum vitae. Well-designed assessment centre best predicts success of an applicant on a work position but it can only be used within the most complicated work positions or with university based applicants.

Recruiting and selection process are the most interesting functions for western researchers when we write about green human resources management **(Shahriari and Hassanpoor, 2019)**. In commitment-based human resource management, employees are hired based on their knowledge, their expertise is developed, and they are empowered to take reasonable risks in the interest of long-term outcomes. HRM policies, which mediated by innovative work practices, enable firms to realize their strategic intention to engage in innovation **(Ko and Ma, 2019)**. Effective leadership of human capital is a major managerial issue. Hiring and keeping employees is key to sustainable competitive advantage **(Smith and Rupp, 2004)**.

CONCLUSION

The important assumption for working and prospering organisation is to ensure the whole process, from human resource planning through searching and recruitment of work force, employees´ selection, their adaptation, education and development, communication and motivation, support of creativity and work environment and all the other areas should be secured on the highest level possible within active implementation of innovative processes to all the areas of human resource management. Based on realized analysis we can see the effort of companies to understand importance of implementation of innovative processes within personnel management, however practical application of processes in practice is very rare. If company wants to work effectively, investment into planning, recruitment, development and sustainability of employees is the cleverest decision possible.

Resulting from the results of the analysis of implementation of innovative processes within personnel management in food businesses in Slovakia, we recommend to:

- provide professional planning of human resource management in short time and in ling time perspective regardless the size of company, organisation. legal form, capital participation and establishment,
- immediately start intensive using available, effective and especially financially less demanding innovative ways of searching and recruitment of employees, like for example social networks,
- think and implement strategy of obtaining the best employees, who would be willing to work for a company and remain there; for example by headhunting, together with searching for talents, necessary for the company to have,
- intensively search for information and opportunities to discuss things with professionals, educational institutions and other organisations, how to apply new processes to every kind of activity within work with human resources, as new trends are used by food businesses in each area of human resource management minimally or not at all,
- within employees´ selection, apply maximally principle of diversity and get rid of any prejudices, support employees´ selection through time less demanding and effective video interviews, role playing and with maximum usage of assessment centre and so forth.

SUBSTANTIATION OF BASIC STAGES OF GLUTEN-FREE STEAMED BREAD PRODUCTION AND ITS INFLUENCE ON QUALITY OF FINISHED PRODUCT

Olga Shanina, Sergii Minchenko, Tetyana Gavrysh, Yuriy Sukhenko, Vladyslav Sukhenko, Volodimir Vasyliv, Natalia Miedviedieva, Mikhailo Mushtruk, Myroslav Stechyshyn, Tatyana Rozbytska

ABSTRACT

Development and introduction of high quality gluten-free products is one of the priorities of food industry. Feasibility of producing gluten-free steamed bread based on rice and corn flour using flaxseed, sunflower, sorghum and quinoa flour additives is proved in the article. Recommended ratios of flours are established: Frc:Ffs 95:5, Frc:Fsn 95:5, Fcn:Fqn 85:15, Fcn:Fsg 90:10. The parameters of dough kneading are studied and the influence of additives on relative elasticity, plasticity and resilience is established. Use of additives leads to a decrease in irreversible relative deformation of dough for 36 – 68% and relative plasticity for 16 – 18%, to increase of its elasticity relative resilience up to 2.3 times. Dough fermentation process is investigated. It is established that amount of carbon dioxide accumulated in gluten-free dough increases by 10 – 30%. Process of acid accumulation during fermentation is studied. A flow chart for the production of gluten-free steamed bread is proposed. The parameters for the production of gluten-free steamed bread were established and justified. Product is prepared in a single-phase method, adopted in practice of baking bread. The duration of dough mixing is 10 – 15 min, fermentation 20 – 35 min. Steam treatment is carried out under atmospheric pressure. Recommended steam processing time is 35 min for bread based on rice flour, 30 min for based on corn flour. In comparison with the traditional technological scheme, it is recommended to use a double boiler instead of an oven.

Keywords: gluten-free; steamed bread; rheology; dough slackness; fermentation

INTRODUCTION

The imbalance of the diet of the world population in modern economic conditions leads to a constant shortage of essential nutrients that are necessary for consumption, especially in case of diseases associated with gastrointestinal tract functioning. Unfortunately, today quality, biological value, safety and pricing of food products do not always meet the requirements of sick people. Therefore, the development and introduction of high quality gluten-free products is one of the priorities of food industry.

Production of specialized food products, free from certain ingredients, and gluten-free products are one of the largest segments of this market today. Use of structure-forming additives of polysaccharide nature in technologies of bakery, confectionery, macaroni products can simulate a structure similar to traditional flour products. The main drawback of such products is their reduced nutritional and biological value, lack of protein, vitamins and minerals. This problem can be solved by introduction of high protein ingredients, primarily soy isolates and concentrates, peanut protein isolates, lupine, caseinates, synthetic vitamins and trace elements, etc.

At present scientists have developed a wide range of gluten-free foods – breads, muffins, biscuits made of buckwheat and rice flour **(Havrylova, 2007; Drobot, Mykhonic and Hryschenko, 2010; Kuznetsova, 2010; Lazorenko, 2013; Dorokhovych, Lazorenko and Omelyanchenko, 2014)**. However, the segment of Ukrainian market of steamed bread production is still not developed. The fact is that steamed bread is a traditional Chinese bread made from wheat flour or its mixture with rice. This product is widely distributed in the eastern countries (mainly in China, Japan, Korea, Thailand), as well as in the USA, Canada and some European countries **(Huang et al., 1996)**. Its advantages include slowing of glucose absorption processes during steam treatment, which reduces glycemic index; absence of melanoid formation reaction, which reduces losses of lysine and other water-soluble amino acids; absence of harmful acrylamides that are not formed during steam treatment **(Addo et al., 1991; Liu et al., 2012; Zhang et al., 2014; Huang and Miskelly, 2016; Fu, Chang and Shiau, 2015)**.

To create a competitive technology of steamed bread scientists are currently searching for the following directions:

- adaptation and correction of world experience in the production of steamed bread;
- expansion of raw material base and assortment of gluten-free steamed bread products;
- improvement of structural and mechanical properties of steamed bread.

Understanding the main aspects of regulating the nutritional value of gluten-free steamed bread, forming its quality, regulating the properties and expediency of using enriching flour raw materials will contribute to developing products with high nutritional and organoleptic quality indicators available to all population groups.

There are three main types of traditional steam bread in China: Northern Type, Southern Type and Taiwan Type. Northern steamed bread is used as the main food product, while Southern and Taiwan, with a sweet taste, are used most as desserts **(Lin, Miskelly and Moss, 1990; Wang et al., 1995; Zhu et al., 1997; Fan et al., 2009; Hao and Trust, 2012; Ma et al., 2014; Fu, Shiau and Chang, 2014; Zhu, 2014; Wu and Shiau, 2015)**.

The variety of steamed bread technology can be combined according to such classification feature as a way of dough making into three main groups: sourdough, sponge and straight dough method.

The first method is usually used in domestic production and in small private enterprises. In this way, sourdough is added by 10% to the mass of flour, than a required amount of water is added and dough is mixed for 5 – 10 minutes. The fermentation lasts 3 hours at temperature of 26 – 28 °C and a relative humidity of 75%. Due to the presence of lactobacilli, dough pH is 3.7 – 4.0, so after fermentation 40% of Na_2CO_3 solution is used. To achieve the desired pH value of dough (6.4 – 6.7), on average, it is necessary to add a solution of Na_2CO_3 in an amount of 0.5% to the mass of flour. Neutralization of dough is critical in the production of steamed bread, since with excessive amounts of Na_2CO_3, color of products varies from yellow to dark gray, and the smell is expressed in alkaline. If the dough is not brought to the required pH, steamed bread has an acidic smell, low volume, unobtrusive appearance and excessively rigid structure. The introduction of an alkaline solution neutralizes acids that are released by lactobacilli when the dough precipitates, which helps to increase the release of carbon dioxide. Depending on the technology, the dough can be subjected to swirling after neutralization **(Li et al., 2012, Wu and Shiau, 2015)**. The finished dough is rolled and twisted into a long baffle and divided into pieces weighing 100 – 130 g, and then formed in oblong or rounded billets. Further, the dough pieces are subjected to proofing for 30 minutes at a temperature of 32 – 36 °C and relative humidity of 75 – 80% and steamed for 15 – 20 minutes **(Wu and Shiau, 2015)**.

Sponge dough method is widely used in steamed baking technology. The production process involves the following operations: sponge preparation, fermentation, dough kneading, rolling, forming, splitting into pieces, proofing and steaming. 80% of flour is mixed with yeast and water for sponge preparation. Yeasts are pressed or dried. After 60 minutes of fermentation at a temperature of 32 °C and a relative humidity of 80%, 20% of flour is added together with other ingredients **(Fu, Shiau and Chang, 2014; Li et al. 2015)**. There are two main advantages to using the sponge dough method. First, it is possible to develop a flexible fermentation schedule for different batches of bread; and secondly, the bread has a finely porous homogeneous structure of crumb and bright aroma. However, the sponge dough method requires higher labor costs, production space and a long process of production **(Fu, Shiau and Chang, 2014; Zhang et al., 2014)**.

Straight dough method is much simpler than previous one, because of simplicity and speed of the process, and therefore the most widespread. Straight dough method of steamed bread preparation is significantly shorter than the first two, but rather sensitive to duration change of technological process in industrial production. For example, if a technological scheme is not developed sufficiently, one batch of dough can achieve the optimum fermentation, while others will be overfermented or underfermented. In addition, bread will have less homogeneous structure and lower organoleptic and technological characteristics than bread produced by sponge dough method or using sourdough **(Kawamura-Konishi et al., 2013; Fu, Shiau and Chang, 2014)**.

The most important stage that results in the receipt of high quality products is bread proofing **(Meredith, 1965; Chen and Gan, 1997; Moayedallaie, Mirzaei and Paterson, 2010)**. The degree of proofing affects the shape, color, structure and aroma of finished products. Traditionally, proofing of the dough pieces is carried out at a temperature of 32 – 37 °C and a relative humidity of 70 – 80%. In most cases, the optimal duration of the process is determined visually by pressing on the surface of a piece. It is believed that optimally fermented dough pieces have shining and elastic surface that quickly restores its shape after pressing **(Meredith, 1965)**. However, this method of estimation lacks stability, so D. Chen **(Chen et al., 2010)** developed a standard method for evaluating the optimal duration of dough proofing. Under this method, 25 g of dough for the production of steamed bread is placed in a cylinder, diameter 3 cm and a volume of 45 mL. The amount of dough on average is 21 – 22 mL. After proofing, the final volume of dough for Southern steamed bread should be 38 mL, for Northern and Taiwan 45 mL **(Hou, 1991)**.

The final stage of production is the steamed treatment of dough pieces. The pieces are placed in an oven with steam convector and stem for 15 – 30 minutes at atmospheric pressure **(Sivaramakrishnan, Senge and Chattopadhyay, 2004)**.

The assessment of steamed bread quality is carried out by evaluation of the specific volume of products, organoleptic and consumer indicators. The standard specific volume of steamed bread of different types differs because of the differences in prescription composition. Southern steamed bread traditionally has a higher specific volume (average 3.5 – 3.7 $mL.g^{-1}$) than Northern (average 2.0 – 2.5 $mL.g^{-1}$) due to greater porosity. Steamed bread should have an elastic structure and quickly turn the shape on after pressing. High quality steamed bread should have a smooth and shiny surface of white color without yellow stains and symmetrical shape. Crumb of steam bread should be of white color, uniform fine porosity structure,

elastic and with high humidity **(Turabi, Sumnu and Sahin, 2008; Kim et al., 2009)**.

Increasing cases of celiac disease diagnosis, as well as low quality of available gluten-free products, prompts researchers to find new ingredients and technologies that can replace gluten and improve the properties of gluten-free bakery products.

Many scientists around the world are working on the development of gluten-free products. The main areas of development are the exclusion or modification of gluten from gluten-free raw materials and the complete exclusion of gluten-free raw materials from prescription mixtures. Relatively to the first direction, today research is conducted on the selection of gluten-free wheat, using genetic engineering **(Stoven, Murray and Marietta, 2012)**. However, the research data are under development. Therefore, the second direction of the solution of gluten-free products issue is more widespread. According to it, it is recommended to mix different types of gluten-free flour (mainly rice, corn, millet and buckwheat). The main problem of these technologies is to provide the structure of products, which is usually provided by gluten. In most cases, hydrocolloids (xanthan, gum, modified starches, etc.) **(Lobacheva, 2013; Medvid et al., 2017)**, enzymes (for example, transglutaminase) **(Shanina, Lobacheva and Gavrish, 2013; Lobacheva, 2015)** and sourdough **(Yeh et al., 2009)** are suggested to be used to solve this problem.

As a rule, gluten-free flour mixtures include four groups of food components: flour with high content of starch and non-starch polysaccharides; emulsifiers, dough fluffers, flavor ingredients; hydrocolloids; high protein ingredients **(Barsukova, Reshetnikov and Krasilnikov, 2011)**.

In our opinion, the most prospective enhancer of the bread structure made of rice flour (Frc) or corn flour (Fcn) is flour gluten-free raw materials with enriching action (FGFRM) – sorghum (Fsg), flaxseed (Ffs), quinoa (Fqn) and sunflower (Fsn) According to review of literary sources, the listed additives can improve structure of gluten-free products and their nutritional value due to the high content of complete proteins, as well as macro- and micronutrients. All of the given data relate to gluten-free bread, which is subject to baking, however, when steam is used for treatment, other thermal and biochemical processes can change the organoleptic, structural and mechanical properties of the final product, as well as its nutritional and biological value.

Scientific hypothesis

Conducted researches are aimed at determining the peculiarities of main stages behavior in gluten-free steamed bread production. Therefore, in order to achieve this goal, the primary task is to study the effect of FGFRM on the progress of main technological stages in steamed bread production, the structural and mechanical properties of dough, quality and consistency of final product.

MATERIAL AND METHODOLOGY

The following flour products are selected for experimental research and production testing:
-rice flour TM «Sto pudov»;
-corn flour TM «Sto pudov»;
-sorghum flour TM «Asparagus-LTD»;
-flaxseed defatted flour TM «Viva»;
-sunflower defatted flour TM «Efavit»;
-quinoa flour TM «Vivan».

For experimental studies flour is sieved through a laboratory nylon sieves with a hole size of 120 μm. The following ratio of components in flour mixes is selected:
-rice flour : flaxseed defatted flour (Frc:Ffs) – 95:5,
-rice flour : sunflower defatted flour (Frc:Fsn) – 95:5,
-corn flour : quinoa flour (Fcn:Fqn) – 85:15,
-corn flour : sorgum flour (Fcn:Fsg) – 90:10.

To obtain the liquid phase of dough, 1.75% of yeast is added to the mass of flour mixture in whole formulation of water (58 – 59% for bread based on rice flour and 63 – 64% for bread based on corn flour), salt is added in amount of 1.5% and stirred until a homogeneous solution is obtained. The flour mixture is moistened with a liquid phase to a given humidity and left for 25 – 30 minutes at a temperature of 30 – 35 °C for fermentation. After that, the dough pieces of 50 g are placed in baking pans pre-greased with sunflower oil, and left for 20 minutes at a temperature of 30 – 35 °C for proofing. Further, baking pans are placed in a laboratory steam oven TM «Moulinex» and subjected to steam treatment for 25 – 35 minutes. After that, bread is removed from baking pans and left at room temperature until it is completely drained.

Acidity of flour is determined by titrating water-flour suspension and aqueous-alcohol extract from the 0.1 N solution of NaOH in the presence of phenolphthalein **(Fedin, 1989)**. Rheological properties of dough are investigated using the Tolstoy elastoplastometer. Irreversible deformation, relative elasticity, plasticity and resilience are determined according to the standard method **(GOST, 1988)**.

Dough slackness is determined by **(Fedin, 1989)**. The titrated and active acidity of dough is determined according to **State standard DSTU 5024:2008** Total nitrogen of flour is determined by the Kjeldahl method **(GOST, 1987)**. Amount of protein is found by multiplying the content of total nitrogen by a conversion factor of 6.25. Gas-forming ability and rate of gas formation are determined in parallel with degree of dough loosening by the method **(Kuznetsova, 2010; Zapototska, Pichkur and Lysyj, 2013)**. Calculation of dry matters loss while fermentation is carried out in terms of glucose by the amount of CO_2 released during fermentation, using the fermentation Gay-Lusak equation for glucose **(Drobot, Mykhonic and Hryschenko, 2011)**.

Loss of carbon dioxide during fermentation is found by integration of area under fermentation curves. Changes in dough volume during fermentation are determined using 500 mL measuring cylinder, which contained 10 g of dough and kept at a temperature of 30 – 35 °C. Volume of dough is fixed every 60 seconds during 60 minutes. Water-retaining ability of dough is determined using a moisture balance **(Fedin, 1989)**.

Statistical analysis

Approximation of obtained experimental data was carried out using the least squares method, as well as MathCAD Prime 3.1 mathematical package and EXCEL 2016 spreadsheet packet, SPSS professional statistics version

17, statistical software Statistica 10.0. Degree of credibility for all experiment is 0.95.

RESULTS AND DISCUSSION

Dough mixing stage has a significant impact on the quality of finished products. During the mixing, structure of dough and subsequent structural and mechanical properties of products are formed. Dough has at the same time elastic-resilience and plastic-viscous properties. The phenomenon of resilience contributes to preservation of a given shape of products during formation, and elasticity allows to increase the productivity of dough kneading. Hydrocolloids addition significantly increased the gelatinization temperature (from 52.0 to 64.2 °C) and water absorption (from 56.22 to 66.50%) of dough **(Liu et al., 2018)**.

To evaluate elastic-resilience and plastic-viscous properties of dough for gluten-free steamed bread, study is conducted on a Tolstoy elastoplastometer. The humidity of the prototype samples is 45%.

Figure 1 shows the loading and unloading curves of gluten-free dough based on rice and corn flour. At the loading part of the curve, three areas can be distinguished – instantaneous resilience deformation, high elastic deformation, and a section of system flow. It can be noted that flour additives affect the resistance of rice flour dough and increase its strength. The effectiveness flaxseed and sunflower flour is not significantly different. The obtained results of corn dough research show similar tendencies. First of all, introduction of FGFRM significantly affects the reduction of irreversible relative deformation by 36 – 68%.

Introduction of flaxseed or sunflower flour contributes to an increase in relative elasticity of dough and to a decrease in resilience (Table 1). This result can be explained by high fat content in flaxseed or sunflower flour.

The results indicate that addition of FGFRM to corn dough in all cases contributes to increasing of its elasticity. This tendency is positive because of significant fragility of corn dough. At the same time, the relative plasticity decreases slightly by 16 – 18% and relative resilience increases (up to 2.3 times when using sorghum flour).

Obtained data correlates well with studies of dough slackness (Figure 2). It was established that for 3 hours of dough relaxation with addition of FGFRM slackness is 11 – 23% less than control samples which agrees with the reduction of irreversible relative deformation.

Thus, improvement of rheological characteristics of gluten-free dough based on rice or corn flour with addition of sorghum, flaxseed, quinoa and sunflower flour is experimentally proved. Therefore, these types of FGFRM can be considered as prospective in terms of structure formation of dough for gluten-free bread. According to research of rheological characteristics of dough, the introduction of FGFRM leads to improvement of dough resilience and elasticity, therefore, the increase of kneading duration, used in traditional technology of steamed bread, has no grounds. Thus, it is recommended to knead dough for 5 – 10 minutes.

The viscoelastic properties of the different doughs strongly influenced the bread volume and the crumb texture. Thus, starch-based breads showed higher specific volume and lower hardness during fermentation **(Martínez and Gómez, 2017)**.

The most important indicator of fermentation process efficiency is gas-forming ability, since this indicator directly affects the specific volume and porosity of final product. Change in dough acidity also has a great practical importance: with its increasing, the processes of protein swelling and peptization are intensified, which is accompanied by a change in their rheological properties **(Kuznetsova, 2010; Drobot, Mykhonic and Hryschenko, 2011)**. Active acidity of dough determines the presence of sour taste in bakery products, as well as intensity of enzymatic processes and influences on activity of microorganisms (in particular, yeast).

An important factor that determines baking properties of flour raw materials is intensity of dough fermentation. Use in gluten-free dough formulation FGFRM in order to regulate its technological properties significantly influences fermentation intensity and activity of amylolytic enzymes of flour (Figure 3 and Figure 4). It should be noted that fermentation of gluten-free dough is more intense than wheat, so the study is conducted for 100 minutes. Results show that addition of FGFRM leads to an increase in the amount of carbon dioxide in gluten-free dough by 10 – 30%. We believe that this dependence is due to the sufficient amount of sugars in FGFRM, especially flaxseed and sorghum, which can provide high quality products during technological process. In comparison with advanced technologies which include ultrasound treatment and increase this index only by 6.7% **(Luo et al., 2018)**, it is a significunt result.

On the basis of experimental data on flour gas-forming ability, speed of gas formation in dough was calculated (Figure 4).

In order to establish recommended dough fermentation regimes, study of dough volume changes is conducted. It is found that the addition of FGFRM slightly shifts the peak of fermentation process (Figure 5).

The results of research show that use of FGFRM leads to a slight slowdown in the process of dough fermentation. In most cases, accumulation peak of carbon dioxide is shifted by 10 minutes. In all cases of FGFRM use gas-retaining ability increases, which correlates with an increase in specific volume and porosity of bread.

Thus it is determined that the recommended duration of fermentation of dough based on rice flour with addition of flaxseed is 35 – 40 minutes, with the addition of sunflower 20 – 30 minutes, dough based on corn flour with addition of quinoa or sorghum 25 – 35 minutes.

Intensity of acid accumulation in dough is estimated by changing the active and titrated acidity parameters during fermentation. The results of experimental studies are presented in Figure 6 and Figure 7.

It should be noted that for the use of FGFRM indices of initial and final acidity of dough are different, however, the intensity of acid accumulation process has a similar nature.

It is noteworthy that flaxseed flour reduces active acidity of dough, and sunflower, on the contrary, increases this index. For 100 minutes of fermentation, the index of titrated acidity varies for a sample made from rice flour from 1.22 to 2.18 °H (a difference is 0.96 degrees) in sample Frc + Ffs – from 1.5 to 2.0 °H (difference is 0.50 degrees) in the sample Frc + Fsn – from 1.1 to 2.0 °N (difference is 0.9 degrees).

Change in active acidity of dough based on rice flour during fermentation is also identical. Thus, for 100 minutes of fermentation, the sample Frc has a pH value of 5.3, sample Frc + Ffs – 4.98, sample Frc + Fsn – 5.51.

Reducing pH value when we add flaxseed flour and higher values of the initial acidity of the sample Frc + Ffs are due to the accumulation of oxidation products of fats contained in this raw material.

Thus, according to the research complex, it can be concluded that dough with addition of FGFRM in the process of fermentation can provide necessary level of microbiological and enzymatic processes for obtaining bakery products with organoleptic properties of high quality.

Although the production of gluten free bread still remains a technological challenge, research continues to find innovative approaches to improve the quality of gluten free bread. Literature shows that an important aim is to imitate the gluten-network by combining several ingredients, from which hydrocolloids play a crucial role. Also crosslinking enzymes have been increasingly investigated. On the other hand, a carbohydrate network formed by arabinoxylans offers an innovative and more natural approach for improving gluten free products **(Wang, Guo and Zhu, 2016; Bender and Schönlechner, 2020)**.

In production of gluten-free steamed bread baking process is replaced by steam treatment to prevent formation of acrylamides and other carcinogens and preserve food and biological value of final product. Steam treatment is more gentle mode, which is significantly different from traditional baking. When the processing time in the steam chamber increases, the quality is almost unchanged, but the cost is increased. Therefore, to assess the quality of steamed bread, it is important to find the value of heat treatment duration, in which film-like crust is formed on surface of products, the starch is gelatinized, proteins are denaturated, crumb loses excessive

adhesiveness and the products acquire good consumer properties.

Taking into account the foregoing, to determine the duration of heat treatment by steam, adhesiveness of surface of gluten-free bread, smell, taste and yield of finished products are determined with addition of FGFRM (Table 2 and Table 3).

Steam treatment of gluten-free steamed breads based on a mixture of rice and flaxseed flour for 20 minutes results in a sticky texture of the crumb and surface. Products can not be completely separated from baking pads. After 25 minutes after the start of heat treatment bread is well separated from baking pads, but there is increased adhesiveness in the middle of crumb. 30 minutes later bread is well baked throughout the volume, but still there is a yeast smell and taste of raw dough. Thus, recommended durability of heat treatment with steam of bread based on rice and flaxseed flour is in a ratio of 95:5, which is 35 minutes.

With an increase of steam treatment duration, the yield of finished products is slightly increased, which can be explained by moisture binding by biopolymers of flour raw materials. A similar trend is observed in the sample based on rice and sunflower flour in the ratio of 95:5. Study of gluten-free steamed breads based on corn and sorghum flour in the ratio of 90:10 and corn and quinoa flour in the ratio of 85:15 shows that good consistency of the crumb and surface can be achieved with steam treatment duration for 30 minutes. In such conditions, the smell and taste of bread corresponds to ready products. Recipes and methodologies are grouped by (main) starch source and list other ingredients, additives and treatments used **(Masure, Fierens and Delcour, 2016)**. Additional ingredients significantly change quality of steamed bread. Thus, implementation of inuline, fresh steamed bread gained the highest score, possessing a lighter color, higher specific volume and softer texture **(Kou et al., 2019)**. Use of bran is also able to rise quality of steamed bread, improving surface smoothness, crumb structure and stress relaxation scores **(Ma, Lee and Baik, 2018)**.

The results confirm that it is possible to reach the full readiness of bread based on rice flour after 35 minutes of steam treatment, and on the basis of corn flour after 30 minutes.

According to the results of experimental studies, it is established that the technological stages of gluten-free steamed bread production do not undergo significant changes. A new kind of equipment is the steamer that is installed to replace the oven. Product is prepared in a single-phase method, adopted in practice of baking bread. The duration of dough mixing is 10 – 15 min, fermentation 20 – 35 min. Steam treatment is carried out under atmospheric pressure.

FGFRM is supplied to the plant bakery by flour tracks. Flour from cistern of a flour track is loaded into silos for storage under pressure through pipes and filter. Additional raw materials (salt, sugar) are dissolved and sent for storage in containers. Preparation of other raw materials for production is carried out in accordance with "Technological instructions for the production of bread and bakery products". Yeasts are diluted with water in containers and sent to a dosing station for liquid components, followed by dough preparation. When working on the line, gluten-free flour from the silos is dispensed and supplied to scales automatically. Then flour enters the intake filter. The flour is cleaned from impurities on a screen with a magnetic trap. Next, a gluten-free flour mixture is formed. A better usage of cereal by-products as valuable ingredients in foods would aid the economics and the sustainability of cereal chain **(Čukelj Mustač et al., 2020)**. Components of mixture are weighed on automatic scales, mixed in a screw mixer and loaded into silos. To knead dough, gluten-free flour is weighed and sent to a dough machine. Additional raw materials (solutions of salt, sugar, yeast) are sent to dough machine from containers, through the station for liquid components dispensing. Kneaded and fermented dough is sent to dough separator, with help of which portions of the dough of the same mass are received. After this, the manipulator, using a dividing table, stack the dough pieces of a certain mass and form into proofing cabinet. Proofing of dough pieces is carried out during 10 – 15 min at temperature of 30 – 32 °C and relative humidity of 65 – 70%. Dough pieces after proofing are put to the steamer for steam treatment. Products are treated with steam for 30 – 35 min at a temperature of 92 – 97 °C. Finished products get to the circulation table by drain device gutter of finished product, a stacker loads them to a container. Trays with products are loaded to truck. Gluten-free steamed bread can be packed in different ways, for example there is effective technology with use of vacuum degree **(Xu et al., 2020)**.

CONCLUSION

Obtained results show that addition of FGFRM leads to a change in the main stages behavior of gluten-free steamed bread production.

Use of FGFRM leads to a decrease in irreversible relative deformation of dough for 36 – 68% and to increase of its elasticity. At the same time, the relative plasticity decreases by 16 – 18% and the relative resilience increases (up to 2.3 times when using sorghum flour). The recommended duration of dough mixing is 10 – 15 min.

In the presence of FGFRM, the amount of carbon dioxide accumulated in gluten-free dough increases by 10 – 30%.

Recommended duration of fermentation of rice flour dough with the addition of flaxseed is 35 – 40 minutes, with the addition of sunflower 20 – 30 minutes, for dough based on corn flour with the addition of quinoa or sorghum 25 – 35 min.

Use of FGFRM does not affect the intensity of acid accumulation process. It is established that flaxseed flour reduces active acidity of dough, and sunflower, sorghum and quinoa flour, on the contrary, increases this index.

Recommended steam processing time is 35 min for bread based on rice flour, 30 min for based on corn flour.

Technological scheme of production of gluten-free steamed bread is offered. Compared to the traditional one, it is recommended to use a steamer instead of oven.

EXTRACTIVE STRIPPING VOLTAMMETRY AT A GLASSY CARBON PASTE ELECTRODE FOR ANALYSIS OF COW'S MILK AND CREAM

Granit Jashari, Michaela Frühbauerová, Milan Sýs, Libor Červenka

ABSTRACT

In this paper, a procedure based on extractive accumulation of milk fat globules (MFGs) into a pasting liquid (lipophilic binder) of glassy carbon paste electrode (GCPE) with subsequent electrochemical detection by square-wave voltammetry (SWV) in 0.1 mol L^{-1} Britton-Robinson buffer of pH 4.0 has been tested to find out whether it can be utilized as a simple screening analytical method for cow's milk and cream nutrition control. Since there is assumption that the necessary alkaline hydrolysis of cow's milk and subsequent extraction of lipophilic vitamins into an organic solvent could be avoided, several GCPEs differing in type (atactic polypropylene, paraffin oil, paraffin wax, silicone oil, and vaseline) and content (5, 10, 15, 20, and 25%; w/w) of pasting liquid used were tested as part of complex optimization. The obtained results show that MFGs contain predominantly vitamin A (carotenoids and retinoids), especially all-*trans*-retinol, which could serve as significant marker of the fat content. However, their individual forms were not possible to distinguish due to the considerable anodic peak broadening (overlapping).

Keywords: carbon paste electrode; cow's milk; extraction; milk fortification; nutrition control; voltammetry

INTRODUCTION

In the mammary glands, milk fat globules (MFGs), ranging in size from 0.1 to 15 μm in diameter **(Logan et al., 2014)**, originate as fat droplets composed largely (>98%) of triacylglycerols (TCGs). These fat droplets are evenly emulsified throughout the volume and contain lipophilic (fat-soluble) vitamins dissolved in them **(Heid and Keenan, 2005)**. Losses of naturally occurring lipophilic vitamins are significant after mechanical separating the milk fat (cream) from the raw milk. Obtained skimmed milk is then homogenized that is a process of breaking down the large fat droplets under high pressure so that they stay together and do not separate as cream. To improve the nutritional values, the homogenized milk is usually fortified by extra vitamins (retinyl palmitate and cholecalciferol) and minerals that are not naturally found in milk in significant amounts **(Trinidad et al., 2015)**.

The cow's milk and products made from it are considered as very complex sample matrixes and their analysis is often complicated and time-consuming **(Trenerry et al., 2011)**. Valid reference analytical methods used for lipophilic vitamins determination in foodstuffs in laboratories of the Czech Agriculture and Food Inspection Authority 211/2004 Coll4. utilize a HPLC with UV detection, known as standard: ČSN EN 12823 (vitamin A), ČSN EN 12821 (vitamin D), ČSN EN 12822 (vitamin E) and ČSN EN 14148 (vitamin K). In addition, a gravimetric method (EN 1211) is used to determine milk fat content.

Evaluation of the lipophilic vitamins content in milk (also dairy produce) has its substantiation, especially in case of human nutrition which deals on provision of essential nutrients in food necessary to support human life and health **(Haug et al., 2007)**. Moreover, analytical methods for simultaneous determination of lipophilic vitamins and their provitamins in milk using microcolumn **(Gomis et al., 2000)**, narrow-bore column **(Blanco et al., 2000)** and two-dimensional liquid chromatography **(Zhang et al., 2015)** have been developed.

Time-consuming sample preparation is the most challenging step in the analysis as it involves several steps (alkaline hydrolysis, liquid-liquid extraction, filtration and evaporation of organic solvent) in which the analytes may be lost **(Trenerry et al., 2011)**. To avoid degradation of analytes, the alkaline hydrolysis shoud be carried out in presence of an antioxidant, under an inert atmosphere, and in absence of light.

A simple semiquantitative method for the determination of vitamin D in skim milk is worth mentioning **(Michlová et al., 2012)** when a sample is diluted with water, ethanol, and an aqueous ammonia solution. Vitamin D is subsequently extracted with a mixture of ether and hexane

for 4 hours. After evaporation of the organic solvent, vitamin D is transferred to the appropriate solvent (usually methanol or acetronitrile). The advantage of this procedure is that the sample does not need to undergo alkaline hydrolysis.

This paper offers a simple screening voltammetric method for monitoring vitamin A content (sum of retinoids and carotenoids) in cow's milk and cream samples without the need for a use complicated sample preparation. Since all lipophilic vitamins are electrochemically active organic compounds that undergo oxidation (vitamins A, D and E) or reduction (vitamin K) electrode reactions **(Lovander et al., 2018)**, they can be directly extracted from the milk into a pasting liquid (nonpolar binder) of glassy carbon paste electrode (GCPE). After transferring GCPE into an aqueous working medium (medium−exchange approach), the electrochemical detection of accumulated vitamins can be performed using a pulse voltammetric technique **(Sýs et al., 2019)**, namely square-wave voltammetry (SWV).

Scientific hypothesis

In this work, an effort was to find out whether square-wave anodic stripping voltammetry at GCPE can represent a suitable method for rapid determination of vitamin A.

MATERIAL AND METHODOLOGY

Chemicals and reagents

All-*trans*-retinol (≥95%) and ethanol (≥99.5%) were purchased from Sigma-Aldrich. Universal 0.1 mol.L^{-1} Britton-Robinson buffer (BRB), prepared by mixing of appropriate amounts of boric acid, glacial acetic acid, 85% phosphoric acid, and sodium hydroxide all from the aforementioned company, was used in selection of suitable detection medium. BRB was prepared using deionized water (minimum electric resistivity 18.2 MΩ cm, maximum 3 µg L^{-1} of total organic carbon) made in a Milli-Q® ultrapure water system from Merck Millipore (Burlington, USA).

Instrumentation

Voltammetric detection of accumulated lipophilic vitamins into the pasting liquid was performed in a conventional three-electrode arrangement containing always GCPE (working), silver chloride electrode with 3 mol.L^{-1} KCl salt-bridge (reference) and platinum sheet (auxiliary electrode). These electrodes were connected to the potentiostat Autolab PGSTAT101 controlled by software Nova (Version 1.11.0), both from Metrohm (Prague, Česká republika).

Preparation of carbon paste electrode

Glassy carbon powder of type Sigradur G (mixture 5 – 20 µm, HTW Maintingen, Germany) and one of randomly selected pasting liquids were mixed in a ceramic mortar for 15 min to create homogenous glassy carbon paste. The amount of tested pasting liquid differed from 5 to 30% (w/w). The resulting glassy carbon paste was packed into the cavity of the Teflon® piston-driven electrode holder with an end-hole of 3 mm in diameter. It is necessary to mention that the height of column in the cavity must be less than 2 cm due to difficult extrusion of glassy carbon paste. It is recommended that freshly prepared GCPEs should not be employed in any experiments due to their rather unstable electrochemical behaviour attributed to an incomplete homogenization. Consequently, freshly prepared GCPEs were left at the laboratory conditions for one day. After this self-homogenization process, GCPEs can be used for following voltammetric measurements **(Sýs et al., 2017)**.

Methods

Principle of medium-exchange extractive stripping voltammetry is illustarted in Figure 1. The extraction of lipophilic vitamins into the pasting liquid was carried out from 10 mL non-treated milk and cream samples (available in Czech stores) without need to apply a potential in the electrode cell (nonelectrolytic preconcentration), which is an approach known as "open circle procedure". After 10 min, GCPE enriched with analytes was rinsed with a stream of deionized water and immersed together with others electrodes into 0.1 mol.L^{-1} BRB. Final voltammetric detection was performed using square-wave voltammetry at potential range from 0 to +1.4 V, potential step (E_{step}) of 5 mV, potential amplitude (E_{ampl}) of 25 mV and frequency (f) of 50 Hz.

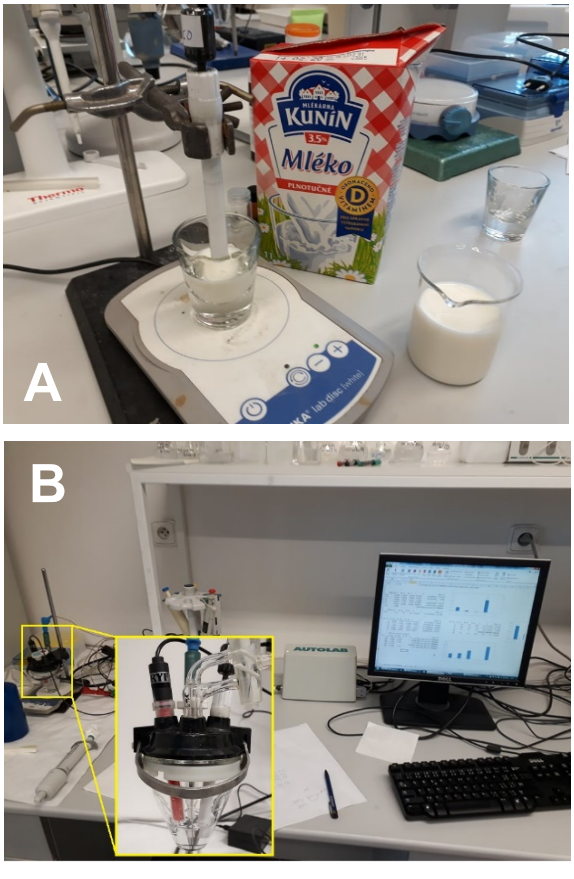

Figure 1 Individual steps of extractive stripping voltammetry with medium-exchange (A; accumulation and B; electrochemical detection using SWV).

Statistic analysis

Extraction repeatability

Generally, the repeability may be expressed by several indexes, nemaly coefficient of repeatability (CR), coefficient of variation (CV) and intra-class correlation

coefficient (ICC). CR defined by formula (1) is a precision measure which represents the value below which the absolute difference between two repeated test results may be expected to lie with a probability of 95%. The standard deviation (σ) under repeatability conditions is part of precision and accuracy.

$$CR = 1.96\sqrt{2\sigma^2} \quad (1)$$

However, the repeatability is more often given by CV defined as the ratio of the standard deviation (σ) and to the mean (μ). If this ratio is expressed as a percentage (see Eq. 2) then it will be referred to as relative standard deviation (RSD).

$$RSD = \frac{\sigma}{\mu} * 100 \quad (2)$$

Sufficient extraction repeatability constitutes the main criterion for development of voltammetric methods utilizing extractive accumulation to be able to use them for analytical purposes. ICC could not be used because units of two physical quantities (variables) were statistically tested only. Therefore, using RSD can be probably expected to be sufficient.

RESULTS AND DISCUSSION

Selection of pasting liquid type

Several GCPEs differing in the type of pasting liquid and containing always 20% (w/w) portion were investigated in SWASV of cow's milk (3.5% fat) to choose the optimum one. Working conditions for this experiment were as follows: accumulation for 10 min, stirring at 400 rpm, electrochemical detection in 0.1 mol.L^{-1} BRB (pH 4.5) at E_{start} = 0 V, E_{end} = +1.4 V, E_{step} = 5 mV, E_{ampl} = 25 mV and f = 10 Hz. Due to relatively high current response and required reproducibility (Table 1), silicone oil should be taken for optimum extraction of lipophilic vitamins.

Table 1 Comparison of glassy carbon paste electrodes.

Pasting liquid	R (Ω)	E_p (V)	I_p (μA)
Atactic polypropylene	10.5 ±0.8	0.831	0.075
Paraffin oil	7.1 ±0.2	0.851	3.69 ±1.6
Paraffin wax	4.7 ±0.3	0.836	0.24 ±0.1
Silicone oil (8000 cSt)	8.0 ±0.2	0.844	1.14 ±0.2
Vaseline	17.4 ±1.0	0.829	0.013

Note: Values (R; ohmic resistance; E_p; peak potential, I_p; peak current response) given as $\mu \pm 2\sigma$ (95% probability) for five repetitions.

Ratio between carbon powder and pasting liquid

Under the prediction, an amount of extracted lipophilic vitamins would increase with a higher content of paste liquid in GCPE. However, electrochemical properties of GCPE are affected by ratio between glassy carbon powder and paste liquid. In principle, it can be stated that carbon particles remain in intimate contact (electrically conductive) until the amount of paste liquid exceeds 30% (w/w) **(Švancara and Schachl, 1999)**.

Surprisingly, it was found that the highest peak current response (unfortunately, background current (I_b) as well) was obtained at GCPE containing 5% (w/w) silicone oil, as demonstrated in Table 2. Despite high current yield, the content of 15% (w/w) silicone oil was chosen as optimum, thanks to the high reproducibility of accumulation. A non-specific adsorption of milk fat onto electrode surface, which acts as an electrical insulator causing a significant increase of background current (baseline signal), can be considered as possible explanation.

Table 2 Effect of silicone oil content in GCPE.

Content (%)	R (Ω)	I_p (μA)	I_b (μA)
5	6.7 ±0.2	10.0 ±0.3	66.4 ±3.50
10	7.0 ±0.3	4.7 ±0.3	8.9 ±0.90
15	4.8 ±0.2	5.1 ±0.3	4.4 ±0.50
20	8.0 ±0.2	1.1 ±0.2	0.9 ±0.02
25	6.0 ±0.1	0.9 ±0.1	0.7 ±0.02

Note: Values (R; ohmic resistance; I_p; peak current response; I_b; background current) given as $\mu \pm 2\sigma$ (95% probability) for five repetitions.

Effect of accumulation time

Principally, the optimum value of accumulation time is defined as a period required for reaching the equilibrium of lipophilic vitamins distribution between a nonopolar pasting liquid of GCPE and used milk sample. The cow's milk can be considered as a direct emulsion (so-called the first type emulsion) because a small amount of fat droplets (organic phase) are uniformly distributed throughout the milk volume (aqueous phase).

Resulting saturation curve describing dependence of current peak height on accumulation time showed a typical extraction equilibrium isotherm, as shown in Figure 2. The extraction equilibrium has been achieved after 600 s because using accumulation for longer period did not cause any significant increase in peak current response. Hence, accumulation time of 10 min was chosen as optimum.

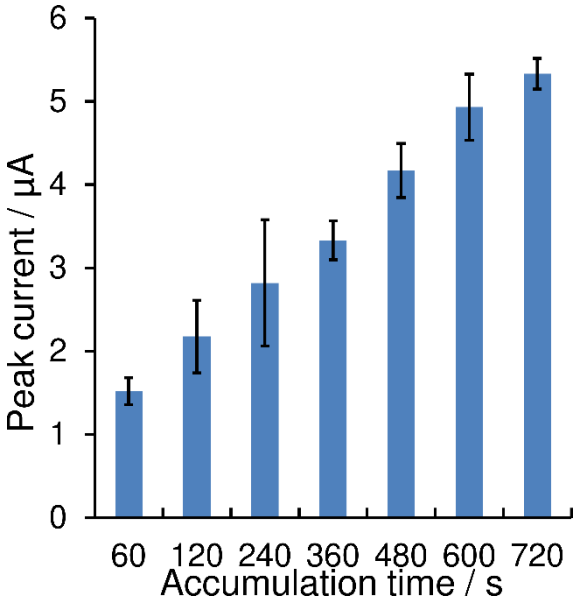

Figure 2 Effect of extraction time on extraction yield of lipophilic vitamins from the cow's milk (3.5% fat).
Note: Data obtained from SWV at GCPE containing 15% (w/w) silicon oil, E_{step} = 5 mV, E_{ampl} = 25 mV, and f = 20 Hz.

Effect of stirring speed

Stirring speed affects the rate of fat droplets transport to the electrode surface where these droples containing lipophilic vitamis are then extracted into the pasting liquid of GCPE. Under this study, it was found that setting the rate of magnetic stir bar higher than 300 rpm did not have any significant effect on increase in final peak current response. Therefore, the above mentioned value can be considered as an optimum for subsequent experiments.

Identification of lipophilic vitamins in cow's milks

The fat dispersed in cow's milks and creams is formed by non-polar TCGs that are surrounded by phospholipids and membrane lipoproteins **(Heid and Keenan, 2005)**. At the natural pH of the cow's milk, they carry a negative charge and thus prevent bonding of MFGs. It is worth considering whether whole MFGs are extracted into the pasting liquid or a further equilibrium distribution of present lipophilic vitamins between the TCGs and the pasting liquid cannot exist. It can be assumed that both processes take place simultaneously. TCGs extracted (adsorbed) block surface of GCPE and therefore cause a dramatic increasing the background current.

From the literature **(Indyk and Woollard, 1997; Hulshof et al., 2006; Trenerry et al., 2011; Musara and Nyagura, 2017)**, lipophilic vitamins are found primarily in the milk fat. Unlike cholecalciferol (vitamin D3) and phylloquinone (vitamin K1) present in limit amounts (0.1 µg per 100 g), α-tocopherol (vitamin E), and retinol together with its provitamines (carotenoids) such as β-carotene, zeaxanthine and luteine (vitamin A) are the major representatives (40-110 µg per 100 g). Moreover, an artificially added retinyl palmitate **(Jensen et al., 1991)** can be present as well.

Generally, most extracted lipophilic vitamins and their provitamins usually provide very broad sensitive oxidation/reduction peaks (up to 250 mV) due to slow kinetic of corresponding electrode reactions occurred at liquid-liquid interface **(Sýs et al., 2019)**. As confirmation, a broad anodic peak beginning +0.705 V at and ending at +1.007 V was obtained for all investigated cow's milks and creams.

It is therefore impossible to distinguish and determine the individual forms of retinoids and carotenoids **(Žabčíková et al., 2018)**. Nevertheless, a number of published scientific papers suggest that the all-*trans*-retinol occupies a dominant position **(Jensen, 1994; Hulshof et al., 2006; Hodulová et al., 2015)**. Thus, it can be assumed that the peak obtained most likely corresponds to the anodic oxidation of all-*trans*-retinol a +0.852 V (compare with (overlapping peak at +0.886 V for cow's milk), as shown in Figure 3.

It seems that proposed extractive stripping voltammetry (ExSV) based on direct immersing of GCPE into continuously stirred cow's milk (3.5% fat) and subsequent electrochemical detection using SWV provides the desired sensitivity for detecting the sum of retinoids and carotenoids. A quantitative or at least semi-quantitative determination of vitamin A in cow's milk and cream samples was not the aim of this study. Voltammetric analysis of cow's milk enriched by differently defined amounts of all-*trans*-retinol could be probably considered as semi-quantitative analytical method.

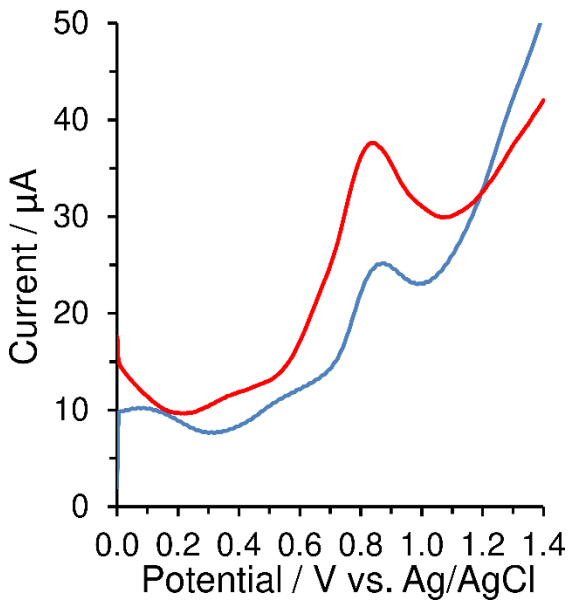

Figure 3 SWV voltammogram.
Note: SWV voltammogram of extracted (at 400 rpm for 10 min) cow's milk (3.5% fat) into GCPE containing always 15% (w/w) silicone oil with subsequent voltammetric detection in 0.1 mol.L^{-1} BRB (pH 4.5) at E_{step} = 5 mV, E_{ampl} = 25 mV, and f = 50 Hz (blue). SWV voltammogram of all-*trans*-retinol extracted (at 400 rpm for 5 min) from its (500 µmol.L^{-1}) 60% ethanolic solutions into GCPE containing always 20% (w/w) silicone oil with subsequent voltammetric detection in 0.1 mol.L^{-1} BRB (pH 4.5) at E_{step} = 1 mV, E_{ampl} = 25 mV, and f = 25 Hz (red line).

Selection of detection medium and supporting electrolyte

Optimisation consisted in finding out proper working conditions for an anodic oxidation of lipophilic vitamins which are presented in MFGs accumulated into silicone oil. At first, the electrochemical detection has been subjected to pH study which was investigated for 0.1 mol.L^{-1} RBRs of pH values from 2 to 7. A linear relationship between peak potential and pH values of used supporting electrolytes, statistically evaluated as E_p = -0.0558 pH + 1.0891 (R^2 = 0.9978), was observed. The peak potential was shifted to more negative values with increased pH of used BRBs. This phenomenon probably occurs due to lowering the energy barrier and easier deprotonation of present lipophilic vitamins. The value of slope 0.0558 indicates the transition of electrons together with protons in a 1:1 ratio. The most sensitive peak current response was achieved using BRBs of pH values 4 and 5. It seems that BRB would be replaced by an acetate buffer of pH 4.5, more simple in composition.

Optimization of square-wave voltammetry

Parameters of SWV, potential amplitude and frequency, were optimised at constant potential step of 5 mV. Extracted lipophilic vitamins provided a broad anodic peak which height increased with increasing potential amplitude up to value of 25 mV. Therefore, potential amplitude of 25 mV was chosen for following analysis of cow's milks and creams. As shown in Figure 4, the height of anodic peak linearly increased with higher frequency. However, it

was observed that background current (baseline) increased as well. Hence, a value of 50 Hz representing a compromise was chosen as optimum.

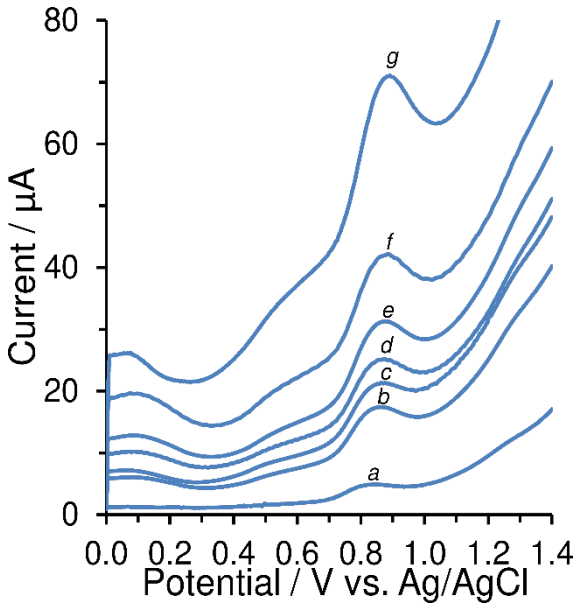

Figure 4 Voltammograms of lipophilic vitamins.
Note: Voltammograms of lipophilic vitamins sum (predominantly all-*trans*-retinol and β-carotene) extracted from cow's milk (3.5% fat) in GCPE containg 15% (w/w) silicone oil at 300 rpm and for 10 min. After rinsing with distilled water, subsequent voltammetric detection was performed in 0.1 mol.L^{-1} BRB (pH 4.5) at E_{step} = 5 mV, E_{ampl} = 25 mV, and f = 10 (*a*), 20 (*b*), 30 (*c*), 40 (*d*), 50 (*e*), 60 (*f*) and 100 (*g*) Hz.

Analysis* of *cow's milks and creams

At first, it is necessary to mention that a sample of whipped cream (40% fat content) could not be analysed using designed protocol due to high viscosity **(Van Vliet and Walstra, 1980)**. The whipped cream completely covered GCPE used and did not allow rinsing the surface with distilled water. At first glance, someone may think that peak current will be higher for creams (*'more milk fat more vitamins'*) **(Gaucheron, 2011)**. According to Figure 5, demonstrating a dependence of anodic peak current on milk fat content in selected samples, it seems that the assumption is misleading. An explanation could be summarized as follows: lipophilic vitamins present in samples are equally distributed between pasting liquid and milk fat during (*'liquid-liquid'*) extraction and these vitamins are more detained in creams (12 - 31%) than in milks (0.5 - 3.5%) due to many times higher fat content (*'like dissolves like'*).

Extraction repeatability

Assuming that MFGs are homogeneously dispersed throughout the volume of cow's milks and creams and their diameter is not higher than 1 µm **(Robin and Paquin, 1991; Michalski et al., 2004)**, an extraction repeability will be affected only by homogeneity of glassy carbon paste used **(Sýs et al., 2017)**. If recovery of developed HPLC-based methods ranging approximately from 85 to 110% **(Blanco et al., 2000; Gomis et al., 2000)** is taken to account, satisfactory repeatability of extraction characterized by RSD lower than 9% was achieved. Even despite the relatively short error bars (see Figure 5), it is not possible to determine, on the basis of the peak heights received, whether it is cream or milk with a 3.5% fat content.

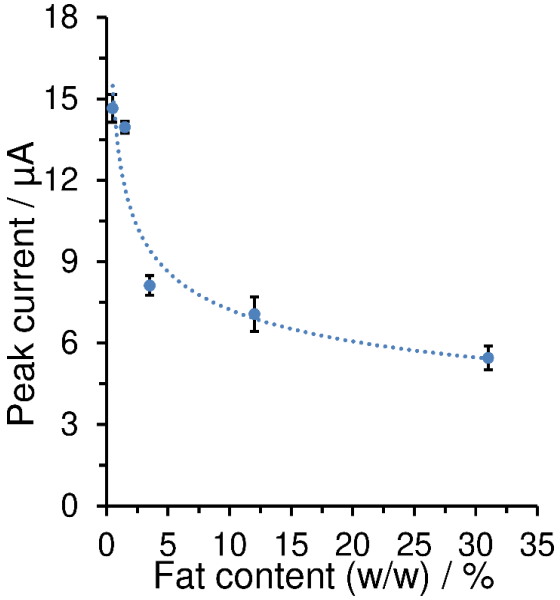

Figure 5 Dependence of peak current response (anodic oxidation of present lipophilic vitamins) on the content of fat in cow's milks and creams.

CONCLUSION

Everyone agrees that the most important part of whole analysis represents a sample preparation at which significant losses of analytes may occur and cannot be detected during the final analysis. Because the extractive stripping voltammetry requires a minimum sample preparation, it was tested as suitable analytical tool for cow's milks and creams quality control. However, the results obtained suggest that direct extraction of lipophilic vitamins (dominantly all-*trans*-retinol) from a continuously stirred sample and subsequent voltammetric detection using square-wave voltammetry could only be used for semi-quantitative determination of milk fat, at this stage of development. Finally, it can be concluded that the scientific hypothesis was refuted.

EVALUATION OF THE FOLIAR NUTRITION INFLUENCE ON SELECTED QUANTITATIVE AND QUALITATIVE PAPRAMETERS OF SUGAR MAYZE (*ZEA MAYS* SK *SACCHARATA*)

Samuel Adamec, Alena Andrejiová, Alžbeta Hegedűsová, Marek Šemnicer

ABSTRACT
We evaluated the effect of foliar application of fertilizer Tecnokel amino Zn on selected quantitative (weight of one corn cob, average length of corn cob, number of grains per row and number of rows per cob) and qualitative (total yield, total carotenoid content, total sugar content) parameters of sweetcorn. The small trail experiment was founded in 2016 in the Botanical Garden of the Slovak University of Agriculture. We observed 7 selected varieties of sweetcorn and two variants: control and with leaf nutrition. 15 plants we revaluated for each variety under both variants. The corn was grown in three repetitions for each variant. Based on the obtained results, we found that both the qualitative and quantitative parameters were mainly dependent on the genotype. Statistically significant was effect of the variety on the total sugar content in maize grains. Influence of foliar nutrition was not confirmed as statistically significant, but Tecnokel amino Zn has a positive impact on several quantitative parameters as weight of one maize ear or average length of corncobs. Content of total carotenoid doesn´t depend on genotype or variant.

Keywords: sweet corn; carotenoids; total sugars; zinc; foliar application

INTRODUCTION
Sweet corn, also known as green maize or sweet maize in many parts of the world, is a crop of New World origin **(Welbaum, 2015)**. It is one of the oldest crops cultivated on the world. Indigenous people in both Americas have known corn as early as 5000 years ago **(Černý, 2011)**. Now, the USA is a leading producer of sweet corn with 236,860 ha with production totalling 3,788,030 metric tonnes. In Slovakia we have sweet corn production with only 1,110 ha and total yield 7,498 t **(Meravá, 2017)**. Sweet corn (*Zea mays* L var. *saccharata* Strut) is one of several types of maize, which also includes flint corn, dent corn, popcorn, flour corn, and pod-corn but sweet corn differs from other corns. The primary difference is gene expression that determines endosperm carbohydrate content as well as many other genes that affect maize growth. Sweetcorn world consumption has increased over the past 30 years. As consumable part are grains of milk ripeness, while production is focused on three distinct markets: fresh, canning, and freezing **(Alan et al., 2014; Andrejiová and Šlosár, 2015; Khan et al., 2018)**. *Z. mays* var. *saccharata* is a warm-season, frost sensitive, annual monocot which belong to family *Poaceae*. For reaching high yields it´s necessary harmonic and balanced effect of all agroecological factors. Accurate growth and development depend on suitable temperatures and proper water regime in deep humous soils **(Welbaum, 2015)**. In animals, carotenoids are the precursors for vitamin A and serve as important antioxidants to prevent many diseases such as cardiovascular disease, cancer and light-induced erythema. Studies have also shown that dietary intakes of lutein and zeaxanthin can reduce the risks of cataracts and age-related macular degeneration (AMD), which is the leading cause of blindness among the elderly. Corn is one of the essential sources of these carotenoids, contains significant amounts of lutein, zeaxanthin, and other carotenoids. Carotenoid content of sweetcorn can reach up to 1,978 $mg.g^{-1}$ of fresh weight. In recent years, many studies have been carried out on carotenoids in sweetcorn. They observed several parameters, among them changes of carotenoids in sweetcorn during thermal processing or the quantification of carotenoids in different genotypes of sweet corn **(Liu et al., 2017; Scott and Eldridge, 2005)**. Sweetness is the major component of flavour affected by the amounts of sugar and starch in the endosperm. Selection more tender and crispy genotypes with higher sugar, lower starch concentration and more intensive sweet corn aroma would increase the eating quality of the product. But sweetness is determined not only by genetics, but also by the agronomics practices, how the respective varieties are managed and harvested **(Alan et al., 2014)**. Zinc (Zn) is an essential micronutrient for plant life and it is a recommended micronutrient in fertilizer programs for production of corn and sweet corn **(Sutradhar, Kaiser and**

Fernándeza, 2017). To fully explore grain production potential of sweet corn, it is essential to know how plants interact morphologically and physiologically in a community and to realize management practices, which allow them to utilize growth resources in their environment **(Hayat et al., 2018)**.

Scientific hypothesis

Foliar application of Tecnokel Amino Zn had not a significant effect on the qualitative and quantitative parameters of corncob. Used preparation positively affected sugar content and the ear of maize size while carotenoids were not negatively affected. The influence of the variety was statistically significant.

MATERIAL AND METHODOLOGY

The trial establishment

An experiment was founded in 2016 in Botanical Garden of Slovak University of Agriculture (below BG SUA) in the field conditions. Area is situated in very warm agro-climatic region, very dry sub-region. The mean annual temperature was 10 °C (Table 1) with average annual rainfalls 62.4 mm per month (Table 2). Meteorological measurements were carried out by the help of meteorological station in the area of botanical garden, SUA in Nitra. The mean monthly air temperature and average rainfall for the year 2016 were evaluated by the climate normal 1961 – 1990.

In the experiment we investigated the effect of foliar nutrition with Tecnokel Amino Zn on selected quantitative and qualitative parameters in the following variants:

- 1st variant (C) – (control) without applying of Tecnokel Amino Zn.
- 2nd variant (Tecnokel Amino Zn) – foliar application of Tecnokel Amino Zn.

For both variants, based on the agrochemical analysis of the soil and the recommended normatives for the cultivation of sweet corn, we applied nitrogen one week before sowing in the form of nitrogen fertilizer LAD (27% N) (60% of the recommended normatives for corn) at a dose of 72 $kg.ha^{-1}$. When plants were 50 cm tall, we applied 40% of recommended LAD normative (27% N) in dose 48 $kg.ha^{-1}$.

Sowing the seeds was into pre-prepared soil on April 26, 2016. Before sowing, we made soil air spacing and removed the weeds. The seeds were sown in space 0.8 m between rows and 0.3 m within rows. During the vegetation. the supplementary irrigation was applied, as well as loosening and weeding of the crop. As corn tended to expel side shoots, we removed them on 8 June.

In the growth phase of 6 – 8 true leaves, (06.06.2017) we applied foliar fertilizer Tecnokel Amino Zn, which plays a key role as a building material and a regulating factor of wide range of enzymes and positively influences the transport of substances in the plant. The dosage of application was 30 $mL.10L^{-1}$ of water applied to the Tecnokel Amino Zn variant. The second application of Tecnokel Amino Zn with dosage 30 $mL.10L^{-1}$ of water was carried out on 21st July after flowering.

Harvesting of sweet maize ears was carried out gradually according to the maturation of individual varieties, in the period from 26th July to 1st August in the milky matured grains stage. Within each variety we evaluated 15 plants from the control and 15 from Tecnokel Amino Zn variant.

Table 4 Agrochemical characteristics of the soil before the foundation of the experiment in 2017.

pH/KCl	humus %	Nutrients content in $mg.kg^{-1}$ of the soil					
		N_{an}	P	K	S	Ca	Mg
7.14	4.17	13.0 M	198.8 VH	487.5 VH	2.5 VH	610 H	816 VH

Note: Nutrient content: M – medium content, H – high content, VH – very high content.

Evaluation of selected quantitative parameters:

In the labs of the Department of Vegetables production at SUA we evaluated the following parameters: weight of one corn cob, length of corn cob, the number of grains per row and the number of rows per cob. Based on the average weight of maize cobs and cultivation spacing, the total yield was calculated.

Laboratory analyses – qualitative parameters

Qualitative characteristics were estimated in the laboratory of Department of Vegetable Production, SUA, in Nitra. For laboratory analysis were used only fresh corn ears in phase of milk grains within of all observed varieties. Weight of one sample – 20g. Both control as well as the Tecnokel Amino Zn variant were observed. Fresh fruit analysis took a place directly after each harvest. Total carotenoids were estimated by spectrophotometric measurement of substances absorbance in petroleum ether extract on spectrophotometer PHARO 100 at 450 nm wavelengths according to **Hegedüsová et al. (2015)**. The determination of total sugars according to **Somogyi (1952)** was carried out at the Department of Agrochemistry and Plant Nutrition.

Statistical analysis

The analysis of variance (ANOVA), the multifactor analysis of variance and the multiple Range test were done using the Statgraphic Centurion XVII (StatPoint Inc. USA).

RESULTS AND DISCUSSION

Total carotenoids

The content of total carotenoids in selected varieties of sweet corn grains without foliar application of Zn ranged from 0.75 to 1.35 mg.100g^{-1} of fresh matter. In the Tecnokel Amino Zn variant, the values ranged from 0.65 to 1.83 mg.100g^{-1}. The highest content of total carotenoids was recorded in the variety Escalante 1.83 mg.100g^{-1} for observed variant. The positive influence of Zn on the content of total carotenoids was observed in varieties Rising Sun, Astronaut, ZHY 1312 OR, Escalate and ZHY 0874 OV (Figure 1). In different experiment **Howe and Tanumihardjo (2013)** reported higher carotenoid content in four varieties of sweet corn ranged from 0.99 to 3.53 mg.100g^{-1}.Based on statistical evaluation of our data obtained by the multifactor analysis of variance, we can state that the variant hadn´t significant influence on the total carotenoids content in fresh corn grains (Figure 4). Effect of the variety on the total carotenoid content wasn´t statistically significant.

Total sugars

Based on the results, we can conclude that all evaluated varieties of sweet corn belong to the Sh-2 group with a storage period of 4 – 7 days. The total sugar content ranged from 3.85% to 8.60% what is comparable with results of **Zaniewicz-Bajkowska et al. (2010)**. They observed the total sugars content in sweet corn in range from 5.61% to 9.02%. In our experiment, the lowest content was recorded for variety ZHY 1312 OR 3.85%. Overture variety obtained highest value of 8.60% (Figure 2). By foliar application of Tecnokel amino Zn at a dose of 30 mL.10L^{-1} of water, we found that the ingested preparation had no statistically significant effect the increase of total sugars in corn grains (Figure 5). Based on statistical analysis, we can conclude that the genotype has a significant effect on the total sugars in the grains at the stage of milk maturity.

Total yield

Haytova (2013) in her review referred that additional foliar application during the growth and development of crops can improve their nutrient balance, which may lead to an increase in yield and quality of crops. Harvesting of maize in our experiment proceeded gradually according to maturation of individual varieties. The average calculated yield achieved in individual varieties and variants is compared in (Figure 3).

During the evaluation of total corn cob yield, we found that within the control variant, total yield ranged from 8.97 t.ha^{-1} in SF 681 variety to 12.52 t.ha^{-1} in Escalate variety. However, the highest hectare yield was 13.14 t.ha^{-1} for the Overture variety without the application of the foliar fertilizer. Similar result was observed also by **Rosa (2015)**, where the average marketable ears yield was 13.0 t.ha^{-1}. The lowest yield per hectare in our experiment reached the SF 681 variety with 8.97 t.ha^{-1}. However, the greatest difference between crops was recorded for the ZHY 1312 variety in favour of the Tecnokel Amino Zn variant 24.01% (Figure 3). Similar results stated also **Fahrurrozi et al. (2016)**. In their study additional foliar fertilization of sweet corn did not significantly influenced growth and yield. **Szczepaniak et al. (2018)** event stated that zinc (Zn) fertilizers applied to maize simultaneously with amino acids (AA) at early stages of its growth may decrease the yield variability due to correcting its nutritional status during the 'critical window' but simultaneously confirm the benefits in order to ameliorate the influence of abiotic stress. However, this combination has positive effect on lettuce plants **(Ghasemi et al., 2013)**. **Grzebisz et al. (2008)** wrote that according to other authors maize plants responded to zinc fertilizer and yielded 10 – 20% more. It supported by positive result of **(Tariq et al., 2014; Liu et al., 2016; Ruffo et al., 2016, Shabaz et al., 2015)**. However, our result may be influenced by an inappropriate proportion of the nutrients applied. **Shabaz et al. (2015)** concluded that this significant enhance of corn yield is because trace elements had a synergic affiliation with other units. **Wang et al. (2017)** and **Iqbal et al. (2016)** also state that Zn combined with K or N can slightly or significantly increased grain yield. The influence of Zn uptake and its effect on corn yield depends on Zn supply in soil **(Eteng et al., 2014)**, what should caused our results. All these results are in consonance with **da Silva et al. (2017)** exhibited increase in corn yield by 0.342 t.ha^{-1} with 83.7% probability of positive response after foliar application of amino acid bio stimulant. **Popko et al. (2018)** confirmed these results. Amino acids bio stimulants increased wheat grain yield and agronomic productivity.

Foliar supply of Zn in the form of complexed with amino acids resulted in a significant increase of total yield and quality also for other species, for example pistachio nuts **(Najizadeh and Khoshgoftarmanesh, 2018)** or soybean **(Teixeira et al., 2018)**. Using the statistical analysis of variance, statistically significant differences in total yield were not proven between the evaluated varieties or variants.

Ear of maize weight

The weight of the corn cobs is one of the most important features for growers when choosing the right variety of sweet corn. During evaluating the weight of the cobs, we found that the highest average weight reached the variety Overture 315.5 g. The lowest average weight was recorded for variety ZHY 0874 OV 218.3 g (Table 5). In the Tecnokel

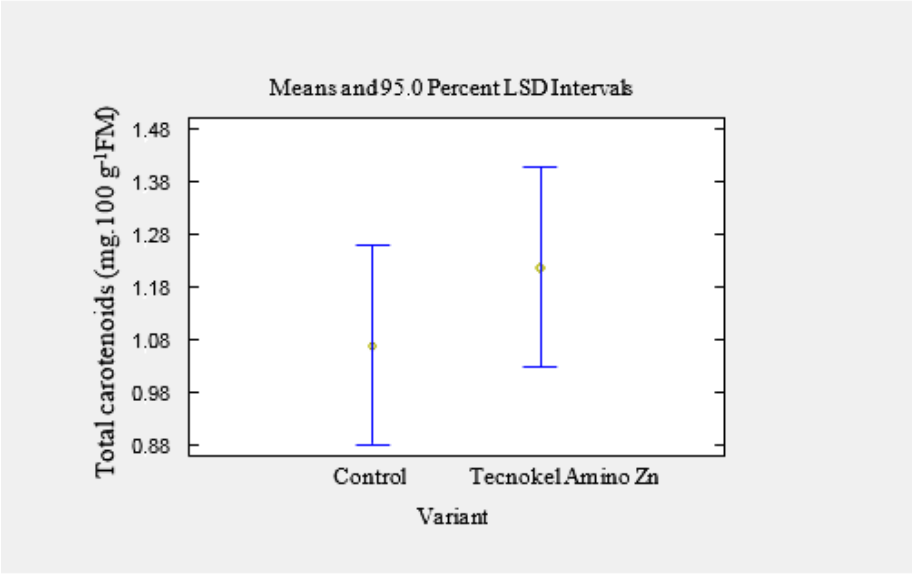

Figure 4 Graphical representation of 95% confidence intervals (p >0.05) for the tested averages of carotenoids content in fresh sweet corn grains and its variants (LSD test).

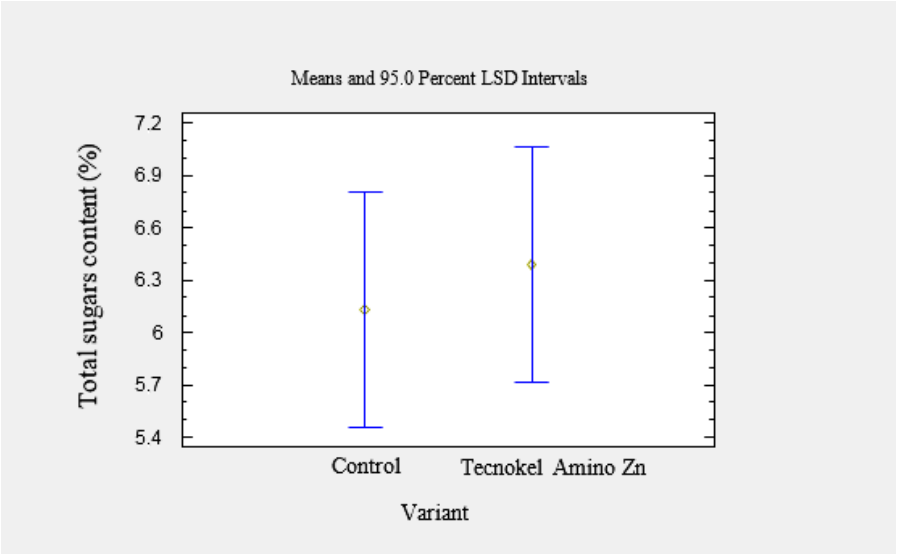

Figure 5 Graphical representation of 95% confidence intervals (p >0.05) for the tested averages of total sugar content in fresh sweet corn grains and its variants (LSD test).

Amino Zn variant, we noted an increase in the weight of the maize-ears for 3 genotypes: Astronaut (by 18.87%), ZHY 0874 OV (by 18.96%) and ZHY 1314 OR where foliar fertilization involved to the highest ears weight grain by 23.92% with average value of 259.7 g. By statistical analysis, we found a statistically demonstrable effect of the variety (genotype) on the weight of the maize ears. We also found that foliar application of Tecnokel Amino Zn fertilizer did not have a statistically significant effect overall, but significantly influenced some individual varieties (Table 5).

Ear of maize length

Barátová (2012) in her work reported results from the evaluation of 8 different varieties of sweet corn. Their ear length ranged from 18 cm to 21 cm. The average length of the strains in our experiment was quite similar and ranged from 19.3 cm to 25 cm. Highest value was caused by extremely long genotype Escalante, which reached average length of corn cobs 25 cm for control and 24 cm for Tecnokel amino Zn variant (Table 6). Due to the foliar application of fertilizer, we observed a slight increase in length for five varieties: Rising sun F1 3.13%, Astronaut 0.51%, ZHY 0874 OV 1.51%, SF 681 1.50%, Overture 1.82%. Statistical evaluation of results showed a statistically significant influence of the variety on ears length (Table 6), but the application of foliar fertilizer Tecnokel Amino Zn did not have a statistically significant effect on the length of corn cobs. It was similar in study **Tadros et al. (2019)** where foliar application of amino acid bio stimulant on sweet corn did not show significant effect on sweet corn ears.

Number of rows in one ear of maize

Strube D&S GmbH gives the following characteristics for cultured genotypes: Rising sun F1 – 14, Astronaut – 20, ZHY 1312 OR – 20, Escalate – 18, ZHY 0874 OV – 18, SF 681 – 20, Overture – 20. For sugar corn, the number of rows

in the ear should be even. In our experiment we recorded average number of rows in the interval between 16 – 21 rows. The highest average value in the number of rows in width 21, was recorded in the Overture variety. By applying zinc to this variety, we have not seen any greater increase in the number of rows. The smallest average values were recorded for the variety Rising sun F1 with 16 rows, but this is more than what the seller report. Also, for variety Overture was measured 8.62% fall in number of rows compared to variant with foliar fertilizer (Table 7). Average values obtained from our tested maize ears were comparable with **Barátová (2012)**. She referred that the average number of rows in ranged with the width of 16 – 18. After statistical analysis of the variance, we found a statistically significant effect of the variety on the number of rows in the ear, but at the same time the effect of the foliar fertilizer Tecnokel Amino Zn was not significant (Table 7).

Number of grains in one row

Number of grains in one row ranged between 34 – 49. The highest average values obtained genotype Escalate with yield 49 grains. The ZHY 1312 OR variety showed the lowest number of grains in row with 34 grains, but for this variety can be declared greatest increase over control variant with 10.81%. In addition to this variety, the number of grains increased in two more cases: ZHY 0874 OV and Astronaut (Table 8). Similar result referred **Mosavifeyzabad et al., (2013)**. They confirmed positive effect of Zn fertilizer on number of corn grains in one row. However, based on statistical analysis of the variance, variety has a significant influence and increase in the number of grains in a row within the variant Tecnokel Amino Zn was not statistically confirmed (Table 8).

CONCLUSION

Foliar application of Tecnokel amino Zn had not a significant effect on the increase of quantitative and qualitative parameters of sweet corn, but positively affected total yield, especially in case of SF 681 and Overture variety as well as some quantitative parameters like average weight of maize ear. This parameter showed better results within 3 varieties with increase about 20%. However, the effect on carotenoids and total sugar was negligible. Based on our results, we can conclude that statistically significant changes were indicated especially between different genotypes. Greatest results reached varieties Escalate and Overture. Variety Overture achieved highest total yield 13.14 $t.ha^{-1}$.

MINERAL COMPOSITION OF *ALLIUM CEPA* L. LEAVES OF SOUTHERN SUBSPECIES

Victor Nemtinov, Yulia Kostanchuk, Svetlana Motyleva, Alena Katskaya, Lidiya Timasheva, Olga Pekhova, Vladimir Pashtetskiy, Ivan Kulikov, Sergei Medvedev, Alexander Bokhan

ABSTRACT
The mineral composition of *Allium cepa* L. leaves was measured by using the scanning electron microscope of Japanese company JEOL, model JSM600LA with EDS system. 11collection samples of FRC "All-Russian Institute of Plants Genetic Resources named after N. I. Vavilov" and 4 samples of FSBSI "Research Institute of Agriculture of the Crimea" were studied. 12 main elements (in mass., %) contained in onion leaves were evaluated. The samples with the maximum macro- and micronutrient elements accumulation in the leaves used for the sourthern subspecies breeds and hybrids selection were revealed. These samples can be used to prevent the elements deficiency in the human body. The following samples number with a high accumulation of the elements in the leaves was revealed: K – nine (from 20.0 to 3.3 max %: B12132B, trimontzium, Rouge pale, Red Wetherstfield, Blood red flat, Valensiya, Tavricheskiy, Yaltinskiy lux, Yaltinskiy rubin), P – five (from 1.8 to 2.8 mass., %:B12132B, Mestniy, Valensiya, Yaltinskiy lux, Yaltinskiy rubin), Mg – one (2.23 mass., %: Rouge pale), Ca – nine (from 5.4 to 8.3 mass., %: Mestniy, Rouge pale, Mestniy, Red Wetherstfield, Blood red flat, Valensiya, Brown Beauty, Yaltinskiy lux and Yaltinskiy rubin), Fe – two (from 0.5 to 0.8 mass., %: B12132B, Tavricheskiy), S – seven (from 2.2 to 2.5 mass., %: B12132B, Mestniy, Red Wetherstfield, Tavricheskiy, Yaltinskiy lux, Yaltinskiy rubin, Yaltinskiy model No. 3), Na – two (from 1.3 to 1.5 mass., %: B12132B, Mestniy), Cl – five (from 4.0 to 7.0 mass., %: Mestniy, B12132B, Trimontzium, Red Wetherstfield, Yaltinskiy model No. 3), Cu – one (1.9 mass., %: Yaltinskiy model No. 5), Mo – eight (from 5.2 to 7.0 mass., %: Tavricheskiy, Yaltinskiy lux, Yaltinskiy rubin, Yaltinskiy model No. 3, Mestniy, Trimontzium, Red Wetherstfield, and B12132B), Zn – seven (from 0.5 to 4.97 mass., %: Yaltinskii model No. 3, Mestniy, B12132B, Rouge pale, Blood red flat, Brown Beauty, Yaltinskiy rubin) and Si – one (0.5 mass.%,%: Yaltinskiy lux). The order of the elements accumulation variation in the onion samples was distributed as follows: Zn > Fe > Si > Na > P > Cl > Mo > Mg > S > Ca > Cu > K.

Keywords: *Allium cepa* L.; leaves; analytical scanning electron microscopy; energy dispersion X-ray analysis; ash elements

INTRODUCTION
The plants natural feature is their ability to extract and assimilate mineral elements from the soil and water solutions. The following macro nutrient elements are necessary for plants growth and development: N, P, S, K, Ca, Mg, Fe and micro-nutrient elements Cu, Mo, Zn, Mn, B. However, in addition to these elements such useful elements as Na, Cl, Si were also included. They are used in the metabolic processes, with their absence in the environment the plant cannot go through the whole development cycle. The onion green leaves are a source of mineral elements that get into the human body in the form of ions in balanced concentrations. The soil and other multifactorial conditions that accompany the onions growth affect the onions mineral composition **(Golubkina, Agafonov and Dudchenko, 2009; Golubkina et al., 2015)**.

Onions - the main vegetable crop, it is actively used in the food and canning industry, modern medicine. Onions are consumed in the fresh, fried, boiled form, used for salads, minced meat, in the vegetables canning, in the meat and fish industry **(Borisenkova, 1993; Vodyanova and Alpysbaeva, 2004)**. Green onions and garlic are recommended for eating during flu epidemics, at atherosclerosis and heart disease, especially if the basis of nutrition is foods high in fat and low in fiber. Onions in this case suppress the cholesterol synthesis, reduce the level of fibrinogen (complex protein, blood plasma glycoprotein, the most important blood clotting ability component) **(Galkin et al., 2000)**. Onions are potential sources of prostaglandins, substances that regulate blood pressure **(Platonova, 2000; Agafonov et al., 2005)**. An important component of the onion chemical composition is quercetine, used in combination with vitamin C as a vasodilator **(Danikov, 1998; Ulyanova, 1998; Platonova, 2000)**.

The biochemical composition of both bulbs and green leaves varies in different development stages depending on

the breed, environmental and agro-technical conditions of the plant growing **(Ananyina, and Glukhova, 1988; Dudchenko, 2009; Kielak et al., 2006; Nemtinov et al., 2019)**.

The following onions nutritional value is given by **Skurikhin and Tutelyan (2007)**, mg per 100 g product: K – 175, Ca – 31, Mg – 14, Na – 4, S – 65, P – 58, Cl – 25, Fe – 0.8, Cu – 0.09, Zn – 0.85 mg and other trace elements. The elements content of K – 259, Ca – 100, Mg – 18, Fe – 1.0 ($mg.100g^{-1}$) in green onions significantly exceeds the analogue parameters of onion bulbs, but the lower level of Zn – 0.39 $mg.100g^{-1}$. The development of the latest technologies in physiological and medical research confirms the important role of micro nutrient elements in metabolic reactions and submolecular processes the activity of which depends on the presence of certain macro- and micro nutrient elements in the daily human diet **(Avtsyn et al., 1991; Kavita and Puneet, 2017; Motyleva et al., 2017)**. The purpose of our work is to study the peculiarities of mineral elements accumulation in 15 samples of *Allium cepa* L., including 11 collection ones, originating from 9 countries of the world and 4 ones selected by FSBSI "RIA of the Crimea".

Scientific hypothesis

There are no comparative data on the mineral composition of the different samples of *Allium cepa* L. onion leaves, originating from 9 countries of the world, grown in the conditions of the Crimea. We evaluated differences in macro- and micronutrient content in the range of consumer properties of hub varieties.

MATERIAL AND METHODOLOGY

The objects under study were *Allium cepa* L. collection samples. The onions collectable and commercial material was grown in FSBSI "RIA of the Crimea" fields. The green onions leaves were prepared for the mineralization at the bulbs early formation stage (Table 1).

The content of each element in the onion samples was conventionally divided into the groups: high, medium, low.

The soils of FSBSI "RIA of the Crimea" experimental and production base are represented by the southern carbonate black earth. The onion plants were grown on the pure (background) soils uncontaminated with high-density metals (within permissible rates accepted in Russia).

The data of the quantitative elemental composition, given in the present paper, are taken in the laboratory of physiology and biochemistry of the Centre of the plants genofond and bioresources of Federal State Budgetary Scientific Institution All-Russian Horticultural Institute for Breeding, Agrotechnology and Nursery, Moscow. The researches are original and are fulfilled with the usage of the modern analytical equipment. The average seeds weighing with the mass of 10 g was mineralized in the muffle furnace Naberterm (Germany) at T = 400 ºC. The received ash was dispergated by ultrasound at 18 kHz frequency for 15 minutes. The dispergate even layer was applied on the object table covered with carbonic scotch.

The chemical composition of the basic ash components (Na, P, S, K, Mn, Fe, Mg, Ca, Al, Si, Cl, Zn, Se, Mo) was determined by the method of energy dispersive spectrometry (ESD) on the analytical raster electron microscope JEOL JSM 6090 LA. The microscope resolution is 4 nm at accelerating voltage 20 kV (secondary electrons image), zooming is from x 10 till x 10 000. While performing the elemental analysis the working distance (WD) is 10mm. Energy-dispersive spectrometer allows to carry out the quantitative X-ray microanalysis with the desired analysing area: in a point or a really, and to receive the maps of elements allocation. X-ray microanalysis data are presented in the form of standard protocols which contain the microstructure picture of the sample under study, the table of the data in weighting and atomic correlation, spectra and histograms. The spectrum example is shown in Figure 1.

Statisical analysis

Taking into consideration the spectrum lines intensity the concentration of the desired element can be determined. The fractional accuracy of the chemical analysis is spread in the following way: at the element concentration from 1 till 5% the accuracy is less than 10%; from 5 till 10% the accuracy is less than 5%; at the element concentration more than 10% the accuracy is less than 2%. 100 ash areas of each sample were studied. The local analysis is 3 mm, the scanned area is not less than 12 μm. We used the statistical analysis of the Excel package (Microsoft Excel, v. 2016).

Table 1 *Allium cepa* L. onion samples.

Sample name	Origin
Collectable samples	
Mestniy	Russia
B12132B	Australia
Southport red	the USA
Trimontzium	Bulgaria
Tavricheskiy	Russia
Rouge pale	Algeria
Mestniy	Azerbaijan
Red Wetherstfield	Bolivia
Blood red flat	the Netherlands
Valensiya	Portugal
Brown Beauty	the USA
Samples selected by FSBSI "RIA of the Crimea"	
Yaltinskiy model No. 3	Russia
Yaltinskiy model No. 5	Russia
Yaltinskiy lux	Russia
Yaltinskiy rubin	Russia

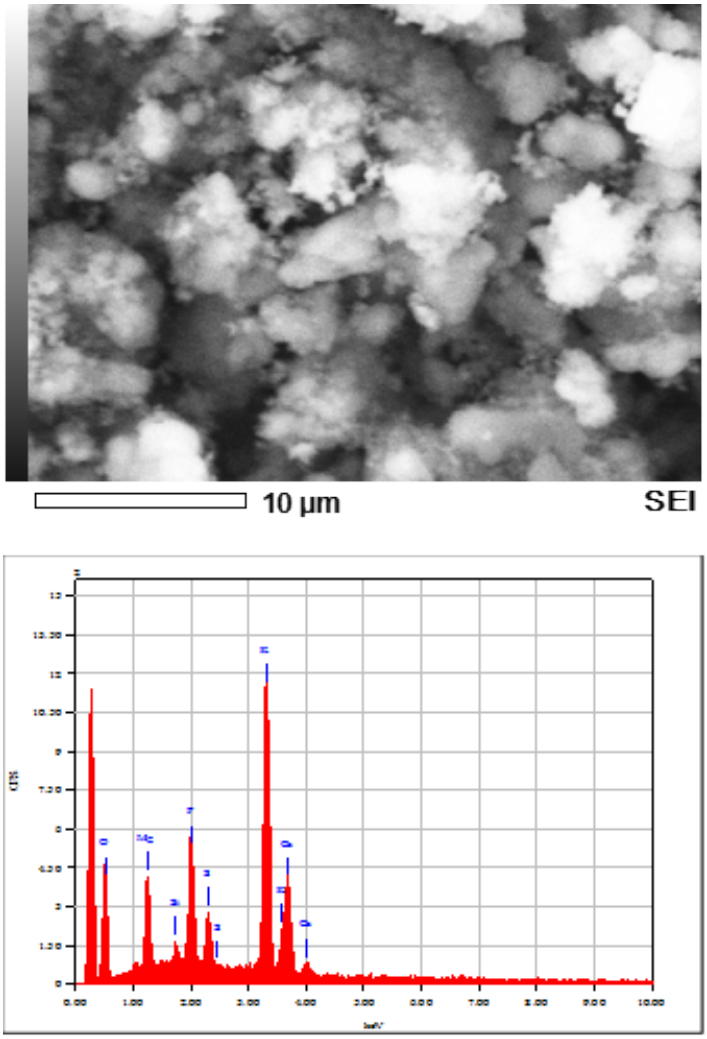

Figure 1 The microstructure picture of the sample under study (1) and the general view of the X-ray spectrum lines that show the elements presence in the analyzing area (2).

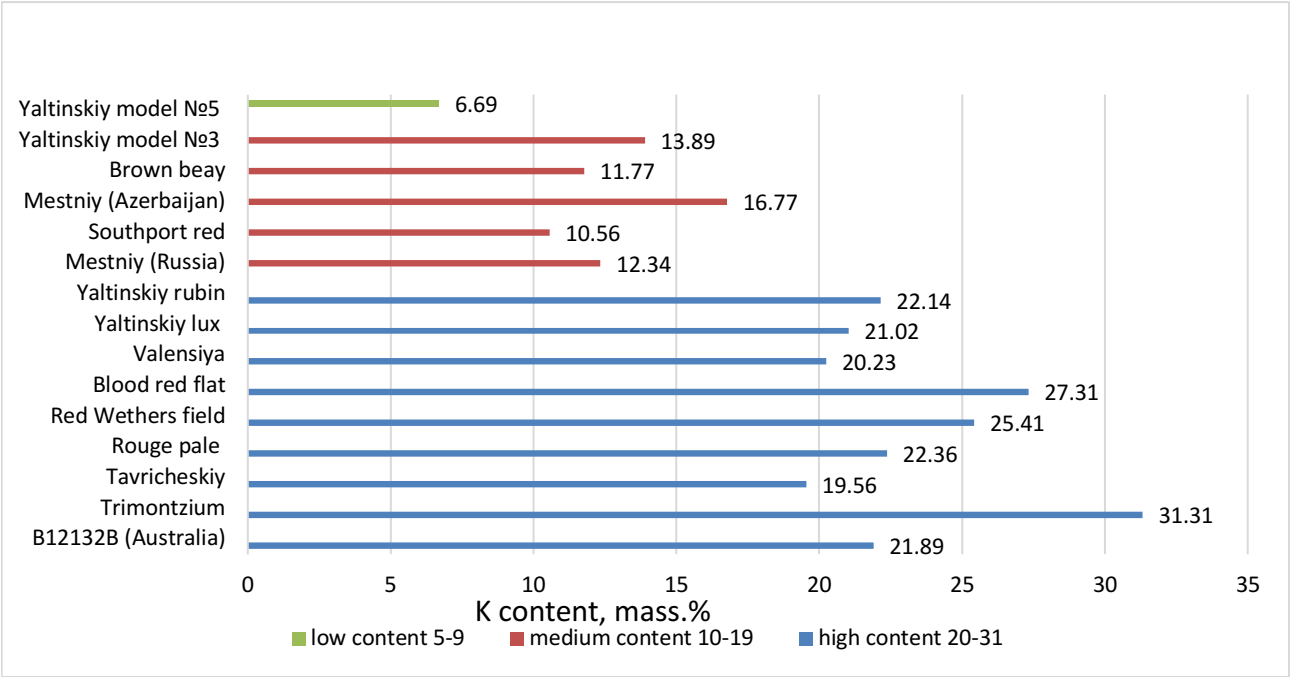

Figure 2 The cultivar differences at K accumulation in *Allium cepa* L. leaves.

RESULTS AND DISCUSSION

Onions or young leaves are used for eating in onion crops. Green leaves have less dry solids and soluble carbohydrates than bulbs, but contain a significant amount of nitrogen compounds, minerals and vitamins. While having hepatic and bile ducts diseases, traditional medicine recommends eating 100 grams of green onion daily, as it contains a significant amount of trace elements the daily dose of which for a person is 200 mg. However, the role of micro-nutrient elements is not yet fully investigated, new data that constantly appear contradict the previous ones. In this regard, we analysed 12 most significant macro and micro-nutrient elements found in green onion leaves. 17 trace elements were found in the onion's ash. Micro-nutrient elements – Cu, Zn, Co, Mo are parts of enzymes and participate in their activation, improve the plants growth and development.

K is necessary for the muscle contractions, the heart muscle normalization, the nerve cells activity, the blood osmotic concentration, the acid-alkaline and water balance. It controls the transmembrane potential of osmotic pressure, the cathode-anion balance, the pH of cell hemostasis. In ion form K increases the concentration of other ions and is found in all the human body organs **(Meathnis et al., 1997)**.

The highest value of K from 20 to 31 mass., % was accumulated in 9 samples of *Allium cepa* L. onion leaves originating from 7 countries: B12132B (Australia), Trimontzium (Bulgaria), Tavricheskiy (Russia), Rouge Pale (Algeria), Red Wetherstfield (Bolivia), Blood red flat (the Netherlands), Valensiya (Portugal), 2 breeds selected by FSBSI "RIA of the Crimea" - Yaltinskiy lux and Yaltinskiy rubin (Figure 2). The other 5 samples from different places of origin contained a medium amount of K in the leaves - from 10.6 to 16.8 mass., % and the sample Yaltinskiy model No. 3 (Russia) accumulated only 6.7 mass., % of K.

In the paired correlation ratios of K the medium connection was revealed with Mg, Cl, S, Cu at r = 0.4 – 0.6 and the high correlation with Mo at r = 0.7 and the low one with Na, Ca and Zn at r = 0.16 – 0.24. The connection with Fe was practically absent (r = 0.02) (Figure 3).

P (phosphorus) is a part of humans and animals skeleton, more than 50% of it is represented in tissues in the form of inorganic compounds. It is an integral part of DNA, RNA, phospholipids, ATF, ADP, where it performs a structural function. Its role in cellular energy is great.

Its greatest value in the onion leaves ash is noted in 6 samples: Blood red flat (the Netherlands), B12132B (Australia), Mestniy (Azerbaijan), Valensiya (Portugal), Yaltinskiy lux and Yaltinskiy rubin (Russia). The medium rates (1.2 – 1.4 mass., %) are found in 3 samples: Trimontzium (Bulgaria), Yaltinskiy model No. 3 (the Crimea) and Rouge pale (Algeria). The low level of P content (0.4 – 0.7 mass., %) is marked in 5 samples: Mestniy (Krasnodar, Russia), Southport red (the USA), Red Wethers field (Bolivia), Brown beauty (the USA), Yaltinskiy model No. 5 (Russia). And a very low value (0.22 mass., %) is identified in Tavricheskiy (Russia).

In the paired correlation ratios of P a medium connection was revealed with S, K, Fe and Mo at r = 0.3 – 0.6 and an insignificant correlation with Ca at r = 0.2 and a very low one with Cl, Cu and Zn at r = 0.01 – 0.02 (Figure 3).

Mg (magnesium) is necessary for Ca absorption, the metabolism of glucose, amino acids, fats, the nutrients transportation, is involved in the process of protein synthesis, the nerve signals transmission. It is necessary for the cells, tissues and organs regeneration processes. It activates a large number of enzymes that are involved in CO_2 and N consumption process. It is necessary for keeping the cathode-anion and pH balance.

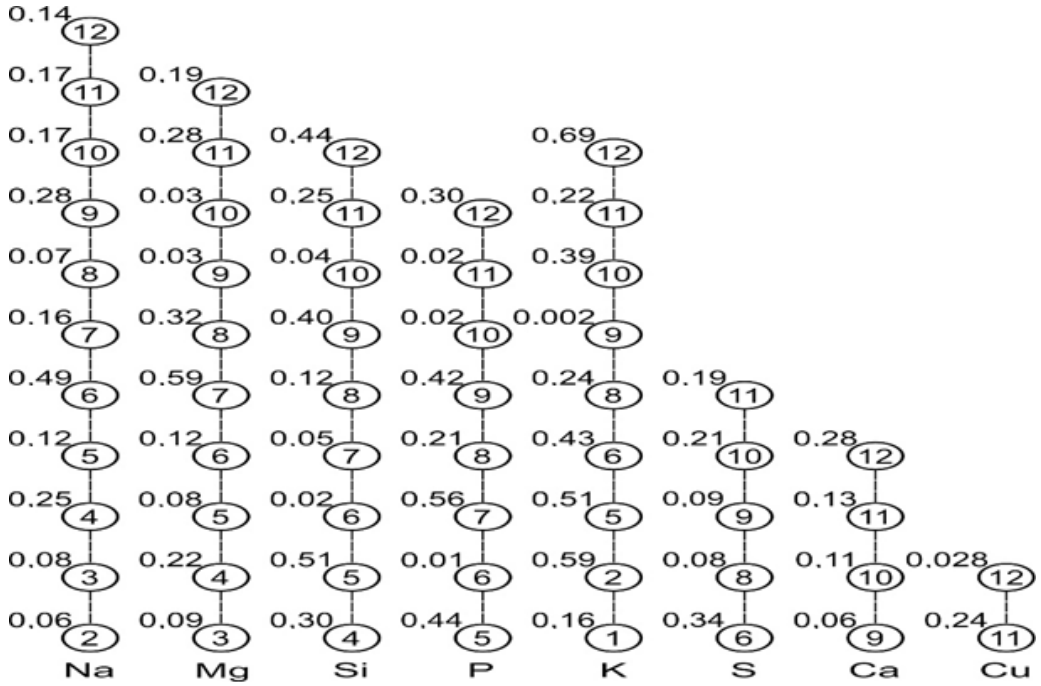

Figure 3 The paired values of the elements content correlation coefficients in *Allium cepa* L. onion leaves: 1 – Na, 2 – Mg, 3 – Si, 4 – P, 5 – S, 6 – Cl, 7 – K, 8 – Ca, 9 – Fe, 10 – Cu, 11 – Zn, 12 – Mo.

Its highest value was found only in one onion leaves sample (2.23 mass.,%): Rouge pale (Algeria), in the other 6 samples the medium rates are marked: 1.1 – 1.5 mass., %: B12132B (Australia), Southport red (the USA), Trimontzium (Bulgaria), Red Wetherstfield (Bolivia), Valensiya (Portugal).

Mg low value (0.4 – 1.0) was presented in 9 samples: Mestniy (Russia), Tavricheskiy (Russia), Mestniy (Azerbaijan), Blood red flat (the Netherlands), Brown Beauty (the USA) and 4 samples selected by FSBSI "RIA of the Crimea": Yaltinskiy model No. 3, Yaltinskiy model No. 5, Yaltinskiy lux and Yaltinskiy rubin.

In the paired correlation ratios of Mg the medium connection was revealed with K, Ca and Zn at r = 0.3 – 0.6, an insignificant correlation with Si, P, S, Cl, Fe and Cu at r = 0.08 – 0.22 (Figure 3).

Ca (calcium). The major part of the human skeleton and teeth consists of Ca. Its ions are involved in blood clotting processes, as well as in providing constant osmotic pressure. It is involved in the cell growth and development processes, is a part of enzymes, affects the metabolism and immunity **(Gusev, 1998; Gins and Gins, 2011)**.

In the onion leaves ash Ca is represented at high rates (5.43 – 8.27 mass., %) in 9 samples: Mestniy (Russia), Rouge pale (Algeria), Mestniy (Azerbaijan), Red Wetherstfield (Bolivia), Blood red flat (the Netherlands), Valensiya (Portugal), Brown Beauty (the USA) and 2 breeds selected by FSBSI "RIA of the Crimea" - Yaltinskiy lux and Yaltinskiy rubin.

Five sort samples showed a medium content (3.74 – 4.92 mass., %) – B12132B (Australia), Southport red (USA), Trimontzium (Bulgaria), Tavricheskiy (Russia), Yaltinskiy model No. 3 (Russia) and a low level one (1.93 mass., %) – Yaltinskiy model No5 (Russia).

In the paired correlation ratios of Ca there was revealed the correlation with Mo at r = 0.3, with Fe, Cu and Zn at r = 0.06 – 0.13 (Figure 3).

Fe (iron) is the main active element of blood hemoglobin, is a part of other cells enzymes, it catalyzes the breathing processes in them. Organic Fe is an important compound of the body, it is a part of many oxidation-reduction enzymes.

In the onion ash 2 samples had an increased Fe accumulation (0.49 – 0.78 mass., %): B12132B (Australia) and Tavricheskiy (the Crimea). The other 9 samples had the medium Fe accumulation (0.11 – 0.21 mass., %): Mestniy (Russia), Trimontzium (Bulgaria), Rouge pale (Algeria), Blood red flat (the Netherlands), Red Wetherstfield (Bolivia), Valensiya (Portugal), Brown Beauty (the USA) and 2 breeds from the Crimea - Yaltinskiy lux and Yaltinskiy rubin. The low Fe accumulation (0.06 – 0.08 mass., %) was found in 4 samples: B12132B (Australia), Mestniy (Azerbaijan) and Yaltinskiy model No. 3 and Yaltinskiy model No. 5 (Russia).

In living organisms S (sulfur) regulates the synthesis of the protein quantity and quality, is a part of its composition, has antioxidant activity. It ensures the process of the electrons energy transfer in the cell. It participates in the methyl groups transportation and fixation, in the production of various hydrogen compounds, which allows the transmission of genetic information **(Gins et al., 2018)**.

The highest S accumulation (from 2.16 – 2.5 mass., %) was found in 7 onion samples: B12132B (Australia), Tavricheskiy (Russia), Mestniy (Azerbaijan), Red Wetherstfield (Bolivia), Yaltinskiy model No. 3, Yaltinskiy lux and Yaltinskiy rubin (Russia). The medium content (1.34 – 1.69 mass., %) was noted in 4 samples: Trimontzium (Bulgaria), Rouge pale (Algeria), Blood red flat (the Netherlands), Valensiya (Portugal). The other 4 samples were characterized by the low S accumulation (0.6 – 0.8 mass., %) in the onion leaves ash: Mestniy (Russia), Brown Beauty (the USA), Southport red (the USA) and Yaltinskiy model No. 5 (Russia).

In the paired correlation of S the medium connection was marked with Cl at r = 0.3, with other macro- and micro nutrient elements (Ca, Fe, Cu and Zn) the low one at r <0.3 (0.08 – 0.21) (Figure 3).

Na (sodium) a part of the plants enchylema that creates high osmotic pressure, is found mainly in intercellular fluid. Na in combination with K is involved in the membrane potential creation, enzymes and muscle contractions, acid-alkaline and water balance activation provides membrane transfer **(Avtsyn et al., 1991)**. A great number of Na salts are found in green onions, garlic, beetroot, parsley, tomatoes and dill.

Na accumulation in the samples of *Allium cepa* L. onion leaves was marked in the following content (mass.,%): high (1.28 – 1.47) Mestniy (Russia), B12132B (Australia); medium (0.5 – 0.9) Trimontzium (Bulgaria), Rouge pale (Algeria), Mestniy (Azerbaijan), Red Wetherstfield (Bolivia), Blood red flat (the Netherlands), Brown Beauty (the USA); the other 7 samples showed low and very low values.

In the paired correlation ratios of Na, the medium connection was revealed with *Cl* and Fe at r = 0.49 and 0.28, with other elements the connection was low at r = 0.12 – 0.25 and very low at r = 0.06 – 0.08 (Figure 3).

Cl (chlorine) is one of the biogenic elements, a constant component of plants, human and animals' tissues. Cl-ions together with Na and K atoms are involved in osmotic equilibrium maintenance and acid-alkaline equilibrium regulating. Na chloride plays a major role in chemical composition homeostasis and water-salt exchange maintenance helping to keep water in tissues. Cl is also an integral part of hydrochloric acid found in gastric juice and actively affects digestion.

Cl accumulation of in the samples of *Allium cepa* L. onion leaves was marked in the following content (mass.,%): high (4.25 – 6.88) Mestniy (Russia), B12132B (Australia), Trimontzium (Bulgaria), Red Wetherstfield (Bolivia) and Yaltinskiy model No. 3 (Russia), medium (3.44 – 3.69) Southport red (the USA), Tavricheskiy (the Crimea) and Valensiya (Portugal); the other 5 samples contained low rates: low 1.99 – 2.99 and one sample very low 0.79.

Cu (copper) is an important essential micronutrient element in human metabolism, as it is connected with enzymes, hormones and vitamins **(Fraga, 2005)**. According to the U.S. Institute of Medicine and the European Union's Food Science Committee, the daily requirement of an adult is 1 – 1.5 mg. Cu carries out the biological mechanism of enzyme biocatalysis, electron transfer, interaction with Fe. It participates in the generational organ and hemoglobin formation, growth and development processes, is a part of melanin, i.e. together with Fe, Mn, Zn, Cu, Se Cu belongs to the 4th group of Mendeleev Periodic System and is an essential micro nutrient element for humans and mammals **(Avtsyn et al., 1991)**. The importance of onion

Table 2 The cultivar diffrences at Cu, Mo, Zn, Si accumulation in *Allium cepa* L. leaves.

The sample name, (origin)	Micronutrient elements (mass %, ±*SD*)			
	Cu	Mo	Zn	Si
Mestniy (Krasnodar, Russia)	1.11 ±0.14	1.86 ±0.13	0.49 ±0.05	0.06 ±0.01
B12132B (Australia)	1.09 ±0.06	6.14 ±0.04	0.58 ±0.01	0.24 ±0.04
Southport red (the USA)	0.88 ±0.07	1.73 ±0.03	0.28 ±0.01	0.03 ±0.01
Trimontzium (Bulgaria)	1.06 ±0.11	5.52 ±0.44	0.22 ±0.01	0.14 ±0.02
Tavricheskiy (the Crimea)	1.23 ±0.11	6.83 ±0.31	0.11 ±0.02	0.07 ±0.01
Rouge pale (Algeria)	0.69 ±0.01	3.54 ±0.22	0.65 ±0.02	0.07 ±0.01
Mestniy (Azerbaijan)	1.11 ±0.11	5.49 ±0.24	0.22 ±0.02	0.29 ±0.02
Red Wetherstfield (Bolivia)	0.12 ±0.01	5.59 ±0.33	0.2 ±0.01	0.12 ±0.01
Blood red flat (the Netherlands)	0.88 ±0.01	2.68 ±0.24	0.47 ±0.04	0.08 ±0.01
Valensiya (Portugal)	1.41 ±0.13	4.01 ±0.14	0.07 ±0.01	0.13 ±0.01
Brown Beauty (the USA)	0.89 ±0.02	1.35 ±0.11	0.68 ±0.01	0.09 ±0.02
Yaltinskiy model No. 3 (the Crimea)	0.77 ±0.01	5.15 ±0.25	4.97 ±0.15	0.29 ±0.01
Yaltinskiy model No. 5 (the Crimea)	1.93 ±0.14	0.44 ±0.01	0.33 ±0.01	0.15 ±0.06
Yaltinskiy lux (the Crimea)	1.15 ±0.09	5.88 ±0.54	0.31 ±0.01	0.51 ±0.05
Yaltinskiy rubin (the Crimea)	1.32 ±0.10	5.42 ±0.45	0.82 ±0.03	0.06 ±0.02

Note: Means within a column with at least one identical superscript are not significantly different by Student`s t-test (p <0.05).

consumption as a source of Fe, Mn and Cu for humans is great **(Golubkina et al., 2013; Skalnaya et al., 2004)**.

According to Cu accumulation the highest value is noted in 1 sample (1.93 mass.,%) Yaltinskiy model No. 5 (Russia) (Table 2), medium one was found in 8 samples (1.0 – 1.5 mass., %): Mestniy (Russia), B12132B (Australia), Tavricheskiy (Russia), Mestniy (Azerbaijan), Valensiya (Portugal) and breeds Yaltinskiy lux and Yaltinskiy rubin (Russia). Low Cu accumulation had 6 samples (0.12 – 0.9 mass., %): Southport red (the USA), Rouge pale (Algeria), Red Wetherstfield (Bolivia), Blood red flat (the Netherlands), Brown Beauty (the USA) and Yaltinskiy model No. 3 (Russia).

In the paired correlation ratios of Cu low connection was revealed with Zn at r = 0.24 and a very low correlation with Mo at r = 0.028 (Figure 3).

Mo (molybdenus) ensures the enzyme catalysis mechanisms, as well as the electrons transfer, is involved in the aminoacids synthesis, in the vitamins C, E, and B12 exchange **Avtsyn et.al. (1991)**. A human's daily need for Mo is 0.5 mg. Mo accumulates mainly in the liver, the kidneys, the internal secretion glands and the skin.

The high Mo accumulation was found in 8 samples: Yaltinskiy model No. 3, Yaltinskiy rubin (the Crimea), Mestniy (Azerbaijan), Trimontzium (Bulgaria), Red Wetherstfield (Bolivia), Yaltinskiy lux (the Crimea) and B12132B (Australia) (from 5.15 – 6.14 mass., %) with the highest value in Tavricheskiy (the Crimea) (6.83 mass., %) (Table 2). The medium Mo content was revealed in 3 samples (from 2.68 – 4.01 mass., %): Blood red flat (the Netherlands), Rouge pale (Algeria) and Valensiya (Portugal); the low rates – in 3 samples (from 1.35 – 1.86 mass., %): Southport red (the USA), Brown Beauty (the USA), Mestniy (Russia) and Yaltinskiy model No. 5 (Russia) showed the lowest value (0.44 mass., %).

Zn (zinc) stabilizes the molecules structure, plays an important role in DNA and RNA metabolism, in the protein synthesis and cells division, in the process of signal transmission inside the cell **(Nechaev, Trauberg and Kochetkova, 2007)**. There are plants-concentrators and even superconcentrators, which accumulate micronutrient elements and can be used for Zn deficiency treatment and prevention measures in the human body.

In our example, *Allium cepa* L. samples accumulated a very high content (4.97 mass.,%) in Yaltinskiy model No. 3 (Russia) and the high one in 6 samples (0.47 – 0.82 mass., %): Mestniy (Russia), B12132B (Australia), Rouge pale (Algeria), Blood red flat (the Netherlands), Brown Beauty (the USA), Yaltinskiy rubin (Russia) (Table 2). The other 7 samples accumulated Zn at low values (0.2 – 0.33 mass., %), with the highest rate in Yaltinskiy model No. 5 (Russia). A very low *Zn* content (0.07 – 0.11 mass., %) corresponded to two breeds - Tavricheskiy (Russia) and Valensiya (Portugal).

Si (silicon) is an obligatory element for plants **(Kolesnikov and Gins, 2001)**. It is accumulated in large quantities in leaves, especially in the leaves and roots conductive tissues. Si is not only the basis of tissues, but it also controls a number of biological and chemical processes in humans and animals. The skin, tendons, vascular walls elasticity is due mainly to *Si* contained in them. *Si* increases the plants specific resistance to abiogenic stresses.

Si accumulation in the samples of *Allium cepa* L. onion leaves was noted in the following rates, mass., %: high (0.5) Yaltinskiy lux (Russia), medium (0.21 – 0.3): B12132B (Australia), Mestniy (Azerbaijan) and Yaltinskiy model No. 3. (Russia), low (0.11 – 0.2): Mestniy (Russia), Trimontzium (Bulgaria), Red Wetherstfield (Bolivia) and Yaltinskiy model No. 3 (Russia) and a very low (0.03 – 0.1): (6 samples) (Table 2).

Cu and Zn content in plant products controlled by sanitary standards, which are 5 $mg.kg^{-1}$ (Cu) and 10 $mg.kg^{-1}$ (Zn) **(SANPIN 2.3.2 1078-01, 2013)**. According to our data, the content of Cu and Zn in the studied onion samples does not exceed permissible norms.

CONCLUSION

Allium cepa L. onion samples, the concentrators, with the highest accumulation of macro- and micronutrient elements in the leaves have been studied. The breeds that can be used for the selection purposes and elements deficiency prevention in the human body were revealed. The following number of the samples with high elements accumulation in the leaves were identified: K – nine, P – five, Mg – one, Ca – nine, Fe – two, S – seven, Na – two, Cl – five, Cu – one, Mo – eight, Zn – seven and Si – one.

MILK YIELD AND SOMATIC CELLS IN DAIRY EWES WITH RESPECT TO THEIR MUTUAL RELATIONS

Marta Oravcová, Kristína Tvarožková, Vladimír Tančin, Michal Uhrinčať, Lucia Mačuhová

ABSTRACT

The objective of this study was to analyze milk yield and somatic cell count (SCC) expressed as somatic cell sore (SCS) in Lacaune dairy breed. Data from milk performance testing recorded between 2016 and 2018 (farm in West Slovakia) were used. A total, 377 individual milk yield and SCC records of 61 ewes (first, second and third lacation, respectively) were analysed. Mixed model for milk yield included fixed factors: SCC class (lowest, low, middle, high and highest), year of measurement, lactation number, month in milk and interaction between month in milk and SCC class, and random factors of ewe and error. Mixed model for SCS included milk yield class (lowest, low, middle, high, highest), year of measurement, lactation number, month in milk and interaction between month in milk and milk yield class. Random factors of ewe and error were considered as well. Milk yield was significantly affected (p <0.05 or p <0.01) by all investigated factors. Except for interaction between month in milk and milk yield class, the remaining factors significantly affected (p <0.05 or p <0.01) also SCS. The analyses confirmed that SCC may be used as a useful indicator of udder health. It may help in identifying infected ewes, and thus, avoiding mammary infections to be spread throughout the whole flock.

Keywords: Lacaune; milk yield; somatic cell count and score; SCC; Slovakia

INTRODUCTION

Dairy sheep sector is a traditional branch of livestock in Slovakia. In order to be competitive, an increase of milk yield of good quality remains one of the most important goals od sheep farms. However, this aim may be a potential risk for udder health. Consumers, on the other hand, are more iterested in welfare of animals **(Tančin et al., 2019)**, when deciding which food to buy. Types of breeding systems and (also welfare) thus influence both ewe production abilities and health/desease conditions. Somatic cells are considered to be of a negative effect on health of mammary gland and are used for detection of udder infection in ewes **(Gonzalo et al., 1994; Gonzáles-Rodríguez et al., 1995; Tvarožková et al., 2019)**. The consequence of increased SCC is decreasing raw milk quality, which has further consequences for milk processing **(Hag, 2001)**. Mastitis is a costly health problem in dairy ewes **(Arias et al., 2012)**; mammary infections damage udder tissue **(Burriel, 1997)**.

Tvarožková et al. (2019) summarised knowledge about defining the physiological/pathological levels of somatic cell count (SCC) and of proposing the possible tresholds for healthy mammary gland in ewes **(Pengov, 2001; Berthelot et al., 2006; Sutera et al., 2018)**. These values vary among dairy sheep breeds and no single value to differentate between uninfected and infected udder was accepted **(Berthelot et al., 2006; Tančin et al., 2017)**. For example, tresholds for healthy udders in ewes may be as follows: $265x10^3$ somatic cells.mL^{-1} **(Caboni et al., 2017)**, $300x10^3$ somatic cells.mL^{-1} **(Kern et al., 2013)** or $500x10^3$ somatic cells.mL^{-1} **(Sutera et al., 2018)**. **Gonzalo et al. (1994)** and **El-Saied, Carriedo and San Primitivo (1998)** recommended SCC values ranging from 2.5×10^5 to 3×10^5 cells.ml^{-1} as thresholds between healthy and infected udders. According to **Jaeggi et al. (2003)**, thresholds above $1000x10^3$ somatic cells.mL^{-1} decrease the cheese yield and increase the development of rancid flavours in the cheese.

No routine determination of SCC in individual ewes is undertaken on national level in Slovakia; however, there are farms interested in SCC to be known due to fact that costs to cure infected individuals and the decrease of milk yield may affect the profitability. In Slovakia, reports aimed at investigation of SCC and distributions of ewes in respective SCC classes as well as their influence on milk yield and composition were published **(Idriss et al., 2015; Tančin et al., 2017)**; possible values that enable to distinguish between ewes infected/uninfected with mastitis were discussed **(Oravcová, Mačuhová and Tančin, 2018; Tvarožková et al., 2019)**.

In spite of fact that some analyses were done, this study was aimed at providing in-depth investigation of mutual relations between SCC and milk yield on a level of a

single farm. Purebred Lacaune ewes were included in the analysis.

The hypothesis was as follows: SCC negatively influences amount of milk yield; vice versa amount of milk yield negatively influence SCC.

MATERIAL AND METHODOLOGY

Data were collected from the farm located in western Slovakia during the period of three years (from 2016 to 2018). Milk yield and somatic cell count (SCC) of Lacaune (LC) ewes were analysed. Test-day records were taken once per month (under the the guidance of certificated organisation for milk recording i.e. Plemenárske služby, š. p. SR Bratislava). Ewes were machine milked two times per day after lambs were weaned. However, only morning milkings were taken into account.

A total of 667 records of 61 ewes with 95 lactations i.e. 1.56 lactation per ewe) were included. Ewes were in their first, second and third lactation, respectively.

Ewes predominantly lambed in February and March. According to their lambing, ewes were on their second to sixth month in milk (MIM): MIM 2 (30 to 60 days after lambing), MIM 3 (61 to 90 days after lambing), MIM 4 (91 to 120 days after lambing), MIM 5 (121 to 150 days after lambing) and MIM 6 (151 and 180 days after lambing). Due to only six measurements taken between 181 and 194 days, these were included in MIM6. At least, ewes with three test-day records per lactation were considered.

According to SCC, five classes were formed: lowest SCC (under or equal to 200×10^3 cells.mL^{-1}), low SCC (between 200×10^3 and 400×10^3 cells.mL^{-1}) middle SCC (between 400×10^3 and 600×10^3 cells.mL^{-1}), high SCC between 600×10^3 and 1000×10^3 cells.mL^{-1}) and highest SCC (above 1000×10^3 cells.mL^{-1}). Because of non-normal distribution of SCC, these values were transformed and somatic cell score i.e. SCS= $\log_2$(SCC/100000)+3, as mentioned by **Riggio et al. (2007)**, was analysed. According to milk yield (MY), five classes were also formed: lowest MY (under or equal to 200 ml), low MY (between 200 and 400 ml) middle class MY (between 400 and 600 ml), high MY between 600 and 1000 ml) and highest MY (above 1000 ml).

The mixed model methodology using MIXED procedure **(SAS 9.2, 2009)** was applied to study the influence of factors affecting the variation of milk yield and SCS. Two different models were considered. The model equation (1) was used for milk yield:

$$y_{ijklmn} = \mu + Y_i + L_j + M_k + C_l + M_kC_l + u_m + e_{ijklmn} \quad (1)$$

where:

- y_{ijklmn} – individual observations of milk yield
- μ – general mean
- Y_i – fixed factor of year class (2016, 2017, 2018); $\sum_i Y = 0$
- L_j – fixed factor of lactation number (1, 2, 3); $\sum_j L = 0$
- M_k – fixed factor of month in milk (2, 3, 4, 5, 6); $\sum_k M = 0$
- C_l – fixed factor of SCC class (5 levels as mentioned above); $\sum_l C = 0$
- M_kC_l – fixed factor of interaction between month in milk and SCC class; $\sum_{kl} MC = 0$
- u_m – random factor of ewe (1, 2 to 61); $u_m \sim N(0, I\sigma_m^2)$
- e_{ijklmn} – random error; $e_{ijklmn} = N(0, I\sigma_e^2)$

The model equation (2) was used for SCS:

$$y_{ijklmn} = Y_i + L_j + M_k + C_l + M_kC_l + u_m + e_{ijklmn} \quad (2)$$

where:

- y_{ijklmn} – individual SCS
- μ – general mean
- Y_i – fixed factor of year (2016, 2017, 2018); $\sum_i Y = 0$
- L_j – fixed factor of lactation number (1, 2, 3); $\sum_j L = 0$
- M_k – fixed factor of month in milk (2, 3, 4, 5, 6); $\sum_j MIM = 0$
- C_l – fixed factor of milk yield class (5 levels as mentioned above); $\sum_l C = 0$
- M_kC_l – fixed factor of interaction between month in milk number and milk yield class; $\sum_{kl} LMIM = 0$
- u_m – random factor of ewe (1, 2 to 61); $u_m \sim N(0, I\sigma_m^2)$
- e_{ijklmn} – random error; $e_{ijklmn} = N(0, I\sigma_e^2)$

Fixed factors included in the models (1) and (2) were estimated using the Least Squares Means (LSM) method. Statistical significances of fixed factors were tested by Fischer's F-test; statistical significances of individual differences between estimated levels of fixed factors were tested by Scheffe's multiple-range tests. Differences were considered statistically significant when p <0.05 or p <0.01. Ewe and residual error variances were estimated using the Restricted Maximum Likelihood (REML) method. Estimated variances enable to estimate repeatability of MY and SCS and can be interpreted as the proportion of total variance attributable to within-individual variance:

$$r^2 = \frac{\sigma_m^2}{\sigma_m^2 + \sigma_e^2}.$$

RESULTS AND DISCUSSION

Analysis of variance of fixed factors affecting milk yield (MY) and (SCS) of Lacaune (LC) ewes is given in Table 1. The factors of year of measurement (three years included to increase number of observations), lactation number and month in milk (MIM) were significant (p <0.05 or p <0.01). Both, the factor of somatic cell count (SCC) class when MY as dependent variable was analysed and the factor of MY class when SCS as dependent variable was analysed, were significant (p <0.01). The factor of interaction between MIM and SCC class (model 1) was significant (p <0.01). The factor of interaction between MIM and MY class (model 2) was non-significant (p >0.05). Differences in studied traits with respect to individual levels of factors included in models are discussed below.

Table 1 Analyses of variance (statistical significance of Fisher F-test) for milk yield and somatic cell score.

	Traits	
Factor	**MY**	**SCS**
Year	$^{++}$	$^{+}$
Lactation number	$^{+}$	$^{+}$
MIM	$^{++}$	$^{+}$
SCC class	$^{++}$	N.C.
MY class	N.C.	$^{++}$
MIM*SCC class	$^{+}$	N.C.
MIM*MY class	N.C.	$^{-}$

Note: MY – milk yield, SCS – somatic cell score, MIM – month in milk, SCC – somatic cell count, N.C. – not considered, ^{++}p <0.01, ^{+}p <0.05, ^{-}p >0.05.

Table 2 Least squares means and standard errors for milk yield by somatic cell count class and for somatic cell score for somatic cell score by milk yield class.

Note: MY – milk yield, SCS – somatic cell score, n – number of observations, ^{++}p <0.01, ^{+}p <0.05.

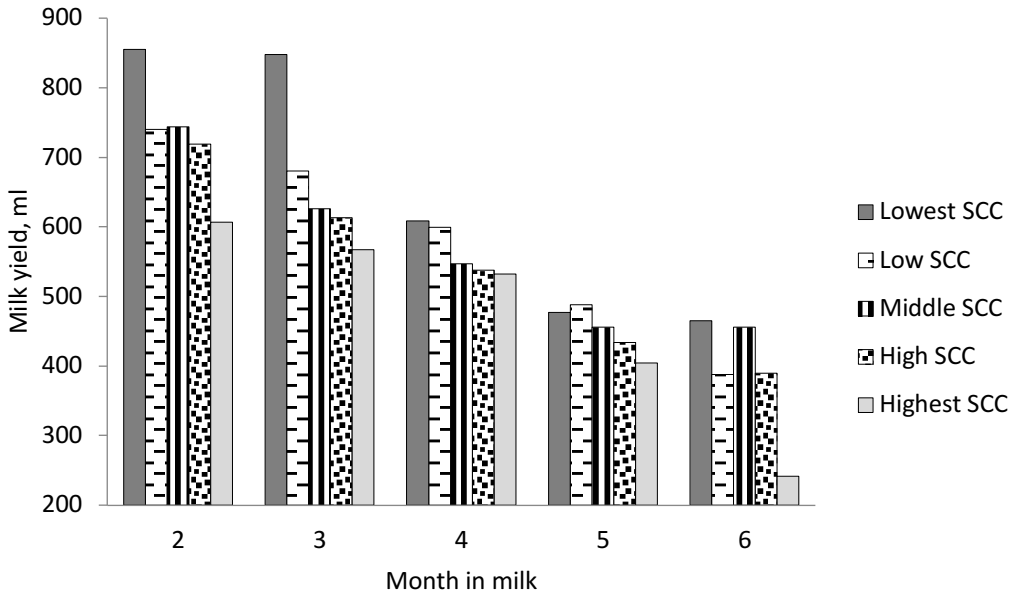

Figure 1 Milk yield in dependence of month in milk and somatic cell count class.

Least squres means (LSM) of MY and SCS confirmed negative relations between these traits (Table 2) i.e. the higher MY, the lower SCS is found. With increasing SCC (model 1), MY deacreased, with exception between classes with SCC>600≤1000 and >1000×10^3 cells.mL^{-1}. The differences between these classes, however, were found non-significant and respective LSM are probably affected by distribution of observations and their lower number (especially in highest SCC class). Accordingly, SCS increased with decreasing MY (model 2). Some differences between individual levels of MY class were also found non-signignicant. The proportion of highest SCC class of i.e. SCC above 1000×10^3 cells.mL^{-1} was 8 % of milk records. The proportion of records with SCC under or equal to 200×10^3 cells.mL^{-1} (lowest class of SCC) was only 3 %. The most of records fell in classes with SCC>400x10^3≤600x10^3 cells.mL^{-1} (middle SCC class) and SCC>600x10^3≤1000x10^3 cells.mL^{-1} (higher SCC class) i.e. 37 % per each. The remaing proportion (15 %) fell in class with SCC>200x10^3≤400x10^3 cells.mL^{-1} (lower SCC class). According to these findings, about 90 % of ewes had healthy udders (or may be of subclinical mastitis udders) as compared with report of **Gonzalo et al. (1994)**, who recommended SCC values ranging from 500×10^3 to 1000×10^3 cells.mL^{-1} as thresholds between healthy and infected udders. When comparing with reports **El-Saied, Carriedo and San Primitivo (1998)**, **Caboni et al. (2017) and Kern et al. (2013)** who recommended SCC values ranging from 250×10^3 to 300×10^3 cells.mL^{-1} as thresholds of healthy udders, the proportion of ewes those could suffer from subclinical mastitis icreased. Regarding distribution of ewes in dependence on SCC class, **Tvarožková et al., (2019)**, who analysed Tsigai, Lacaune and Slovak Dairy breed ewes, reported the following frequencies: about 88 % in lowest class of SCC (under or equal to 200×10^3 cells.mL^{-1}) and about 8 % in highest class of SCC (above 1000×10^3 cells.mL^{-1}) in 2017. Frequencies in 2018 were found to differ: about 21 % and 32 % in lowest and highest class, respectively. High changes between years were probably due to fact that more heterogeneous data were studied (various breeds and various flocks) than data analysed in this study. These also might indicate differences in managment between 2017 and 2018. **Idriss et al. (2015)**, reported highest proportion of ewes in lowest class of SCC and lowest proportion of ewes in highest class of SCC. These proportions slightly differed between breeds (Tsigai, Improved Valachian and Lacaune and their crossbreds, although the same pattern was was found in dependence of breed.

When comparing estimated changes in MY according to SCC class found in this study, these were between 12 and 25 %. **Tančin et al., (2019)**, who also investigated relationships between MY and SCC in Lacaune breed, estimated these changes between 10 to 18 %. When investigated these changes on farm level (five farms), these changes were higher **(Tančin et al., 2017)**. **Sutera et al. (2018)** reported that estimated losses in MY according to SCC level used were about 16% at maximum (in Valle del Belice ewes studied). Although no analyses of microrganisms in udders were done, the negative effect of increased SCC level on milk yield could be supposed when comparing with literature. For example, **Martí De Olives et al. (2013)**, who performed the bacteriological analysis in Manchega ewes, found that milk yield between healthy and infected ewes differred by about 17 % in favour of healthy ewes.

The fluctuation in LSM of MY (also of SCS) in dependence on year of measurement (Table 3) may indicate some problems in management practice of flock, especially when evaluating these traits between 2017 and 2018; probably worse conditions occurred in 2018. A rough increase of MY (and decrease of SCS) were found with increasing lactation number, although some differences were found non-significant (significant difference between first and second lactation was found). The effect of MIM showed significant influence on MY

and SCS although variation of SCS was lower (less significant differences revealed) in comparison to variation of MY (more significant differences revealed). Finding about influence of lactation number partly agreed with previous studies **(Oravcová et al., 2006; Oravcová, Mačuhová and Tančin, 2018)**, who reported no significant differences in MY in dependence on lactation number when LC, Tsigai (TS) and Improved Valachian (IV) ewes and LCxTS and LCxIV crosses were analysed. For log_{10}SCC, the latter authors revealed all differences between invidual lactations to be significant. Detailed comparisons of MY in this study and study of **Oravcová, Mačuhová and Tančin (2018)** those related LC ewes in the same flocks showed worse levels of flock mangement, also in terms of mastitis control might be supposed: in earlier period (2010-2013) higher MY was observed. **El-Saied, Carriedo and San Primitivo (1998)** reported that lactation number and stage of lactation (could be considered as MIM) significantly affected SCS in Churra ewes. In contrast, **Othmane et al. (2002)** found age of ewe (could be considered as lactation number) and stage of lactation to be non-significant when SCC in ewes of the same breed were analysed later. According to the latter authors, no differences were a result of strict mastitis control (teat dip after milking, selective dry therapy and culling of ewes with chronic mastitis) and high levels of husbandry applied in flocks investigated. The lower variation of SCS and higher variation of MY in dependence on stage of lactation was reported for French Lacaune ewes **(Barillet et al., 2001)**.

The influence of interaction between MIM and SCC (Figure 1) was significant when MY (model 1) was analysed. Within individual months, some significant differences between SCC classes were revealed. However, most of differences were found between lower SCC classes (mostly MIM 2 and MIM 3) on the one hand and higher SCC classes (mostly MIM 4, MIM 5 and MIM 6) on the other hand. Comparisons with literature could not be done: to our best knowledge, no study which included interaction between MIM and SCC class in similar way was performed. However, a relationship between lactation stage and comatic cells showed that milk yield seemed to be of the higher influence on SCC at the end of lactation (MIM 6) than at the beginning, which is in accordance with findings of **Arias et al. (2012)**.

Figure 1

When interation between MIM and MY class was considered when SCS (model 2) was analysed, the differences were non-significant, although trends were similar to those found when individual MIM and MY classes were investigated (not shown).

CONCLUSION

The findings of this study confirmed fact that somatic cells were present in ewe milk and may used to indicate udder health and contribue to improve levels of management, in terms of preventing the mastitis to be spread. Because number of somatic cells increases when infectious agents enter the udder, further research aimed at relationships between somatic cells, microorganisms and quality of ewe milk is needed.

ANTIOXIDANT PROPERTIES OF PROCESSED CHEESE SPREAD AFTER FREEZE-DRIED AND OVEN-DRIED GRAPE SKIN POWDER ADDITION

Michaela Frühbauerová, Libor Červenka, Tomáš Hájek, Richardos Nikolaos Salek, Helena Velichová, František Buňka

ABSTRACT

Processed cheese spread (PCS) is a popular product with high nutritional value and containing protein, fat and minerals. Grape skin is waste from winery processing plants that still has phenolic substances with significant antioxidant activity that could be used for valorisation of processed cheese and increasing the content of nutrients, phenolics and overall antioxidant properties. Both oven-dried (OD) and freeze-dried (FD) grape skin (GS) powder was characterised by the principal ingredients, the content of phenolic compounds and antioxidant capacity. Similarly, the influence of the addition of OD-GS and FD-GS powders on processed cheese spread (PCS) at 1% and 2% (w/w) levels were examined. The OD-GS and FD-GS powders were characterised by protein content, fat content, moisture and dietary fibre, thus showing that drying technique did not affect those parameters. The OD-GS powder exhibited higher content of rutin, (+)-catechin, (-)-epicatechin and total flavonoid content (TFC), while higher total phenolic content (TPC) and ABTS radical cation were observed for freeze-dried GS powder. Fortification of PCS with 1% and 2% (w/w) of GS powder increased protein content. An ANOVA procedure revealed that addition of FD-GS powder to processed cheese spread was superior to TPC values together with rutin, (+)-catechin, and (-)-epicatechin contents. The higher phenolic contents reflected the higher antioxidant capacity of PCS samples fortified with FD-GS powder. Freeze-dried grape skin powder was the better choice for valorisation of processed cheese spread.

Keywords: grape; valorisation; processed cheese; antioxidant; chromatography

INTRODUCTION

Processed cheese spread (PCS) is a multi-component mixture made from water, cheese, fat, and emulsifying salts (phosphates or citrates). This mix is processed by stirring and melting in temperatures ranging from 85 to 110 °C for up to 20 min **(Černíková, et al., 2018)**. The obtained hot mixture is poured into cups, cooled down and stored at refrigeration temperature. Processed cheeses are products with extended shelf life that deliver bioactive proteins, fats, minerals and vitamins to consumers **(Henning, et al., 2006)**. Despite the high nutritional value, various types of cheese have been enriched by addition of herb or medicinal plant extracts during their preparation, for instance, the addition of rosemary leaves to ripened semi-hard cheese **(Marinho, et al., 2015)**. The fortification of frequently used food products may enhance the consumption of various health-promoting substances and might be helpful for human health **(Rashidinejad, et al., 2015)**. The authors found that hard low-fat cheese fortified by catechin maintained its antioxidant activity after *in vitro* digestion experiment.

Grape berries (*Vitis vinifera L.*) are used in the winemaking industry to produce alcoholic beverages by pressing berries and subsequent fermentation of liquid. The press residues constitute 20% (w/w) of the total grapes used for wine production **(Teixeira, et al., 2014)**. Grape pomace from white grape varieties is an excellent source of phenolic compounds (for example gallic acid, catechin, epicatechin and procyanidins) **(Genova, Tosetti and Tonutti, 2016)**; therefore, it can be used for the valorisation of various food products. Grape skin powder or grape flour has been successfully incorporated into bread **(Šporin, et al., 2018)** or yoghurts **(Karnopp, et al., 2017)**. Only a limited number of studies regarding the enrichment of processed cheese, probably due to the higher processing temperature and high-fat content, exist. In our recent studies, we described the effect of processing parameters on the antioxidant properties of processed cheeses fortified by quercetin or/and rutin **(Přikryl, et al., 2018)**. Functional processed cheese spreads have been prepared with the addition of tomato paste **(Mehanna, et al., 2017)**, carrot paste **(Mohamed, Shalaby and Gafour,**

2016) and pulp from apricots **(Mohamed and Shalaby, 2016)**. In a study of **Torri et al. (2016)**, grape skin powder was added to cow's milk curd before ripening process to produce Robiola (soft-ripened cheese), focusing on optimisation of enrichment using sensory evaluation. The authors found that the amount of powders exceeding 0.8% and 1.6% (w/w) for Barbera and Chardonnay powder, respectively, negatively affected the acceptability of cheeses. In a recent study, various fruit and vegetable by-products were added into the curd to produce Primosale cheese **(Costa, et al., 2018)**. They found wine pomace to be an excellent source of polyphenolic compounds with antioxidant activity. The main aim of this study is to determine the effect of the addition of grape skin powder on principal ingredients and antioxidant properties of processed cheese. We assumed that the addition of freeze-dried grape skin powder would enhance the functional properties of enriched processed cheese spread.

Scientific hypothesis

Freeze-dried grape skin powder enhances the antioxidant status of fortified processed cheese spread more than the oven-dried grape skin powder does.

MATERIAL AND METHODOLOGY

All solvents for extraction, chromatographic analysis and chemicals used for determination of antioxidant activity were purchased from Sigma-Aldrich (Prague, Czech Republic).

Preparation of grape skin powder

Grapes of the white variety 'Müller Thurgau' were harvested from the Prostřední Hory (Bzenec, Czech Republic) vineyard track during September 2017. After pressing the grape berries to obtain a liquid for wine manufacturing, a portion of grape pomace was immediately stored at -20 °C in an evacuated plastic package. Before processing, grape pomace was thawed and the needles and seeds were removed using an analytical sieve (mesh size 0.5 × 0.5 cm). Grape skins (GS) were dried at the following conditions: oven-drying (OD) was performed in laboratory air-forced oven (HS62A, Chirana, Brno, Czech Republic) at 46 °C for 24 h. Freeze-dried (FD) samples were prepared at -40 °C (12 Pa) for 48 h (CoolSafe 100-4, Trigon Plus, Čestlice, Czech Republic). Dried grape skins were milled at 5000 rpm for 10 s with a Grindomix GM 200 (Retsch GmbH, Haan, Germany) and sieved to obtain particles <800 μm. Both GS-OD and GS-FD powders were stored in a tightly sealed plastic pack at -20 °C until use. The contents of crude protein (Method 960.52), fat (Method 920.39), moisture (Method 934.01), ash (Method 930.05) and total dietary fibre (Method 985.29) were determined according to AOAC **(Horwitz, 2000)** procedure in duplicate. The total content of saccharides was calculated from differences.

Processed cheese manufacturing

The composition of raw materials, including Eidam cheese (dry matter ≈50 g.100 g^{-1} and fat in dry matter ≈30 g.100 g^{-1}, 8-week maturity), butter (dry matter ≈84 g.100 g^{-1} and fat in dry matter ≈98 g.100 g^{-1}) and water, was adjusted to obtain processed cheese with dry matter ≈37 g.100 g^{-1} and fat in dry matter ≈50 g.100 g^{-1}. A ternary mixture of monosodium dihydrogenphosphate (19%), disodium hydrogen phosphate (37%), tetrasodium diphosphate (22%) and the sodium salt of polyphosphate (22%) was used in a total concentration of 2.8 g.100 g^{-1}. For the preparation of functional processed cheese spread (PCS), OD-GS and FD-GS powders were added to produce PCSOD-GS and PCSFD-GS samples. Both grape skin powders were added at 1.0 and 2.0% (w/w) levels. Processed cheese without grape skin powder served as a control. Model processed cheese was manufactured in Stephan UMC-5 (Stephan Machinery GmbH, Halmen, Germany) equipment with indirect heating as is described in the flow chart below (Figure 1). Eidam block cheese and butter were cut into small pieces, put into the kettle and minced for 30 s. Then water, emulsifying salts and GS powder were added into the blend. The mixture was heated at 90 °C for 13 min at a constant agitation of 1500 rpm. Samples were poured into 80 g polystyrene doses with caps. The packages were cooled down to 6 °C and stored at -20 °C to avoid deterioration. Dry matter (DM), fat and protein contents were evaluated according to Method 969.19, Method 2001.14 and Method 960.52 as described in **Horwitz (2000)**, respectively, in three repetitions.

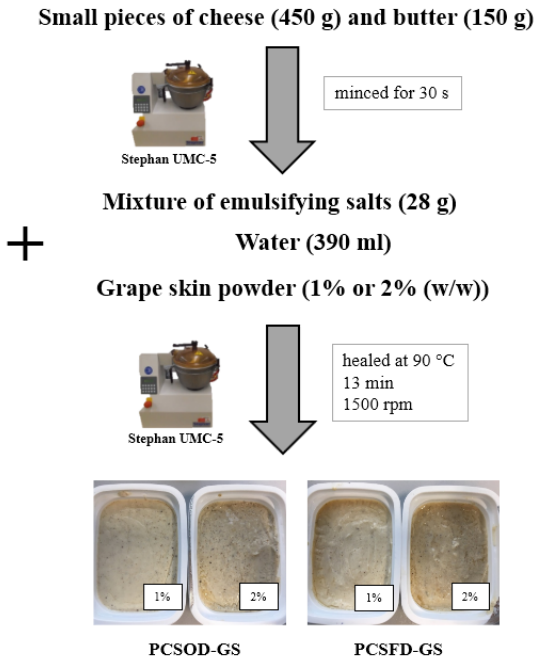

Figure 1 Flow chart of the cheese-making process. PCSOD-GS = processed cheese spread with oven-dried grape skin powder, PCSFD-GS = processed cheese spread with freeze-fried grape skin powder.

Extracts preparation

A glass test tube with 1.0 g of dried GS sample and 10.0 mL of 50% methanol solution was put in ultrasonic bath Sonorex TK52 (Bandelin Electronic, Berlin, Germany) for 30 min. A clear supernatant after centrifugation at 4100 rpm for 5 min (Universal 320, Hettich, Tuttlingen, Germany) was obtained.

Extract of PCS samples was obtained according to the procedure described in **Přikryl et al. (2018)**, i.e. 1.0 g of frozen PC sample was extracted into 10.0 mL of 50% methanol solution in an ultrasonic bath for 30 min. Subsequently, elimination of proteins and salts was performed using the procedure of **Khalifa, Omar and Mohamed (2017)** with a slight modification; the pH of extract was adjusted to 4.0 using HCl (2 M) and precipitated proteins were removed by centrifugation at 6000 rpm for 10 min. Then, the pH of clear supernatant was adjusted to 7.0 using NaOH (1 M) followed by centrifugation at 6000 rpm for 10 min to remove remaining proteins and salts. Supernatants were kept refrigerated and used for antioxidant assays and HPLC analysis. Two extracts per sample were prepared, and each extract was measured in duplicate, resulting in a sample size N = 4.

Chromatographic analysis of the extracts (HPLC analysis)

First, GS were screened for the presence of the following phenolic compounds: quercetin, rutin, (+)-catechin, (-)-epicatechin, resveratrol, caffeic acid, p-cumaric acid and ellagic acid. Secondly, phenolic substances identified in GS extracts were determined in PCSOD-GS and PCSFD-GS extracts. Before injection, each extract was filtered through a syringe filter (0.45 μm, Labicom, Olomouc, Czech Republic). Samples were injected into an Agilent 1290 Infinity (Agilent Technologies, Santa Clara, CA, USA) equipped with a degasser, an autosampler, a binary pump, a thermostated column compartment and DAD detector. A Zorbax Elipse Plus 1.8 μm C18 (50 × 2.1 mm; Agilent Technologies) column thermostated at 40 °C was used. For the analysis, 2 μL of the sample were injected. A mixture of 0.01 M ammonium acetate adjusted to pH 3.1 using formic acid (solution A) and acetonitrile (solution B) was used as mobile phase with a flow rate 0.6 mL.min^{-1}. The gradient for solution B was 0-3 min at 3%; 10 min at 20% and 20 min at 80%. The signal was detected at 280 nm. The identification of each peak in chromatograms of the extracts was carried out by comparing retention time and absorption spectrum against a pure standard. Quantitative determinations were done using calibration plots of a selected external standard.

Determination of antioxidant properties

Total phenolic content (TPC) was determined by measuring the complex of antioxidants with Folin-Ciocalteau reagent at 765 nm (DU 530, Beckman Coulter Inc., Brea, USA) using the procedure described in **Přikryl et al. (2018)**. The results were expressed as gallic acid (GAE) equivalents (mg.g^{-1} of dry matter (DM)). Total flavonoid content (TFC) was determined using aluminium chloride assay **(Denni and Mammen, 2012)**. The increase of absorbance at 415 nm was proportional to the increase in the content of flavonoids. Results were reported as quercetin (QUE) equivalents (mg.g^{-1} DM).

ABTS (2,2´-azino-bis-3-ethylbenzthiazoline-6-sulphonic acid) radical scavenging activity assay was adopted from our previous study **(Červenka, et al., 2018)**. The reaction between ABTS$^{\bullet+}$ and antioxidants was monitored at 734 nm, and the results were reported as Trolox equivalents antioxidant capacity (TEAC) in mg.g^{-1} DM.

Reducing power (RP) of extracts was determined via the formation of Prussian blue at 700 nm (ferric-ferrous complex) according to the procedure of **Pavithra and Vadivukkarasi (2015)**.

Statistical analysis

Order statistic methods for small sample size were used throughout this study. The mean and its deviation were calculated according to Horn's procedure **(Horn, 1983)** and were expressed as pivot half sum (P_L) and pivot range (R), respectively. Nonparametric statistical methods were used in this study. The sign test was applied for pair-wise comparisons between means for grape powder samples. As far as processed cheese is concerned, the pair-wise comparison procedure was performed using Tukey's method. A two-factor Kruskal-Wallis analysis of variance (ANOVA) was applied to determine whether the drying method of GS powder (factor A) and the amount added to PCS sample (factor B) influenced the antioxidant properties in fortified PCS samples. To determine associations among variables, Spearman rank-order correlation coefficients (r) were assessed. All the statistical treatments were done at the probability P = 95%) (Statistica CZ, 12.0, StatSoft CR s.r.o., Prague).

RESULTS AND DISCUSSION

Composition of grape skin powder

As can be seen from Table 1, there were no statistical differences between the contents of crude protein, fat, total dietary fibre and ash for oven-dried and freeze-dried GS powders. On the other hand, the type of drying process affected the TPC and antioxidant properties of samples. Freeze-dried GS powder has a higher level of TPC (19.97 ±1.60 mg GAE.g^{-1} DM) and more than twice as high $TEAC_{ABTS}$ value (127.10 ±27.28 mg Trolox.g^{-1} DM) in comparison with the oven-dried GS samples. It has been previously concluded that the freeze-drying process is superior for the preservation of antioxidant compounds, and probably higher efficiency of extraction due to pronounced disruption of plant cells via the formation of ice crystals **(Kamiloglu, et al., 2016, Kamiloglu and Capanolgu, 2014)**. However, such a release of flavonoid compounds from plant cells may cause their pronounced exposure to oxygen. As was described in a study of **Nunes et al. (2016)**, oven drying of guava powder released more soluble flavonoids than the freeze-drying technique. In the chromatogram (Figure 2) of dried grape skin powder extract, fourteen well-resolved peaks were observed. However, from eight selected polyphenolic compounds, only the presences of (+)-catechin, (-)-epicatechin and rutin were confirmed in grape skin powder samples using retention time and absorption spectra in the current study. There was no difference in the number of peaks/compounds in oven-dried and freeze-dried GS powder extracts. The chromatograms differed in the heights of the peak showing that oven-dried GS powder extracts contained more polyphenolic substances.

Table 1 The main composition and antioxidant properties of grape skin powders (pivot half sum (P_L) ±pivot range (R), N = 2).

	Oven-dried	Freeze-dried
Main composition (g.kg^{-1})		
Protein	157.5 ±7.0^{A}	150.5 ±4.2^{A}
Fat	74.2 ±5.1^{A}	72.3 ±4.5^{A}
Moisture	55.0 ±4.3^{A}	59.5 ±6.4^{A}
Ash	13.2 ±2.0^{A}	14.6 ±3.1^{A}
Total saccharides	701.2	703.5
Total dietary fibre	228.8 ±8.5^{A}	231.7 ±9.1^{A}
Phenolic content (mg.g^{-1} DM)		
(+)-catechin	1712.5 ±1.2^{B}	1450.0 ±1.5^{A}
(-)-epicatechin	1383.3 ±3.0^{B}	1023.4 ±2.2^{A}
Rutin	221.8 ±1.0^{B}	112.0 ±1.2^{A}
Total phenolics (mg GAE.g^{-1} DM)	10.1 ±0.93^{A}	19.97 ±1.60^{B}
Total flavonoids (mg QUE.g^{-1} DM)	0.73 ±0.01^{B}	0.52 ±0.02^{A}
Antioxidant activity		
$TEAC_{ABTS}$ (mg Trolox.g^{-1} DM)	54.44 ±2.44^{A}	127.10 ±27.28^{B}
Reducing power (absorbance unit)	1.140 ±0.010^{A}	1.136 ±0.012^{A}

Note: DM, dry matter; GAE, gallic acid; QUE, quercetin; $TEAC_{ABTS}$, Trolox equivalent antioxidant capacity using 2,2´-azino-bis-3-ethylbenzthiazoline-6-sulphonic acid. Values sharing the same superscript letters in row $^{(A-B)}$ are not statistically significant different from each other (the sign test, p <0.05).

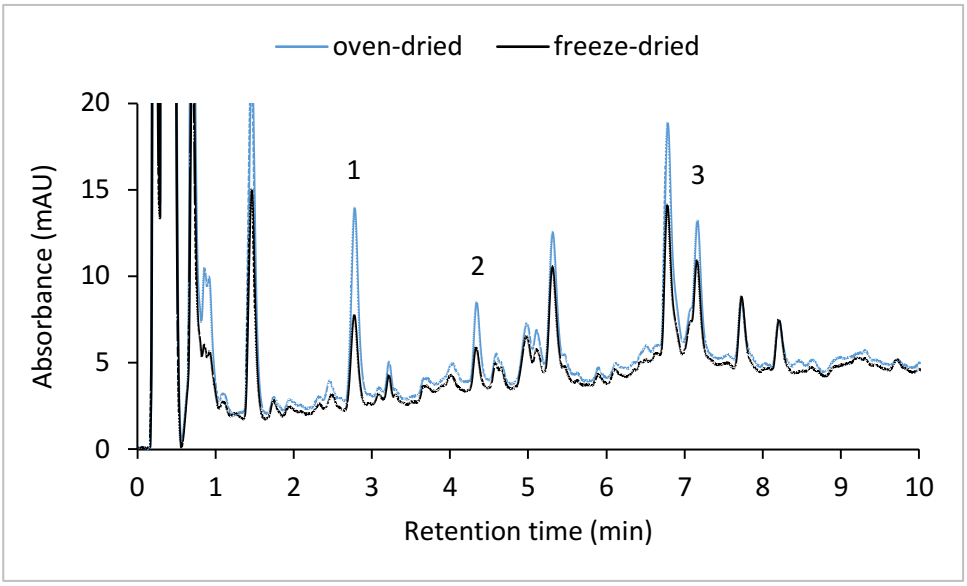

Figure 2 Separation of phenolic compounds in oven-dried and freeze-dried grape skin powder extracts using HPLC/DAD, detection at 280 nm; (+)-catechin (**1**), (-)-epicatechin (**2**) and rutin (**3**).

As shown in Table 1, significantly higher contents of (+)-catechin, (-)-epicatechin and rutin were observed in oven-dried GS powders, which corresponded to TFC values.

Properties of processed cheese spread containing grape skin powder

Table 2 shows the differences in the main composition of fortified processed cheese. The addition of grape skin powders significantly increased the protein content in processed cheese samples when added in 2% (w/w) levels, i.e. from 112.5 ±5.0 g.kg^{-1} (in control) to 128.4 ±5.7 and 129.7 ±2.3 g.kg^{-1} for processed cheese enriched with freeze-dried and oven-dried GS powders, respectively (p <0.05). Since we used the same amount of ingredients (cheese, butter, polyphosphate salts) for the preparation of all of the processed cheese samples, the variation in protein content was due to the addition of grape skin powder. Although the values of dry matter content increased linearly with the level of addition of grape skin powder, the effect of fortification was recognized as insignificant (p >0.05). On the contrary, **Khan et al. (2018)** found that fortification of Gouda cheese with the mango kernel did not significantly change the protein content.

Pair-wise comparison tests revealed that only processed cheese with 2% (w/w) of oven-dried GS powder had significantly higher dry matter content than that found in

Table 2 The main composition of processed cheese spread (PCS) fortified with oven-dried (OD) and freeze-dried (FD) grape skin powder (GS). Pivot half sum (P_L) ±pivot range (R) (N = 3).

Ingredient (g.kg^{-1})	PCS control	PCS fortified with OD-GS powder (%, w/w)		PCS fortified with FD-GS powder (%, w/w)	
		1.0	2.0	1.0	2.0
Protein	112.5 ±5.0^{A}	120.3 ±4.3^{A}	129.7 ±2.3^{B}	118.0 ±3.8^{A}	128.4 ±5.7^{B}
Fat	191.0 ±3.1^{A}	188.5 ±2.7^{A}	187.4 ±3.0^{A}	189.3 ±4.2^{A}	186.9 ±1.8^{A}
Dry matter	368.2 ±14.0^{A}	394.6 ±6.2^{AB}	419.0 ±18.0^{B}	387.3 ±7.0^{AB}	395.9 ±4.8^{AB}
Ash content	39.5 ±1.8^{A}	40.8 ±2.2^{A}	42.1 ±1.4^{A}	40.9 ±1.1^{A}	42.4 ±2.0^{A}

Note: Values sharing the same superscript letters in row $^{(A-B)}$ are not statistically significant different from each other (Tukey's pair-wise comparison test, p <0.05).

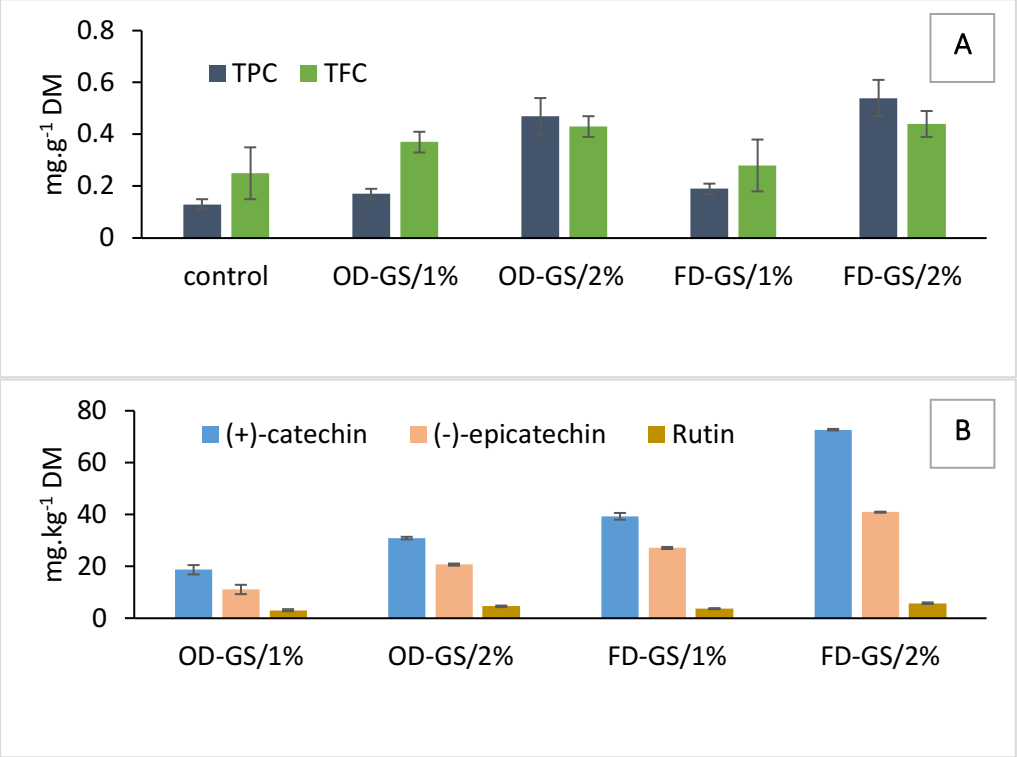

Figure 3 The content of **A**) total flavonoid (TFC), total phenolic contents (TPC), and **B**) phenolic individuals in processed cheese spread supplemented with oven-dried (OD) and freeze-dried (FD) grape skin (GS) powder at 1% and 2% (w/w) levels. Results are expressed as gallic acid and quercetin equivalents for TPC and TFC, respectively.

control (p <0.01). Fat and ash contents remained similar for all the processed cheese samples (p >0.05).

Antioxidant properties of processed cheese spread containing grape skin powder

The content of phenolic individuals is depicted in Figure 3B and show their higher content in processed cheese fortified with freeze-dried grape skin powder at both levels. Total phenolic content of processed cheese samples was determined using Folin-Ciocalteau's assay (Figure 3A). Significant increase of TPC values was obtained for processed cheese supplemented with GS powder at 2% (w/w) level from 0.13 ±0.02 mg GAE.g^{-1} DM (control sample) to 0.47 ±0.07 and 0.54 ±0.07 mg GAE.g^{-1} DM for oved-dried and freeze-dried GS powder, respectively. The addition of OD-GS powder to processed cheese spread resulted in the increase in TFC values from 0.25 ±0.10 mg QET.g^{-1} DM (control sample) to 0.37 – 0.43 mg QET.g^{-1} DM without respect to GS level. Freeze-dried GS powder enhanced processed cheese samples with flavonoids at a higher level (2%, w/w). It is interesting to note that even the control sample exhibited TFC value that then slightly increased with the addition GS powder. It has been reviewed that antioxidant properties of milk and milk products are due to the presence of sulphur-containing amino acids, vitamins, enzymes, peptides and oligosaccharides **(Khan, et al., 2019; Usta and Yilmaz-Ersan, 2013; Atmaca, 2004; Egger and Ménard, 2017; Alenisan, et al., 2017)**. Although oven-dried GS powder exhibited higher levels of (+)-catechin, (-)-epicatechin and rutin, their content in PCS samples with OD-GS powder decreased in comparison with PCS fortified with FD-GC powder. TPC values showed very high correlation with the content of all phenolic constituents (0.746 < r < 0.826, p <0.01) while low correlation coefficients have been

observed for TFC values showed values where (r = 0.610, p <0.05).

Antioxidant capacity of processed cheese samples in terms of $TEAC_{ABTS}$ significantly increased with the increase of GS level (p <0.05). Surprisingly, $TEAC_{ABTS}$ values were approximately tenfold higher (0.31 – 0.72 mg Trolox.g^{-1} DM) for processed cheese with 1% (w/w) of GS in comparison with that of the control, followed by an additional tenfold increase (5.22 – 6.69 mg Trolox.g^{-1} DM) when 2% (w/w) of GS powders were added (Figure 4). Such an increase may be attributed to the higher temperature used for melting the processed cheese in this study (90 °C for 13 min). It was previously published that pasteurization enhanced antioxidant properties of grape juice by releasing some polyphenolic compounds that were previously bound to other molecules **(Genova, Tosetti and Tonutti, 2016; Fuleki and Ricardo-da-Silva, 2003)**. For instant, general increase in ABTS scavenging was detected in fresh and technologically harvested grape juices followed by pasteriuzation at 78 °C for 30 min **(Genova, Tosetti and Tonutti, 2016)**.

In our previous work, the antioxidant properties of processed cheese fortified by rutin or quercetin increased with the increase of melting temperature as measured by ABTS•$^{+}$ assay **(Přikryl, et al., 2018)**. In addition, polyphenolics contributed differently to antioxidant capacity measured by ABTS•$^{+}$, as was observed in a study of **Lingua et al. (2016)**. They found that (-)-epicatechin, peonidin-3-glucoside and peonidin-3-acetylglucoside positively correlated with the assay, while pigment A and siringetin-3-glucoside had a negative effect. Similarly, strong positive correlation was observed for $TEAC_{ABTS}$ values and the content of (+)-catechin, (-)-epicactechin and rutin (r = 0.955, p <0.001; r = 0.739, p <0.01 and r = 0.951, p <0.001, respectively). Considering that high correlation coefficient reflects the strong association between variables, we may conclude that $TEAC_{ABTS}$ was mainly influenced by (+)-catechin and rutin contents followed by TPC values (r = 0.877, p <0.01).

The addition of GS powder had influence on reducing the power of processed cheese samples (Figure 4), where an increase was observed with the increase of GS powder level. Even though oven-dried and freeze-dried GS powders had similar RP values (see Table 1), processed cheese samples enriched with freeze-dried GS powder showed significantly higher RP values than in the case of incorporation of oven-dried GS powder, particularly at the 2% level (w/w) (p <0.05). Those discrepancies can be explained by the formation of new compounds, which may have enhanced the antioxidant capacity of the samples. Although the masking of antioxidant properties of various plant-based extracts by the addition of milk or whey proteins is common in literature, an interaction of protein and polyphenolic compounds may also increase antioxidant capacity. For instance, the mixing of α-casein or β-casein with epigallocatechin gallate led to the increase of inhibition of ABTS•$^{+}$ during storage **(Almajano, Delgado and Gordon, 2007)**. In a study by **Sęczyk, Świeca and Gawlik-Dziki (2017)**, the addition of green coffee extract into soymilk significantly elevated ABTS radical scavenging ability (3.5-fold) and reducing power (13.8-fold). The study of interactions between polyphenolic compounds and β-conglycinin revealed that antioxidant capacity increased after the formation of the protein-phenolic complex **(Zhao, et al., 2018; Murray, 2002)**. The authors also demonstrated the increase of antioxidant capacity of the protein-phenolic mixture after heating at 90 °C for 30 min. Thus, we suppose a formation of new products during the preparation of enriched process cheese with enhanced antioxidant activity towards ABTS•$^{+}$. Both TPC and TFC values had the greatest influence on reducing power. Strong positive associations have been found for RP vs. TPC (r = 0.97, p <0.001) and RP vs. TFC content (r = 0.944, p <0.001).

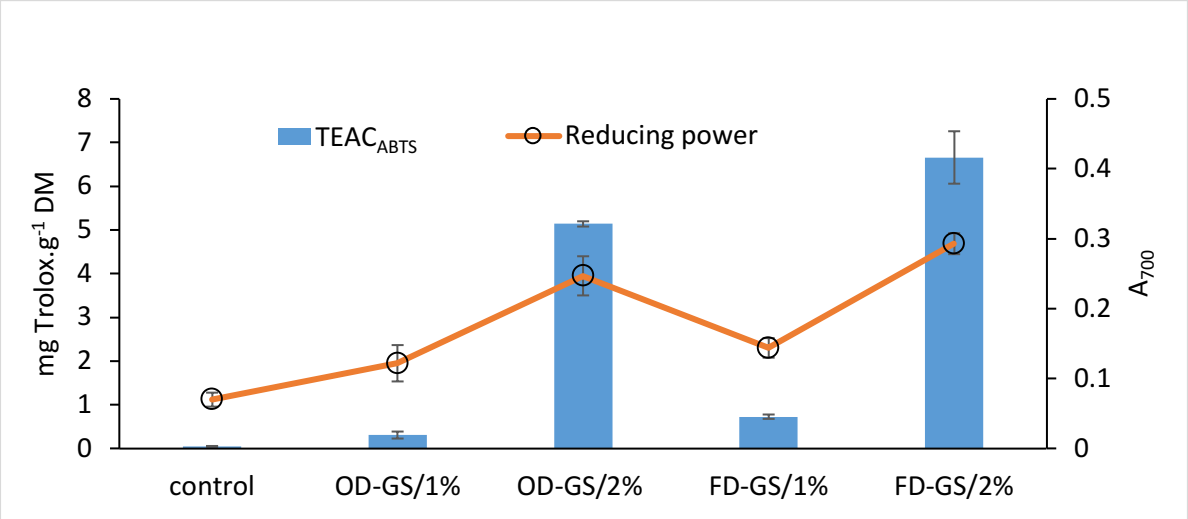

Figure 4 Trolox equivalent antioxidant capacity using ABTS ($TEAC_{ABTS}$, left y-axis) and reducing power (right y-axis) of processed cheese spread supplemented with oven-dried (OD) and freeze-dried (FD) grape skin (GS) powder at 1% and 2% (w/w) levels.

Rutin, (+)-catechin and (–)-epicatechin also showed strong positive correlations with reducing powder (p <0.001) of processed cheese enriched with GS powder, i.e. r = 0.859; 0.842 and 0.917, respectively.

Two-factor Kruskall-Wallis ANOVA was applied to study the effect of grape skin powder levels and type of drying used for their preparation (oven-dried vs. freeze-dried). As can be seen from Table 3, the drying technique has a significant effect on the TPC values, all the phenolic individuals, and reducing power (p <0.01) in processed cheese spreads where the addition of freeze-dried GS powder assured their higher values. Total flavonoids and $TEAC_{ABTS}$ values were not influenced by the drying technique. The effect of GS powder level was found to be significant for all parameters except for (-)-epicatechin content. As expected, the addition of GS powder at a higher level was reflected in higher values of TPC and TFC values, rutin and (+)-catechin contents, and antioxidant capacities in terms of $TEAC_{ABTS}$ and reducing power.

Table 3 The effect of drying technique (Factor A) for preparation of grape skin powder and its amount (Factor B) added to precessed cheese spread using two-factor Kruskall-Wallis ANOVA procedure.

	Factor A	Factor B
Total phenolics	p <0.05	p <0.001
Total flavonoids	p <0.05	p <0.01
(+)-catechin	p <0.01	p <0.001
(-)-epicatechin	p <0.01	p <0.05
Rutin	p <0.001	p <0.01
$TEAC_{ABTS}$	p <0.05	p <0.001
Reducing power	p <0.01	p <0.001

Note: $TEAC_{ABTS}$, Trolox equivalent antioxidant capacity using 2,2´-azino-bis-3-ethylbenzthiazoline-6-sulphonic acid.

CONCLUSION

Grape skin powder, a waste product from wine production, can be used as an ingredient for the production of processed cheese with enhanced properties. Grape skin powder samples have a high content of protein (150.5 – 157.5 $g.kg^{-1}$) and total dietary fibre (228.8 – 231.7 $g.kg^{-1}$). Freeze-dried grape skin powder possessed higher total phenolic content and the ability to scavenge $ABTS^{\bullet+}$, but lower total flavonoid content as well as the levels of rutin, (+)-catechin, and (-)-epicatechin. The incorporation of grape skin powder at 2 % (w/w) levels into the processed cheese significantly increased the protein content to 128.4 and 129.7 $g.kg^{-1}$ for for freeze-dried and oven-dried grape skin powders, respectively. Addition of freeze-dried grape skin powder into processed cheese was beneficial to antioxidant capacity in terms of reducing power. Higher contents of rutin, (+)-catechin and (-)-epicatechin, as well as total phenolic content, were achieved through the incorporation of freeze-dried GS powder, as was determined using two-factor ANOVA procedure. Based on the chemical analysis, we may conclude that using freeze-dried grape skin powder for the valorisation of processed cheese spread is the better choice in comparison with oven-dried grape skin powder. The hypothesis of this research was confirmed.

MODELLING OF THE PROCESS OF VYBROMECHANICAL ACTIVATION OF PLANT RAW MATERIAL HYDROLYSIS FOR PECTIN EXTRACTION

Igor Palamarchuk, Mikhailo Mushtruk, Vladislav Sukhenko, Vladislav Dudchenko, Lidija Korets, Aleksandr Litvinenko, Olena Deviatko, Sergii Ulianko, Natalia Slobodyanyuk

ABSTRACT
Centrifugal and vibrational technological effects are among the main approaches to intensify the process of plant raw materials hydrolysis for pectin extraction. With the impulse intensification of such a process, it is possible not only to increase its efficiency, but also to achieve the compactness of the equipment, reduce the cost of electricity and improve the quality of the product of hydrolysis. The hypothesis is confirmed, according to which the vibro-centrifugal intensification of hydrolysis increases the driving force of the process by not only activating the material flows of raw materials and reagents, but also by reducing the resistance in the technological environment.
Graphical and analytical dependencies of the power and energy parameters of the oscillatory system were obtained, which proved the overcoming of the flow resistance of the liquid medium in the entire speed range of the drive shaft with the potential to intensify the process at a power consumption of 2.0 – 3.0 kW and or by the force of 2.3 – 2.5 kN using the Lagrange and Cauchy methods for composing and solving the equations of motion of the moving components of the tested hydrolyser with vibrating activators, and the methods of mathematical analysis and their processing in the MathCAD. The analysis of the presented parameters of the studied process of mixing the pectin-containing mass in the hydrolyser allowed us to determine the rational mode parameters of processing, which correspond to the angular velocity of the drive shaft $\omega = 150 - 150$ rad/s at the power consumption of 500 – 600 watts.

Keywords: plant raw material; hydrolysis; pectin; vibration motor; vibrator

INTRODUCTION
The process of plant raw material hydrolysis is one of the most common mass exchange processes of food technologies, in particular, the pectin extraction technologies **(Krasnikov et al., 1985)**.

There are different methods of solving the problem of removing solids outside the zone of intense mass exchange in the industry, for example, the use of ultrasound, firehoses for breaking foam, the addition of various surfactants that reduce the surface tension of the liquid. Any defoamers introduced into the solution impair the quality of the solute **(Kolyanovska et al., 2019)**. The intensification of this mass transfer process is implemented through the mixing of raw materials, which requires the study of the motion of the solid phase in the hydrolysate medium, allowing to form the necessary basis for the further theoretical study of the flow patterns and modes of hydrodynamic suspensions motion **(Bubelová et al., 2017; Zverev and Sesikashvili, 2018)**.

Mixing of raw materials in the process of hydrolysis of finely chopped fruits and vegetables for pectin extraction is implemented in the machine with mechanical or pneumatic stirring, with a fluidized bed of technological environment, with the help of the fluid or air jet, in screw and other machines with a moving and stationary solid layer. The mixing units with compressed gas and physical-mechanical volumetric activation methods based on cavitation and vibration effects are becoming widespread. The use of mechanical methods of intensifying the stirring of reagents in hydrolysers is somewhat limited due to the possibility of corrosion damage to metal surfaces and the need to use sufficiently expensive protective coatings or special methods of forming the surface layer of mixers. The erosion and corrosion products of the mixing devices further contaminate pectin, the target hydrolysis product, which is unacceptable **(Krasnikov et al., 1985; Kolyanovska et al., 2019; Czako et al., 2018)**.

Among the various forms of mechanical action on dispersion in technological processes, vibration action is one of the most effective methods for creating and correcting the required dynamic state. The adding of a vibration field on the technological environment significantly activates and intensifies the processes of heat and mass transfer, improves the quality of mixing of materials with different physical and mechanical properties, and helps to reduce the duration of technological operations and energy costs **(Palamarchuk**

et al., 2015; Sukhenko et al., 2017). The vibrating mixing effects allow for a uniform and intense mass exchange between the solid and the liquid phase and have a great potential for energy-saving technologies. Vibrating mixers, compared to conventional ones, have a higher specific performance (5-6 times higher), provide a reduction of mixing time by 2 to 3 times, metal usage by 17 %, power consumption by 30%, capital costs for manufacturing by 18 % and drive power by 30 – 35 %, which results in the decrease of the total energy consumption by 3 – 4 times **(Palamarchuk et al., 2019 a)**.

The process of hydrolysis with such stirring of a suspension of ground plant pectin-containing raw materials in hydrolysers allows increasing the propelling power of the process and energy dissipation in the technological environment. Therefore, the justification of the effective conditions of hydromechanics of the plant raw materials hydrolysis process formation based on the laws of motion of the hydrolyser working parts in the conditions of vibration centrifugal mixing of the hydrolysis suspension study, the saturation of the technological environment with energy that is necessary for the conversion of protopectin into pectin, are relevant problems that are solved in the current scientific research **(Krasnikov et al., 1985; Kolyanovska et al., 2019; Sukhenko et al., 2020)**.

Scientific hypothesis

The research is based on the scientific hypothesis, the main provisions of which are: increasing the driving force of the dissolution process, reducing the cohesive forces of the interaction of the dispersed particles with the blade and increasing the number of equilibrium conditions of the dispersed particles in a liquid dispersive medium, provided that to reduce the resistance in the liquid process mass during mixing, to increase the speed of the blade shaft and to reduce the energy consumption during the operation of the mixer; improve the quality of mixing; to improve the conditions of the bottom of the working area from sediment and to self-clean the working bodies of the sediment.

MATERIAL AND METHODOLOGY

The Lagrange equations of the second kind were used for the theoretical analysis and justification of the power and energy characteristics of the developed machine for hydrolysis of pectin-containing raw materials with vibration centrifugal excitation of the technological environment. The Cauchy method was used for solving these equations. Methods of mathematical analysis and processing in the MathCAD were also applied to obtain the necessary graphical and analytical dependencies of the basic operating parameters of the vibrating system **(MathCAD 12).**

Statistic analysis

Analysis of variance methods was used for the mathematical processing of the results of the experimental studies by means of Microsoft Excel 2013 and the statistical analysis software for crop production "AGROS".

RESULTS AND DISCUSSION

Enabling the oscillatory motion for the moving parts of the tested hydrolyser allows to reduce the resistance of the liquid technological environment during mixing, which, accordingly, reduces the energy consumption during the operation of the stirrer; increases the speed of the blade shaft; increases the degree of mixing; improves the conditions for cleaning of the bottom of the hydrolysers from the sediment; allows to carry out self-purification of the working parts from the sediment by reducing the adhesive forces of the interaction of the dispersed particles with the blade of the agitator and the cohesive forces between the particles of the raw material **(Rachmat et al., 2010; Zheplinska et al., 2019; Palamarchuk et al., 2019 b; Barbaro et al., 2009)**.

Hydrodynamic and mechanical methods for creating a non-equilibrium oscillatory system can be implemented for the equipment under study.

The hydrodynamic method involves the use of a liquid medium as an elastic component of the process, and the periodic change of pressure as a force, which greatly simplifies the regulation of the driving force, reduces the number of actuator elements and, accordingly, increases the reliability of the mechanism. At the same time, the design of the working capacity is complicated because of the need to install guides to ensure periodic braking of the flow and there is an unpredictability of its interaction with the moving fluid from the mixing of the technological environment. It is also necessary to provide an additional hydrodynamic circuit with the pump to ensure the periodic change in fluid pressure complicates the design of the hydrolysers **(Palamarchuk et al., 2013; Ha and Liu, 2009; Burger et al., 2007; Degond and Motsch, 2008.)**.

The mechanical method requires additional introduction into the system of the spring element 2 and the unbalanced unstable elements 3, the specific arrangement of which allows for linear oscillatory motion of the blade shaft 4 and, accordingly, the working blades of the machine in Figure 1.

The main disadvantages of such a model are the increase in dynamic loads on the bearing units 5 and the need to disassemble the mechanism for performing tuning operations, which are not significant enough compared with the disadvantages of the hydrodynamic system **(Nowak and Lewicki, 2004; Palamarchuk, Turcan and Palamarchuk, 2015; Palamarchuk Bandura and Palamarchuk, 2013; Ballerini et al., 2008)**.

To ensure linear oscillatory motion of the blades of the mixer, the model with a combined imbalance of the working elements under the action of circular forcing torque $M_к$ and circular forcing force F_k was used, which causes an increase in dynamic loads on the support units and, at the same time, allows to implement more intensive oscillatory motion **(Palamarchuk Bandura and Palamarchuk, 2013)**.

The presented compelling factors of mechanical unbalance can be determined by the value of the centrifugal force *F* and the moment from the action of two forces in Figure 2:

$$F = m_d \cdot L_d \cdot \omega^2 \quad (1)$$

where: m_d – unbalanced mass; L_d – the distance from the centre of mass of unbalanced mass to the axis of rotation

of the drive shaft; ω – the angular velocity of the blade shaft.

The torque is:

$$M_k = F_k \cdot a = m_1 \cdot L_d \cdot \omega^2 \cdot a = m_1 \cdot L_d \cdot \dot{\varphi}_1^2 \cdot a \qquad (2)$$

where a – the distance between the lines of action of forces F_k, φ_1 – the tilt angle of unbalanced masses m_d.

The developed system has 4 main masses and 3 degrees of freedom. The main masses of the system are the masses of unstable elements or unbalanced masses m_1, the drive shaft and bearing units on which it stands – m_2, the propeller or screw blades and the mounting unit – m_3, the scraper with the mounting unit and the brush or rubber elements for cleaning the bottom of the hydrolysers **(Bandura et al., 2015; Palamarchuk et al., 2016; Couzin et al., 2005).**

The basic degrees of freedom of the system include the angle of rotation of the unbalanced masses φ_1, the linear displacement of the drive shaft X_2, the angular displacement of the drive shaft ψ_2.

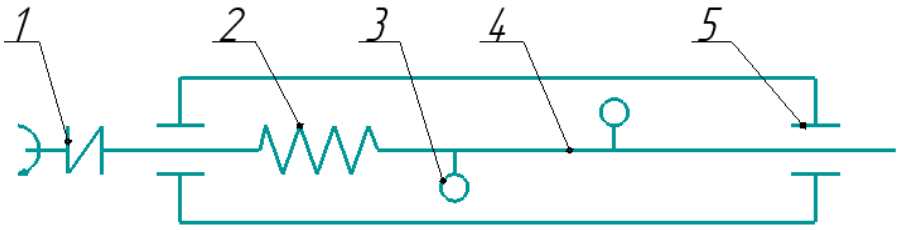

Figure 1 Model of mechanical unbalanced vibration excitation of the oscillatory motion of the blade shaft of a hydrolyser of pectin-containing raw materials: 1 – spring coupling, 2 – spring element, 3 – unstable element in the form of unbalanced masses, 4 – blade shaft, 5 – shaft bearing.

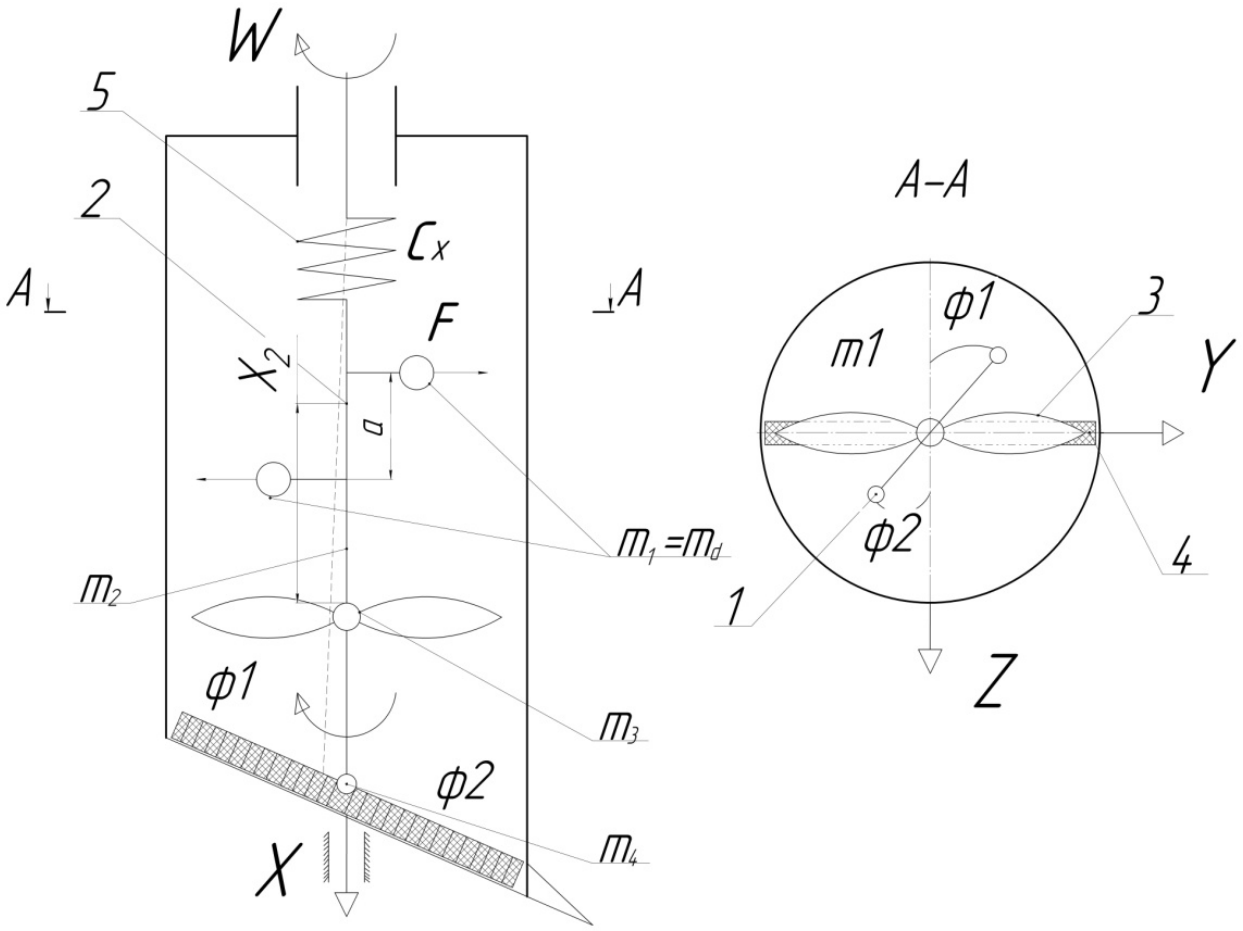

Figure 2 Calculation model of pectin-containing raw material hydrolysers with vibrating centrifugal mixer: 1 – unbalanced masses, 2 – drive blade shaft, 3 – blade, 4 – scraper, 5 - spring element with rigidity C_x.

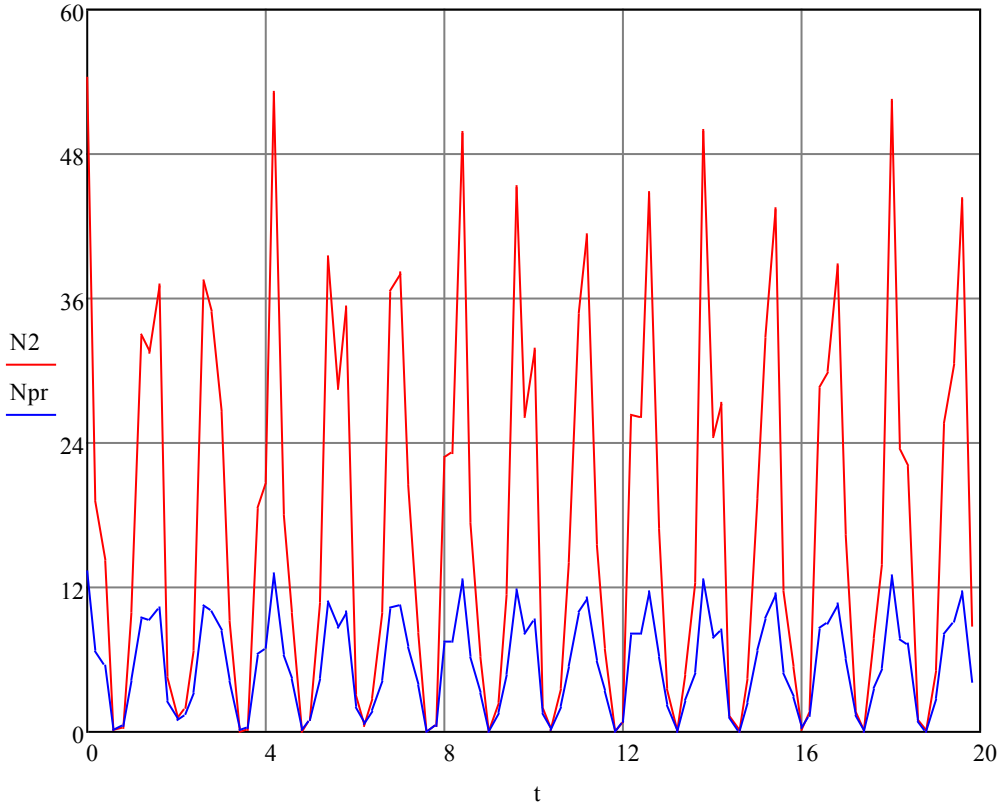

Figure 3. Energy (a) and power (b) characteristics of the system under study versus the processing time t: N_2 – power on the drive shaft of the agitator · 10^2W; N_{pr} – the power consumption due to the resistance of the technological environment ·10^2 W; F_2 - the driving force of the process ·10^2 N; P_r is the resistance of the technological environment · 10^2 N.

The Lagrange method is effective when composing the differential equations of motion of the working elements of the system, representing the desired expressions in the following system of equations:

$$\begin{cases} \left(\ddot{X}_2\right)+K_X^2\cdot X_2=K_m\cdot L_d\cdot(\dot{\varphi}_1)^2\cdot\left(1-f_{fr}\right) \\ \left(\ddot{\varphi}_1\right)+\left[m_1\cdot L_d\cdot a\cdot f_{fr}\right]\cdot(\dot{\varphi}_1)^2= \\ =\left[m_1\cdot L_d\cdot\dfrac{g}{I_0}\right]\cdot\sin\varphi_1+\dfrac{\left[M_{res}-P_r\cdot r_b-M_{ad}\right]}{I_0} \\ \left(\ddot{\varphi}_2\right)+K_\psi^2\cdot\psi_2=\left(I_2+I_3+I_4\right)^{-1}\cdot \\ \cdot\left(m_2\cdot g\cdot r_в+m_1\cdot L_d\cdot a\cdot(\dot{\varphi}_1)^2\right) \end{cases} \quad (3)$$

where: k_m – mass utilization coefficient; k_x^2 , k_φ^2 , k_ψ^2 – natural oscillation frequencies; C_x ,C_φ ,C_ψ – the rigidity of the spring element relative to the free motion of the coordinate; g –the gravitational acceleration; $r_в$ – the shaft radius, P_r – the fluid resistance forces; f_{fr} – the friction coefficient; r_b – the blade radius; M_{res} – the moment of resistance; M_{ad} – the moment of resistance by adhesive forces; adhesion I_0 , I_1 , I_2 , I_3 , I_4 – the moments of inertia of the corresponding masses of the system under study.

For the composed system of equations (2), taking into account the practical aspects of the implementation of the process under study, the following assumptions can be used: given the sufficiently small angular displacement of the drive shaft, it can be neglected, i.e. ψ = 0; we assume that the drive shaft rotates at a constant angular velocity, i.e. ω = const; the adhesive forces of the sediment to the bottom can be neglected, i.e. $M_{зч}$=0.

The system of equations for the independent constants φ_1 and x_2 was solved using the Cauchy method, in particular, for the first two expressions were obtained:

$$X_2=\frac{A_x}{K_X^2\cdot\left(1-\cos K_X t\right)}= \\ =\left[\frac{m_1\cdot\left(1-\cos K_X t\right)\cdot L_d\cdot\omega^2\cdot\left(1-f\right)}{K_X^2\cdot\left(m_2+m_3+m_4\right)}\right] \quad (4)$$

$$\varphi_1=m_1\cdot L_d\cdot g\cdot\frac{\left(\sin\omega t-\left(\dfrac{\omega}{K_\varphi}\right)\cdot\sin K_\varphi t\right)}{I_0\cdot\left(K_\varphi^2-\omega^2\right)}+ \\ +\left[\frac{\left(M_{Kp}-P_r\cdot r_л-m_1\cdot L_d\cdot a\cdot f_{sl}\cdot\omega\right)\cdot\left(1-\cos K_\varphi t\right)}{I_0\cdot K_\varphi^2}\right] \quad (5)$$

where: A_x – coefficient that was introduced to simplify the expression $A_x=K_m\cdot L_d\cdot\omega^2\cdot\left(1-f\right)$, then $\ddot{X}_2+K_X^2+X^2=A_X$, t – the operating time of the corresponding element; f_{sl} – the slipping coefficient.

Resistance, created by the fluid when the mixer's working elements rotate in it, without friction is:

$$P_r=K_0\cdot K_{OП}\cdot S_0\cdot\left(v_b\pm v_v\right),H \quad (6)$$

where: K_o – the experimental coefficient; K_{op} – the optical coefficient; S_o – the area of the projection of the working element to a plane perpendicular to the velocity vector of the blade, m^2; υ_b - the blade velocity; υ_v – the velocity of the liquid.

Based on the obtained dependences (4, 5, 6) and using the MathCAD, we created the following graphs of the power and energy characteristics of the system under study, depending on the processing time t in Figure 3 and the angular velocity of the blade shaft ω in Figure 4 and Figure 5.

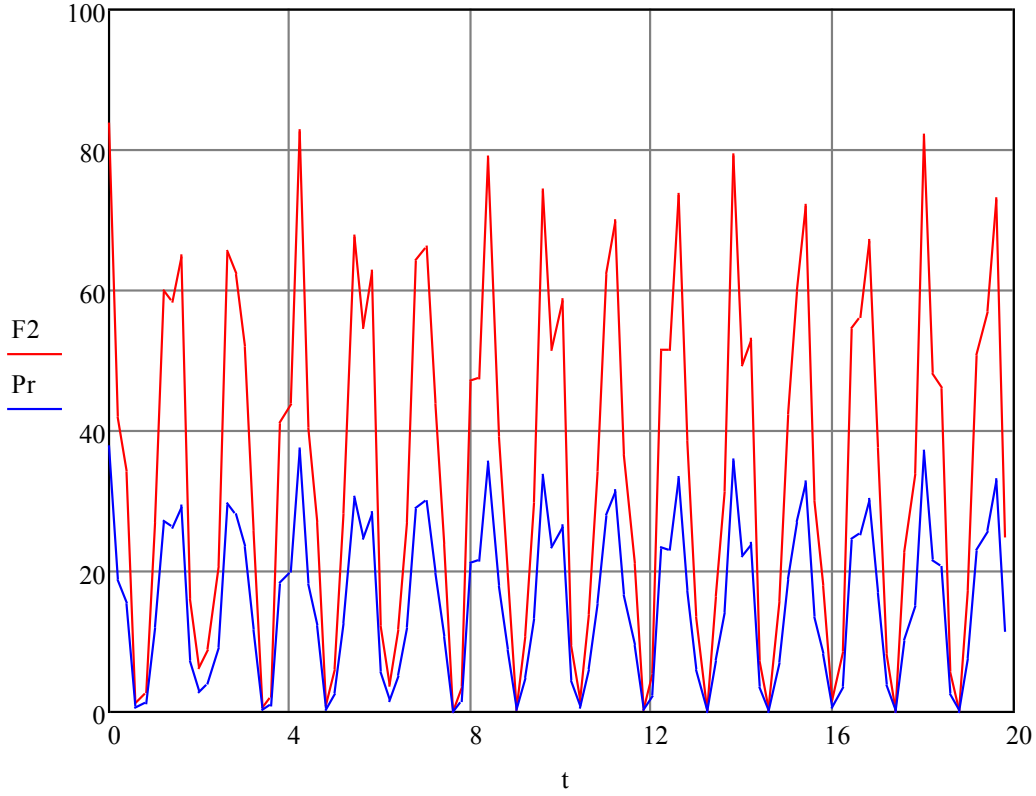

Figure 4. Energy characteristics of the system under the study N_2 and N_{pr} ($\cdot 10^2$ W) versus the angular velocity of the blade shaft ω ($\cdot 10^2$ rad/s).

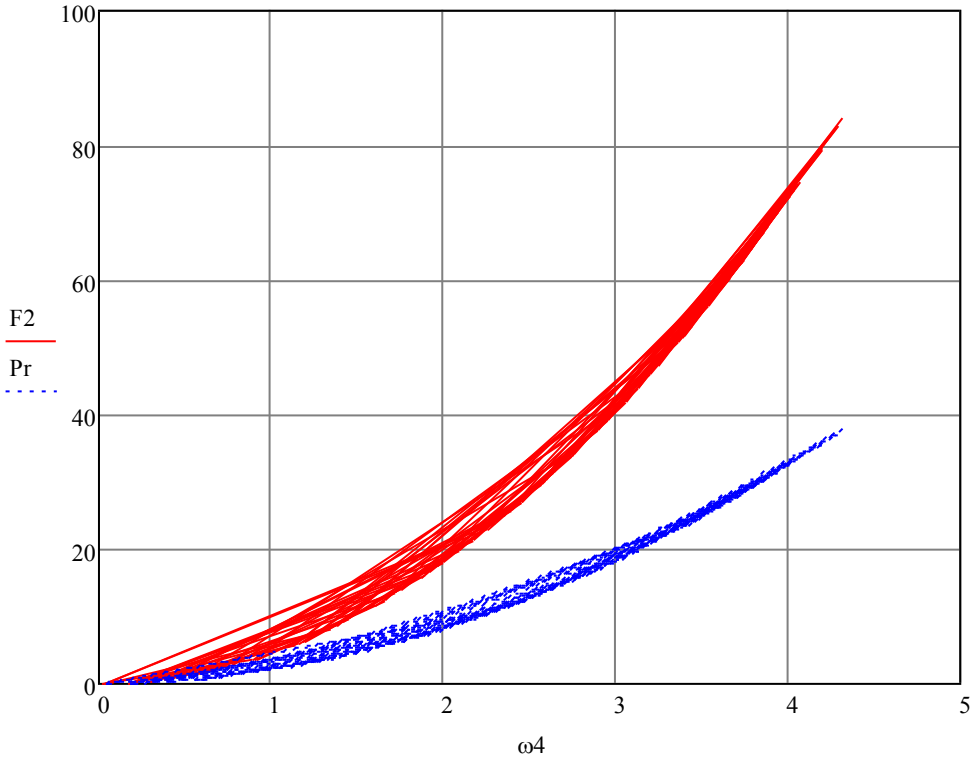

Figure 5. Force characteristics of the system under the study F_2 and P_r ($\cdot 10^2$ N) versus the angular velocity of the blade shaft ω ($\cdot 10^2$ rad/s).

Table 1 Different methods of the hydrolysis process of crushed pumpkins.

Suspension mixing conditions	Time of hydrolysis, s	Dissolved pectin content, %	Jelly-forming capacity of paste, mmHg
Without vibration, the angular speed of the stirrer shaft is ω = 150 rad/s	3600	1.5	315
With superimposing of 500 W of the vibration power using the same angular velocity	2400	2.8	378

From Figure 3 it is obvious that in the implementation of the experimental hydrolysis process with vibration centrifugal activation, the driving force is sufficient to overcome the resistance of the liquid technological environment. Also, 2.3 – 2.5 kN of driving force and 2.4 – 3.0 kW of drive motor power can be used to intensify this process **(Zavialov et al., 2015; Yanovich et al., 2015; Chuang et al., 2007; Carrillo et al., 2007)**.

For the angular velocity $\omega = 150$ rad/s of the drive shaft, the power consumption is 600W with a resistance of the fluid environment of 250W, and, if the angular velocity is doubled, the energy consumption increases by 7.2 times in Figuru 4. There is a significant increase in the technological impact of the vibration centrifugal driving force of the experimental hydrolysis process - from 1.5 kN for $\omega = 150$ rad/s to 4.6 kN for $\omega = 300$ rad/s sn Figure 5, which requires a corresponding significant energy consumption of 2.4 kW in Figure 4. Therefore, the effective angular velocity of the drive mechanism of the designed hydrolysers can be considered $\omega = 100 - 150$ rad/s, which is also recommended to provide the necessary reliability parameters of such equipment.

Pectin paste from the pumpkin "Hybrid – 75" was made on the developed hydrolysers to experimentally confirm the positive effect of hydrolysis of plant raw materials in the conditions of vibration mixing of the hydrolysis suspension.

The hydrolysis of the crushed pumpkin was performed at a temperature of 80 – 85 °C in the apparatus under a pressure of 0.05 – 0.1 MPa with 1.5 % solution of lactic acid **(UIIP, 1993)**, in the hydromodule GM 15, with the temperature of the hydrolyzed suspension during the experiment is not exceeded 65 °. After the addition of sugar syrup with sucrose content of 41% was carried out by evaporation at a temperature of heating medium 90 – 92 °C in the apparatus at a pressure of 0.1 – 0.15 MPa for 60 – 70 min. to a dry matter concentration of 68 – 70 %, with the temperature of the hydrolyzed suspension during the experiment did not exceed 70 °C. Hydrolysis was performed by mechanical stirring without the use of vibrational vibrations of the system and after vibration excitation of the shaft of the hydrolyzer.

The content of oxymethylfurfural in the finished product was determined in Ukrainian Laboratory for Quality and Safety of Agroindustrial complex according to state standard of Ukraine 7466-2001 **(DSTU 7466-2001)**. For which the permissible content did not exceed 25 mg / kg.

The standard complies with ISO 7466: 1986 Fruit and vegetable products - Determination of 5-hydroxymethylfurfural (5-HMF) content.

The results of the experiments are given in Table 1.

The Table 1 shows that the vibrational effect on the hydrolysis suspension allows to reduce the hydrolysis time by 1.5 times, increase the amount of dissolved pectin of higher quality by the jelly-forming capacity in the paste by almost 2 times.

CONCLUSION

Based on the analysis of the activation methods of technological flows during the implementation of the experimental hydrolysis process, a vibration centrifugal scheme of its intensification was selected, which potentially allows reducing the energy consumption for mixing of pectin-containing raw materials of plant suspension; increasing the driving force of the process, increasing the degree of mixing; improving the conditions of cleaning of the bottom of the hydrolysers from the sediment; and carrying out the self-cleaning of working elements.

Based on the mathematical model, analytical and graphical dependencies were obtained for the main power and energy characteristics of the process, which confirmed the overcoming of technological resistance of the liquid environment in the entire speed range of the drive shaft with the potential for process intensification at the power consumption of 2.4 – 3.0 kW, or a driving force of 2.3 – 2.5 kN.

The effective mode of operation of the drive mechanism of the designed hydrolysers is recommended: the angular speed of the shaft is $\omega = 150 - 150$ rad/s, which requires power consumption of 500 – 600 W.

EFFECT OF PROCESS PARAMETERS ON THE FUNCTIONAL AND PHYSICOCHEMICAL PROPERTIES OF EXTRUDATES ENRICHED WITH STARCH-BASED NUT FLOUR

Davit Tsagareishvili, Otari Sesikashvili, Dodo Tavdidishvili, Gia Dadunashvili, Nugzari Sakhanberidze, Shalva Tsagareishvili

ABSTRACT
Widening the range of products produced on the basis of agricultural raw materials and improving the quality of these products and increasing their nutritional value represent urgent challenges. Therefore, the production of new mass consumption products with high nutritional and biological value brings to the fore the use of local nut flour as an enriching supplement in innovative technological processes. The high nutritional value of nuts (nuts, walnuts, and peanuts) is due to their chemical composition, including lipids, a large amount of soluble proteins that are well absorbed by the human body, sufficiently large quantities of vitamin B1 and a small amount of vitamins PP and E. It is known that in peanut grains, lipids have a balanced composition of fats and acids, as well as sufficiently large amounts of essential amino acids, which makes their protein composition closer to that of animal proteins. This study considers the influence of thermoplastic extrusion parameters on the functional and physicochemical properties of extrudates in their formation process. The technological and design parameters of the process and their variation ranges are based on studies conducted on model systems. The ratio of the extrusion mixture components (formulation) is also developed. Based on the methodology for multifactorial experimental design, the variation of the volume weights, expansion rates, and mechanical specific energy expenditure of porous extrudates enriched with starch-based nut flour is studied. It has been established that the best quality indicators of the products are achieved with the minimum volume weight and the maximum expansion rate.

Keywords: extrudate; process; starch; walnut; parameter

INTRODUCTION
Extruded products with different compositions and functional properties are produced on the basis of starch-containing raw materials using various plant and animal supplements. We have experimentally substantiated the use of non-traditional raw materials, namely, nut flours, in the production of porous extrudates, as enriching supplements. This will expand not only the range of these products, but will also improve their quality and nutritional value. **(Sesikashvili, Zverev and Berulava, 2018)**.

Based on previous studies, we have investigated the influence of raw materials in shaping the structure of extrudates and conducted studies on extrudate model systems, using starch gel from various origins. This article describes the process of producing extrudates by the method of thermoplastic extrusion as a thermotropic process for the formation of biopolymer gels in the stream **(Tsagareishvili et al., 2019)**. The study of the properties of the obtained gels allows us to identify the moisture function in the process of thermoplastic extrusion, as well as during the storage of the obtained product. It is established that:

- During the process of extrusion, moisture determines the gelatinization point of the processed raw materials, whilst also influencing the shaping of the structure of extrudates **(Tsagareishvili et al., 2019)**.
- Minimal physicochemical transformations occur in gels in an amorphous state, that is, when their moisture content is minimal. Therefore, the storage of porous extrudates is recommended at low (4–7%) moisture contents **(Tsagareishvili et al., 2019)**.

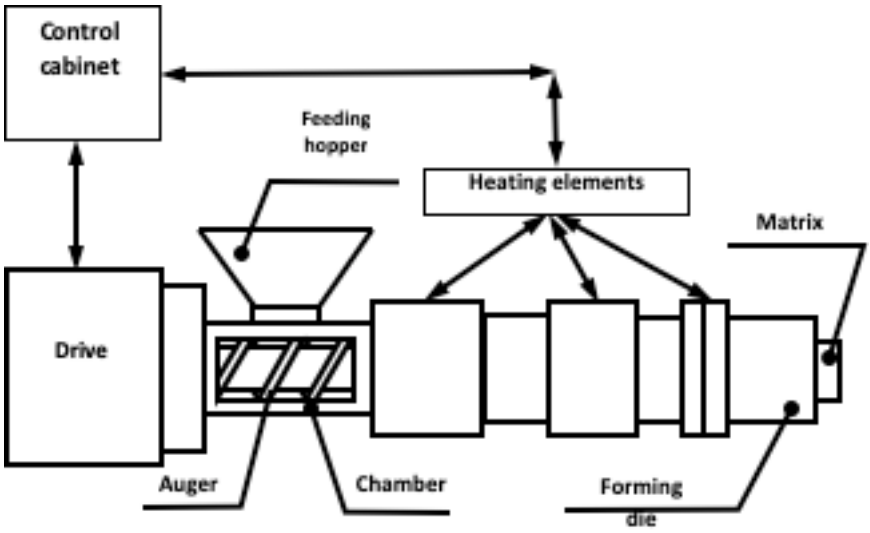

Figure 1 Schematic of the extruder.

Based on a literature review, it can be concluded that in addition to the composition (formulation) and technological parameters (moisture content, temperature and processing time), the shaping of the structure of the extrudates is also influenced by the parameters of the thermoplastic extrusion process (technological and design parameters).

Currently, the development of new formulations for products manufactured by the method of thermoplastic extrusion is mostly based on the empirical selection of the components of processed raw materials and the process operating and design parameters. In the best-case scenario, the systems analysis method is used for the multifactorial process **(Van Lengerich, Meuser and Pfaller, 1989; Meuser, 1984)**.

(Meuser, 1984) showed that the functional properties of the product depend on the system parameters of the process, with the latter being a function of the process parameters (moisture content, temperature, auger speed, die hole diameter and pressure on the auger).

Therefore, the task of studying the structure of extrudates is based on studying the forms of the isotropic and anisotropic microstructural forms of products based on starch, proteins or their mixtures. As shown in the thermoplastic extrusion process scheme (Figure 1), the raw materials to be processed in the mixing zone are moistened, mixed and by means of the auger, they move into the channel and in the melt zone transform into a plastic state. Studies by **(Van Lengerich, Meuser and Pfaller, 1989; Meuser, 1984)** note that during the process of biopolymer flow movement, under the action of shear deformation at the end of the cylinder and in the forming die, there occurs the process of especially intensive structuring of the melt. After leaving the forming die, the product is finally formed.

In order to explain the mechanism for shaping the anisotropic structure of extrudates **(Harper, 1986)**, a concept was proposed where macromolecules change their position under the action of shear deformation when raw materials transform into a plastic state during the gelatinization of starch and the denaturation of proteins. During the melt cooling process, the macromolecules bind and link together.

Based on the above, the purpose of this study is to investigate the influence of the extrusion process parameters on the functional characteristics of the extrudates (volume weight – ρ and expansion rate - Exp) and physicochemical properties (mechanical specific energy - E).

SCIENTIFIC HYPOTHESIS

Based on the studies conducted, the influence of thermoplastic extrusion process parameters (W, T, n, s and d) on the formation of the functional (ρ and Exp) and physicochemical parameters (E) of extrudates will be determined. The advantage of using the systems analysis method for solving the optimization problem to produce functional products with useful properties will be shown.

MATERIAL AND METHODOLOGY

For the purpose of carrying out experimental studies, in accordance with the formulations, we selected the following materials: cornflakes – **GOST 6002-69**; corn starch - **GOST 7697-82**; walnut, peanut and table salt - **GOST 13830-84**.

For the extrudates, we used an extruder K - 30 (Ukraine), composed of an extrusion chamber, an auger kit, a forming die with different matrix diameters and a control panel.

The extruder chamber is a hollow cylinder with a 400 mm length and a 19 mm inner diameter of the auger, with six longitudinal channels designed to transport the mass processed when using raw materials with the floury structure. On the outer surface of the cylinder, there are two mounted heating elements. In general, the extruder has three zones: mixing, plasticizing and charging. From the top of the cylinder, there is a vertical single-screw proportioning feeder secured with a pyramid hopper. Inside the chamber, a single-thread variable-pitch auger is placed with an outer diameter of 19 mm.

Table 1 Factor variation range.

	Factors	Levels				
#		1	2	3	4	5
1	Mixture's moisture content, %	15	20	25	30	35
2	Temperature in the cylinder, °C	150	160	170	180	190

During the studies, we used the auger kit with varying values of charging. At the end of the extruder chamber, the forming die with a matrix is connected by a threaded connection.

We used matrices with different hole diameters. We varied the auger speed from 150 to 230 min^{-1} and measured the rotary speed by means of a tachometer. The temperature in the cylinder was measured using a thermocouple.

The testing methodology used in the experiments is as follows. In the preliminary studies, the ratio of the extrusion mixture components was determined by a sensory analysis of taste, color and rigidity:

- Cornflakes – 56.8%;
- Corn starch – 10%;
- Walnut – 12%;
- Peanut – 4.5%;
- Table salt – 0.7%;
- Moisture content of mixture with added water – 16%.

During the experiments, the moisture content of the mixture varied between 16% and 35%. The mixture components were hydrated before the extrusion process and settled at a temperature of 5 °C for 24 h. We extruded the mixture for the determined values of moisture content, temperature, auger speed, auger types and matrix size. A temperature of 70 °C was maintained in the feed zone of the extruder.

After the extruder was operated in a stable mode, we took samples and determined their volume weights and expansion rates, and in parallel, we calculated the mechanical specific energy expenditure.

The volume weights of the extrudates were determined using vessels of a previously-known capacity of $0.5 \cdot 10^{-3}$ dm^3 that were filled with extrudates and then weighed on an analytical balance. The volume weight was calculated by the following formula (1):

$$\rho = G / V \quad (1)$$

where G is the weight of the extrudates, kg, and V is the volume occupied by the extrudates, m^3.

The expansion rate of the extrudates was calculated as follows (2):

$$Exp = D / d \quad (2)$$

where D is the extrudate diameter, mm, and d is the matrix die hole diameter, mm.

The mechanical specific energy was calculated using the formula (3):

$$E = (M \cdot n) / Q \quad (3)$$

where M is the auger torque, nm, N is the auger speed, min^{-1}, and Q is the extruder capacity, kg/h.

To further optimize the process of obtaining the base product, we used a mathematical method multifactorial experimental design **(Grachev, 1979)**. The main factors for obtaining the base product were the moisture content of the extrudate mixture (W), the temperature in the forming die of the extruder (T), the auger's number of rotations (n), the charging degree of the extrudate (S) and the matrix diameter (d). According to **(Grachev, 1979)**, in order to further optimize the process in the case of five-factorial experiments, it is necessary to conduct 25 experiments and vary each factor at five levels. The factor variation range was chosen on the basis of literature reviews and studies that we conducted previously on model systems. The factor variation range is given in Table 1.

The experiment performance grid is shown in Table 2.

STATISTICAL ANALYSIS

To analyze the test parameters (the moisture content of the starch paste, gelatinization point, starch paste transparency, starch paste embrittlement temperature and starch paste modulus of elasticity) of the extrusion products, a statistical analysis of the data was carried out and the reliability of the data was evaluated by a T-test using the Windows IBM SPSS Statistics program (version 20.0). To describe the ordered sample, we used the statistical functions of the average arithmetic value and the average standard error. A graphical interpretation of the results was made using Microsoft Excel. Figure 2, Figure 3 and Figure 4 illustrate the data of typical tests and each value is an average of at least ten determinations. We selected the value of reliability as $p < 0.05$.

RESULTS AND DISCUSSION

As is known, any production technology requires establishing the process parameters. The extrusion process parameters are as follows: the moisture content of raw materials, the temperature in the extruder's cylinder, the auger speed, and the extruder design parameters (the auger type and a matrix die hole diameter).

Based on the experimental studies, we have determined the relationship between the process parameters and the functional and physical characteristics of extrudates. The results of the studies are presented in Table 3.

Based on the experimental results, we have constructed the experimental curves for the relationship between the process parameters and the functional and physical characteristics of extrudates.

Figure 2 illustrates the influence of the process parameters on the volume weight of extrudates. As the graphs show, the moisture content of the mixture has a particular influence on the volume weight. The best indicator of this functional characteristic is in the 15-20% moisture content range. Further increase in the moisture content results in an increase in the volume weight, which worsens the quality of extrudates - the extrudate becomes more rigid. All other parameters in the same moisture content range do not adversely affect the volume weight variation. The end product is more airy and tender.

Enrichment of rice-based extrudates with the salts of calcium reduces the volume weight from 0.224 to 0.126 $g \cdot cm^{-3}$, and the expansion index from 3.21 to 2.93 (**Janve and Singhal, 2018)**. Sugar crystallization during the thermo-hydro-mechanical processing of extrudates based on corn starch with sugar-containing supplements reduces the degree of expansion of extrudate **(Wang, Gu and Ganjyal, 2019)**. Infusion of nitrogen injection during extrusion significantly increases the degree of expansion of extrudate and its porous structure **(Li, Masatcioglu and Koksela, 2019)**.

Table 3 The influence of the process parameters on the functional and physical characteristics of extrudates

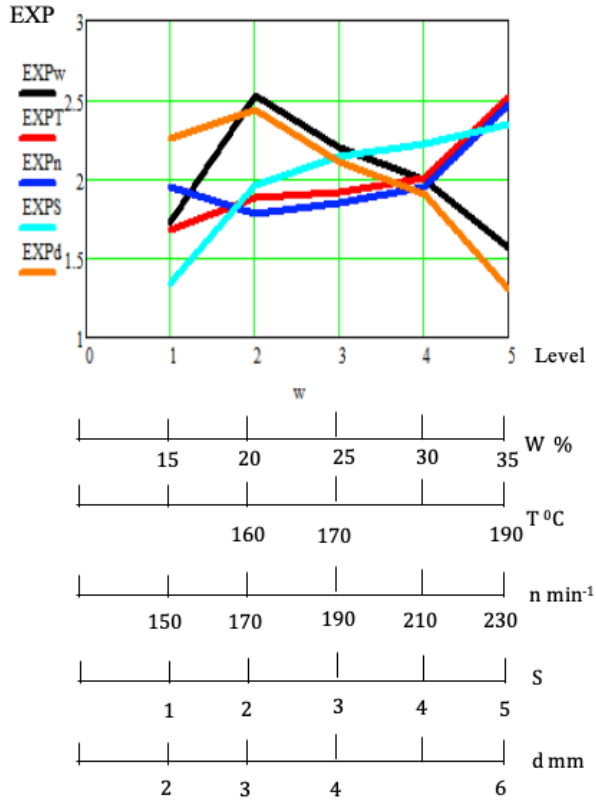

Figure 2 The influence of the process parameters on the volume weight of extrudates.

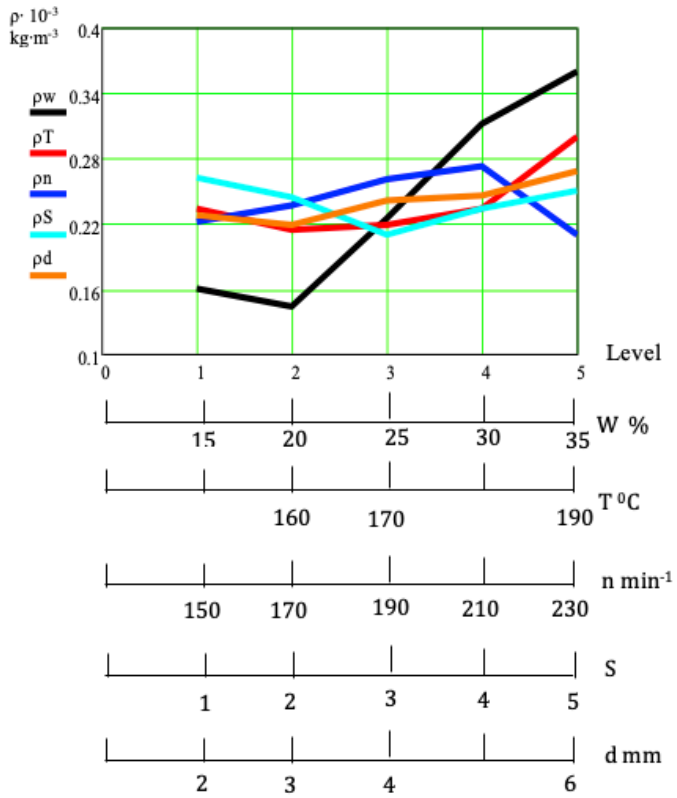

Figure 3 The influence of the process parameters on the expansion rate of extrudates.

The addition of coconut to extrudates produced from corn and rice flour reduces the degree of expansion, increases the volume weight and is characterized by relatively dark color, but they were rich in protein, minerals, and have antioxidant properties **(Arivalagan et al., 2018)**.

Many studies **(Skamniotis et al., 2018; Beck et al., 2018; Do Carmo et al., 2019; Da Silva Teba et al., 2017; Singh et al., 2019)** have reported similar functional characteristics of extrudates enriched with various supplements and their results concur with ours.

Figure 3 illustrates the influence of the process parameters on the expansion rate of the extrudates.

It is known that the greater the expansion rate of the extrudates, the greater the number of porous masses and the better their visual side and organoleptic characteristics. Compared to other parameters, the moisture content of the raw materials and the matrix die hole diameter have a greater influence on the expansion rate of the extruder. The maximum expansion rate is observed in the case of a 20% moisture content and a matrix die hole diameter of 3 mm.

In this case, the relatively low values of the volume weights and expansion rates of the extrudates, compared to the similar data of extrudates based on pure starch or corn flour, is explained by the supplement of nut flour, due to the fat content, which partially impedes the extrusion process.

Enrichment of extrudates based on corn flour with barley, fondant apple and sugar-beet reduces the degree of their expansion, deteriorates their structure, increases their density and firmness, while addition of 1% pectin improves the degree of their expansion **(Ačkar et al., 2018)**. When studying the physical properties of extrudates produced corn and yellow chickpea, it has been established that the best results were achieved by thermoplastic extrusion process parameters as follows: cell temperature - 158.64 °C, auger speed -372 m^{-1}, moisture content -18.4% **(Jacques-Fajardo et al., 2017)**. Regression analysis of the production of functional extrudates with high nutritional value based on corn flour by adding of dry broccoli or olive paste extrudates revealed that the increase in the concentration of broccoli or olive paste, as well as reducing the temperature and auger speed led to obtaining more dense extrudates with lower density.

At a moisture content of 14% and a 4%-concentration of product and the, extrudates had the highest expansion ratio at an auger speed of 250 m^{-1} **(Bisharat et al., 2013)**.

The relationship between the expansion rate of extrudates and the process parameters has been extensively studied **(Arivalagan et al., 2018; Sharma, Srivastava and Saxena, 2019; Carvalho et al., 2010; Zhang et al., 2020; Wang, Gu and Ganjyal, 2019)**. These studies confirm the accuracy of the tests that we conducted.

Figure 4 illustrates the influence of the thermoplastic extrusion process parameters on the mechanical specific energy. The plots clearly show the influence of each process parameter on mechanical specific energy expenditure, in particular, the increase in the rotary speed and in the charging rate of extruder results in increasing the mechanical specific energy, while the increase in the moisture content, temperature and matrix die hole diameter leads to a downward trend in the share of the mechanical specific energy. The results obtained concur with the previous studies **(Jacques-Fajardo et al., 2017; Sharma, Srivastava and Saxena, 2019; Carvalho et al., 2010; Beck et al., 2018)**.

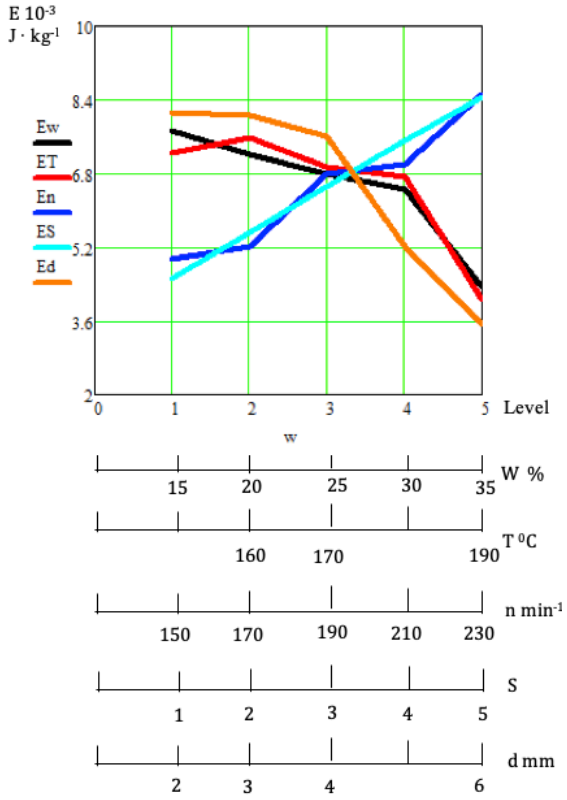

Figure 4 The influence of the thermoplastic extrusion process parameters on the mechanical specific energy.

CONCLUSION

This work allows us to understand the physical nature of the influence of each factor affecting the thermoplastic extrusion process on the functional and physical characteristics of extrudates enriched with nut flour.

By varying the process parameters, studies of the volume weights and the expansion rates show that they are inversely proportional to each other. In particular, the greater the extrudates expansion rates, the less their volume weights. In addition, the obtained products are airier, more tender and have better nutritional and consumer values. Therefore, in order to optimize the process of producing extrudates with a porous structure, it is necessary to solve the optimization problem: ρ(W; T; n; s; d) = min; Exp(W; T; n; s; d) = max.

^{137}Cs ACTIVITY CONCENTRATION IN MUSHROOMS FROM THE BOBRŮVKA RIVER VALLEY

Petr Dvořák, Jana Doležalová, Katarína Beňová, Martin Tomko

ABSTRACT
A total of 505 mushrooms belonging to 9 species were collected in the 2017 and 2018 mushrooming seasons near Dolní Rožínka in the Bohemian-Moravian Highlands and analysed by gamma spectrometry for ^{137}Cs activity. The greatest ^{137}Cs activity of 575 Bq kg^{-1} was detected in the species *Boletus edulis*, which is just below the permitted limit in its native state. In contrast, the detected activity level was only 316 Bq kg^{-1} in the mushroom *Imleria badia*, which is reported to be associated with the highest cumulative capability of all fungi species. However, differences in mean contamination values were not significant (p <0.05) due to high variability. It was shown that activity concentration is not dependent on the weight (size) of *Imleria badia*. Our results also confirmed the generally well known lower ^{137}Cs activity in *Russula* species belonging to the group of gill-bearing or lamella-bearing mushrooms.

Keywords: radiocaesium; mushrooms; river valley; *Boletus*; *Imleria*

INTRODUCTION
The ^{137}Cs isotope is one of more than 20 radioactive isotopes of caesium. ^{137}Cs isotopes are formed at relatively high concentrations, reaching as much as 6.3 %, during the fission (nuclear chain) reaction in nuclear reactors **(Söderlund et al., 2011)**.

Its negative biological effect is due to the emission of beta particles with the subsequent conversion of ^{137}Cs to metastable ^{137}Ba, which emits gamma photons of an energy of 661.7 keV **(Wasek et al., 2014)**.

Despite the fact that more time than the physical half-life of ^{137}Cs (30.17 years) has elapsed since the Chernobyl nuclear power plant accident (26 April 1986), there are still geographical areas with long-term persistent contamination **(Smith and Beresford, 2005; Beňová et al., 2016)**.

There are species of mushrooms in coniferous forests with a great ability to accumulate radiocaesium. Mushrooms probably contribute to the long-term retention of radiocaesium in organic layers of forest soils, especially spruce stands **(Steiner, Linkov and Yoshida, 2000)**. The radiocaesium activity concentration in mushrooms from different areas of the Czech and Slovak Republics in 2000–2004 was reported by **Dvořák et al. (2006)**.

The highest ^{137}Cs activity concentration, representing 6.263 Bq kg^{-1} of dry matter, was measured in *Imleria badia* (syn. *Xerocomus badius*) from the area called Staré Ransko (the Bohemian-Moravian Highlands in the Czech Republic). The results also show significantly lower levels of ^{137}Cs activity in Slovakia as compared to the Czech Republic.

^{137}Cs activity depends not only on the contamination of the environment, but also on the mushroom species **(Kalač, 2001)**. The highest levels of radioactive caesium contamination are found in saprophytic mushrooms **(Duff and Ramsey, 2008)**. The mycelium of the non-edible mushroom *Lactarius turpis* (formerly *L. necator*) in Ukraine (1996 – 1998) showed an average activity of 52.700 Bq kg^{-1} **(Vinichuk and Johanson, 2003)**.

Most of the published papers are based on mushroom collection from a relatively large area **(Chiaravalle et al., 2018)**. In such large areas there are a number of different factors that affect the final mushroom contamination **(Kalač, 2001; Dvořák et al., 2006)**.

First and foremost, the deposition of ^{137}Cs is unevenly distributed depending on the precipitation intensity, latitude and altitude of the area **(Lehto, Vaaramaa and Leskinen, 2013; Bulko et al., 2014)**. The contamination of Europe by post-Chernobyl radiocaesium shows a mosaic pattern with significant differences in relation to area activity **(Nilsson, 2009)**.

Scientific hypothesis

The aim of this work is to compare the ^{137}Cs contamination of various mushrooms in a small relatively homogeneous conifer forest ecosystem in a river valley.

MATERIAL AND METHODOLOGY

Mushrooms were collected at a defined location in the Bobrůvka River Valley (near Dolní Rožínka in the Bohemian-Moravian Highlands) in the 2017 and 2018 mushrooming seasons. A total of 505 mushrooms of 9 different species, both common and rare in this particular area, were collected **(Table 1)**.

Native mushroom samples were homogenised. Activity determination was carried out in the geometry of a 450ml Marinelli vessel or a 200ml polyethylene vial. These two geometries corresponded to the quantities of mushrooms per sample.

Determination of ^{137}Cs activity was performed by two gamma spectrometry systems using HPGe GC4018 (40% efficiency) and HPGe GC2020 (20% efficiency) germanium detectors, both with a resolution of 1.8 keV, verified by the Czech Metrology Institute. The measurement time was 18 hours.

The programs Genie 2000 (Canberra) and Gamwin (Nuwia Třebíč) were used for evaluation. The ^{137}Cs activity in all measured samples was higher than the minimum detectable activities (MDA). In addition to the mass activity, the total combined standard uncertainty was calculated using the formula:

$$u_a = \left(u_E^2 + u_p^2 + u_y^2 + u_s^2 + u_{ss}^2 + u_r^2 + u_t^2 + u_A^2 + u_M^2 \right)^{\frac{1}{2}}$$

where the individual standard uncertainties are as follows: relative uncertainty for efficiency (uE), relative uncertainty for peak area (up), relative uncertainty for yield (uy), relative uncertainty for time coincidence summing (us), relative uncertainty for electronic stability (uss), relative uncertainty for time (ut), relative uncertainty for decay (ur), relative uncertainty for self-absorption (uA), relative uncertainty for reproducibility (uM).

Statistical analysis

The weighted arithmetic mean, average total standard uncertainty, and maximal and minimal value of mass activity were calculated for statistical evaluation. A two-sample unequal variances t-test was used to compare the mean differences. A correlation coefficient was calculated to compare the dependencies.

RESULTS AND DISCUSSION

Mushrooms, as one of the most important components of the forest ecosystem, are able to accumulate a significant amount of radionuclides, including ^{137}Cs **(Heinrich, 1992; Škrkal et al., 2013; Guillen and Beaza, 2014)**. The first mention of contamination of mushrooms with radiocaesium comes from the nineteen sixties. Mass activity values in a range of 10 to 2.500 Bq kg^{-1} have been published in Germany (Grüter, 1964 and 1971). According to **Kalač (2001)**, contamination comes from nuclear weapons tests. Other factors that can affect the value of mushroom contamination in addition to the growth medium properties are the climate and the associated amount of precipitation, as well as the sampling time and the fungus type itself **(Heinrich, 1993)**. Furthermore, it has been found that the levels of radiocaesium in the underground parts of fungi (mycelium) are higher than the ^{137}Cs levels in the aboveground parts such as the medulla and the cap **(Vinichuk and Johanson, 2003)**. The distribution of radiocaesium in various above-ground parts of fungi is uneven, with higher activity found in fungi caps **(Heinrich, 1993; Mukhopadhyay et al., 2007)**. Mushroom samples collected in coniferous forests are characterised by a high content of radionuclides compared to mushroom samples collected in deciduous forests **(Čipáková, 2004)**. ^{137}Cs activity ranged between 273 and 1.165 Bq kg^{-1} in fresh mushrooms collected in the French Alps in 1999 – 2002 (**Pourcelot et al., 2003)**. In contrast, the highest contamination measured in the dry matter of mushrooms originating in the Bohemian-Moravian Highlands (Czech Republic) was 2.263 Bq kg^{-1}. Contamination levels in Slovakia were significantly lower **(Dvořák et al., 2006)**.

Research conducted in Europe, Japan and North America in 2008 has shown that *Boletus subtomentosus* is the species with the highest contamination levels of the entire Boletus family. The potential danger represented by this mushroom is even bigger due to its presence in large numbers in all types of forests **(Duff and Ramsey, 2008)**. However, we could not find this mushroom species in the Bobrůvka River Valley.

The mushrooms analysed in our study were collected from a small area in pine tree habitats in areas of steeply sloping hillsides modelled by river erosion. The results for ^{137}Cs mass activities are shown in **Table 1**. The largest ^{137}Cs activity was found in the species *Boletus edulis*, amounting to 1.575 Bq kg^{-1} in native state, which is just below the legal limit. However, this species also showed the greatest variation range, as mushrooms with a mass activity of 28 Bq kg^{-1} were also found. In contrast, the greatest activity seen in *Imleria badia*, which as a representative of the Boletaceae family is often quoted in connection with the highest cumulative ability, was only 316 Bq kg^{-1}. The differences between the average contamination values of both mushroom species (197 and 173 Bq kg^{-1}) were not, however, significant due to high variability. **Kunová, Dvořák and Beňová (2006)** reported the highest ^{137}Cs activity value measured in *Imleria badia* from the Staré Ransko locality (the Bohemian-Moravian Highlands). This activity reached 708 Bq kg^{-1}, which is around twice that of the mushrooms studied in our work. Another representative of the Boletaceae family is *Xerocomellus chrysenteron*. The variation range is from 19 to 2 Bq kg^{-1}, which shows a very low ability to accumulate radiocaesium. Given the 33 specimens monitored, this cannot be a coincidence. The results for *Neoboletus luridiformis* are also surprisingly low. In the 7 specimens found, the maximum concentration of contamination measured was 73 Bq kg^{-1}.

Table 1 Mass activity [Bq kg^{-1}] ^{137}Cs in different species of mushrooms.

Mushroom species	n (number)	Mean Bq kg^{-1}	CNS* Bq kg^{-1}	Max Bq kg^{-1}	Min Bq kg^{-1}
Imleria badia	113	**173**	9.7	316	11
Boletus edulis	19	**197**	12.9	575	28
Neoboletus luridiformis	7	**27**	2.7	73	10
Xerocomellus chrysenteron	33	**13**	1.5	19	2
Suillus grevillei	1	**28**	7.4		
Russula aeruginea	29	**27**	1.9	39	9
Russula olivacea	3	**18**	2.4	5	24
Russula vinosopurpurea	2	**13**	1.7	5	20
Russula ochroleuca	1	**9**	1.3		

Note: * Average combined standard uncertainties u_a (Guide to the Expression of Uncertainty in Measurement for Standardization).

Furthermore, the dependence between the average weight of the mushrooms and their activity was also studied. For *Imleria badia*, the highest activity level of 316 Bq kg^{-1} was measured in a mushroom sample weighing 25 g, while the lowest activity level of 56 Bq kg^{-1} was measured in a mushroom sample weighing 24 g. The mushroom sample with the lowest weight (8 g) had an activity level of 106 Bq kg^{-1}.

CONCLUSION

The results show that in the monitored area *Boletus edulis* shows a higher capacity of ^{137}Cs contamination as compared to the more frequently occurring *Imleria badia*. No correlation was found between the radiocaesium mass activity and the size of the collected mushrooms. No ^{137}Cs activity above the limit was found in mushrooms in the monitored area in the years 2017 – 2018.

EFFECTS OF THE ADMINISTRATION OF BREWED ROBUSTA COFFEE LEAVES ON TOTAL ANTIOXIDANT STATUS IN RATS WITH HIGH-FAT, HIGH-FRUCTOSE DIET-INDUCED METABOLIC SYNDROME

Nurmasari Widyastuti, Gemala Anjani, Vita Gustin Almira, Suci Eka Putri, Amali Rica Pratiwi

ABSTRACT
Robusta coffee (*Coffea canephora*) leaves contain phytochemical compounds and have antioxidant and anti-diabetic effects. This study investigated the effect of brewed Robusta coffee leaves on the total antioxidant status in metabolic syndrome rats. Metabolic syndrome in rats was induced by high-fat-fructose diet containing pork oil (20%), cholesterol (1.5%), cholic acid (0.5%), standard feed (80%), and fructose (1 mL per 200 g BW). The animals were categorized into normal control group (K1), metabolic syndrome control group without treatment (K2), mangiferin treatment group (X1), brewed Robusta coffee leaves 0.09 g per 200 BW group (X2), brewed Robusta coffee leaves 0.18 g per 200 BW group (X3), and brewed Robusta coffee leaves 0.36 g per 200 BW group (X4). Each dose of the coffee leaves was brewed with 3.6 mL of water at 70 °C for 10 min. The intervention was administered for 28 days. There was a significant increase in the total antioxidant status (p <0.000) in all the groups. In conclusion, the administration of brewed Robusta coffee leaves increased the total antioxidant status in metabolic syndrome rats.

Keywords: metabolic syndrome; Robusta coffee leaves; total antioxidant

INTRODUCTION
Metabolic syndrome is a cluster of metabolic disorders characterized by hyperglycemia, hypertension, obesity, low high-density lipoprotein (HDL), and hypertriglyceridemia **(Srikanthan et al., 2016)**. Obesity and insulin resistance are the known risk factors for metabolic syndrome. The prevalence of metabolic syndrome has been increasing every year. From 2009 to 2013, the prevalence of metabolic syndrome increased from 28.84% to 30.52% in adults >30 years of age in Korea **(Lee et al., 2018)**. In Indonesia, its prevalence by the province in 1995 − 2007 was about 21.66%, with the highest prevalence noticed in Jakarta **(Herningtyas and Ng, 2019)**.

The main mechanism of obesity and insulin resistance is oxidative stress **(Hurrle and Hsu, 2017; Marseglia et al., 2015)**, which damages both insulin secretion by the pancreatic β-cells and glucose transport in the muscle and adipose tissues **(Marseglia et al., 2015)**. Oxidative stress is caused by increases in lipid peroxide, malondialdehyde (MDA), carbonyl protein, and oxide xanthine activity because of an imbalance between free radicals and antioxidants **(Mancini et al., 2015; Tangvarasittichai, 2015)**. The body has natural defenses in the form of antioxidant enzymes, such as superoxide dismutase (SOD), catalase (CAT), dan glutathione peroxidase (GPx). Besides, consumption of a diet high in antioxidants provides defence against oxidative stress **(de Souza Cardoso et al., 2018)**. Robusta coffee leaves are consumed by the people of West Sumatra, Indonesia, as a healthy beverage **(Rasyid, Sanjaya and Zulharmita, 2013)**. These leaves contain caffeine, chlorogenic acid, flavonoid, and mangiferin, which have antioxidant and anti-diabetic properties **(Chen, Ma and Kitts, 2018)**.

In this study, we evaluated the effect of administration of brewed Robusta coffee leaves processed using the Japanese style green tea process (JGTP) **(Chen, Ma and Kitts, 2018)** and mangiferin on the total antioxidant status in a rat model of high-fat-fructose diet (HFFD)-induced metabolic syndrome.

Scientific hypothesis
Brewed Robusta coffee leaves increase the total antioxidant status in rats with metabolic syndrome.

MATERIAL AND METHODOLOGY
This study is included in the research project Study of The Administration of Brewed Robusta Coffee Leaves for Metabolic Response In Vivo in Metabolic Syndrome supported by funding received from Faculty of Medicine, Universitas Diponegoro 2019.

The processing of Robusta coffee leaves using JGTP

Robusta coffee leaves were picked from 2nd, 3rd, and 4th leaves of each branch of Robusta coffee plants. Leaves were sorted and then blanched for 75 s. They were then dipped in water and placed in a seducer for ±15 min to separate the leaves from the midrib. Next, the leaves were crushed using a crushing-tearing-curling machine 3 times. Finally, the leaves were dried for 4 − 5 h in a rack drier machine at 80 °C. The dried leaves were stored in airtight containers. The process was carried out in a mini-processing green tea processing laboratory at The Tea Quality Processing & Testing Laboratory in The Tea and Quinine Research Center Gambung, Bandung, Indonesia.

Animal treatments

Six-week-old male Wistar rats (n = 36), each weighing 150 – 200 g, were acquired from the Centre for Food and Nutrition of Universitas Gadjah Mada, Yogyakarta-Indonesia. The animals were provided standard feed of Comfeed II at 20 g per rat per day and water ad libitum. Body weight gain was recorded weekly and the remaining food was weighed daily. The experiments were approved by The Ethical Committee of Medical Research of Faculty of Medicine, Universitas Diponegoro (No. 16/EC/H/FK-UNDIP/III/2019), Indonesia. Rats were randomly divided into six groups (n = 6 per group): healthy control (K1), metabolic syndrome without treatment (K2), mangiferin 20 $mg.kg^{-1}$ BW (X1), brewed Robusta coffee leaves 0.09 g per 200 g BW (X2), brewed Robusta coffee leaves 0.18 g per 200 g BW (X3), and brewed Robusta coffee leaves 0.36 g per 200 gBW (X4) groups. All animals, except the K1 group animals, were fed a HFFD for 14 days. This diet contained pork oil (20%), cholesterol (1.5%), cholic acid (0.5%), and standard feed (80%) and was administered orally, while fructose 1 mL per 200g BW was administered by sonde. Metabolic syndrome was defined when the rats had fasting blood glucose ≥110 $mg.dL^{-1}$, triglycerides >150 $mg.dL^{-1}$, and HDL <40 $mg.dL^{-1}$.

Brewed Robusta coffee leaves were administered daily through a gastric sonde. The doses were brewed in 3.6 mL of water at 70 °C for 10 min. Mangiferin was dissolved in 3.6 mL of water and administered through a gastric sonde. The intervention was performed for 28 days.

Blood sample analyses

Fasting blood glucose, triglyceride, and HDL measurements as criteria of metabolic syndrome were performed after 14 days of HFFD administration. Fasting blood glucose, triglyceride, and HDL were analysed by GOD-PAP, GPO, and CHOD-PAP methods respectively. Measurement of total antioxidant status was performed before intervention and at the end of intervention. Total antioxidant status was analysed by ABTS method. Blood sampling to analyze fasting blood glucose, triglyceride, HDL, and total antioxidant status through plexus retroorbital. Blood serum was analyzed in the Centre for Food and Nutrition of Universitas Gadjah Mada Yogyakarta-Indonesia.

Statistical analysis

Statistical analyses were performed using the IBM SPSS Statistic 22 software. Data are presented as mean ±SD or median. Paired *t*-test and one-way analysis of variance were used for parametric results; differences between the groups were evaluated using the *post-hoc* test. Wilcoxon, Kruskal-Wallis, or Mann-Whitney test was used, as appropriate, for non-parametric results.

RESULTS AND DISCUSSION

Oxidative stress occurs when more oxidizing species are produced than the amount of antioxidants present in the body **(Morillas-Ruiz and Hernández-Sánchez, 2015)**. Insufficient antioxidant levels in the body could be overcome by dietary antioxidants **(Mirończuk-Chodakowska, Witkowska and Zujko, 2018; Yadav et al., 2016)**.

In this study, body weight of the animals significantly increased after treatment in all the groups (p <0.05). The X2 group (34.33 ±1.03 g) experienced the highest weight gain after the administration of brewed Robusta coffee leaves compared to other treatment groups (Table 1). The X1 group (22.00 (22.00 – 26.00) g) also experienced weight gain. The weight gain was the highest in the K2 group (43.50 ±1.64 g). The body weight between all groups significantly different before and after treatment (Table 2). Statistically, the body weight in the X4 group was not significantly different from that in the K1 group, as well as the body weight in the X3 group was not significantly different from that in the X4 group. This indicated that the increase in body weight in the X3 group was similar to that in the K1 group.

HFFD administration in rats has been known to cause weight gain and increases in blood glucose, triglyceride, LDL, and cholesterol levels **(Nugroho et al., 2012)**. In this study, rats were administered HFFD for 14 days to achieve metabolic syndrome. In a previous study, HFFD administration caused hyperglycemia and dyslipidemia **(Octavia, Djamiatun and Suci, 2017)**. In another study, a high-fat diet increased fasting blood glucose and a high-fructose diet increased triglyceride levels in rats **(Huang et al., 2004)**. The administration of a high-fat diet increased reactive oxygen species (ROS) and decreased antioxidant enzyme activity **(Du et al., 2012; Sreekumar et al., 2002)**. A high-fructose dietary induces oxidative stress by decreasing the antioxidant defense system **(Zhang, Jiao and Kong, 2017)**.

Rats achieved metabolic syndrome condition with fasting blood glucose (131.14 ±2.13 – 132.70 ±1.48 $mg.dL^{-1}$), triglycerides (153.49 ±1.96 – 157.18 ±4.88 $mg.dL^{-1}$), and HDL (24.59 ±1.99 – 26.22 ±1.69 $mg.dL^{-1}$) as seen in Table 3. Fasting blood glucose and triglyceride levels in the K2, X1, X2, X3, and X4 groups were increased compared to those in the K1 group. Meanwhile, HDL level in the K2, X1, X2, X3, and X4 groups was decreased compared to that in the K1 group.

Table 3 Fasting Blood Glucose, Triglyceride and HDL Level After Administration of HFFD.

Groups	Fasting blood glucose (mg/dl)	Triglyceride (mg/dL)	HDL (mg/dL)
	Mean ±SD	Mean ±SD	Mean ±SD
K1 (n = 6)	71.29 ±1.53	68.77 ±5.97	86.36 ±2.28
K2 (n = 6)	132.70 ±1.48	157.18 ±4.88	25.05 ±1.84
X1 (n = 6)	131.81 ±1.88	153.75 ±3.11	26.22 ±1.69
X2 (n = 6)	131.56 ±2.57	156.12 ±2.48	26.22 ±1.30
X3 (n = 6)	131.14 ±2.13	153.49 ±1.96	26.22 ±2.15
X4 (n = 6)	132.53 ±2.36	156.12 ±2.77	24.59 ±1.99

Note: normal control group (K1); metabolic syndrome control group without treatment (K2); mangiferin treatment group (X1); brewed Robusta coffee leaves 0.09 g/200 BW group (X2); brewed Robusta coffee leaves 0.18 g/200 BW group (X3); brewed Robusta coffee leaves 0.36 g/200 BW group (X4).

Compared to the baseline level, a significant difference in TAS levels was found after the administration of brewed Robusta coffee leaves and mangiferin in the K1 (p = 0.010), X1 (p = 0.000), X2 (p = 0.027), X3 (p = 0.027), and X4 (p = 0.000) groups. Meanwhile, there was no significant difference in TAS in the K2 group (p = 0.063) before and after treatment. Significantly increased TAS levels were found in the X2, X3, and X4 groups, implying that three doses of brewed Robusta coffee leaves could significantly increase TAS levels in rats with metabolic syndrome (Table 4).

After the administration of brewed Robusta coffee leaves, the TAS increased in the treatment groups. The higher the doses administered, the greater was the increase in the TAS in the metabolic syndrome rats. Rats administered mangiferin also experienced an increase in the TAS. This may be attributed to the presence of phytochemical contents, such as mangiferin, flavonoids, chlorogenic acid, and caffeine, in brewed Robusta coffee leaves. The processing of Robusta coffee leaves by the JGTP method contributes to the retention of more number of phytochemical components **(Chen, Ma and Kitts, 2018)**. In previous study, the extract of Robusta coffee leaves has high antioxidant activity. It is equivalent to the content of phenolic components in the leaves. The phenolic components contained in leaves contributes significantly to antioxidant capacity **(Kristiningrum, Cahyanti and Wulandari 2017)**.

Table 4 Total Antioxidant Status Before and After Treatment.

Group	TAS level (mmol/L)		Δ		
	Pre	Post	Mean ±SD	*P*	*p*
	Mean ±SD	Mean ±SD			
K1 (n=6)	2.25 ±0.17	2.06 ±0.90	−0,19 ±0,11	0.010[a*]	0.000[C*]
K2 (n=6)	0.29 (0.15 – 0.44)[d]	0.22 (0.15 – 0.29)[d]	−0.14 (−0.15 – 0.00)	0.063[b*]	
X1 (n=6)	0.29 ±0.12	1.54 ±0.20	1.24 ±0.20	0.000 [a*]	
X2 (n=6)	0.26 ±0.10	0.66 ±0.15	0.44 (0.29 – 0.45)	0.027[b*]	
X3 (n=6)	0.26 ±0.10	1.31 ±0.22	0.74 (0.73 – 1.03)	0.027[b*]	
X4 (n=6)	0.26 ±0.10	1.37 ±0.20	1.10 ±1.18	0.000[a*]	

Note: The rats were classified into the following groups: normal control group (K1); metabolic syndrome control group without treatment (K2); mangiferin treatment group (X1); brewed Robusta coffee leaves 0.09 g/200 BW group (X2); brewed Robusta coffee leaves 0.18 g/200 BW group (X3); brewed Robusta coffee leaves 0.36 g/200 BW group (X4).
a* = paired *t*-test $p < 0.05$ = significantly different; b* = Wilcoxon test $p < 0.05$ = significantly different; c* = Kruskal–Wallis test $p < 0.05$ = significantly different; d = abnormal distribution data, displayed in median (min-max).

The phytochemical caffeine primarily contributes in improving the antioxidant status. The antioxidant effect of caffeine is exerted by scavenging the hydroxyl radicals **(Yamagata, 2018)**. Caffeine directly inhibits lipid peroxidation and has a high inhibitor level against radical formation. This compound can also reduce oxidative stress and ROS, as well as protect antioxidant system **(Jeszka-Skowron et al., 2016; Tellone et al., 2015)**. The administration of caffeine at 30 and 100 $mg.kg^{-1}$ reduces lipid peroxidation and increases antioxidant enzyme activity **(Demirtaş et al., 2012)**. Consumption of caffeine 5 $mg.kg^{-1}$ body weight per day in 2 doses daily can reduce MDA and elevate the total antioxidant capacity **(Metro et al., 2017)**.

Chlorogenic acid also acts as an antioxidant. It donates hydrogen atoms to reduce free radicals and inhibits oxidation reactions. It also oxidizes phenoxyl radicals and stabilizes them through resonance stabilization **(Liang and Kitts, 2016)**. Chlorogenic acid at 5 $mg.kg^{-1}$ for 45 days causes a decrease in lipid oxidation and an increase in antioxidant endogenous enzymes in diabetic rats **(Pari, Karthikesan and Menon, 2010)**. High chlorogenic acid shows a high level of efficiency in scavenging DPPH radicals and converting Fe^{3+} to Fe^{2+}. This compound shows antioxidant activity by donating hydrogen to free radicals **(Liang and Kitts, 2014; Wu, 2007)**. 5-O-caffeoylquinic acid (5-CQA) is a subclass of chlorogenic acid that has a strong hydroxyl radical scavenger activity with a constant scavenger rate HO of $7.73 \times 109\ M^{-1}\ s^{-1}$ **(Liang and Kitts, 2014)**.

Flavonoids are part of antioxidants that contribute to the high antioxidant capacity and are present in fruits and vegetables. High flavonoid intake is associated with high plasma levels of total antioxidant capacity **(Alipour, Rashidkhani and Edalati, 2016)**. Intake of flavonoids, such as flavan-3-ols, flavonols, and anthocyanins, decreases dyslipidemia, induces antioxidant capacity, and prevents insulin resistance in diabetic patients **(Yamagata, 2019)**. Patients with type 2 diabetes administered flavonoid-enriched chocolate at 27 g per day for a year reduced insulin resistance and improved insulin sensitivity **(Curtis et al., 2012)**. The administration of the flavonoid quercetin at 15 mg per kg per day for 4 weeks decreased lipid peroxidation and increased antioxidant enzyme activity in diabetic rats **(Coskun et al., 2005)**. Mangiferin is a xanthone that is found in high levels in several parts of the mango. It is also found in Arabica coffee leaves and is thought to be found in Robusta coffee leaves **(Chen, 2019)**. Mangiferin confers its antioxidant effects by having a high iron-chelating ability **(Imran et al., 2017)**. The administration of mangiferin at 50 and 100 $mg.kg^{-1}$ reduces MDA levels in plasma and cardiac tissues and increases the level of SOD in cardiac tissues **(Arozal et al., 2015)**. In previous study, mangiferin at the dose of 10 $mg.dL^{-1}$ and 20 $mg.dL^{-1}$ in diabetic rats increased antioxidant defense mechanism, such as SOD and catalase **(Muruganandan et al., 2002)** Mangiferin at 40 mg per kg per day significantly reduced blood glucose levels and increased plasma insulin levels and antioxidant enzymes, such as SOD, catalase, and glutathione peroxidase. Mangiferin from *Salacia chinensis* prevents oxidative stress and protects pancreatic β-cells in rats with streptozotocin-induced diabetes **(Sellamuthu et al., 2013)**.

CONCLUSION

The administration of brewed Robusta coffee leaves processed by the JGTP method increases TAS in rats with HFFD metabolic syndrome. The intervention of brewed Robusta coffee leaves with a dose of 0.36 g per 200 BW is the most effective dose in increasing TAS levels.

PERSONALIZED NUTRITION AND "DIGITAL TWINS" OF FOOD

Marina Nikitina, Irina Chernukha

ABSTRACT

Mathematization of research is one of the most effective methods of virtual substantiation of foodstuff recipe and technology. This approach allows creating a product that meets consumer's individual needs, i.e. personalized foodstuff (ethnicity, cultural preferences, regional and environmental characteristics, lifestyle), and at the same time reducing the time and cost of decision-making. The article discusses the hypothesis that the "digital twin" of a food product is a virtual model of the product, namely its mathematical model (simulation model). A simulation model is a logical and mathematical description of a food product that is used to conduct a computerized experiment in order to design desired characteristics and properties. The "digital twin" combines all variety of factors from chemical composition, functional and technological properties to organoleptic indicators. The application of the "digital twin" model of the foodstuff will allow: (1) reacting quickly to changes in the composition, properties and types of raw ingredients, (2) adjusting the product recipe in response to changes in consumer preferences, (3) designing products with a given chemical composition, nutritional value and functional orientation, (4) creating functional, specialized products taking into account the metabolism of nutrients (ethnicity, cultural preferences, health status and clinical factors). Products adapted to the needs of small categories of people will help reducing the risks for those who already have diseases, and will meet the needs of those who would like to make their diet more appropriate to individual needs. The proposed approach to creating a model of the "digital twin" of the foodstuff includes several stages. The first stage involves optimization of the nutritional and biological value of the designed product. The second stage is related to designing the food product's structural forms. But even if the recipe of a food product is optimally selected in the first stage, it does not guarantee its transformation during processing into a stable system with the required structural, mechanical, functional and technological parameters. Evaluation of the developed food product's efficiency is possible only by analysing numerous and various parameters and indicators. It is convenient to generalize (convolute) many parameters and indicators into a single quantitative dimensionless indicator. To assess the quality and adequacy of the food product, it is suggested to use an integral indicator in the form of additive convolution – the 'functional' of the food product quality.

Keywords: simulation model; personalized nutrition; digital twin; food product; integral indicator

INTRODUCTION

Personalized nutrition pursues the idea of individualization **(Ordovas et al., 2018)**, thus, recommendations and nutritional advice should not be based on the average norms of nutritional intake applied to gender and age groups of population differentiated by the level of physical activity.

Personalized nutrition, as other scientific fields at an early stage, applies many concepts and descriptors, for example, accurate nutrition, multi-layer nutrition, and individual nutrition.

As we move from the stratified to personalized and high-accuracy nutrition, it becomes necessary to apply more and more indicators or characteristics to achieve the desired goal. For example, stratification can be performed using one or more parameters, such as age, gender, or health status. Personalized nutrition needs to take into account the complexity of relations between the individual diet and phenotype, thus, a wide range of indicators will need to be used to achieve the goal of accurate nutrition, possibly including "big data" approaches.

At this stage of research, the authors adhere to the concept of creating products for the "individually selected diet".

In 2016, Japan introduced the concept of 'Society 5.0', which offers more comprehensive and more advanced application of digital technology in all areas of human life. According to this strategy, advanced technologies, after having been introduced into all spheres of life, should lead to the emergence of new forms and types of business.

One of the Sustainable Development Goals for Society 5.0. is to improve nutrition through the use of 'smart products' produced by advanced biotechnological methods.

To develop "smart" foodstuff that have a functional effect on the human body, levelling the risks of disease, it is necessary to take into account many different factors (physical and chemical, structural and mechanical, functional and technological, etc.). "Playing" with (imitating) all possible structural relations and restrictions is possible only with the use of a virtual product model.

Grieves (2014) in his work notes that the term 'digital twin' appeared in 2003 as part of reading for the discipline 'Product Lifecycle Management' at the Florida Institute of Technology (https://www.fit.edu/).

The term digital twin has numerous definitions **(Bolton et al., 2018; Claessgen and Stargel, 2012; El Saddik, 2018; Lee, Bagheri and Kao, 2015; Söderberg et al., 2017; Tao et al., 2018)**.

For a digital twin food product, the definition of **Söderberg et al. (2017)** is relevant, objective and realistic – 'using a digital copy of a physical system for real-time optimization'.

Solving the problems of an individual (personalized nutrition) taking into account many parameters, such as health status, lifestyle, clinical factors, ethnicity, cultural preferences, etc., may be associated with the development of specialized foods.

The authors of the article propose an approach to building a digital twin food product, using the example of an *anti-sclerotic meat product*.

Scientific hypothesis

This article discusses the hypothesis that the "digital twin" of a food product is a virtual model of this product, namely its mathematical model (simulation model), which combines the whole variety of factors from the chemical composition, functional and technological properties to organoleptic indicators. A simulation model is a logical and mathematical description of an object that can be used for digital experiments on a computer in order to design, analyse and evaluate the functioning of this object **(Mukha, 2010)**.

Using the digital twin of a food product before its launch into mass production, technological engineers can analyse the nutritional, biological and energy value and other characteristics of the product.

The virtual simulation model will allow technologists reacting to changes in the physical and chemical composition of raw materials used or replacement of main or auxiliary raw materials in a real time mode, and accordingly adjusting the recipe to obtain a product with the specified chemical composition and guaranteed quality.

The "digital twin" will allow scientists obtaining interpolation and extrapolation data without conducting additional laboratory studies with a 95% confidence level (or $p < 0.05$)

MATERIAL AND METHODOLOGY

As an example of applying the virtual modelling approach, the task was set to create a digital twin of a meat product for the functional nutrition from the hearts and aortas of pigs, intended for dietary nutrition, in order to reduce the risk of developing and preventing hyperlipidemia and atherosclerosis. Step-by-step scientific experiment and laboratory research have been described **(Kotenkova and Chernukha, 2019; Chernukha, Fedulova and Kotenkova, 2018)**.

Another object was a meat food product enriched with iodine for school-age children.

When designing these products, we are interested in the best solution to the problem, taking into account the metabolism of nutrients (ethnicity, cultural preferences, health status, lifestyle, and clinical factors). The indicator that characterizes the quality of the task is called the objective function or criterion of optimality. The general optimization problem is formulated as follows: to select for variables $x_1, x_2, \ldots, x_n$ the appropriate values that provide the extremum of the objective function **(Mastyaeva, Goremykina and Semenikhina, 2016)**.

If the objective function and the constraint system are non-linear, the optimization problem is called a non-linear programming problem.

To solve non-linear programming problems, various iterative procedures are used to find the optimum: the gradient method, the coordinate descent method and the steepest descent method.

The software implementation of the models is possible in the universal simulation systems Simplex3, AnyLogic, etc. **(Schmidt, 2001; Ivashkin, 2016; Karpov, 2005)**.

RESULTS AND DISCUSSION

We will consider the mechanism for creating a "digital twin" of a food product, using the example of modelling the recipe and technology of a meat product for elderly nutrition (option 1) and baby food (option 2).

One of the main purposes while creating a functional and/or specialized diet is to provide the nutrients missing in the diet, as well as to reduce the risk of developing and preventing a particular disease.

Formulation of the problem's structural optimization, at different levels of the technology description of the digital twin food product, is reduced to minimizing the deviation of the actual parameters from the specified normative (reference, desired) values by finding a balance for the selected indicators between the input and output flows of the material.

The digital twin of the food product will allow employees of food industry enterprises to respond quickly to changes in the properties and types of raw ingredients, to respond to changes in consumer preferences and to create products with a predetermined chemical composition, nutritional value and functional orientation to a particular category of consumers. The optimal solutions to these problems in the design of food products can be achieved using formalized mathematical descriptions – mathematical models that reflect in an analytical way the set of functional relations between the technological, economic and other parameters inherent to the raw ingredients, the required characteristics of the finished product (objective function or optimization

criterion) and a number of restrictions arising from regulatory documentation requirements.

The first stage is related to the analysis of raw materials.

Option 1 is used to level out pathological processes and reduce the risk of hyperlipidaemia and atherosclerosis.

Based on the initial conditions for *the raw meat* – protein content at least 18%; fat content not more than 15%; the presence of tissue-specific peptides with molecular weights 809.4 ±1.0, 776.5 ±1.0, 765.6 ±1.0, 739.2 ±1.0, 710.8 ±1.0, 229.2 ±1.0, 162.1 ±1.0, 156.0 ±1.0, 148.1 ±1.0, 140.2 ±1.0 and 133.1 ±1.0 kDa; the presence of Apo 1 (which participates in the formation of high-density lipoproteins) or the presence of pre-Apo A-1 (which participates in the suppression of oxidative stress) – pork aorta and pork heart were chosen as the main raw material samples.

Option 2 is used to eliminate deficient conditions – hypovitaminosis, lack of trace elements (in particular iodine), leading to the development of a number of diseases. The amino acid methionine (binds 56 – 60% of iodine) must be present for the absorption of iodine from the fatty acid-iodine complex in the human body.

Restrictive parameters for the development of the product formulation for the raw meat are protein content of not less than 16% and fat content of not more than 16%; for vegetable oils – vitamin E of not less than 10 mg; for vegetable raw materials – content of β-carotene of not less than 5 mg; for iodine-containing raw materials – iodine content of not less than 0.1%.

As a result of the operator's work with the database, a list of raw materials of animal and plant origin that can be used in the formulation of an iodine-enriched product under the above boundary conditions was obtained.

For baby food, it is possible to use raw meat such as the first-category beef and pig meat (the choice is related to the main criterion – the presence of amino acids: tyrosine, phenylalanine, proline and histidine; PUFA).

For vegetable oils - soy oil, corn oil, which contains a sufficient amount of linoleic and linolenic acids along with a high content of vitamin E, as well as sunflower oil and peanut oil due to the high content of vitamin E and PUFA.

When choosing a plant component – a source of β-carotene, the choice of red carrots is obvious because of the high content of β-carotene in its composition. Along with this, the amino acid and vitamin composition of carrots contains histidine, phenylalanine, tyrosine and proline, which are necessary for a young body and contribute to better absorption of iodine.

As an iodine-containing raw material, fucus extract is used – a product of brown fucus seaweed processing, obtained by water extraction of brown fucus seaweed (*Fucus vesiculosus* L.), followed by the distillation of the extractant and obtaining a dry extract by spray drying.

Varying the structural ratio of the recipe components within the present restrictions, we see a way of changing the nutritional and biological values of the product, the ratio between protein and fat, etc.

When designing functional products, for example a meat gerodietic product, one of the main restrictions in optimization problems arises from the amino acid conformity criterion of protein that determines the ratio of mass fractions of amino acids such as methionine, cystine, tryptophan and lysine, taking into account the roles of isoleucine, leucine, phenylalanine and tyrosine as gerontological competitors of tryptophan **(Ivashkin and Nikitina, 2016)**.

The mathematical record of the criterion is as follows:

$$K = \frac{a_{(Met+Cys)}}{a_{Lys} \cdot C_{Trp}} \cdot \frac{\sum_{j=1}^{4} a_{jn}}{\sum_{j=1}^{4} a_{jэ}} = 1$$

Where: K is the coefficient of amino acid conformity, fractional units; $a_{(Met+Cys)}$ and a_{Lys} are the mass fraction of the amino acids methionine + cystine and lysine, g/100 g protein; C_{Trp} is the score of the amino acid tryptophan in the protein of the gerodietic product in relation to the FAO/WHO standard, fractional units; $a_{jn}, a_{jэ}$ are the mass fractions of the j^{th} amino acids in the protein and the FAO/WHO standard, respectively, g/100 g of protein; and index j identifies, respectively, the amino acids: 1 – isoleucine, 2 – leucine, 3 – phenylalanine and 4 – tyrosine.

Using this criterion (ideally K = 1), it is possible to quantify the protein composition of the designed gerodietetic products.

The biomedical requirement for gerodietic products in terms of the mass fraction of saturated (SFA), monounsaturated (MUFA) and polyunsaturated (PUFA) fatty acids is that they should correspond to a ratio of 3:6:1. In a mathematical arrangement, the task looks as follows:

$$\sum_{k=1}^{7}\sum_{j=1}^{m} q_{kj} l_j x_j + \sum_{k=8}^{10}\sum_{j=1}^{m} q_{kj} l_j x_j < 9 \sum_{k=11}^{13}\sum_{j=1}^{m} q_{kj} l_j x_j$$

Where:

q_{kj} is the mass fraction of the k^{th} fatty acid in the fat of the j^{th} recipe component, %; l_j is the mass fraction of fat in the j^{th} component of the recipe, %; x_j is the mass fraction of the j^{th} fat-containing component of the recipe, %; and the coefficient k is 1 – 7 for SFA, 8 – 10 for MUFA and 11 – 13 for PUFA accordingly.

Meat raw materials are multicomponent and variable in composition and properties. This can lead to significant fluctuations in the quality of the finished product. In this regard, it is very important to know the functional and technological properties (FTP) of various types of basic raw materials and their components, to understand the role of auxiliary materials and the essence of FTP changes under the influence of external factors.

Thus *the second stage* is related to designing the structural forms of a food product. The optimal formulation of a food product recipe at the first stage does not guarantee its conversion into a stable system with the required structural-mechanical and functional-technological parameters during technological processing.

Foods have individual structural forms (consistency, appearance, binding coherence, texture, etc.) due to peculiarities in the occurrence of protein–protein, protein–water, protein–fat and water protein–fat types of colloidal chemical processes.

Table 1 Major functional and technological properties of some raw meats **(Zharinov, 1994)**.

Type of raw meat	Before thermic processing							
	Moisture-binding capacity, % of the total moisture		Plasticity, $\times 10^{-1}$ m^2/kg		Water absorption, % of the initial mass		Fat absorption, % of the initial mass	
	3 mm	Mince cutter	3 mm	Mince cutter	3 mm	Mince cutter	3 mm	Mince cutter
Beef, 2nd grade	78.0 ±2.8	87.0 ±5.0	9.74 ±0.4	11.76 ±0.8	56.2 ±4.4	55.3 ±3.8	28.4 ±3.0	30.9 ±1.6
Semi-fat pork	73.8 ±6.0	74.6 ±3.8	9.46 ±0.3	11.5 ±0.5	34.9 ±2.3	64.2 ±4.2	22.5 ±1.2	28.6 ±2.1
Fat pork	-	-	10.52 ±0.2	12.31 ±0.3	29.2 ±2.4	32.2 ±2.6	19.8 ±2.0	23.4 ±1.7
Beef honeycomb	49.8 ±3.7	65.4 ±4.2	5.8 ±0.6	7.7 ±0.4	53.2 ±4.4	58.3 ±3.8	26.1 ±2.2	37.8 ±2.5
Beef lungs	94.3 ±1.6	96.0 ±1.2	11.3 ±0.9	11.5 ±0.8	30.6 ±2.8	35.0 ±4.0	25.2 ±2.2	32.8 ±3.1
Beef spleen	66.6 ±3.4	64.2 ±4.0	18.1 ±0.4	18.8 ±0.3	26.0 ±2.0	29.3 ±2.7	16.6 ±1.1	18.2 ±0.8
Beef oesophagus meat	78.2 ±3.3	80.2 ±2.8	8.1 ±0.6	8.7 ±0.4	15.1 ±1.1	16.5 ±1.4	9.8 ±0.9	12.2 ±1.3
Cattle snout	100 ±0.0	100 ±0.0	4.2 ±0.5	4.8 ±0.5	5.1 ±0.6	6.1 ±0.6	9.34 ±0.8	9.8 ±0.4

The protein component of the recipe usually acts as the main structure-forming agent in meat systems (even with its high quantitative content and balanced amino acid composition). Protein can manifest its native properties to various degrees depending on its origin (muscle, connective tissue, vegetable, milk, etc.), structure (fibrillar, globular), environmental conditions (pH, temperature, ionic strength) and many other indicators (degree of raw material mincing, depth of autolytic changes, etc.) **(Zharinov, 1994)**.

To implement the second stage, it is necessary to have information about the actual FTP values of the main raw materials **(Červenka, Frühbauerová and Velichová, 2019)**, auxiliary ingredients, the kinetics of biochemical and colloid-chemical processes (structuring – first of all) in multicomponent food systems, and the analytical and

Along with the introduction of increasingly convenient tools for big data processing and storage, it becomes possible to increase the frequency of use and number of alternatives for creating a digital twin food product, which in its turn increases the reasonableness and feasibility of decisions.

The following mathematical formulas are used to calculate the FTP of multicomponent products:

1) model of the water-binding capacity (WBC):

$$WBC = \sum_{i=1}^{N} w_i x_i$$

where w_i is the WBC of the i^{th} prescription component;

2) model of the fat-binding capacity (FBC):

$$FBC = \sum_{i=1}^{N} l_i x_i$$

where l_i is the FBC of the i^{th} recipe component;

3) model of the water-holding capacity (WHC):

$$WHC = \sum_{i=1}^{N} v_i x_i$$

where v_i is the WHC of the i^{th} recipe component;

4) model of the critical shear stress (CSS):

$$CSS = \sum_{i=1}^{N} q_i x_i$$

empirical dependencies that characterize the basic laws of heterogeneous dispersed systems with varying physico-chemical factors.

Food product databases now should contain information not only on the main parameters – moisture, protein, fat content, energy value, and amino acid, fatty acid, vitamin and mineral composition, but also on the FTP of raw materials of animal and vegetable origin.

As an example, we give the main characteristics of the FTP of some kinds of protein-containing raw materials (Table 1). They can be used to determine the compatibility conditions of the components in a formulation and optimize the choice of ingredient ratios, taking into account the probability of mutual regulation of the properties both of individual components and of the whole system obtained as a result.

where q_i is the value of the CSS of the i^{th} recipe component;

5) model of the dynamic viscosity (η):

$$\eta = \sum_{i=1}^{N} \frac{V_i x_i}{\eta_i}$$

where η_i is the η of the i^{th} recipe component; and V_i is the volume fraction of the recipe component;

6) model of density (ρ):

$$\rho = \left(\sum_{i=1}^{N} \frac{x_i}{\rho_i} \right)^{-1}$$

where ρ_i is the ρ of the i^{th} recipe component;

7) model of the active acidity indicator (pH):

$$pH = -\lg\left(\sum_{i=1}^{N} x_i 10^{-pH_i} \right)$$

where pH_i is the pH of the i^{th} recipe component; and x_i is the mass fraction of the i^{th} recipe component in the formulations presented here under numbers (1) to (7).

The employees of the Russian Research Institute of the Meat Processing Industry (VNIIMP) (http://www.vniimp.ru) have developed a method to define WHC, fat holding capacity (FHC) and minced meat stability (MMS):

$$WHC = \left(Wm_1 M_1 - Mm_2 \right) \cdot 100;$$

$$FHC = \left(Fm_1 M_1 - Mm_3 \right) \cdot 100;$$

$$MMS = \left[\frac{(m-M)}{m_1}\right]\cdot 100;$$

where W is the moisture content in minced meat, %; F is the fat content in minced meat, %; M is the mass of all separated broth with fat, g; M_1 is the mass of the tested broth with fat, g; m_1 is the weight of minced meat suspension, g; m_2 is the mass of water in the tested broth, g; and m_3 is the mass of fat in the tested broth, g.

The most crucial step in obtaining guaranteed quality in the production of meat products is the heat treatment stage.

To calculate thermograms of heat treatment of meat products, a mathematical model is used that describes a non-stationary field of temperatures containing the product. The mathematical model is a parabolic Fourier's thermal conductivity equation, in cylindrical coordinates with variable coefficients, with specified initial conditions (the initial temperature field in the product before the next stage of processing):

$$\frac{dU(r,t)}{dt} = a\frac{d^2U(r,t)}{dr^2} + \frac{1}{r}\cdot\frac{dU(r,t)}{dr} \quad 0 < r < R, \quad 0 < t < t_k$$

Initial conditions (product temperature before the heat treatment):

$$U(r,t) = U_0 = const, \quad t = 0 \quad 0 < r < R$$

Boundary conditions (on the side surface of the product):

$$\frac{dU(r,t)}{dr} = SU_{cp}(t) - U(R,t), \quad S = \frac{\alpha}{\lambda}, \quad r = R, \quad 0 < t < t_k$$

Conditions for the symmetry of geometry and heating in the center of the loaf

$$\frac{dU(0,t)}{dr} = 0, \quad U(0,t), \quad r = 0, \quad 0 < t < t_k$$

Where: U – current product temperature; U_0 – initial product temperature; U_{cp} – temperature of heating medium; $U_к$ – final product temperature; R – outer product radius; r – radial coordinate; α – heat transfer coefficient; λ – coefficient of thermal conductivity.

Bakery dough is also a complex system where yeast cells produce carbon dioxide during the loosening process. **Stanke**, **Zettel and Hitzmann, 2014** proposed a model that describes the loosening process by introducing the specific rate of CO_2 production as a variable and biomass as a parameter. Using different amounts of yeast at different temperatures, they modeled the process with an average percentage error of less than 0.5%

$$F(q_{co_2}, \eta, N_b) = \sum_{i=1}^{n}\left(V_{rel,i} - \hat{V}_{rel,i}\right)^2 + \left(P_n - \hat{P}_n\right)^2 = min$$

where q_{co_2} - CO_2 specific capacity; η - viscosity; N_b – amount of bubbles per volume; $V_{rel,i}, \hat{V}_{rel,i}$ - relative volume of bakery dough; $P_n, \hat{P}_n$ - porosity.

When producing dairy products, functional and structural characteristics must also be taken into account. The research (**Musina et al., 2018**) substantiates the reason for the swelling of whey protein extract in combination with various berry purees in the recipe of whipped frozen milk dessert at different temperatures.

The third stage is organoleptic assessment of the designed product by expert assessment methods with consistency testing.

Thus, the optimality of various structural options is analysed and verified on the basis of a comprehensive simulation model of a food product, i.e. on the digital twin.

Evaluation of the developed food product's efficiency is possible only by analysing the numerous heterogeneous indicators.

It is convenient to generalize (reduce) a set of indicators into a single quantitative dimensionless indicator. To do this, you have to enter a dimensionless scale for each of them, which must be the same for all the combined indicators. This technique makes them comparable.

One of the most common generalized indicators is the generalized Harrington function **(Harrington, 1965)**.

To assess the quality and adequacy of a food product, **Nikitina, Chernukha and Nurmukhanbetova (2019)** used the 'functional' – an integral indicator in the form of an additive convolution.

First of all, the functional determines the compliance with the set requirements for the chemical composition, FTP and organoleptic parameters. The functional reflects the weighted average total deviation of the actual values of the state parameters from the normative values. Taking into consideration the weighting indicators and the allocation of certain groups of indicators, this functional has the following form:

$$F(x) = 1 - \sqrt{\frac{1}{n}\sum_{i=1}^{n} a_i \sum_{j=1}^{n_i} b_{ij}\left(\frac{x_{ij} - x_{ij}^0}{\Delta x_{ij}^k}\right)} \to \max$$

Where n is the number of joined indicators; x_{ij}, x_{ij}^0 are the actual and desired values; Δx_{ij}^k is the limit deviation from the desired value for the k^{th} level of quality; b_{ij} is the weight coefficient of the j^{th} parameter in the i^{th} group; and a_i is an indicator of the group significance.

The value of the quality indicator changes from 1 (when the obtained values completely coincide with the recommended ones, i.e. best quality) to 0 when the lowest level of quality is reached (limit value), so that in the case of negative values of the functional, the product does not correspond to the specified quality level.

If all the considered indicators n are equal, then weight coefficients are determined by the formula:

$$b_{ij} = \frac{1}{n}$$

When determining weight coefficients at the inequality of weight coefficients one may use the method of expert estimates or the method of full factorial experiment, when columns of the response function (output parameter) y_{kr} of the r-th parallel repetition in the k-th experiment contain values: 1-0.7 – when the product features a very good quality level; 0.7-0.3 – good quality level; 0.3-0 – satisfactory quality level; 0-(-0.2) – poor quality level; less (-0.2) – very poor quality level.

CONCLUSION

When developing products for personalized nutrition, taking into account the metabolism of nutrients, it is necessary to take into account the whole variety of different variables and factors. This is almost impossible in a laboratory scientific experiment, and/or involves a lot of labor. It is possible to choose the optimal version of the recipe when "playing out" various situations in virtual space using a digital (computer, mathematical) model of the foodstuff.

The generalized mathematical model should include not only physical and chemical parameters (fat, protein, etc.), but also knowledge of dependencies of functional, technological, structural and mechanical characteristics that determine the conversion of the optimal formulation in the process of technological processing into a stable system.

Thanks to the use of mathematical modeling methods and a simulation model of the designed product, it is possible to obtain a "digital twin" of the foodstuff. 'New' technologies with the help of a digital twin make it possible to take into account the whole range of qualitative and quantitative indicators of meat products to develop recipes for new food products with a complex composition and characteristics, which allow non-drug prevention of diseases. Testing in the virtual world saves time, money and resources for physical scientific experiments.

Using an example of selected meat products, we showed the possibility of creating a digital model of the personalized foodstuff meeting all requirements.

EFFECTS OF TRADITIONAL FISH PROCESSING METHODS ON THE PROXIMATE COMPOSITION AND PH OF FISH BLACK POMFRET (*PARASTROMATEUS NIGER*)

Ali Aberoumand

ABSTRACT
Fish is an important food in many Iranian diets. This is a good source of protein. Fish is the main source of animal protein in Iran. The effects of three different traditional processing methods (freezing, brining and frying) on nutritive composition of halva sia fish stored under ambient room conditions were determined. Fresh halva sia fish were obtained from Behbahan fish market. Cooking and processing techniques were carried out on fish Halva sia Parastromateus niger. The proximate composition of raw Parastromateus niger was affected by cooking and processing techniques that were carried out by AOAC methods. Moisture contents decreased in fried and brined fillet while protein, fat and ash contents were significantly increased in fried fillet. The loss of moisture in fried and brined samples amounted to the highest levels; also the protein and fat value was proportionally high. The fish Parastromateus niger showed a decrease in their contents of moisture and fat as affected by frozen storage periods while ash and protein contents were increased after frozen storage periods. The nutritional value fish Parastromateus niger preserved until the end of the storage period.

Keywords: frying; brining; fish; *Parastromateus niger*; freezing; proximate composition

INTRODUCTION
Fish can be a source of protein for humans. In addition, with proper processing methods, it can also generate foreign exchange **(Mazrouh, 2015)**. The nutrients composition of fish is essential in fish processing, as it affects both its quality and technological properties **(Farid et al., 2014)**. In addition, conservation and processing can result in fish availability throughout the year **(Ben Smida et al., 2014; Oparaku, and Nwaka, 2013)**. Different methods of processing fish have different effects on their properties physico-chemicals, organisms and nutrients. **(Akinneye, Amoo, and Bakare, 2010)**. These effects can be caused by physicochemical changes, which affect digestion due to protein denaturation and reduced content of unsaturated fatty acids. The quality and shelf life of the fish varies with different methods and with acceptance by consumers **(Mojisola, 2014)**. Freezing and thawing have many effects on the physicochemical properties of frozen fish fillets. **Boonsumrej et al., (2007)** found that rapid shrimp freezing in cryogenic freezers at temperatures of -120 °C, which has very good effects on nutrient composition. Several changes have occurred during fish processing. Depending on the amount of heat and temperature, protein denaturation may result in exposure to reactive groups. Most proteins are compounds that can change in the heat process in terms of quality and quantity. The decrease solubility of temperature-sensitive protein can be used as an indicator of the time and temperature used in the heating process of fish species and fish products **(Akinneye, Amoo, and Bakare, 2010.; Mojisola, 2014; Boonsumrej et al., 2007; Alipour et al., 2010; Sarker et al., 2012)**.

El and Kavas (1996) has been reported that protein digestion to be reduced as a result of chemical reactions of the protein or protein with fat when boiling at high temperatures. **Pourshamsian et al., (2012)** reported that frying has the effects on the nutritional composition and properties of fish fatty acids and fish products. However, no basic information has been reported on the effects of processing methods on the nutritional and physical properties of fish processed in Eritrean fish processing plants. In general, different fish processing methods can include frostbite, freezing, salting, frying and boiling, and various combinations of this kind to give the fish a fresh and attractive form for the consumer and to provide long-term shelf life. These processing methods have many different applications and techniques and have a significant impact on the chemical, physical and nutritional composition of processed fish. This is because heating, freezing, and exposure to high salt concentrations lead to chemical and physical changes.

Figure 1 Fish Black pomfret (*Parastromateus niger*).

Finally, these methods can be of varying quality, so the subsequent effect on the shelf life of processed fish also varies **(Magnussen, Hemmingsen, and Vidar Hardarsson 2008; Lourdes et al., 2007)**. The cooking processes are widely carried out to increase the quality of seafood and to extend the shelf life of the products **(Talab, 2014)**. During the cooking process, some physical and chemical changes occur that decrease the nutritional value of the food. Thus, digestibility is increased due to protein denaturation in foods, while the content of thermo sensitive labile compounds, vitamins or unsaturated fatty acids is often reduced **(Alizade et al., 2009)**. The aim of current study was to follow up the changes which occur in proximate composition of Parastromateus niger by frying, brining and freezing techniques.

The preservation and processing can assure availability of fish in all year round **(Smida et al., 2014; Oparaku et al., 2013)**. The bio-chemical composition of fish is the vital aspect in fish processing, because which influences both the quality and technological properties of it **(Farid et al., 2014)**. Different processing methods of fish have different effect on their physicichemical and nutritional compositions **(Akinneye, et al., 2010)**.

Scientific hypothesis

The processing methods (freezing, brining and frying) have effects on nutritive composition and energetic values of fish *Parastromateus niger*.

MATERIAL AND METHODOLOGY

Sample collection and preparation

The fish samples with three replicates of Black pomfret (*Parastromateus niger*) (Figure 1) with an average weight of 1100-1700 g were procured from the Behbahan city local market, Iran. The fish were gutted and washed with the tap water. The sampled fish was cut down into sex parts; one as fresh sample was used and the three parts were used for freezing 7 , 21 and 35 days and a part was used for frying in oil and last part was used for brining process. All the samples were used for proximate analysis in laboratory.

Proximate analysis

The moisture, protein, lipid and ash content of the fish samples were determined by the **AOAC (2005)**.

Protein determination

Protein was determined using Kjeidahi method which involves digestion, distillation and titration as recommended by **AOAC (2005)**. The percentage protein was obtained using the formula: % Protein = N = 6.26 Where N= Nitrogen free extract.

Moisture determination

Moisture was determined using method as recommended by AOAC (2005). Percentage of moisture was calculated using the formula; % water = Wo – Wi/Wo x 100 Where; Wo = initial weight Wi = final weight.

Fat analysis

Fat was determined using soxhlet method as recommended by Association of official analytical **(AOAC, 2005)** the percentage fat will be obtained

The formula:

$$\% \text{ fat} = Wo - Wi/Wo \qquad (1)$$

Where:
Wo = Initial weight of fat,
Wi final weight of fat.

Determination of pH

A 5 g sample of the fish sample was homogenized in 40 ml of distilled water and the mixture was filtered. The pH of the filtrate was measured using a pH meter (Mettler Toledo 320-s, Shanghi, China) (Vynke, 1981).

Statistical Analysis

Chemical composition data were analyzed statistically using SPSS 15.0. The least significant difference test (LSD) at ($p \leq 0.05$) and Standard Error (Mean ± SE) were calculated.

RESULTS AND DISCUSSION

The effect of frozen storage on moisture, protein, fat, and ash contents of the fish were studied. The obtained results are tabulated in Table 1.

Table 1 showed the effects of storage at -18°C at different periods on the moisture contents of raw the fish. The initial moisture contents of raw, frozen 7 days, 21 days and 35 days fish samples were 84.72, 84.74, 74.65 and 74.18 %, respectively. The differences were duo to a gradual decreasing in their contents of moisture as affected by frozen storage different periods. With increasing storage time, moisture content decreased significantly. The loss of moisture in frozen fish samples can be attributed to the sublimation of ice in frozen storage and the loss of drop during the thawing process **(Abo Taleb, Sherif, and Ibrahim, 2011)**. Similar findings were reported for other species of fish such as Sea bass fillets **(Benjakul et al., 2005)**, Carp fish cutlets **(Surabhi and Das, 2007)**, Tilapia fillets **(Ibrahim and El-Sherif, 2008)**, *Labeo rohita* (**Gandotra et al., 2012)** and Catla fish cutlet **(Vanitha et al., 2013)**. The initial protein contents of raw, frozen 7 days, 21 days and 35 days fish samples were 7.67, 8.52, 18.64 and 20.89 %, respectively (Table 1). These differences were duo to increase in their protein content, which is affected by the frozen storage period. As storage time increased, protein content increased significantly.

The decreasing in fat content of raw, frozen 7 days, 21 days and 35 days fish samples might be due to oxidation and hydrolysis of fats which result in the formation of some volatile chemicals as aldehydes and ketones **(Gandotra et al., 2012)**. The some studies showed a decreasing in ash content in fish during frozen storage which was related to the drip loss during thawing process **(Gandotra et al., 2012)**.

Table 2 showed that moisture content in fresh sample was affected brining process was decreased respectively (84.72% to 33.99%) with significant different (p <0.05), while protein, fat, ash and energy values was affected brining process were increased. The obtained results in this study were agreed with results **Aberoumand and Ziaei-Nejad, (2015)**. The effects of frying cooking technique on the proximate composition (moisture, protein, lipid, ash and carbohydrates) of the studied fish are presented in Table 3. Moisture content of raw and fried fish was 84.72 %, and 21.10% respectively. There was significant loss in the moisture content of raw fish due to the cooking process by frying (p <0.05). This observation agreed with **El Sherif, Ibrahim and Abou-Taleb, (2011)** for fried Tilapia fish as well as for some fish species **(Gokoglu, Yerlikaya and Cengiz, 2004)**. The protein content in raw the fish was significant increased (p <0.05) in the fried samples. Increasing protein content in the cooked fish samples (fried) due to the water loess during cooking. Protein contents were 7.67 % in raw and 14.16% fried, respectively. Similar data showed that deep-fried fish had the highest protein value comparing other cooking methods **(Gokoglu, Yerlikaya and Cengiz, 2004; Kucukgulmez et al., 2006)**. Data given in Table 3 showed that total lipids in raw and fried samples were 6.52, and 62.76%, respectively. These values were differing significantly (p <0.05). The higher lipid content of fried the fish due to the absorption of oil and losing moisture during frying process **(Saguy and Dana 2003)**. Ash contents were 0.99 and 1.97 in raw and fried fish, respectively (Table 3). The differences of ash content higher of fried is due to more loss of moisture took place during deep frying cooking method **(Kucukgulmez et al., 2006)**. The changes found in the chemical composition of fish cooked by frying were similar to several studies carried out in other fish species included Sea bass **(Gokoglu, Yerlikaya and Cengiz, 2004; Kucukgulmez et al., 2006; Marimuthu et al., 2012; Garcia Arias, Ailvarez, and Garcia Linares, 2003)**.

Table 4 showed that pH was found 6.18 in fresh sample and increased significantly (p <0.05) to the value 6.50 in 7 days frozen fish. There was comparatively slow increase in pH between fresh fillets during freezing periods. It was increased from 6.18 to 6.50. There was significant differences (p <0.05) between fresh fish and frozen fish that was frozen for 7 and 21 days. No significant difference between groups of fresh fish that was exposed to the different freezing periods. These results are in accordance with **Erkan and Ozden, (2008)** who stated that the increase was due to an increase in volatile bases from the decomposition of nitrogenous compounds by endogenous or microbial enzymes. Obemeata, Nnenna and Christopher, (2011**)** observed that the increase in pH was higher in the 4 °C stored sample of Tilapia, indicating that biochemical and microbial changes are occurring faster in 4 °C stored fish. **Pawar et al. (2013)** showed slightly increased pH in *Catla catla* from 6.50 to 6.79 when stored at chilled temperature (-2 to -4 °C). The change in pH of fish sample is usually good index for quality assessment. The increase in pH is caused by the enzymatic degradation of fish muscle.

An increase in protein content in processing methods was due to aggregation of proteins after the removal of water molecules present between proteins **(Ninawe and Ratnakumar, 2008)**. The increase in method time and loss of moisture leads to denaturation of the protein **(Begum et al., 2013)**. The fat content increases in brining method with a decrease in water content as the lipid plus water content of fish flesh equal to 80% **(Bligh et al., 1988)**. The higher ash content was due to the substantial loss of moisture **(Mustapha et al., 2014)**. During brining, the mass transfer occurs basically between salt and water: the fish fillets takes up salt and loses water **(Chaijan, 2011; Oliveira, et al. 2012)**. Nutritional composition, such as protein, lipid, and ash, were increased due to the loss of water in fish fillets in the brining process **(Brás and Costa, 2010; Chaijan, 2011)**.

The increased protein degradation is occurred by major changes in the protein fraction of the salted fish and the increased NaCl concentration. Consequently, the decrease pH value is because of the increase of the ionic strength of the solution inside of the cells **(Goulas and Kontominas, 2005; Leroi and Joffraud, 2000)**. The decrease in sample lipid content during freezing was associated to the fat hydrolysis and due to the oxidation rancidity. Similarly **Siddique et al. (2011**) found that total lipid content decreased during frozen storage of three species of *Puntius*. The decrease in ash content was associated to the drip loss during thawing process **(Roopma et al., 2013)**.

Table 1 Proximate composition (g.100g^{-1}) and caloric value of fresh and frozen fish (*Parastromateus niger*), on a dry basis.

Parastromateus niger	Proximate composition					
	Moisture	Protein	Lipids	Ashes	Calories (Kcal.100g^{-1})	Calories (KJ.100g^{-1})
Fresh	84.72 ±0.27^{a}	7.67 ±0.32^{a}	6.52 ±0.21^{a}	0.99 ±0.07^{a}	89.36 ±1.7^{a}	373.52
Frozen 7 days	84.74 ±0.7^{b}	8.52 ±0.96^{b}	5.63 ±0.52^{b}	1.11 ±0.11^{b}	84.70 ±1.51^{b}	354.05
Frozen 21 days	74.65 ±0.3^{b}	18.64 ±0.92^{b}	5.48 ±0.42^{b}	1.23 ±0.12^{b}	123.88 ±1.44^{b}	517.82
Frozen 35 days	74.18 ±0.4^{b}	20.89 ±0.89^{b}	3.77 ±0.41^{b}	1.16 ±0.11^{b}	117.49 ±1.34^{b}	491.11

Note: Mean of samples analyzed in duplicate. The same letters in the row do not differ from each other at the 5% level of significance.

CONCLUSION

Proximate composition and energetic values of *Parastromateus niger* fish showed significantly ($p \leq 0.05$) differences between brined, cooked and raw samples and during frozen storage. The moisture loss in the boiled and fried samples reached its highest level. Also, protein, fat and energy were relatively high. The nutritional value of fish *Parastromateus niger* retained until the end of the storage period. Therefore, it must be beyond the process of useful and optimized processes that can lead to the production of superior products with nutrients, beyond consumer satisfaction. To prevent the impact of processing on fish nutritional and physical and chemical constituents, the use of appropriate methods for fish processing and fish products was essential.

EFFECT OF FUZZY-CONTROLLED SLOW FREEZING ON PUMPKIN (*CUCURBITA MOSCHATA* DUCH) CELL DISINTEGRATION AND PHENOLICS

Yohanes Kristianto, Wigyanto, Bambang Dwi Argo, Imam Santoso

ABSTRACT
Freezing has been widely used to preserve vegetables including seasonal pumpkins. This work aimed to investigate the effects of freezing on pumpkin cell disintegration and phenolics. A fuzzy logic control (FLC) system was built to obtain better temperature control of the freezing system. Changes in cellular disintegration, electrical conductivity and phenolics content were evaluated. The angle measure technique and principal component analysis were used to delineate the surface texture changes of the frozen pumpkin cells. The results showed that FLC offered reliable temperature control performance. Freezing at -18 °C for 7 h caused the highest cell degradation of 0.467 on the disintegration scale. Decomposition was also indicated by an almost double increase in electrical conductivity. The changes in texture were accurately reflected in the mean angle spectra and 81.3% and 7.4% of the variability due to treatments could be explained by two principal components respectively. Freezing pumpkin at -18 °C for 6 h correlated to the maximum increase in total phenolics of 70.44%. The increased phenolics were dominated by caffeic acid, chlorogenic acid and p-coumaric acid. In conclusion, as the freezing system exhibits positive effects on the phenolics content of pumpkin, it may be employed to process seasonal pumpkin to obtain higher value from the produce.

Keywords: pumpkin; freezing; fuzzy; disintegration; phenolic

INTRODUCTION
Pumpkins can be cultivated in warm areas around the world **(Kumar, Rattan and Samnotra, 2016)**, are cheap to grow and provide a high nutrient content **(Provesi and Amante, 2015)**. The valued nutrients of pumpkin include phenolic compounds ranging from 4.44 to 5.65 mg GAE/g dry matter **(Mendelova, et al., 2017)**, flavonoids (4.4 mg/100 g) and anthocyanins (0.14 mg/100 g) **(Oloyede, et al., 2012)**.

The most frequently used preservation method for fresh food from living tissue or cellular food materials is freezing **(Li, Zhu and Sun, 2018)**. Freezing causes plant cells to undergo cellular disintegration related to dehydration and mechanical damage mechanisms. These allow cells to lose water by diffusion, leading to irreversible shrinkage until the cells collapse **(Fellows, 2009)**. The migration of intracellular water to form ice crystals in the extracellular area results in intracellular dehydration and an increase in the ionic strength of the cell. The mechanical damage to cells results from membrane distortion and stress on rigid structures **(Zaritzky, 2011)**. Freezing of plant foods enhances the release of phytochemicals due to the extraction effects induced during the process **(Leong and Oey, 2012)**.

The effect of processing on food structure can be precisely assessed by imaging of the food surface. Within the food image, information about the surface of food and cells is stored as an array of pixels of different intensities to form the image texture **(Quevedo, et al., 2002)**. Using the angle measure technique (AMT), a raw image is converted to a one-dimensional signal, then a number of points are selected along the signal point and the mean angle (MA) at each selected point is calculated. This step is repeated to reach the last point, to generate an MA spectrum of the image. The MA spectra obtained from images of various treatments are then used for principal component analysis (PCA) to obtain image separation **(Fongaro and Kvaal, 2013)**.

There is scarce information on the effect of slow freezing on the cellular integrity and phenolics content of pumpkin. Based on our preliminary study, temperature controls of the currently available household freezers employ a conventional thermostat with which a precise freezing temperature is difficult to achieve. Among other control systems, fuzzy logic control (FLC) is regarded as an updated approach which does not require a precise model to build and would improve refrigeration efficiency **(Saleh and Aly, 2015)**. Furthermore, FLC is considered an intelligent control system that well accommodates the implementation of heuristic knowledge of a system **(Jantzen, 2013)**. This study therefore aimed to elaborate the

effect of fuzzy-controlled slow freezing on pumpkin cellular structures and phenolic compounds.

Scientific hypothesis

Fuzzy-controlled freezing increases pumpkin cell disintegration and phenolics content.

MATERIAL AND METHODOLOGY

Pumpkin samples

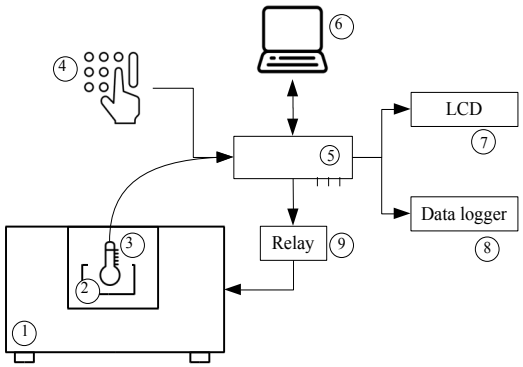
Pumpkin fruits (*Cucurbita moschata* Duch) were obtained from a local market. Confirmation of the correct species was obtained from an expert at the Materia Medica government herbal centre. The fruits were chosen based on the following conditions: fresh, clean, correct maturity stage, free from apparent physical defect and biological spoilage, and weighing approximately between 2.5 and 4.0 kg each. The fruits were kept under controlled conditions within the recommended temperature range of 7 – 13 °C **(Raju, Chauhan and Bawa, 2011)** and RH of 50 – 70% **(Maynard and Hochmuth, 2007)**. A data logger (Extech RHT20, FLIR Systems, Inc., Massachusetts, USA) was used to monitor the humidity and temperature. The actual temperature and RH range during experiments were 10.3 – 10.8 °C and 48 – 68.4% respectively. The fruit exocarp, fibrous strand and seeds were removed, and the pulp was obtained by cutting the fruit following the rib.

For freezing experiments, samples were cut into 2 cm x 2 cm x 3 cm pieces weighing 250 g. For the cell damage experiments, the pumpkins were prepared in the form of a cylinder 1 cm in diameter and 3 cm in length obtained using a stainless steel laboratory borer. Dried pumpkin powder for determining total phenolics content and liquid chromatograph mass spectrometer (LCMS) analyses was prepared by slicing of frozen samples after complete thawing for 2 h at room temperature. The samples were then dried at 55 °C in a hot air-drying oven (FDH6, Maxindo, Indonesia) for 24 h. The samples were finally ground (Philips HR2116, Indonesia) and sieved (Retsch 5657, Germany) at mesh 50 to obtain uniform particles with a maximum size of 300 μm. The powdered samples were vacuum-sealed and stored in a dark container at room temperature for analysis.

Development of fuzzy-controlled freezer

A new household chest freezer (Sansio SAN-153F, China) was used to build the fuzzy-controlled freezing system. The freezer was an air-stagnant type designed for a tropical climate with a capacity of 153 L, R134a cooling medium and cyclopentane insulation. A microcontroller-based FLC was developed to control the temperature and freezing time during the experiment. The design of the freezing system used in the experiment is presented in Figure 1.

The FLC was designed to operate based on two input variables, namely temperature error and delta error, and pulse width modulation (PWM) as the output variable. The temperature error was obtained from the difference between temperature setting and the temperature of food samples. Temperature measurement was carried out by inserting a three-wire WZP-187 PT100 sensor (accurate to ±0.01 °C) into the samples placed on the hanging basket inside the freezer compartment in approximately the geometric centre.



Note: 1. chest freezer, 2. pumpkin sample, 3. temperature sensor, 4. key input, 5. microcontroller, 6. computer, 7. LCD monitor, 8. data logger, 9. solid state relay.

Figure 1 Design of the fuzzy-controlled freezing system.

The temperature difference between two consecutive measurements was assigned to the delta error variable. The input variables were then fuzzified based on their type and range which were determined based on trial-and-error experiments in the initial FLC development. The variables and degree of membership (μ) used to develop the FLC are presented in Figure 2.

The Takagi–Sugeno–Kang method was used during the defuzzification step to obtain PWM values based on 18 rules (Table 1) to produce output values which were then directed to the freezer compressor. A Crydom solid state relay D2450-10 with attached ULN2803A integrated circuit was employed to control the inductive load of the relay. The temperature was read at 1 s intervals and logged using a Deek Robot logging shield.

A computer program was written to implement the developed system and uploaded onto an ATmega2560 Arduino microcontroller using a personal computer. The fuzzy inference system modelling of MATLAB® R2017a was used to help design and simulate the fuzzy logic system. The difference between the PWM output of the modelled and actual systems was expressed as the mean absolute percentage error. Before experiments, the PT100 sensor was calibrated by comparing the resistance of the sensor and the value on the data sheet using 30 temperature points ranging

Table 1 Rule base of the control system.

Error	Delta error		
	Negative	Zero	Positive
Negative	Off	Off	Off
Zero	Low	Medium	Medium
Positive small	Low	Medium	Medium
Positive medium	Medium	Medium	Fast
Positive big	Medium	Fast	Fast
Positive very big	Fast	Very fast	Very fast

from 3 to -15 °C. The developed system was eventually calibrated using a Fluke 724 Calibrator (Fluke Corporation, USA) and method AS 2853:1986 at the Central Laboratory of Science and Engineering, University of Brawijaya, Indonesia.

Freezing experiments

The effects of freezing on pumpkin tissue were investigated at temperatures starting from -3 °C for 4 to 8 h. The starting freezing temperatures for the experiments were determined based on the initial freezing point of pumpkin which was ascertained during pre-experiments using the cooling curve method **(Rahman, et al., 2009)**. For this purpose, the empty freezer was run at a medium temperature setting to reach a stable temperature for at least 2 h. Then, the temperature sensor was inserted into a 200 g sample approximately at its centre to approach the coolest point. The sample was then placed on a 15 mm thick Styrofoam pad in the freezer compartment and allowed to freeze **(Bainy, Corazza and Lenzi, 2015)**. The changes in temperature were recorded on a personal computer and plotted using Gnuplot version 5.2. The process was stopped when the temperature reached the end freezing point. Based on the logged data, a cooling curve was drawn, then the initial freezing and end freezing temperatures were determined based on the zero slope of the starting plateau and end of the plateau on the curve respectively. The freezing rate was determined based on the time required by the coolest sample area to decrease from 0 to -18 °C **(Pham, 2014)**.

Cell disintegration experiments

The effect of treatment on pumpkin cell damage was estimated by measuring the electrical conductivity (EC) of samples with stirring using a CON 700 meter (Oakton Instruments, Singapore). The cell disintegration index Z was calculated using the formula $Z = (\sigma - \sigma_i)/(\sigma_d - \sigma_i)$, where σ is the EC of the treated sample, and σ_i and σ_d refer to the conductivity of intact and maximally damaged cellular samples respectively **(Vorobiev and Lebovka, 2009)**. The latter value was obtained from the EC of thermally processed samples (85 °C, 15 min) to represent the maximum disintegration of the samples **(Maskooki and Eshtiaghi, 2012)**. The samples (1.0 cm in diameter and 3 cm in length) were vacuum-packed in an embossed polyethylene bag to avoid leaching **(Leong and Oey, 2012)** and immersed in hot water at 60 and 80 °C for 15 min. The EC measurements were carried out at a controlled room temperature of 22 °C. The prepared samples were immersed in 100 mL of distilled water in a beaker after the samples reached room temperature.

Microstructure analysis

Samples for microstructure analysis were prepared using the air-drying preparation method **(Pathan, Bond and Gaskin, 2010)**. Pumpkin samples of 20 mm x 15 mm were cut to approximately 1 mm thick using a B Braun 22 scalpel and allowed to dry slowly at room temperature for 12 – 24 h. Images of the prepared samples were then acquired using a scanning electron microscope (SEM) (FEI™ Inspect S50, USA). Before imaging, the dried samples were sputter-coated (Emitech SC7620 Sputter Coater, UK) with a thin layer of gold–palladium (approximately 10 nm, 5 mA, 180 s) at room temperature and a pressure of 10^{-2} Pa. The samples were observed at an acceleration voltage of 15 kV, and difference magnifications were used to obtain images.

Images obtained from the SEM machine were saved at a resolution of 34 pixels per cm (34 bits per pixel) in tagged image file format (TIFF). The complexities of image textures were characterized using the AMT method **(Kvaal, et al., 2008)**. The image processing was carried out using ImageJ software version 1.52p **(Schneider, Rasband and Eliceiri, 2012)** with AMT plugin. The setting values for ATM algorithms were maximum scale 500 pixels, method of unfolding spiral, unfolded pixels start from 0, and 500 sampling points.

Total phenolics content (TPC)

Approximately 0.5 g of dried pumpkin samples was added to 20 mL of 95% ethanol and macerated for 24 h in the absence of light at room temperature. The extracts were then filtered through a Whatman filter paper and stored in a brown bottle before analysis. TPC was estimated using the Folin–Ciocalteu method **(Alara, Abdurahman and Ukaegbu, 2018)**. The TPC in the pumpkin samples was calculated based on the standard curve of gallic acid constructed over a concentration range of 0 to 50 mg/L. The resulting regression line was y = 0.0044x + 0.093; R^2 = 0.9876, where y was the absorbance at 765 nm and x was the concentration from the calibration points. Results were reported as gallic acid equivalent in milligrams per gram of dried samples (mg GAE/g dw).

LCMS analysis

LCMS analyses were performed on untreated pumpkin and samples frozen at -18 °C for 6 h which exhibited the highest TPC. The TPC extracts were further filtered (0.45 μm) and analysed **(Zdunic, et al., 2016)**. The analyses were carried out using a Shimadzu LCMS - 8040 LC/MS equipped with a Shimadzu column Shim Pack FC-ODS (2 mm D x 150 mm, 3 μm) (Shimadzu Corporation, Japan), and run with the following settings: injection volume 1 μL; capillary voltage 3.0 kV; column temperature 35 °C; flow gradient 0/0 at 0 min, 15/85 at 5 min, 20/80 at 20 min and 90/10 at 24 min; flow rate 0.5 mL/min; sampling cone 23.0 V; MS ion type [M]+; collision energy 5.0 V; desolvation gas flow of 6 L/h and temperature of 350 °C; low energy CID fragmentation; ESI ionization with scanning of 0.6 s/scan (*m/z*: 10 – 1000); source temperature 100 °C; and 80 min run time. Ethanol (95%) and water were used as solvents. Curve areas on chromatograms of untreated and treated samples were then compared to determine the individual phenolic changes due to freezing.

Statistical analysis

The average means of the response variables were compared using a one-way analysis of variance test. Pearson correlation was used to determine correlation between the disintegration index and EC of samples. PCA was run to identify the variability of surface texture due to freezing. All statistical tests were carried out using the R software environment for statistical computing, version 3.6.2 **(R Core Team, 2018)** at $p < 0.05$.

RESULTS AND DISCUSSION

FLC performance

The system calibration report showed that the temporal and spatial variations of the freezer were within acceptable values of -1.0 and 1.9 °C respectively. During the performance test at a setting temperature of -10 °C, the freezer demonstrated an average rise time of 21.38 ±2.40 min, settling time of 31.36 ±1.29 min, and steady error positive and negative of 1.55 ±0.11 and -1.28 ±0.33 °C respectively. The small temperature errors could be used as evidence for the high performance of fuzzy-controlled refrigeration systems **(Cheung and Kamal, 1997)**. Other related data that support the system's robustness include the strong correlation between actual and theoretical resistance values ($y = 1.0001x - 0.0211$; $R^2 = 0.9996$) and the small mean absolute percentage error value of the system (9.52%).

Based on the freezing rate of pumpkin samples in the experiment (4.2 °C/h) as shown in Table 2, the developed freezing system can be classified as slow freezing. This process is typically characterized by a freezing rate of 1 – 10 °C/h **(Brown, 1991)**. The determination of this freezing rate is important to ensure the correct slow rate applied in the experiment. The initial freezing point of pumpkin samples was -3.06 °C (Table 2). This point is close to freezing temperature of similar vegetables (-0.8 to -2.8 °C) **(Fellows, 2009)**. Differences in the water content and other chemical compounds in the sample and the values used in the literature may have been responsible for the disparities. The observed freezing point of pumpkin was then used as the basis for further freezing experiments to have a correct starting point for temperature assignments for the rest of the experiments.

Table 2 Freezing parameters of pumpkin.

Run number	Freezing point (°C)	End point of freezing (°C)	Time to reach from 0 to -18 °C (min)	Rate of freezing (°C/min)

M	-3.06	-6.97	262.40	0.07
SD	0.12	1.08	31.73	0.01

Cell disintegration

The fuzzy-controlled freezing of pumpkin caused great cell disintegration (Figure 3). There was a tendency for decomposition to increase as the temperature was lowered for a longer process time. This was notable particularly for freezing of less than 7 h and prolonged treatments would eventually have decreased the disintegration. The maximum disintegration of 0.467 ±0.051, as a result of freezing at -18 °C for 7 h, corresponded to an increase of EC from 36.2 µS/cm for untreated samples to 74.75 µS/cm. This ionic elevation could be caused by intracellular water which migrates extracellularly to form ice crystals during the freezing process **(Zaritzky, 2011)** and the presence of damaged cells **(Vorobiev and Lebovka, 2009)**. This result is consistent with other work by **Marra (2013)** which showed that slow freezing increases the EC of potato, carrot and apple, attributable to changes in the structure of the food samples used. Furthermore, that work also indicated a greater increase for quick freezing.

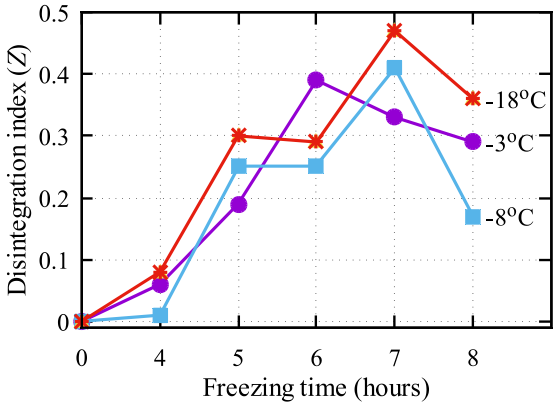

Figure 3 Effect of freezing on disintegration of pumpkin cells.

The degree of cell disruption in the present study could be considered sufficient with respect to heat-sensitive nutrient retention. More severe cell degradation may be achieved by applying a higher temperature during the thermal processing of samples, but this could destroy heat-sensitive polyphenols. **Moreira et al. (2019)** have shown that boiling and steaming of pumpkin accounts for 23.41 − 44.63% and 24.39 − 43.00% losses of total phenolic compounds respectively. Epimerization of polyphenols may occur under high-temperature processing; therefore, low-temperature processing and storage are preferred **(Deng, et al., 2018)**.

The cell disintegration and EC of samples was positively correlated (Pearson's $r = 0.95$; $p < 0.001$). This indicates that EC could be used for rapid assessment of pumpkin cell disintegration during freezing storage. Several studies have also suggested the use of EC to assess cell degradation due to food processing of potato, carrot, apple and sugar beet **(Marra, 2013; Maskooki and Eshtiaghi, 2012)**.

Microstructure changes

Untreated pumpkin tissue consisted of cells which are closely bound together by the cellular structure, roughly circular in shape and notably different in size (Figure 4a). This characteristic of visual structure is similar to the result reported in other work **(Rojas and Augusto, 2018)**. The disintegration of cells after freezing may be conventionally concluded by comparing the images for frozen samples (Figure 4b) and their untreated counterparts. The frozen

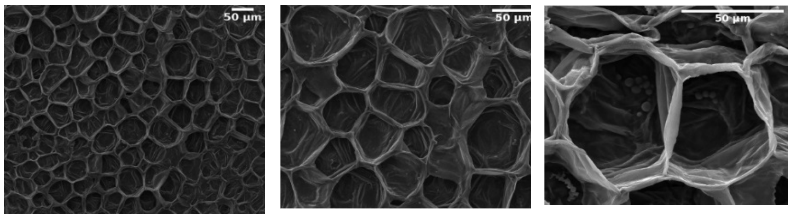

Figure 4a Microstructure of intact, untreated pumpkin cells at different magnifications, from left to right 500x, 1000x and 2.500x; scale bar 50 µm.

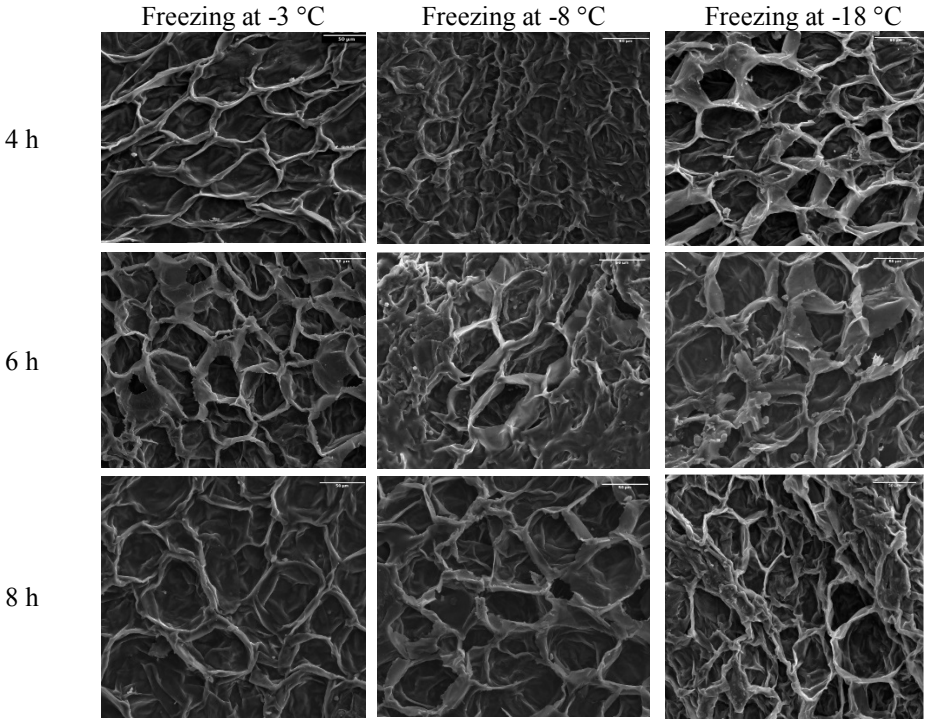

Figure 4b Comparison of microstructure of pumpkin samples after treatment at different temperature (°C) and duration of freezing (h); magnification 1000x, scale bar 50 µm.

tissue became distorted, some cells undergoing rupture and suffering from an increase in irregularity in shape. The cellular disintegration of plant tissue could be a result of water losses from the cell which lead to cell shrinkage **(Fellows, 2009)**. Membrane distortion and stress on rigid cell structures due to ice crystal growth can also cause mechanical damage to cells **(Zaritzky, 2011)**. Generally, the main factors affecting cellular structure during freezing are the formation of ice crystals, migration of water, and the intrinsic characteristics of the cells **(Li, Zhu and Sun, 2018)**.

In the present study, AMT was used to delineate and to conform the changes in surface texture of pumpkin samples as a response to freezing treatment. As the microstructure undergoes changes, the surface texture is expected to change accordingly. Along with other factors such as the illumination and imaging system used during experiments, the surface texture of samples is a determinant characteristic of the visual texture **(Kvaal, et al., 2008)**. Based on the MA spectra obtained, it was evidenced that frozen pumpkin exhibited a higher MA compared to untreated pumpkin (Figure 5). Increases in MA in the MA spectrum correspond to the irregularity, coarseness and intricacy of surfaces **(Huang and Esbensen, 2000)**. The rough texture could be the result of surface texture changes which reflect cellular decomposition following the freezing treatments. Therefore, it is clear that the surface texture of the samples deviated from that of untreated pumpkin, indicating the effects of the treatments.

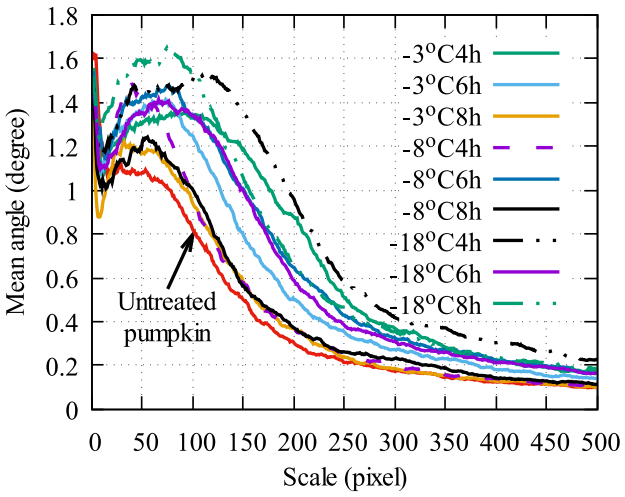

Figure 5 Mean angle spectra of pumpkins after freezing; a higher mean angle value indicates rougher surface texture.

The PCA results provide more specific information on the variation of texture as a result of various freezing treatments. The majority of the variability of sample texture in the projection model can be addressed by two principal components, accounting for 88.2% and 7.4% of variability respectively (Figure 6). The result clearly shows that untreated samples contribute a small degree of variability to the data set as signalled by the AMT spectra. The results also indicate that samples frozen at -18 °C have clearly

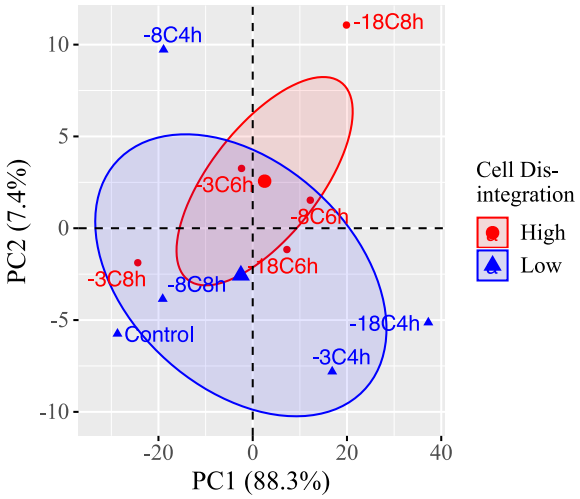

Figure 6 PCA result for pumpkin samples from different freezing treatments.

different texture characteristics compared to those frozen at -8 or -3 °C as they are separated on the PCA graph. Frozen samples which have undergone more severe cell disintegration seem to separate apart from the rest. This could indicate the correlation between cell disintegration and the texture of pumpkins due to freezing. A similar correlation has been demonstrated on red sweet pepper tissue using high hydrostatic pressure and pasteurization treatments **(Hernández-Carrión, et al., 2015)**. Due to the apparent complexity of the image textures, the MA spectra and valuable PCA outputs would substantially increase the accuracy in drawing conclusions compared to solely visual analysis of the sample images.

TPC

The TPC of untreated pumpkin was 8.49 ±0.08 mg GAE/g which is higher than the range of 4.44 – 5.65 mg GAE/g db **(Mendelova, et al., 2017)** reported previously. This may be attributable to differences in variety, environment and agricultural practices. The freezing treatments substantially increased the TPC of pumpkin samples, ranging from 9.02 ±0.03 to 14.47 ±0.05 mg GAE/g. The most notable increase resulted from freezing at -18 °C for 6 h (Figure 7). The effect of lowering temperature on the TPC increase was statistically significant (p <0.05). Although the freezing time appeared to increase the TPC, the effect was not statistically significant (p >0.05).

The increase in TPC can be attributed to the extraction effect of slow freezing on food **(Leong and Oey, 2012)**. The maximum gain of TPC in the present research (70.44%) is higher compared to other findings. The increase in TPC of strawberries frozen in an air-stagnant household freezer at -

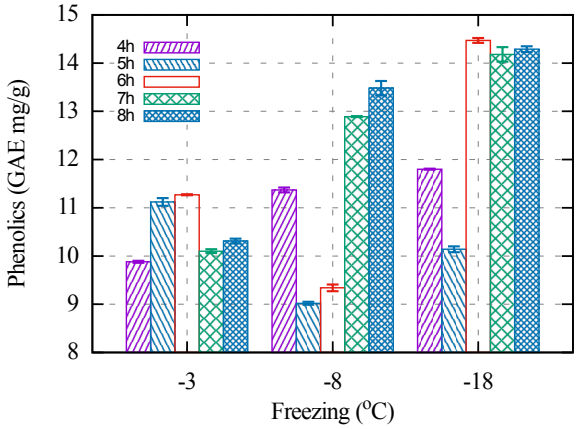

Figure 7 Total phenolics content of frozen pumpkins.

Note: Different notations within values in respective group indicate difference values at p <0.001.

27 °C for 1 week reported by **Bulut et al. (2018)** is 3.01%. An increase in TPC of 27.34% has been also reported for cagita fruit following freezing at -40 °C **(Santos, et al., 2018)** and of 17.15% for 'Hudson' spinach after 3 months of freezing **(Bystrická, et al., 2015)**. The extent to which these increases vary could be related to different influencing factors including the food matrix **(Leong and Oey, 2012)** and process parameters used in the experiments. The use of FLC to achieve better control of temperature is an interesting independent variable to which attention may be drawn. The scarcity of published data on the type of freezer temperature controller and on performance tests before systems are used in experiments makes comparison of any results difficult to attain. A precise freezing temperature of a desired point for experimental purposes is difficult to achieve when an air-stagnant household freezer with an analogue thermostat controller is employed. As **Cheung and Kamal (1997)** showed that the performance of a refrigeration system controlled by fuzzy logic is better than that controlled by a proportional derivative method, the small temperature errors observed during the freezer performance test in the present research could serve as evidence for better temperature control or process performance.

LCMS results

The LCMS test showed that slow freezing increased phenolic compounds, primarily caffeic acid, chlorogenic acid and p-coumaric acid (Table 3). Significant increases in other phenolics such as isorhamnetin-3-O-rutinoside, ferulic acid and naringenin were also detected. The increase in phenolic compounds such as anthocyanins and flavonol glycosides due to the extractability effect of freezing has also been demonstrated for grapes **(Tomaz, et al., 2017)**. LCMS provides individual changes in phenolics which cannot be observed by Folin–Ciocalteu assay alone. LCMS tests are also more precise. Ascorbic acid in pumpkin flour samples may act as a reducing agent and interfere with the Folin–Ciocalteu assay, hence reducing test specificity **(Sánchez-Rangel, et al., 2013)**. Dried pumpkin samples used for LCMS analysis may contain ascorbic acid as revealed by related work that pumpkin powder produced by fluidized drying still contains as much as 21.16 mg vitamin C/100 g **(Khan, et al., 2019)**.

Table 3 Increase in pumpkin phenolics due to freezing as detected by LCMS.

Retention time (min)	Compound	Formula	Exact mass	Curve area increase
1.84	p-Coumaric acid	$C_9H_8O_3$	164.0473	1158.7066

CONCLUSION

In the present study, a slow freezing system controlled by a fuzzy logic algorithm was developed to study pumpkin cell disintegration. Freezing causes severe cell degradation which can be clearly observed by an increase in disintegration index and surface texture changes. Frozen pumpkins exhibit rougher texture or a higher MA at the respective scale as compared to untreated samples. As a result of cell damage, increases in EC and phenolic compounds are also detected. The maximum increase in TPC of 70.44% resulted from freezing at -18 °C for 6 h. The increased phenolics compounds are mainly caffeic acid, chlorogenic acid and p-coumaric acid. Information obtained from cell damage, texture analysis and phenolics content are all in agreement to support the favourable effects of fuzzy-controlled slow freezing on phenolics from pumpkin.

EVALUATION OF THE PHYSIOLOGICAL STATE OF FEIJOA (*FEIJOA SELLOWIANA* BERG) IN SUBTROPICAL RUSSIA

Zuhra Omarova, Nataliia Platonova, Oksana Belous, Magomed Omarov

ABSTRACT

The article presents the results of research examining varietal diversity with respect the activity of oxidative enzymes (EC 1.11.1.6) and the dry matter and Proline accumulation of leaves under optimal and stressful conditions. For feijoa, the most stressful period in the subtropics of Russia, with respect to hydrothermal conditions, occurs between July and September. Studies have shown that the highest degree of enzymatic activity is observed in August in the 'Superba' variety of feijoa, which was used as a control in this study, and the lowest level of activity was observed in the 'Sentjabrskaja' variety. The long-term water deficit experienced in September coincides with fruiting in feijoa. This causes a change in catalase activity in leaves, which is maintained until it is inhibited. Form ShV-1 of feijoa is characterised by its metabolic stability. In fact, the activity of oxidative enzymes in leaves of the variety is stable. Dry matter content per unit area increases as the leaf grows. During the drought period, which coincides with active fruiting, the leaves of the 'Dachnaja' variety and the ShV-1 form accumulate significantly less dry matter than other varieties. In the 'Dagomysskaja' variety, the intensity of organic matter consumption via respiration and outflow exceeds visible photosynthesis, which is expressed as a negative value (average = 1.96 $g.dm^{-2}$ h). To fully characterise the physiological state of feijoa plants under the influence of abiotic factors and catalase activity in the humid subtropics of Russia, indicators of dry matter accumulation and true photosynthesis intensity can be used.

Keywords: feijoa; enzymes; catalase; photosynthesis; stability; stress factors

INTRODUCTION

According to the modern Botanical classification, feijoa belongs to the *Myrtaceae* family of the order Myrtales **(Bose, Mitra and Sanyal, 2001; Omarova and Kulyan, 2019; Ryndin, 2019)**. The family includes 72 genera and about 100 species that grow in the tropics and subtropics, mainly throughout America, North-West Africa and Australia. Feijoa is native to the subtropical zone of South America. In its wild form, it grows over a large area consisting of shrubby and mixed forests in southern Brazil, Paraguay, Uruguay, and Northern Argentina. These areas lack sharp fluctuations in air temperature and precipitation **(Belous, Omarov and Omarova, 2014; Kedelidze et al., 2015; Phan et al., 2019)**. The genus Feijoa includes three species, *F. obovata* Berg, *F. shenkiana*, and *F. sellowiana* Berg. In culture, *F. obovata* and *F. shenkiana* do not occur. Since its use is advantageous relative to the other varieties of feijoa, only *F. sellowiana* (synonyms: *Acca sellowiana* Berg, *Orthostemon sellowiana* Berg) is widely known and industrially significant.

Feijoa Zellova (*F. sellowiana*) is an evergreen tree/shrub that grows to a height of 3 to 5 meters or more. The crown of a young plant is compact, but with age, usually after entering the fruiting season, it spreads out. Before fruiting, bushes tend to increase in height. Afterward, apical shoots slow growth, and side shoots contribute to increases in the diameter of each plant. When grown industrially, different forms of feijoa plants are used that consist of erect plants with a pronounced stem, vigorously growing types that are structurally similar to trees, squat types with dense branching and a low-growing, compact and leafy type.

Feijoa is one of the most valuable crops, since its fruits are made up of 11.4 – 12.4% dry substances, 7.92 – 9.16% total sugars, 1.56 – 1.84% sucrose, 6.20 – 7.41% invert sugars, 1.60 – 2.45% glucose and fructose 3.36 – 5.24%. The dry weight of feijoa is also, 0.94 – 1.43% acids, producing a sugar acid index is of 6.09 – 9.06 units. Other components include vitamin C (26.0 – 32.4 mg), starch (0.92 – 1.16%), pectin (1.28 – 1.91%) and hemicellulose (3.63 – 4.25%) **(Bontempo et al., 2007; Belous, Omarov and Omarova, 2014; Aoyama, Sakagami and Hatano, 2018; Kedelidze et al., 2015; Montoro et al., 2020)**.

Plants of different varieties can be characterised by their metabolic features and considering what type of physiological and biochemical processes occur in a plant can facilitate the elucidation of adaptation mechanisms that are used to maximise plant fitness under changing environmental conditions. The purpose of our study was to examine metabolic characteristics of a number of varieties

and forms of feijoa. For example, the main indicators of the water status, and features of enzymatic activity, characteristics of the pigment apparatus and accumulation of free Proline were assessed. These indicators were selected because the photosynthetic apparatus is highly sensitive to environmental factors, and the content of plastid pigment has traditionally been used as a diagnostic indicator of the plant health **(Belous, Klemeshova and Malyarovskaya, 2018; Horčinová Sedláčková et al., 2018)**.

The enzymatic activity of catalase (CAT), an oxidative enzyme, varies in plants as they react to adverse factors **(Hodges et al., 1997; Apel and Hirt, 2004; Belous, 2012; Abilfazova and Belous, 2018)**, and the accumulation of damage can inactivate the enzyme. The strength of CAT inhibition depends on many factors (plant age, varietal characteristics, etc.). The accumulation of free Proline occurs as a response to various damaging factors, since Proline helps to reduce the magnitude of damage **(Nilsen and Orcutt, 1996)**. Finally, the intensity index of true photosynthesis is used to characterise overall photosynthesis, and is directly related to the functional state of the plant. The intensity of true photosynthesis is associated with the accumulation of assimilates within the plant **(Osmond et al., 1987; Gaspar et al., 2002)** and can be calculated by assessing changes in the amount of dry matter within leaves over a defined period.

In this article, we have assessed CAT activity in feijoa leaves, which is a diagnostic characteristic of the functional state of the plant. Also, we have determined levels of protein and dry matter accumulation, and have measured the intensity of true photosynthesis, which determines assimilation levels within the plants assessed.

Scientific hypothesis

Determination of CAT activity is a marker of the adaptive potential of plants and can be used to identify crop resistance to hydrothermal stress.

Active defense mechanisms in feijoa plants allow plant leaves to accumulate a large amount of dry matter.

Evaluation Proline accumulation in leaf is necessary for fully characterizes the physiological status of feijoa plants.

MATERIAL AND METHODOLOGY

Plants used in the study were a one-zoned ‘Superba’ variety of feijoa, three varieties from the institution (‘Dagomysskaja', 'Dachnaja’ and 'Sentjabrskaja’) and well as a promising (ShV-1), which was grown in the collection garden of the Russian Research Institute of Floriculture and Subtropical Crops. The determination of physiological parameters was carried out at the laboratory of plant physiology and biochemistry of the Institute. Leaf samples consisting of 52 – 60 leaf pieces were collected dynamically during both the most optimal and highly stressful dry growing season. Experiments were conducted using three field and three laboratory replicates.

The analysis of CAT activity in leaves was performed using by gasometrical method **(Tretyakov, 1990)**. The principle of the method for determining CAT activity is based measuring the quantity of oxygen released throughout the decomposition of hydrogen peroxide. CAT activity was expressed in mL oxygen released per g of raw plant tissue.

Percentage dry substance values were calculated by drying samples at a temperature of 105 °C **(Erzhanov, 2016)**. The process is designed to remove both hygroscopic and external moisture. To calculate the content of components within the dry substance, the mass of the determined component was expressed as a percentage of the mass of the dry sample.

The intensity of true photosynthesis was calculated based on measured quantities of accumulated dry matter **(Marakaev, 2005)**. The intensity of true photosynthesis is equal to the sum of the intensity of visible photosynthesis and the intensity of the consumption of organic substances for respiration and outflow to other organs (since the fluctuation of water in the leaf masks change in dry matter mass, leaves were cut when fully saturated with water).

To determine free Proline content, the Bates method was used **(Bates, Waldren and Teare, 1973)**. The method is based on the interaction between free proline and ninhydrin reagent, which can be measured colourimetrically as a pink-red colour is produced. Free Proline content was determined using a calibration curve constructed using Proline solutions ranging from 50 to 150 mgL^{-1}, and values were expressed in micrograms Proline per 1 g of raw mass.

Statistical analysis

Statistical processing of experimental data was carried out using the ANOVA package in STATGRAPHICS Centurion XV (version 15.1.02, StatPoint Technologies) and MS Excel 2007. Statistical analyses included univariate analysis of variance, which is a method for comparing averages using variance analysis and a t-test) and variance analysis (ANOVA). Differences between means compared using least significant difference (LSD) were considered significant when $p < 0.05$. All experiments were performed in triplicate and values were expressed as mean ± standard deviation (SD). Differences between the samples were assessed using unpaired t-tests.

RESULTS AND DISCUSSION

The resistance of plants to adverse environmental factors is largely determined by the activation of the antioxidant enzyme system, which inhibit the damaging effects of oxidative stress. CAT is a key enzyme involved in protection against oxidants, and the enzyme catalyzes a number of metabolic reactions. In particular, it catalyzes the decomposition of hydrogen peroxide to water and molecular oxygen. CAT activity is a marker of the adaptive potential of plants and can be used to identify the resistance of crops to hydrothermal stress, thus establishing their adaptive potential **(Belous, 2012; Apel and Hirt, 2004; Hodges et al., 1997)**.

The effect of factors such as drought on plants includes the suppression of many physiological processes. Simultaneously, drought stress activates protective mechanisms. In recent years there has been a significant increase in temperature throughout the summer period during which has prolonged drought periods for active vegetation. There ideal conditions were determined to study the effect of hydrothermal stressors on the metabolic

activities of subtropical crops, in particular, feijoa. If May precipitation of 70 – 100 mm exceeds the norm (on average 110 mm), then in other periods will experience a stable water deficit. Precipitation is reduced from 82% (June) to 21 – 26% (August) of the average annual precipitation rate. This is accompanied by increased air temperatures, which reach daytime maximum values of 34.1 – 37.0 °C, which is 4 – 9 °C higher than long-term parameters. This causes not only early attenuation of growth processes, but also fruiting in many crops, which affects the crop quality and quantity.

Changes in enzymatic activities were measured during a period of peak hydrothermal stress, which occurred as the crop was fruiting. According to a number of authors, when plants get into water deficit conditions, there is an increased regulation of certain AOS-producing enzymes (for example, catalase, ascorbate peroxidase, guaiacol peroxidase, etc.) **(Arbind, Sheela Devi and Sundareswaran, 2014; Hodges et al., 1997)**. An increase in the activity of a number of enzymes during the progression of water deficiency in plants has shown that a direct consequence of water deficiency is damage to the cell membrane. The results highlight the important role of certain antioxidant enzymes and compounds in protecting against drought stress **(Sofo, Dichio and Xiloyann, 2010)**. Our studies have shown that, in general, the enzymatic activity of CAT ranges from 104.4 to 170.4 mL O2.g^{-1} of raw weight. The highest CAT index is expected in August (the most stressful period of vegetation) was observed in the 'Superba' variety, which is a control, and the lowest activity observed was determined using the 'Sentjabrskaja' variety (Figure 1). Long-term water deficiency provoked a change in the CAT activity of feijoa leaves. This was especially true in September, when plants were in the fruit loading phase, which enhanced plant stress in nearly all varieties. This was reflected by the inhibition of CAT activity, which was observed in all varieties with the exception of the 'Sentjabrskaja', whose enzymatic activity was 1.3 times higher in September than its annual average value. It must be noted that form ShV-1 did not experience noticeable changes in CAT activity, which suggests that metabolic processes on the form are stable, despite changes observed regarding the strength and duration stress experienced.

The dynamics of dry matter accumulation in feijoa leaves revealed that dry matter content per unit area increased with leaf area (Figure 2). Water stress can limit the accumulation of dry matter in the leaves, so it is important to select varieties resistant to water deficiency **(de Lacerda et al., 2003; Apel and Hirt, 2004; Amirjani, 2010; Boussadia, Ben Hassine and Braham, 2018)**. Moreover, during the drought period, which coincided with the processes of active fruiting, leaves of the 'Dachnaja' variety and the ShV-1 form accumulated dry matter significantly less than other varieties. The most active protective mechanisms observed were in plants of the 'Sentjabrskaja' variety. The continuing drought allowed leaves, despite the active formation of fruits, to accumulate greater quantities of dry matter than other varieties ('Sentiabraskaja' averaged up to 53.90 g dry matter, while other varieties averaged 49.85 – 52.91 g).

Proline levels in the leaves of varieties and forms in July ranged from 93.75 to 201.79 mg.g^{-1}, and depend on the genotypic characteristics of plants (Figure 3). Throughout the period of high stress (August), we observed a 1.5 – 2.8 fold increase in Proline levels in feijoa leaves. The greatest numbers observed were determined in 'Dachnaja', 'Dagomysskaja' varieties and form ShV-1 (266 – 270 mg.g^{-1}). Low concentrations of Prolin in 'Sentjabrskaja' and 'Superba' varieties confirmed their resistance to abiotic stressors. These data in which Proline levels increasing under stressful conditions is consistent with studies by other authors **(de Lacerda et al., 2003; Ashraf and Foolad, 2007; Amirjani, 2010)**, who reported that increasing Proline content is a common physiological response to drought, mineral nutrition deficiency, and other adverse effects in plants. Determination of free Proline content can serve as an express method for determining the level of plant resistance, which will allow at the early stages of the selection process to reject less than stable breeding material **(Bates, Waldren and Teare, 1973; Nilsen and Orcutt, 1996; Amirjani, 2010)**.

The activity of photosynthetic processes, determined by measuring increases in the amount of dry matter present within cells, is a key indicator of plant resistance, since the active accumulation of photosynthetic products in conditions of stress is associated with high levels of plant resistance **(Marakaev, 2005, Horčinová Sedláčková et al., 2018)**. Calculations of the intensity of true photosynthesis during this period confirmed the physiological state of feijoa plants. Thus, the 'Superba' variety (4.82 – 13.56 g.dm^{-2} h dry matter) is characterised as being highly resistant to stress. It is known that not all dry matter that is formed accumulates in leaves. Some is consumed in the process of respiration. Thus, in the 'Dagomysskaja' variety, the intensity of organic matter consumption for respiration and outflow exceeded visible photosynthesis, which was expressed as a negative average value (-1.96 g.dm^{-2} h). The result was in accordance with the small difference observed in the dynamics of dry matter accumulation of the variety (Figure 2).

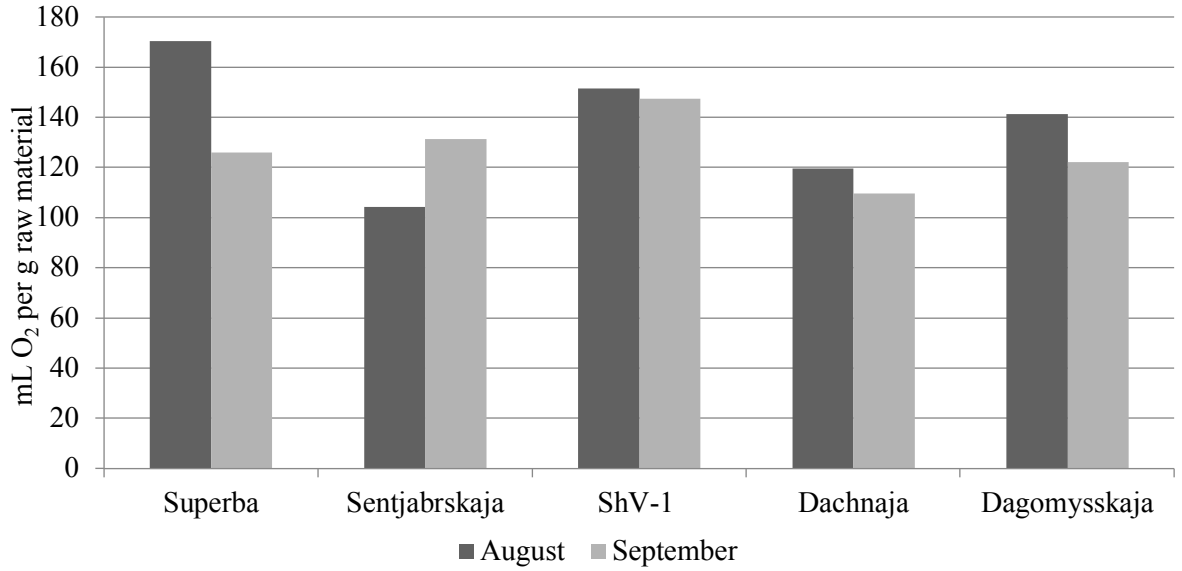

Figure 1 Catalase activity in feijoa leaves. Note: LSD ($p \leq 0.05$) = 12.16 (August) and 5.54* (September); * – NS.

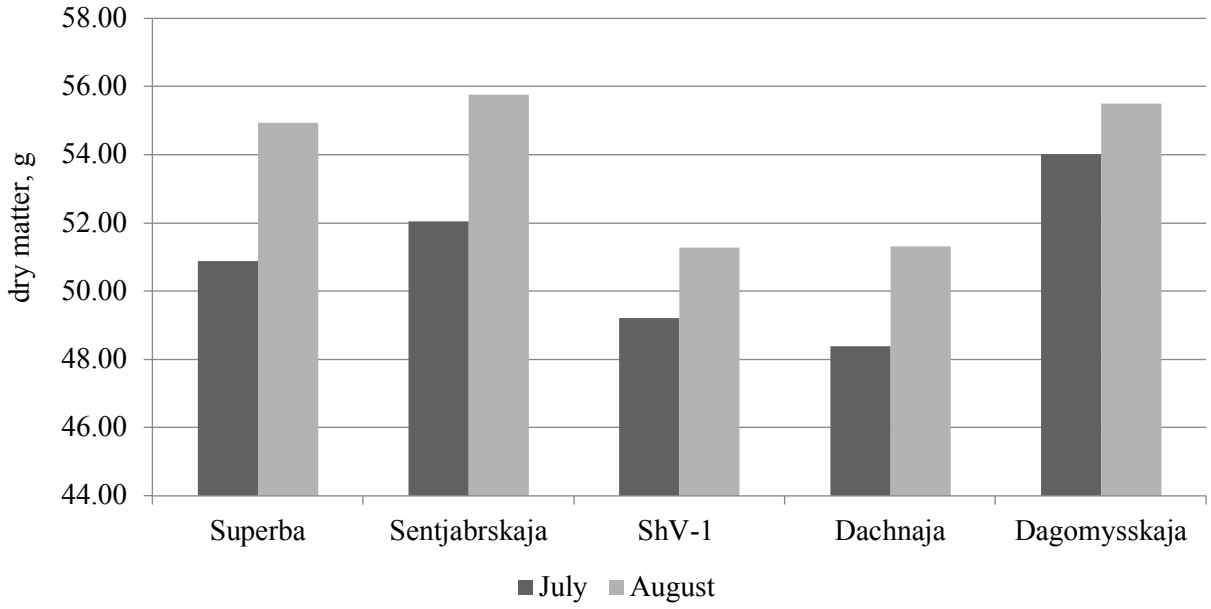

Figure 2 Dynamics of dry matter accumulation (%) in feijoa leaves. Note: LSD ($p \leq 0.05$) = 3.02 (August) and 2.15 (September); all differences were significant.

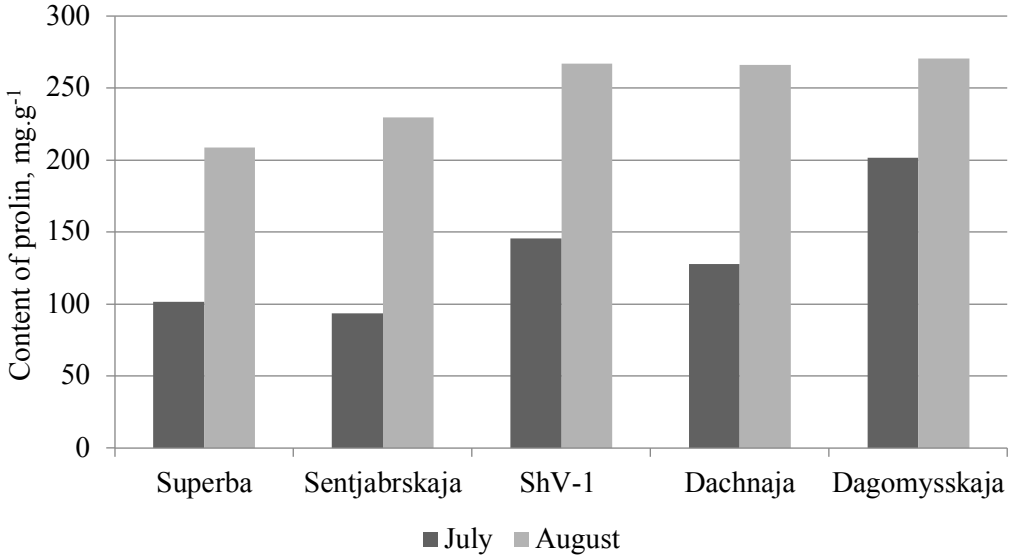

Figure 3 Dynamics of Proline accumulation (mg.g^{-1}) in feijoa leaves. Note: LSD ($p \leq 0.05$), NS.

CONCLUSION

The study has shown that varieties and forms of feijoa subjected to stress factors (drought and high air temperatures during active vegetation) altered CAT activities in their leaves. It should be noted that form ShV-1 did not significantly alter CAT activity indicators as its stress level increased, which indicates that it is a form that is highly resistant to the stress factor. To fully characterise the physiological state of feijoa plants under the influence of abiotic factors in the humid subtropics of Russia, in addition to the activity of the oxidative enzyme CAT, it is necessary to use indicators of dry matter accumulation and the intensity of true photosynthesis.

THE EFFECT OF INFRARED DRYING TO THE MICROSTRUCTURAL STRUCTURE AND TEXTURE OF WHOLE DUKU INTACT SKIN BY MEANS OF SCANNING ELECTRON MICROSCOPY (SEM) TECHNIQUE

Laila Rahmawati, Daniel Saputra, Kaprawi Sahim, Gatot Priyanto

ABSTRACT
The Infrared method has the potential to extend the shelf life of duku fruit by drying the duku's skin into "shell likeness". Duku's skin drying using infrared method could change the shape and characteristics of duku's skin which would significantly affect the length of fruit shelf life. The texture of duku's skin for the treatment of infrared emitter distance of 6 cm, temperature of 400 °C and exposure time of 80 seconds was increasing with the storage time which made the fruit inside the skin to experience a passive modified atmosphere and increase the shelf life of duku. The 3D visual depiction of the optimization result on drying process using infrared had the largest porosity and cavity value in the treatment of infrared emitter distance of 10 cm, temperature of 300 °C, and exposure time of 80 seconds. At the magnification of 2500 times, with a resolution of 10 μm, it was found that the porosity and thickness of the duku's void were greater than duku fruit without treatment. The result of the porosity also found that drying process with the infrared emitter distance of 6 cm at temperature of 400 °C, and exposure time of 80 seconds has more stable porosity (without collapsing) which confirmed the result found on the texture of the skin. The results of scanning electron microscopy analysis and 3D visual analysis confirmed the results of optimization that had previously performed in the drying process of duku fruit using infrared method.

Keywords: Infrared; drying; SEM Image; duku

INTRODUCTION
Electron microscopy is a method of using a beam of electron instead of light that interact with the atom in the sample. This interaction is in the form of sample reflectance which contain the information of the sample. One type of electron microscopy is called Scanning Electron Microscopy (SEM). The image produced by SEM is a result of a reflectance of heat, emission of low energy and high energy backscattered electrons, light emission which due to the beam of electron will contain the detail information about the properties of the surface of the sample. These signals were then converted into a very detailed image. SEM has been used to analyse the conditions of processing materials and food structures. Besides being used to analyse the material and structure of the food, SEM also provides more complete information about the structure of food materials by displaying three-dimensional imaging and could facilitate to obtain quantitative and qualitative information. SEM is used to visualize the structure of food materials because it combines several features of both light microscopy and transmission electron microscopy **(Aguilera et al., 2000; Falcone et al., 2006)**.

The study of the microstructure of food has become important part of food research because the structure of food could have an influence on nutritional value, rheology and some texture attributes **(Lyu et al., 2017)**. Food processing such as thermal and non-thermal processes could affect the structure and composition of the food **(Mercier et al., 2011; Lewicki and Pawlak, 2003)**. Thermal food processing could reduce the nutrition or the nutritional bioavailability, and cause damage to the chemical and the organoleptic properties. Some examples of thermal food processing technology is drying. Drying is one of the food processing methods that could prolong the shelf life or preserve grains, fruits, vegetables and food in all varieties. The quality of dried fruits depends on the conditions of the drying process. Infrared radiation has been used in drying food product. Infrared radiation has been widely implemented in the food process because it has several advantages including reducing water content in food, having low energy consumption and relatively short processing time, and could maintain and ensure the condition of product quality **(Pan et al., 2009)**. Infrared radiation could also inactivate pathogens in the material. Infrared radiation could preserve volatiles **(An et al., 2015)** inactivate bacteria, spore, yeast, and mold by

controlling some of the influential parameters such as power of infrared heater **(Hamanaka et al., 2000)**, sample temperature **(Sawai et al., 2003)**, wavelength and the target wavelength **(Krishnamurthy et al., 2008)**, sample thickness **(Sawai et al., 2000)**, and sample water content **(Hamanaka et al., 2006)**. Some drying processes with infrared have been widely used including for fruits and foods. The unique characteristics of infrared radiation is the heat from emitter energy only hit the surface of food ingredients in a short time without raising the temperature of the material **(Li and Pan, 2014a)**.

The uniqueness of infrared radiation could be used to dry the skin of whole intact duku fruit. The relatively short time infrared exposure in drying of the skin would make the water on the skin of the whole intact duku to evaporate and dry the skin. Skin drying would turn the skin of the whole intact duku to dry and in turn made it into the "shell likeness". This "shell likeness" of the duku skin would mimic the condition of the inner flesh of duku fruit into a state of passive modified atmosphere **(Rahmawati et al., 2018; Rahmawati et al., 2019** which was shown to increase the shelf life of duku **(Saputra and Pratama, 2013; Saputra and Pratama, 2018)**. During the process of forming "shell likeness" on duku's skin, the heat and mass transfer simultaneously were involved in this drying process. In these processes, the fruits would undergo some volume changes either by shrinkage due to moisture loss or by expansion due to gas generation or pore formation. This shrinkage or expansion process would result in the changes of porosity of the fruit **(Aydogdu et al., 2015)**. The measurement of porosity is needed to solve the transport process for these conditions **(Hayakawa and Futura, 1989; Witrowa-Rajchert and Rząca, 2009; Pongpichaiudom and Songsermpong, 2018)**. The changes in pore formation in food during the drying process could be used to predict the thermal conductivity, mass diffusivity, thermal diffusivity, and other transport properties of food **(Rahman, 2007; Mavroudis et al., 1998; Xiong et al., 2015; Vincent, 1989; Scanlon et al., 1998)**.

Textural and mechanical properties of food process had been shown to have a correlation to the porosity. Crispiness also was shown to have a high correlation to the food porosity. The higher the apparent density of the agglomerate of the lower porosity, the stronger the agglomerate. Besides of porosity, the binding forces or adhesion of particle (i.e., structure) also affect the mechanical strength **(Pietsch, 1999)**. The variation of porosity, size of pore and pore size distribution have significant effects on the textural characteristics of dried foods **(Huang and Clayton, 1990)**.

The objective of this study was to determine the effect of infrared drying on the microstructural structure (porosity) and texture of whole duku intact skin by means of Scanning Electron Microscopy (SEM) technique.

Scientific hypothesis

The hypothesis of this research was that the microstructural changes of intact duku's skin caused by the infrared drying could create a passive modified atmosphere within duku which was shown by the scanning electron microscopy

MATERIAL AND METHODOLOGY

Samples of Duku

Duku (*Lansium domesticum*) used in this study was bought from a local farm in the area of South Sumatra Province, Indonesia. Duku fruit selected based on the appearance of smooth yellowish colour of the skin without blemish, free from contamination of microorganism, and were selected in the diameter range of 2. 5 to 3. 5 cm. The fruits were then exposed to a pair of Infrared emitter (IRE) with the distance between the emitter at the top and bottom of 6 and 10 cm, the IRE temperature of 200, 300, and 400 °C, the exposure time of 50, 60, 70 and 80 seconds respectively according the treatment allocated by the experimental design. After exposing duku to the IRE, the fruit was stored in a showcase at 11 – 15 °C for 25 days. The physical and chemical properties of duku's were then measured periodically as described on previous study **(Rahmawati et al., 2018)**. The result of previous study on the effect of IRE distance, temperature, and time of exposure on the physical and chemical properties changes were then optimized to by means of using Response Surface Methodology **(Rahmawati et al., 2019)**. The skin of duku's from the result of the optimization were then peeled and its microstructure were determined by means of SEM to reconfirm the result of Response Surface Methodology.

Scanning Electron Microscopy (SEM) Analysis

Analysis of SEM was carried out by selecting the optimum treatment of IRE with the RSM method (Design Expert Program® Version 11, 2018). Duku's were peeled and then the skin was freeze dried. The freeze dried of duku's skin was then cut longitudinally and the skin texture was observed using the Scanning Electron Microscope (SEM, JEOL® serial number 6510 LA) with the magnification of 100 times, 500 times, and 2500 times, and the resolution of 100 μm, 50 μm, 10 μm and with the depth of field 10 mm and 11 mm. The process of taking pictures and sample composition with a SEM instrument were performed by placing and pasting the sample on the SEM specimen holder with the longitudinal cross section leading upward of the objective lens. The space of the specimen holder was then vacuumed to 10^{-6} torr to ensure that the SEM column was free of air molecules. SEM was operated with the standard operating parameters including, High Voltage (HV) = 25 kV; Spot Size (SS) = 50; Work Distance (WD)= ±50 μm.

Data from SEM analysis were then analysed by using the Mountain Map Program® version 7. Mountain map measured the peak and valley of the duku's skin microstructure and measured the void within the surface of duku's skin.

Statistical analysis

The analysis of variance (ANOVA) and optimization for this research was performed with the help of Statistical Package (SAS® version 9. 4). The statistical design was a split-split plot. The details of the design could be seen on the previous paper **(Rahmawati et al., 2018; Rahmawati et al., 2019)**.

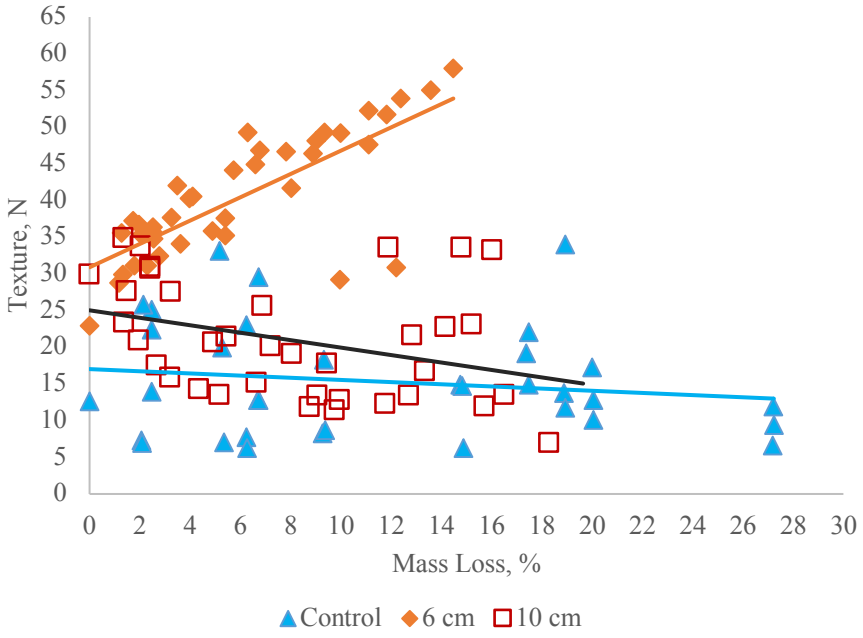

Figure 1 The correlation of duku's skin mass loss versus texture of duku.

RESULTS AND DISCUSSION

Mass loss on duku's skin and Fruit Firmness

Mass loss on the fruit skin, in general, had a correlation with the destruction of the skin due to deterioration. As expected for the plant product especially fruit and vegetables, the higher the mass loss the lower the texture. The lowering of the texture was due to the loss of liquid in the cell that would lower the turgor pressure of the cell which in turn would lower the texture. The lowering of texture for the control one was due to the deterioration or decaying of cells within the skin (Figure 1). However, in this study, the objective of the study was to dry the skin of duku which would make the skin turn into a cocoon likes and would make the fruit flesh inside the fruit to experience a passive modified atmosphere. So, the drying of the duku's skin would be expected to increase the texture. Unfortunately, for the treatment of IRE 10 cm, the correlation between the mass loss and the texture was a negative one. The texture of the skin did not increase with the increase of mass loss. Similar tendency to the treatment of IRE 10 cm was also shown by the control one. Initially, it was expected that the treatment of IRE at 10 cm would follow the hypotheses, however, even though duku's treated with infrared at IRE 10 cm showing a higher texture due to infrared drying but its texture had a similar tendency to the control. It seems the infrared drying treatment with IRE at 10 cm was not good enough in creating the passive modified atmosphere within the duku. It might be that the infrared radiation only hit the outermost of the skin but was not deep enough to penetrate the whole skin. This would make the surface of the skin dry but the inner part did not dried enough and the water from the inner part diffuse to the surface of the skin and this diffusion would make the surface of the skin became wet and lower the texture of the skin. It was observed that the wet skin on the IRE treatment of 10 cm start showing a decaying process.

Contrary to the result showing by duku on the infrared treatment of 10 cm and the control one, it was found that on this study the treatment of IRE at distance of 6 cm show a result as expected on the hypotheses which was showing that the higher the mass loss of the skin, the higher the texture. This tendency indicates that the increasing of the mass loss was due to the infrared drying process. The treatment of IRE of 6 cm seems dried the skin of duku deep enough and did not resulted in the diffusing of water from the inner part. The complete drying of the skin from the inner part to the outer part of the skin would result in harder shell of the skin which covered the duku's flesh. The increase hardness of duku's skin would in turn increase the texture of the skin and creates a cocoon or shell like which enclose the duku's flesh. This enclosure would create or mimics the environment of a passive modified atmosphere to the flesh of duku which would slow down the gas transmission to and out of the inside part of the duku as expected on the hypotheses. This condition confirms the result showed on the previous study **(Rahmawati et al., 2018**; and **Rahmawati et al., 2019)** which show that the treatment of infrared at IRE 6 cm gave an optimum result for infrared treatment of duku. Another measurement was performed to confirm this finding by means of inspection of duku's skin with Scanning Electron Microscopy (SEM).

SEM Analysis

Drying of fruit using infrared has been widespread **(Li and Pan, 2014a; Li and Pan 2014b; Pan et al., 2009; Ding et al., 2015; Léonard et al., 2008)**, but there was a limited literature which explains infrared drying for fruit skin without damaging the flesh of the fruit. The infrared drying process was widely used because it has high heat transfer coefficient, short processing time, and relatively low costs. Two aspects that were important for designing infrared heaters are the distribution of the spectrum and the energy or power intensity.

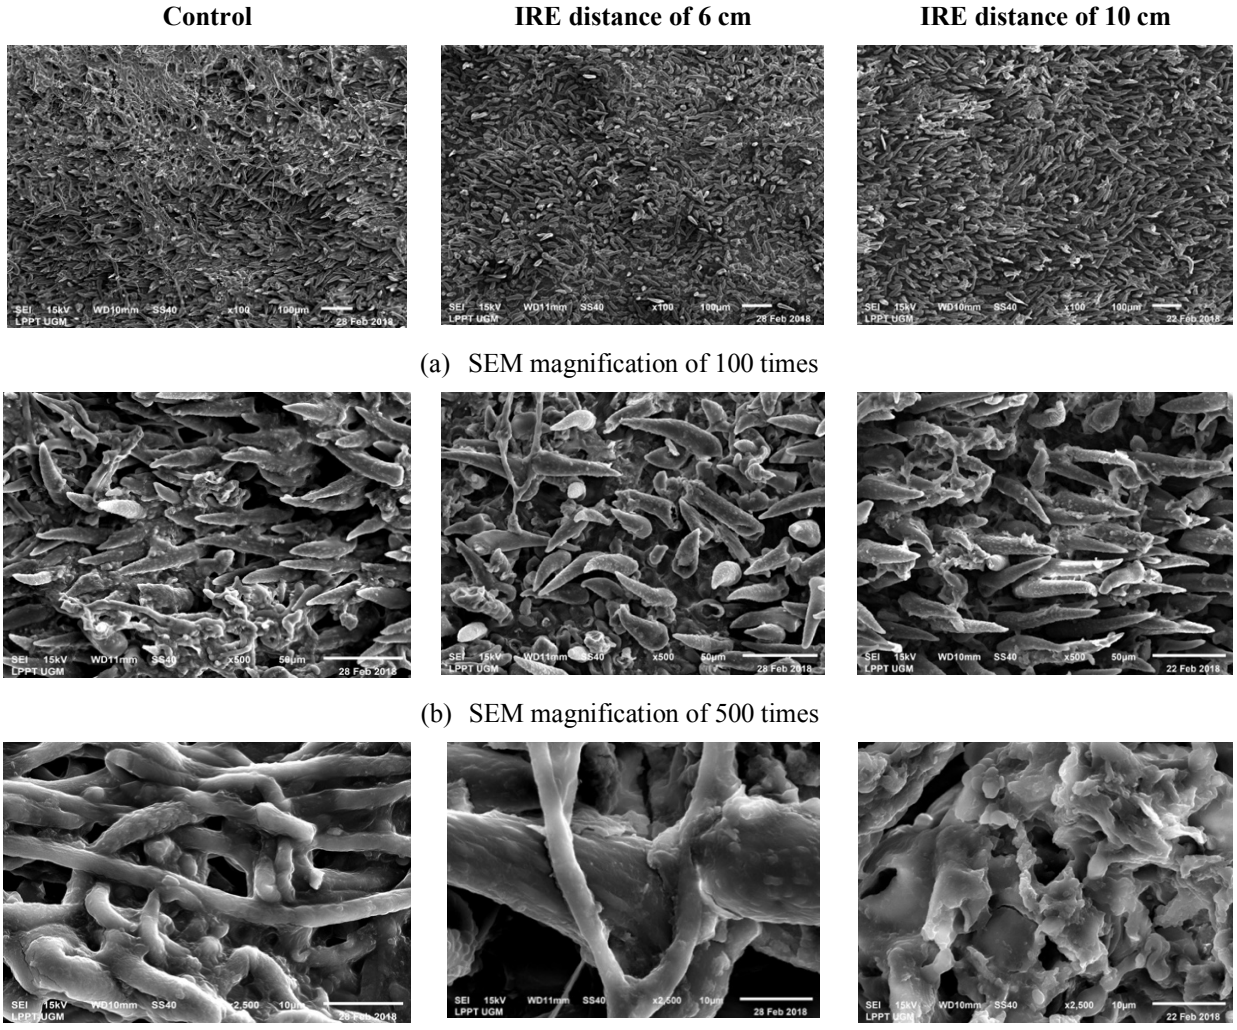

Figure 2 The Scanning Electron Microscopy of duku's skin.

The infrared heating spectrum needs to be considered because the energy which coming out of the emitter consists of different wavelengths, and the radiation fraction depends on a number of factors such as the temperature of the emitter, emissivity and others that would affect the texture of the fruit surface/heated material. Increasing infrared power would result in an increase in the drying rate. However, the faster drying rate would increase the process of mass transfer and might damage the fruit skin texture. Based on the result of optimization on previous study **(Rahmawati et al., 2019)** and the finding on Figure 1 about the effect of infrared drying to duku's skin, an attempt was performed to confirmed this finding by performing a Scanning Electron Microscopy (SEM). The microstructural observations of duku's skin was performed using the SEM method with the magnifications of 100, 500, and 2500 times, and the resolution of 50 μm, 10 μm respectively. The SEM was performed for the treatment at IRE 6 cm and IRE 10 cm, temperature of 400 °C, and exposure time of 80 seconds on the 14th days storage as the best treatment (Figure 2).

Visually, it could be seen the effect of infrared radiation to the structure of duku's skin. It could be seen that on the magnification of 500 times, the cell structure of duku's skin experiencing a change to the skin microstructure. The epidermal cells of the duku's skin undergoing an exfoliation in the cuticle part. The exfoliation of the cuticle could also be indicated that the waxy layer of the duku's skin has been destroyed by the heating process. Further observation on the magnification of 2500 times and the resolution of 10μm show that the skin of duku with IRE distance of 10 cm had some damage to the microstructure of its epidermal which was similar to the finding of condition of duku without magnification that duku's skin exposed to infrared radiation with IRE distance of 10 cm had deteriorated. A different result was found on the duku exposed to infrared with IRE distance of 6 cm. The microstructure of the skin, relatively, more intact and firmer which was due to a better texture of the skin show on the Figure 1.

However, even though it could be seen from Figure 2 that the microstructure of duku for the control one show a similar pattern with the one exposed to infrared radiation with IRE distance of 6 cm but its size was smaller compare the the fiber on the skin of duku exposed to IRE distance of 6 cm and 10 cm.

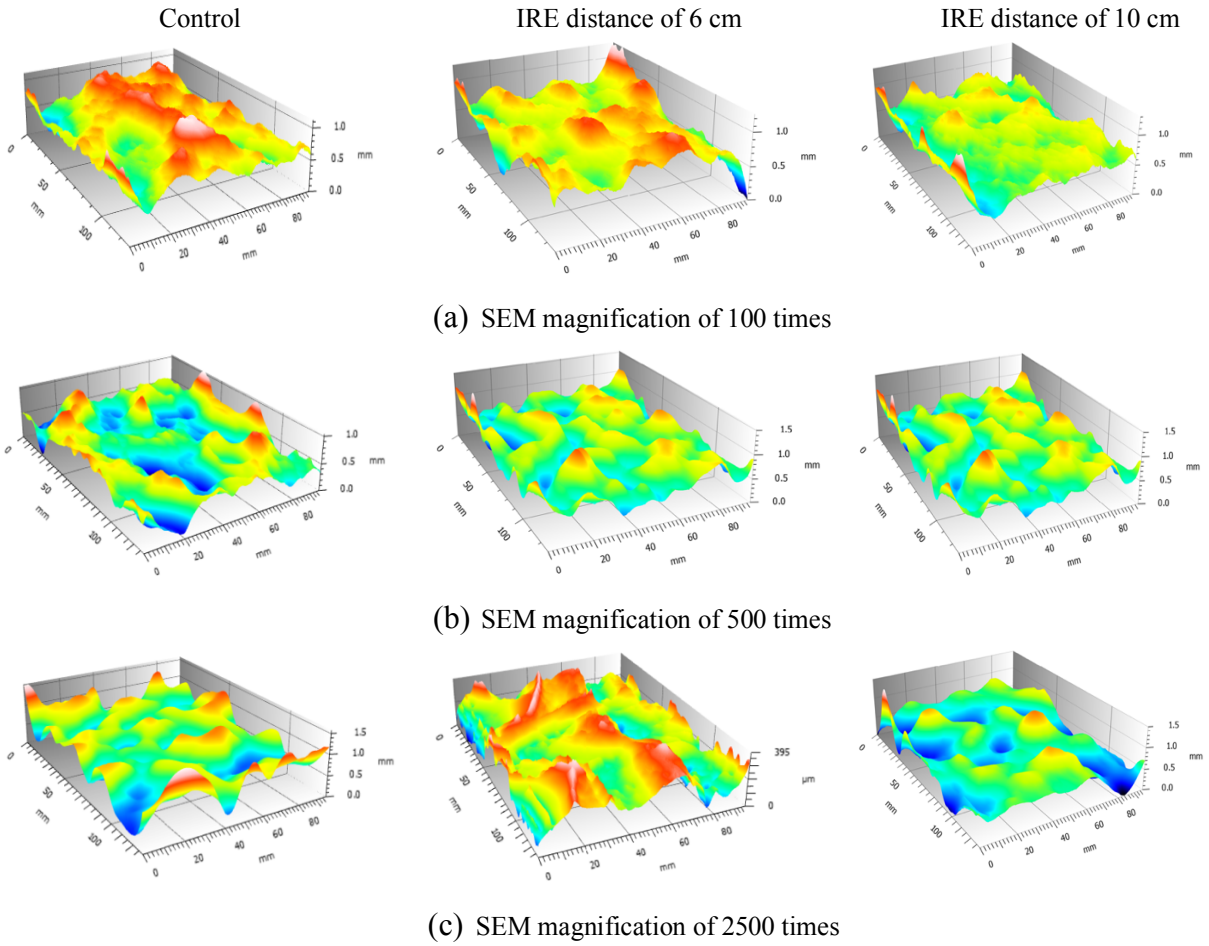

Figure 3 The 3D SEM countour plot of duku's skin processed by the Mountain Map Program.

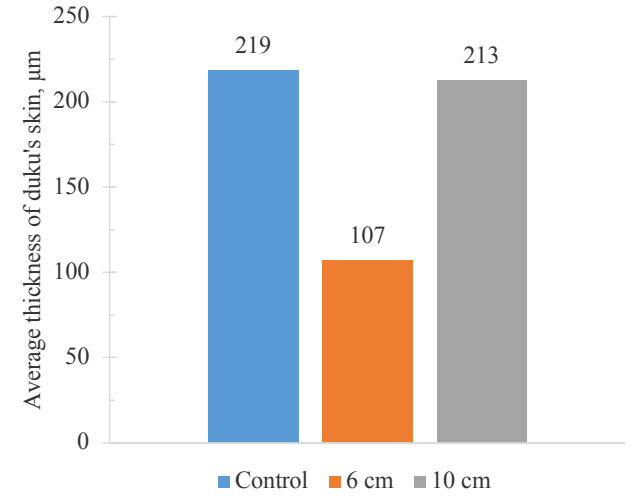
The smaller fiber on the skin of duku for the control one turns out to be a mycelium of mold or fungus which grew on the deteriorated skin of duku. The control duku used on this experiment had started to deteriorate not just due to the loss of turgor pressure but also due to the mold which grew on the surface of the skin.

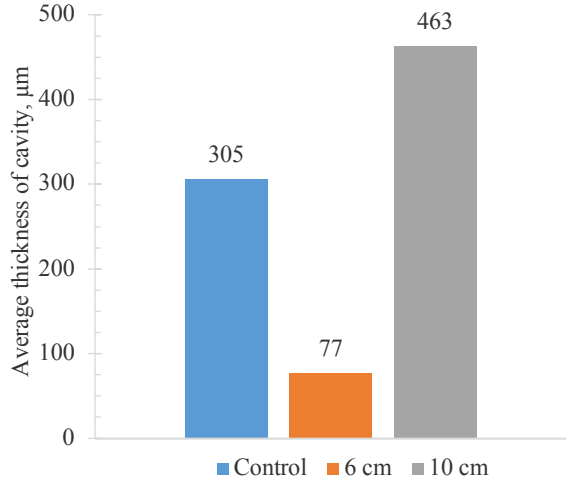
Another way to show the microstructure of duku's skin was by showing the SEM on a 3D picture. By using Mountain Map Program® a 3D picture of duku's skin as shown on Figure 3 were generated. This program besides creating the 3D picture also measured the height of the peak and the depth of the valley of the skin. This valley were the result of the skin which deteriorated due to uncomplete dry of the skin which resulted in the deeper valley of the skin. It was expected that that the fruit which underwent drying would have changes of pressure that modified its shape and deformed its skin **(Mayor and Sereno, 2004)**. This pressure difference would create more valley than the hills on the skin of duku.

At a glance, it could be seen that the infrared radiation with IRE distance of 6 cm, temperature of 400°C, and exposure time of 80 seconds, for the magnification of 100 times and 500 times produces more visual representation of red colour (hill) which indicates that the duku's skin exposed to infrared at IRE distance of 6 cm had a relatively intact dry skin. The hill on the figures show that duku's skin, relatively, still retain the skin layer and a stronger skin which simulate the passive modified atmosphere condition for the flesh of duku and increase its shelf life. However, a closure look at the magnification of 2500 times and resolution of 10 µm, show that even though the skin of duku for IRE distance of 6 cm had more hills compare to the control and duku exposed for IRE 10 cm but the unit and scale of the hills and valley was completely different. The unit for the control and IRE 10 cm were mm but the unit for the IRE 6 cm was µm. This finding indicates that the thickness of duku's skin exposed to IRE 6 cm had a thinner and compact skin compare to the control and IRE 10 cm. This finding also confirm the result showing on Figure 1 which show that the skin of duku exposed to IRE 6 cm had a thinner, stronger, and compact skin which would simulate the packaging of a passive modified atmosphere.

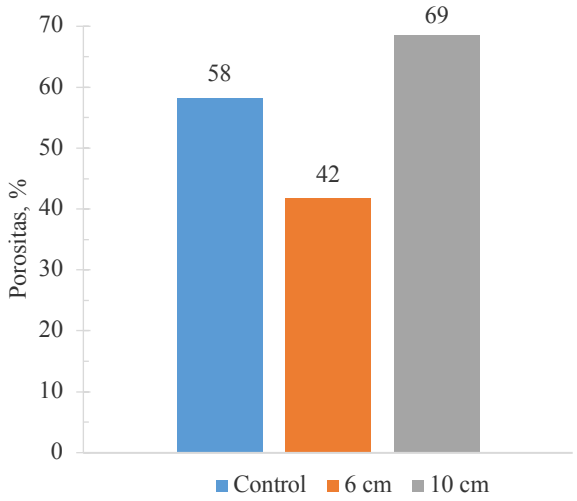
The porosity is the most important part that affects the strength of the agglomerate from the dried material. Porosity, pore size and pore size distribution have a significant influence on the texture characteristics of dry matter **(Huang and Clayton, 1990)**. The pores of the material could be characterized by the fraction of its porosity **(Rahman, 2007)**, shape of the pore, size of pores, number of pores, pore distribution, pore wall thickness, and number wall or face pores. Porosity could be obtained by comparing the volume of void with the total volume of material. Porosity values basically influenced by the overall drawing of SEM results in each magnification, resolution and depth of field values.



(a)



(b)



(c)

Figure 4 Average thickness (a), thickness of cavity (b), and porosity (c) of duku's skin for the control IRE 6 cm, and 10 cm.

The results of testing SEM with 2500 magnification, and 10 µm resolution show that the porosity and thickness of the duku's void without treatment was thicker than the exposure at 400 °C, 80 s at 6 cm distance of IRE. This was caused by the exposure process with IR has a solid and hard effect on the fruit skin, so the thickness of the void in the IR treatment was lower than the control treatment.

While the value of porosity and void thickness at the measurement of 2500 magnification, and 10 µm resolution at a distance of 10 cm has a higher value compared to the control, because during storage time the damage occurs on the texture besides that it could also be caused by the decay process.

A furthermore calculation of the peak and valley and the distribution of the area resulted on the average thickness of duku's skin, the average thickness of the void, and the porosity of the skin. The calculation shows that the thickness of duku's skin of 6 cm had the thinnest thickness (Figure 4 a). This result means duku's skin of IRE 6 cm is more compact than the duku's skin of IRE 10 cm and the control. The more compact skin would make duku's skin becoming a cocoon like and parallel to the result shown on Figure 1. A cocoon like skin would create an environment inside the skin like a passive modified atmosphere and prolong the shelf life duku.

The amount of porosity calculated for each SEM visual result would increase with the thickness of the voids **(Moon et al., 2014)**. The formation of pores could be divided into two types with inversion point and the other without inversion points. Factors that affecting the pore formation include internal and external factors. External factors include temperature, RH, pressure, gas atmosphere, and the radiation produced from dryers **(Rahman, 2007)**. From the statement it could be concluded that the biggest radiation produced at drying distance of 6 cm at 400 °C and exposure time 80 s has more stable porosity (without collapsing) when compared to drying with a distance of 10 cm at 300 °C and exposure time 80 s (Figure 4 b and 4 c).

CONCLUSION

The treatment of IRE 6 cm, temperature 400 °C and exposure time of 80 second increase the texture of duku's skin with the storage time. This increase made the fruit inside the skin to experience a passive modified atmosphere and increase the shelf life of duku. The 3D visual depiction of the optimization result on drying process using infrared had the largest porosity and cavity value in the treatment of 10 cm distance of IRE with 300 °C temperature of IR and 80s of exposure time. At the magnification of x2500, with a resolution of 10 µm, it was found that the porosity and thickness of the duku's void were greater than duku fruit without treatment. The result of the porosity also found that drying process with distance of 6 cm at 400 °C and exposure time 80 s has more stable porosity (without collapsing) which confirmed the result found on the texture of the skin. The results of SEM analysis and 3D visual analysis could confirm the results of optimization that had previously been done in the drying process of duku fruit using infrared method.

EFFECT OF COMMERCIAL YOGURT STARTER CULTURES ON FERMENTATION PROCESS, TEXTURE AND SENSORIC PARAMETERS OF WHITE YOGURT

Peter Zajác, Lenka Kúšová, Lucia Benešová, Jozef Čapla, Jozef Čurlej, Jozef Golian

ABSTRACT

In this work, we have compared and described the fermentation process of two commercial yogurt starter cultures during the white yogurt production. We used freeze-dried thermophilic starter culture YoFlex® YF - L812 and deep-frozen starter culture Delvo® Fresh YS – 241 for the production of white yogurts. We analysed titration acidity, active acidity, total viable counts, texture, and sensory parameters of white yogurts produced in laboratory conditions. This research was performed for dairy company Mliekareň Kopanice Selce, s.r.o., Slovakia. We did not found statistically significant differences (p >0.05) in titration acidity of both yogurts after 7 hours of fermentation. We did not found statistically significant differences (p >0.05) in the pH of both yogurts after 7 hours of fermentation. We found statistically significant differences (p <0.05) in all textural parameters (hardness, consistency, cohesion, and viscosity). The total viable count of microorganisms in yogurts after 24 hours of fermentation was 6.28×10^7 and 7.14×10^7 respectively.

Keywords: white yogurt; fermentation; titration acidity; texture; sensory parameters

INTRODUCTION

Yogurt is commercially produced through fermentation by lactic acid bacteria (commonly *Lactobacillus* spp. and *Streptococcus* spp.) at temperatures usually in the range of 27 to 40 °C **(Aguirre-Ezkauriatza et al., 2008)**.

Yogurt is an acid-milk product characterized by symbiotic cultures of *Lactobacillus delbrueckii* subs. *Blgaricus and Streptococcus thermophilus* and senanother *Lactobacillus* species. According to the Codex Alimentarius **(CA, 2003)** and legislation of the Slovak Republic, excess of living characteristic micro-organisms in acid-milk products like yogurt and yogurt with alternative culture has to be at least 10^7 CFU.g^{-1} and if the specific microorganism is presented in the label o the product then it has to be at least 10^6 CFU.g^{-1} **(MARDSR, 2016)**.

Yogurt is one of the most popular fermented dairy products, and its consumption is increasing worldwide **(Shiby and Mishra, 2013)**.

Its popularity is due to its sensory properties, health claims, and therapeutic effects. The most important sensory attributes of yogurt include texture, color, and flavor **(Sodini et al., 2004; Salvador and Fiszman)**.

Yogurt is typically characterized as a smooth, viscous gel with a characteristic taste of sharp acid and a green apple flavor **(Cheng, 2010)**.

Interaction of taste and odor with other sensory properties increases the complexity of the human perception of yogurt. The fat content, source of milk, and textural properties play an important role in the sensory properties of yogurt **(Routry and Mishra, 2011; Mende, Rohm and Jaros, 2015)**.

The decision to change the starter culture is very important and should be supported by information. The dairy must-have information on how the fermentation will take place.

This experiment was performed specifically for dairy company Mliekareň Kopanice Selce, s.r.o (Slovakia).

Scientific hypothesis

We are expecting the significant differences in TVC, physico-chemical, and sensory parameters of yogurt produced by two commercial starter cultures YoFlex® YF - L812 and Delvo® Fresh YS – 241.

MATERIAL AND METHODOLOGY

Chemicals

All chemicals used in the experiment were analytical grade and obtained by Centralchem (Slovakia).

Yogurt starter cultures

We used two thermophilic yogurt starter cultures in our experiment:

- **YoFlex® YF – L812**, Chr. Hansen Holding A/S
- **Delvo® Fresh YS – 241**, DSM Food Specialties.

Yogurt production

Yogurts were produced under sterile conditions in our microbiology laboratory of the Department of Food Hygiene and Safety at the Faculty of Biotechnology and Food Sciences of the Slovak University of Agriculture in Nitra.

We weighed a lyophilized thermophilic frozen culture on an analytical balance (Sartorius, Genius). To prepare 30 pieces of yogurt, we used 5 liters of full 3.5% pasteurized milk and 0.2360 g of starter culture (YoFlex® YF – L812) and 0.347 g of starter culture Delvo® Fresh YS – 241. The milk was heated to 40 °C and the starter culture was then added with gently stirring 5 min. When the culture dissolved, we poured the inoculated milk into the prepared sterile 150 mL plastic cups and covered them with aluminum foil to prevent contamination. The fermentation process was carried out in a thermostat (Thermo Fisher) at temperature 32 – 33 °C (YoFlex® YF-L812) and 40 °C (Delvo® Fresh YS – 241) for 48 hours.

The amount of weighed starter culture and the fermentation temperature were chosen according to the recommendations of the producers and requirements of the dairy company.

Consequently, samples of both yogurts were analyzed at hourly intervals for period of 48 hours.

Physical-chemical analysis

- Titration acidity was determined in duplicate by titration with 0.25 N NaOH factorised with 0.25 N oxalic acid, using 2 % phenolphthalein as an indicator. Titration of milk was carried out in titration bank and yogurt in a ceramic mortar. Results were expressed in °SH (Soxhlet-Henkel method) STN (1972). Slovak Technical Standard 570530. Methods for testing of milk and milk products. Article no. 58. – Determination of titration acidity according to the Soxhlet-Henkel.
- pH (SI Analytics Lab 845 pH meter milk before coagulation and Testo 206 – pH2 after milk coagulation were used). We used calibration standard solutions with pH 6.8 and 4.0.

Microbiological analysis

The total viable count was determined by the colony-count technique and expressed as (TVC.mL^{-1}). The plates were incubated for 72 h at 30 °C.

- PCA agar with milk powder (Biokar diagnostics). Composition: (1 L of medium): tryptone 5 g, yeast extract 2.5 g, glucose 1 g, skimmed milk powder (no inhibitory substances) 1 g, bacteriological agar 12 g, pH adjusted to 7 ±0.2.
- We have followed the recommendations of ISO 7889 (2003) *Yogurt. Enumeration of characteristic microorganisms.*

Textural analysis

Textural analysis of yogurts was performed after 24 hours of the fermentation process. We used:

- Texturomenter TA.XT Plus (Stable Micro Systems UK).
- Exponent software (Stable Micro Systems).
- Disc-shaped probe with back extrusion.
- The analysis of the textural properties of yogurt sample s was performed at 6 °C.
- The instrument was set up according to the manufacturer's recommendations: mode (a measurement of compression power), options (return to start), pre-test probe speed (1.0mm.s^{-1}), test probe speed (1.0mm.s^{-1}), return speed (10.0mm.s^{-1}), deep of probe penetration into the product (30 mm), Method of measurement (Auto – 10 g), reset mode (auto), frequency of data acquisition (400 pps), the test probe was cleaned after each measurement.

Sensory analysis

Sensory analysis was performed by a sensory panel consisting of twelve assessors (7 men, 5 women) after 24 hours of the fermentation process. The evaluators were first trained. The sensory panel analyzed the samples administered in the sensory laboratory.

- We used the scale and profile method.
- We used a hedonic scale where the value of 1 indicated that the quality of the yogurt was very poor and the value of 7 was excellent.
- We chose the classic profile, which consists of creating a rough profile, then reducing the descriptors were to eliminate hedonic terms (pleasant, tasty, good), quantitative terms (too much, weak, strong), inappropriate terms (salty for smell). We chose an intensity frequency from 0 to 5, where 0 was absent and 5 very strong. Subsequently, we fine-tune the fine profile, which consisted of an overall appearance, texture in the mouth, and taste.
- Then we set the polarity of the descriptors to positive and negative, which indicates the severity coefficient. The value for these coefficients is 1. We calculated the values using the pattern descriptor intensity x severity coefficient. We get both positive and negative numbers, from which we calculated the arithmetic mean and then visualized graphically.

Statistical analysis

Statistical analysis was performed in XLSTAT 2020.1 (Addinsoft).

- Physical-chemical and microbiological analysis: we used the Shapiro-Wilkov W test and t-test.
- Textural analysis: we used the Shapiro-Wilkov W test, F-test, t-test.

We considered the results to be statistically significantly different at the α 0.05.

RESULTS AND DISCUSSION

The development of titration acidity in white yogurts during the fermentation process is presented in the **Figure 1**. We did not found statistically significant differences (p >0.05) in titration acidity of both yogurts after 7 h of fermentation. A titration acid 24 °SH was reached after 7 h of fermentation and 29 °SH were reached after 24 hours of fermentation in both yogurts.

The results of pH development during the fermentation process are presented in **Figure 2**. We did not found statistically significant differences (p >0.05) in the pH of both white yogurts after 7 h of fermentation. The pH values were 4.71 (Delvo® Fresh YS-41) and 4.86 (YoFlex YF-L812). After 24 hours the pH values were 4.46 (YoFlex YF-L812) and 4.44 (Delvo® Fresh YS-41). When we compare

the values of pH, the highest decrease was noticed during the first 6 hours of the fermentation process and that trend continued until the final control point at 48 hours after fermentation. Our results are consistent with other authors **(Tamime and Robinson, 2000; Aguirre-Ezkauriatza et al., 2008; Tomovska, Gjorgievski and Makarijoski, 2016; Akgun, Yazici and Gulec, 2017)**. The pH of commercially available yogurt was 3.94-4.22 **(Matela, Pillai and Thamae, 2019)**. The fermentation process during industrial yogurt manufacture can be continuously controlled by online monitoring of pH, which offers a useful tool for integrated process control **(Soukoulis et al., 2007)**.

The inoculated milk began to coagulate during fermentation after 5 (Delvo® Fresh YS-41) and 6 hours (YoFlex YF-L812) and pH 4.4 was reached after 15 (Delvo® Fresh YS-41) and 16 hours (YoFlex YF-L812) of fermentation in cups.

The total viable count of microorganisms in yogurts after 24 hours of fermentation is presented in **Table 1**. TVC reaches the levels 6.28×10^7 CFU.g^{-1} (YoFlex YF-L812) and 7.14 CFU.g^{-1} (Delvo® Fresh YS-41) respectively. One of the essential characteristics of yogurt is that it must contain live microorganisms used for fermentation. The total amount of living characteristic microorganisms is characterized in the mentioned legislation and is quantified as the amount of colony-forming units (CFU), which for yogurts is equal to 10^7 CFU per gram of product. In both white yogurts, the legislation limit **(CA, 2003; MARDSR, 2016)** was fulfilled after 10 hours of yogurt fermentation.

Textural parameters like hardness, adhesiveness, cohesiveness, chewiness, gumminess, springiness and sensory parameters including taste, flavor and mouthfeel, appearance, and overall acceptance are important for consumers during the shelf-life of the yogurt **(Mousavi et al., 2019)**, this was a logical reason, why we determined textural properties of both yogurths. The results of textural analysis are presented in **Table 2**. We found statistically significant differences (p <0.05) in all textural parameters and total viable counts 24 hours after fermentation. The textural parameters have reached the following mean values (YoFlex YF-L812 and Delvo® Fresh YS-41): hardness 313 and 379 g, consistency 7725 and 9990 g.s^{-1}, cohesiveness -317 and -402 g, viscosity -633 and -788 g.s^{-1}. The higher the hardness value of the yogurt, the stronger the yogurt was. We found that yogurt with Delvo® Fresh YS-241 was harder, more consistent, cohesive and viscose in comparison with YoFlex YF-L812 yogurt at selected experiment conditions, which were proposed by the dairy company. The protein matrix had an important role in cohesiveness **(Tunick, 2000)** and can be affected by the starter culture used for yogurt fermentation.

The results of sensory testing are presented in figures 3 – 8. YoFlex YF-L812 is marked as sample A and Delvo® Fresh YS-41 is marked as sample B.

According to **Figure 3,** sample A had aroma and color very good, the taste good and the consistency was satisfactory. Sample B had taste, consistency, and color very good, the smell good. The difference in taste, consistency, and flavor between both samples. According to **Figure 4** both samples had the typical yogurt flavor and acid flavor. Sample A appeared less sweet. The sensory evaluation of consistency of yogurts is presented in **Figure 5**. We can see a difference only in the softness indicator. The sensory evaluation of overall appearance is presented in **Figure 6**. Both samples were evaluated as very similar, well clothed, soft look, and thick. The sensory evaluation of texture in the mouth is presented in **Figure 7**. Sample A was evaluated as less soft and both samples were not lumpy. The sensory evaluation of taste is presented in **Figure 8**. Both your didn't differ in all taste descriptors.

Even though appearance, texture, and thickness are very important characteristics to contribute to the quality of yogurt, the flavor is generally considered as the most important of all and critical indicators of consumer acceptability **(Olugbuyiro and Oseh, 2011)**. White yogurt with a high consumer acceptance should, in general, have a smooth, uniform, and spoonable texture, and be free from lumps, graininess, and visual whey separation **(Lucey and Singh, 1997; Lucey, 2004)**. Milk heated at pH 6.7 contains significant proportions of both bound and soluble denatured whey protein complexes and this treatment produced the stiffest yogurt gels **(Ozcan, Horne and Lucey, 2015)**.

Clean and typical yogurt flavor is very important. Acetaldehyde, diacetyl, and lactic acid are considered as the major aroma components of yogurt, but also other components, like acetone, acetoin, and acetic, formic, butanoic, and propanoic acids, have been listed as contributors to yogurt flavor **(Routray and Mishra, 2011)**. Yogurt starters that allow the development of acetaldehyde with restricted post-acidification and post-proteolytic activity are favorable **(Jørgensen et al., 2019)**.

Yogurt with YoFlex YF-L812 had better flavor. On the other hand, based on the sensory evaluation we can conclude that yogurt with Delvo® Fresh YS-241 culture had slightly better consistency and taste. We identified, that the flavoring of both yogurts was better after 24 hours of fermentation in comparison with continued fermentation time. This is in agreement with **Görner and Valík (2004)**. These authors found, that formation of flavorings, in particular acetaldehyde, is mainly related to *L. delbrueckii* ssp. *bulgaricus* and is also associated with acidification. It starts at pH 5.0, increases vigorously at pH 4.4 to 4.3 in 3 h at 42 °C, then slows down significantly and stabilizes at pH 4.0.

When the pH drops below pH 5, micelles of caseins, which are amphiphilic proteins, loses its tertiary structure due to the protonation of its amino acid residues. The denatured casein proteins reassemble by interacting with other casein proteins, and these intermolecular interactions result in a network of molecules that provides the semisolid texture of yogurt **(Zourari, Accolas and Desmazeaud, 1992)**.

We agree with these authors, because, it was clearly evident, that textural parameters are developed during the syneresis process and confirmed by analysis of texture. It is not possible to analyse the texture at first stages of syneresis with the disc-shaped probe with back extrusion. We made the texture analysis 24 hours after fermentation started.

Depending on the type of yogurt, the incubation process is done either in a large tank of several hundred liters or in the final individual plastic or glass containers. The textural parameters of stirred yogurt are different in comparison with set yogurt. Stirred yogurt is fermented in the bulk tank, mixed and then poured into the final selling containers.

Set yogurt, also known as French style, is allowed to ferment right in the container it is sold in.

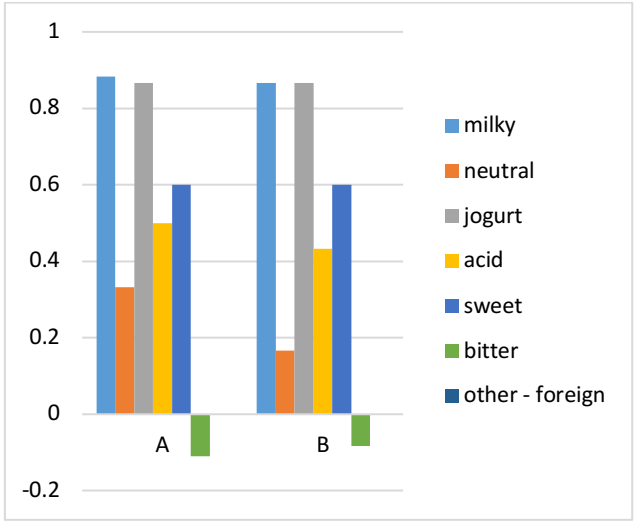

Figure 8 Sensory evaluation of taste.

In both instances, the lactic acid level is used to determine when the yogurt is ready for sale. The acid level is found by taking a sample of the product and titrating it with sodium hydroxide. A value of at least 0.9% acidity (29 °SH – 40 °SH) and a pH of about 4.4 are the current minimum standards for yogurt manufacture.

Industrial yogurt is produced by fermentation of pasteurized milk after inoculation with starter bacteria. These convert lactose to lactic acid. This changes the pH of the milk and coagulates at a certain pH. Industrial milk fermentation in yogurt production takes about 3 hours at 42 – 45 ºC. After this time, the yogurt must be cooled to a storage temperature below 10 ºC in order to interrupt the fermentation process. Durable yogurts are treated with pasteurization, which kills bacteria cultures and other microorganisms. Such treated yogurt loses biological value, mineral usability, and curative effects, especially antibacterial **(Tamime, Robinson, 1999)**.

When the yogurt reaches the desired acid level, it is cooled (10 – 12 °C), modified as necessary, and dispensed into containers (if applicable) **(Tamime and Robinson, 2000)**.

Manufacturing of yogurt has changed from crude and elementary procedures to more controlled procedures over time. A few of the advances in our knowledge that made this possible include use of ingredients in addition to milk, the use of starter cultures, and modern technologies **(Aryana and Olson, 2017)**.

CONCLUSION

Thermophilic starter cultures YoFlex® YF - L812 and Delvo® Fresh YS – 241 are suitable for yogurt production. The fermentation process using these starter cultures is slightly different. We have found, 4.4 was reached after 16 and respectively 15 hours of fermentation. We did not found statistically significant differences (p >0.05) in titration acidity of both yogurts after 7 hours of fermentation. We did not found statistically significant differences (p >0.05) in the pH of both yogurts after 7 hours of fermentation. We found statistically significant differences (p <0.05) in all textural parameters (hardness, consistency, cohesion, and viscosity). The textural parameters have reached the following values: hardness 313 and 379 g, consistency 7725 and 9990 $g.s^{-1}$, cohesion -317 and -402 g, viscosity -633 and -788 $g.s^{-1}$. The total viable count of microorganisms in yogurts after 24 hours of fermentation was 6.28×10^7 $KTJ.g^{-1}$ and 7.14 $KTJ.g^{-1}$ respectively. Based on the sensory evaluation we can conclude that yogurt with Delvo® Fresh YS-241 culture had slightly better characteristics than yogurt with YoFlex YF-L812.

BIOCHEMICAL COMPOSITION OF THE HOPS AND QUALITY OF THE FINISHED BEER

Anatolii Bober, Mykola Liashenko, Lidiia Protsenko, Natalia Slobodyanyuk, Liudmyla Matseiko, Nadiia Yashchuk, Sergiy Gunko, Mikhailo Mushtruk

ABSTRACT

The large varieties of hops and hop products used in the brewing industry. Various in the biochemical composition, individual approaches to the brewing technology of each hop product are required in order to obtain a high-quality beer with a characteristic bitter taste and aroma. The purpose of this work was to study the biochemical composition of pressed conical hops, pellets of hop type 90, type 45, ethanolic and CO_2 extracts of hop of various varieties, and their influence on the quality of the finished beer.

As a result of comprehensive research on hops and hop products of various varieties, using the modern biochemical methods were determined differences in their biochemical composition depend on the absolute values such parameters as the mass fraction of α-acids, β-acids and their composition, xanthohumol, general polyphenols, essential oils, the ratio of their valuable components of hops: β-acids to α-acids and also for quantity of general polyphenols, essential oils per unit of α-acids. Based on the results of the biochemical composition of hops and hop products were investigated their influence on the quality of beer and were determined their using in brewing.

Keywords: Hops, Products, Beer, Biochemical, Composition

INTRODUCTION

One of the main and irreplaceable type of raw material for brewing is hop. Its constituent substances gives beer a specific taste and aroma, promote foam formation and stability quality of beverage. The quality of hop and hop products do not depend on only the quality of beer, but also on the efficiency of brewing production in general. The quality of hop do not directly relate only with varietal characteristics and conditions of cultivation, but also with conditions of post-harvest handling and storage **(Lyashenko, 2002; Pavlovič et al., 2012)**.

High-quality beer with characteristic bitter taste and aroma obtains only with the use of hops and hop products with a certain biochemical composition. At the same time, the efficiency of extraction, isomerization and transformation of separate numerous hop compounds in the process of boiling beer wort is very important **(Protsenko et al., 2012)**.

The using of hop and their products in the brewing is due to the fact that its cones contain large quantity of biologically active substances such as bitter substances, polyphenols and essential oils. Specific substances give to beer a unique bitterness and a specific aroma, participate in the clarification and formation of foam, increase its stability during storage **(Protsenko et al., 2018)**.

The beer production in Ukraine and in the world increasing that stimulates the demand for hop products and necessitates the balanced development of the industry for satisfaction of the brewing industry. However, in a competitive struggle on the market, the winner is not the one who produces more but average hops, but the one who makes it better in quality and cheaper in the price. Even under the current difficult conditions, there are opportunities and reserves for the production of high-quality commodity hops, including aromatic **(Bober et al., 2015)**.

For brewing used about 90 % of hop and hop products. The demand for hop is constantly increasing, but the industry is far from satisfying the domestic market. Currently, the Ukrainian brewing industry used up to 20 % of domestic production. The main part of raw materials is imported, which create dependence on world market conditions. This industry divide inter countries such as Germany, Czech Republic, Poland, Austria, USA, Canada, Australia and China **(Pryimachuk et al., 2018)**.

As marketing research has shown to the world market delivered only about 10 % of natural cones hops but 90 % of granulated and hop processed into extracts from total amount of obtained hop products. Only in the brewery of low-power remained classical beer production technology,

where for brewing beer wort traditionally used pressed hops. Powerful breweries of Ukraine transferred to using different types of pellets, ethanolic and CO_2-extracts of hops **(Zheplinska et al., 2019)**.

The most rational way of processing hop cones is to granulate them. Only this technology provides for a more complete save of all complex of valuable substance hops for a long time before application in the production of beer, more stable use, high quality of the finished product. The most popular and promising are pellets type 90, which according to the chemical composition practically do not differ from the native cones of hops.

Pellets type 45 apply to enriched hop products. They differ significantly in the biochemical composition from native hops, since the amount of polyphenols per unit of alpha acids is halved, and their production associated with additional losses of essential oils. For brewing properties, it is intermediate product between cones and CO_2-extract. Granulated hops are also more convenient to use for packing and adding to wort. In addition, the volumetric mass of granulated hops is much smaller than compressed, thus reducing transport and storage costs **(Zheplinska et al., 2019)**. Another way that make it possible to keep bitter and other valuable substance hops in the unchanged state, it is production of hops extracts with using organic and inorganic solvents. The expediency of producing hop extracts is conditioned by the possibility of obtaining high-quality and efficient products that can be stored for a long time without changing their biochemical composition **(Protsenko and Litvynchuk, 2017)**.

However, despite the fact that in the world more than 90 % of native (cone) hops processed into hop products, there is absent of scientific research about quality hop varieties which have different content and composition of bitter substances, polyphenols and essential oils. The specialists in agriculture and the brewing industry need to know the main advantages and disadvantages of these products and their impact on the quality of the finished beer, especially as in the literature, especially in advertising, as a rule, they write more about their advantages, without emphasizing the disadvantages.

The purpose of this work was to study the biochemical composition of hops and hop products during 2012 – 2017 of various hop varieties and their impact on the quality of the finished beer.

Scientific hypothesis

Studies of hops and hop products of different breeding varieties with using modern biochemical methods will supply to establish differences in their biochemical composition. Peculiarities of the biochemical composition of hop products will allow individually to approach the brewing technology of each hop product in order to obtain high quality beer with a characteristic bitter taste and aroma.

MATERIAL AND METHODOLOGY

Samples

For researches, cones of pressed hops and pellets of type 90 typical representatives of the aromatic group of varieties (Slavyanka, Nationalny, Zagrava) and bitter (Alta, Hercules) which widespread in the production conditions of Ukraine, were used; pellets type 45 varieties Tradition and Spalt Select; ethanol and CO_2-extracts of the Hercules variety of foreign production.

Beer from the samples of hop products was manufactured at the mini brewing biochemistry department of hop and beer of the Polissya Institute of Agriculture of the National Academy of Agrarian Sciences of Ukraine with the output of 100 litres, which adequately reflects the conditions of real breweries.

The hop and hop products added on the mini brewery added on the content of α-acids in them.

The wort was prepared from 100 % barley malt. The norm of hop was calculated in the amount of 50 mg of bitter substances per 1 dm^3 of wort. Duration of wort boiling with hop products was 90 minutes.

Methods

Modern international physical-chemical methods of determining the quality indices of hops and hop products and products of their transformation in the brewing process were used: high-performance liquid chromatography, spectrophotometry and also methods of quality control of beer wort and finished beer, harmonized with the methods of the European Brewery Convention **(Jaskula, et al., 2007)**.

The content and composition of α- and β-acids and xanthohumol were determined by high-performance liquid chromatography. Chromatography was performed using Ultimate 3000 liquid chromatograph with a UV detector at a temperature of 35 °C of the method described in state standard of Ukraine 14164:2019 **(DSTU EN 14164:2019)**. The 100 × 0.0021 m column was used which was filled with a Pinacle sorbent DV E18 3 μ. As a mobile phase, a solution of methanol, water and acetonitrile was used in the ratio of 38:24:38. For the quantitative determination of xanthohumol was used standard-ethanol of xanthohumol with containing 99.8 % of this compound and for α- and β-acids used the international standard franchise (ISF-3) **(Jaskula, et al., 2007)**.

The amount of essential oil was determined by the Ginsberg method **(Lyashenko, 2002)**. The qualitative composition of the essential oil was determined by the gas-liquid chromatography method on 50-60 m capillary quartz columns of chromatograph "Crystal 2000 M". The total amount of polyphenolic compounds and proanthocyanidins was determined by photometric methods in the modification of M.I. Lyashenko **(Lyashenko, 2002)**.

The index of oxidation of bitter substances in hops and hop products was determined by extraction of bitter substances with the following definition on spectrophotometer in an extract of an optical density of oxidized components at wavelength was 275 nm, and a- and β-acids at a wavelength was 325 nm **(Lyashenko, 2002)**.

In beer wort and beer, bitterness was determined by spectrophotometric method of EBC. The method is based on the determination of the optical density of isooctane obtained by removing bitter substances from acidified wort or beer from isooctane (2,2,4-trimethylpentane), with used wavelength is 275 nm. The magnitude of the bitterness expressed by units of the international scale with determining bitterness according to EBC which was

evaluated on the based the index of optical density. The content of polyphenolic compounds in the wort and beer, were measured on a spectrophotometer according to EBC 8.11 and EBC 9.11. **(Kábelová-Ficová et al., 2017)**.

The quality of beer was evaluated organoleptically by tasting of tasting commission according to the requirements for beer according to the branch Instruction by the 25-point integrated estimation **(Punčochářová et al., 2019)**.

Statistic analysis

The mathematical processing of the data was performed with using the method of dispersion (ANOVA) analysis using the programs Statistica 10 and Microsoft Office 2010.

RESULTS AND DISCUSSION

Complex biochemical studies of hops and hop products of various varieties with the use of modern biochemical methods (high performance liquid chromatography) made it possible to establish that hops and hop products of different varieties have different biochemical composition and hence a different brewing value.

The biochemical characteristic of the widespread hop products in the brewing industry was presence in Table 1.

The most valuable compounds of hops and their processing products are bitter substances. Bitter substances are unique and do not presence in the other plants. The most important among the bitter substances are alpha acids, which converted into iso-alpha acids, the main compounds of bitterness of beer, during the process of isomerization at boiling of beer wort.

When added to beer of fresh hops, almost 90 % of bitterness of beer is formed as a result of isomerisation of alpha acids in iso-alpha acids **(Malowicki and Shellhammer, 2006)**. The quantity of alpha acids is the main pricing factor for the evaluation of hops and hop products. The content of α-acids in the studied hop products changed from 3.82 to 52.83 % (Table 1). The highest content of α-acids was found in the CO_2-extract of the Hercules variety – 52.83 %. Among pellets, this index was the maximum in pellets of hop type 90 bitter grade Hercules – 13,64 %.

Beta-acids are not bitter in taste, but in the process of oxidation compounds are formed having a pleasant bitterness. One of their main properties is a high antiseptic effect, which important for increasing the biological stability of beer during storage. Therefore the beta-fraction of hops abroad used in the processing of sugar beets to improve their storage in sugar factories **(Lyashenko, 2002)**. Depending on the variety and type of hops, the content of β-acids ranges from 3.41 till 18.81 %.

As the researches shown, hop pellets of type 90 of domestic production contain the whole complex of necessary for brewing substances and equivalent to hop cones. Characteristic feature of cones hop and pellets of type 90 and type 45, in particular of aromatic varieties, is the high positive coefficient of aromatics between the content of β- and α-acids which ranged from 0.89 till 1.79. This is a main feature in the estimation of the brewing quality of hops and hop products. On average, conducting research in 2012 – 2017 the higher indicator of aromatics were characterized as cones and hop pellets of the Slavyanka and Nationalny varieties. Unlike, the cone-shaped and granulated hop of aromatic varieties, cones and pellets of hops of bitter varieties, characterized by a sharp aroma and high content of α-acids. The ratio of β-acids to α-acids in the cones and pellets of hop of bitter varieties and extracts was less than 1. From 0.26 in hop pellets type 90 of the Hercules variety to 0.53 in hop pellets type 90 of the Alta variety.

Application of high-performance liquid chromatography in our studies allow to established the quantitative and qualitative composition of bitters substances of hops and hop products of various grades (Figure 1, Figure 2 and Figure 3). On the presented chromatograms the composition of bitters substances of the studied hop products clearly shows the difference in their quantitative and qualitative composition. The chromatograms of the composition of bitters substances of investigated hop products, we can see difference between quantitative content of a- and β-acids, and in their composition. The composition of the α- and β-acids, depending on the type of hop cones and the type of hops, changed significantly, and the first it related with the content of cohumulon in the α-acids and the colupulon in β-acids. Thus, the mass fraction of cohumulon in the a-acid content ranged from 22.72 till 38.62 %, and the colupulon - from 42.61 till 59.22 %. As a rule, if more contained in the a-acid cohumulon, than the higher the content of the colupulon was in the β-acids.

The composition of a- and β-acids is important for the production of high-quality beer. The most quality for brewing has hops with mass fraction of cohumulon in the composition of a-acids does not exceed 30 %. Hops with content cohumulon of 40 – 50 % in alpha acids used mainly for the preparation of isomerized preparations, because it is not used in the natural form for the production of beer **(Malowicki and Shellhammer, 2006)**.

Brewers pay particular attention the index of oxidation of bitters substances, because they consider it one of the main indicators of the quality of cones of hops and hop products. This index on a par with the content of alpha acids controlled during the purchase of consignments of hop and hop products. Than the lower index of oxidation of bitters substances then the higher were quality of hop products **(Michałowska, 2017)**.

According to Table 1, the index of oxidation during the years of investigation, both in cones, pellets hops, and hop extracts, fluctuated within 0.27 – 0.50. The minimum index of oxidation is set in the CO_2 extract – 0.27 but the maximum in the pellets type 90 of hop Slavyanka variety - 0.50 and did not exceed the norms of normative documents. It was established that the index of oxidation in the hop pellets was not higher than it was in the cones of hop. This indicates that the quality of the pellets of the hops type 90 is practically the same as the cones hops but the quantitative and qualitative composition of the bitter substances depends on the variety from which they obtained.

The data which we received about the content of xanthohum in the biochemical composition of hops and hop products of various varieties deserved attention (Table 1, Figure 1, Figure 2 and Figure 3).

Table 1 Biochemical characteristics of hops and hop products for brewing.

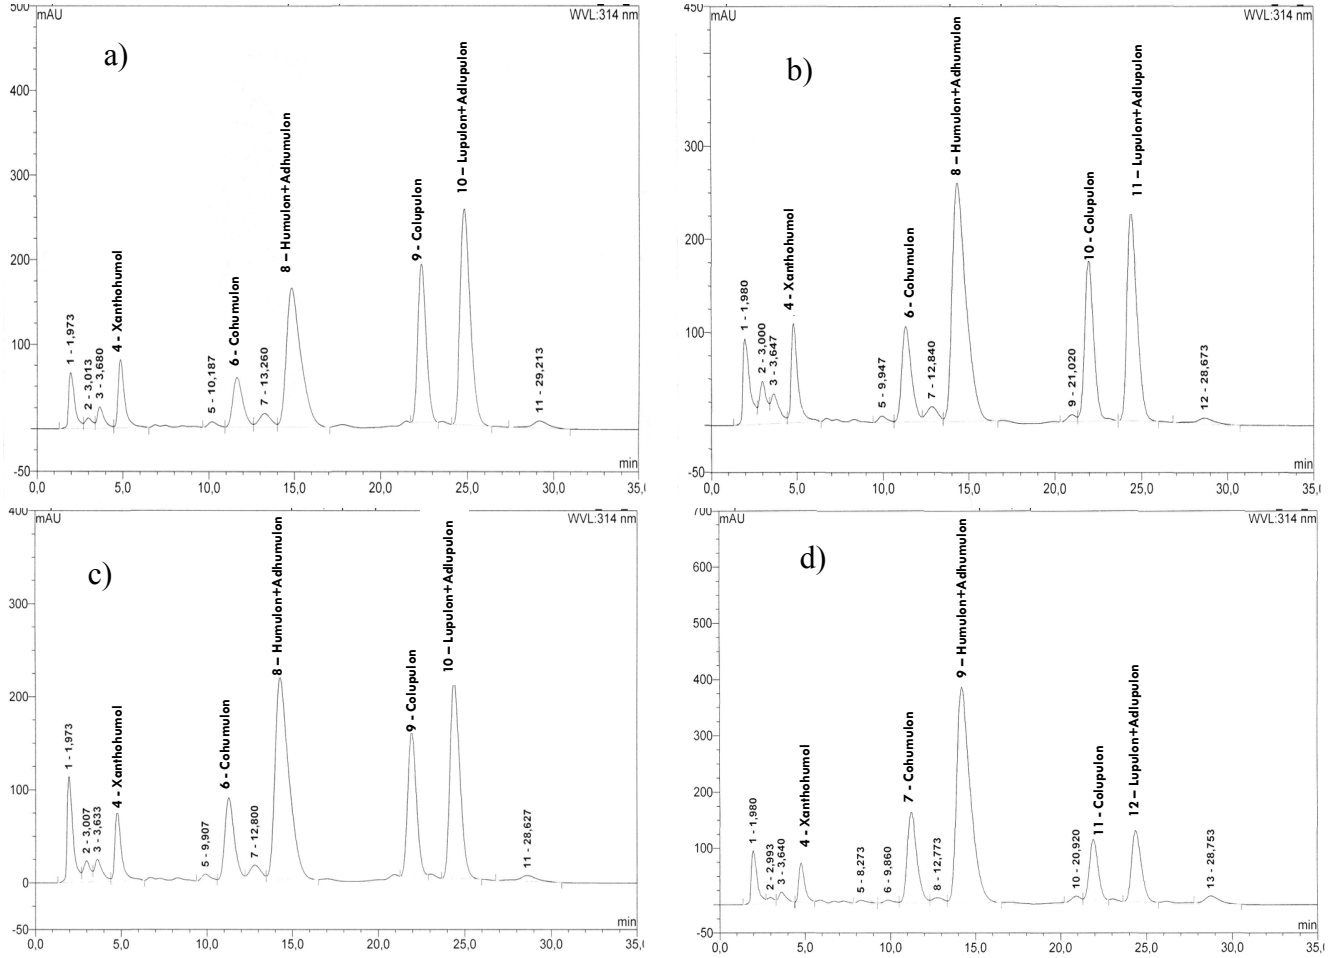

Figure 1 Chromatograms of the composition of bitters substances of cones of hops of various varieties: **a)** Slavyanka variety; **b)** Nationalny variety; **c)** Zagrava variety; **d)** Alta variet.

Depend on the variety of hops and the type of hops products, the amount of xanthohumol ranged from 0.25 till 2.10 %.

The highest content of xanthohumol was found in the ethanol extract of Hercules (2.10 %) and pellets of hop type 45 of the Tradition variety (0.52 %). The quantity of xanthohum in hops and hop products independent from content of bitter substances in the α-acids and β-acids were established.

Thus, in the cones and pellets of the type 90 of the bitter Alta variety with a high content of α-acids, the content of xanthohumol was smallest, which indicate on the absence correlation between the content of α-acids and xanthohumol.

As we seen from the chromatogram (Figure 3), in the biochemical composition of the CO_2 extract of variety Hercules xantohumol was absence.

According to literary sources **(Lyashenko, 2009)**, at the production of ethanol extract it contains at least 90 % of prenylflavonoids (including xanthohumol) of hop but at the production of CO_2-extract, these substances are practically not extracted and remain in the wastes.

Nowadays in the world there are intensive scientific researches about medicinal properties of this compound.

The experimental data obtained concerning the therapeutic effect of xanthohumol indicate that it was quite effective in the treatment of fungi, staphylococci, streptococcus, herpes and hepatitis viruses and has anti-cancer properties. Xanthogumol has negative affect on cancer cells of a person with a diagnosis of large intestine, breast, ovaries, prostate and leukemia, and does not affect on the healthy cells, activates enzymes that inhibit tumor growth, neutralizes the effect of enzymes that contribute to their growth, inhibit the growth of metastases **(Ferk, et al., 2010; Yang et al., 2013)**. The anti-carcinogenic effect of xanthohumol associated with its high antioxidant properties. Such an assessment of the effect of xanthohumulin was confirmed in the German Cancer Center **(Shanina et al., 2019)**.

In the process of beer preparing xanthohumol converted into isoxantohumol, which also has anti-carcinogenic properties **(Żołnierczyk, et al., 2017)**. However, the anti-carcinogenic action of isoxantohumol is 10 % less than xanthohumol. At wort preparation about 70 % of xanthohumol converted to isoxantohumol and in the finished beer left only 30 %.

Therefore, brewers need to pay attention to this when developing technologies for making beer and soft drinks with high content of xanthohumol and isoxantohumol for the prevention of cancer. With aim increasing xanthohumol in the beer have to add to beer at wort process hop products with high content of xanthohumol and also it added at the end of beer boiling for prevent the process of isomerization of this component.

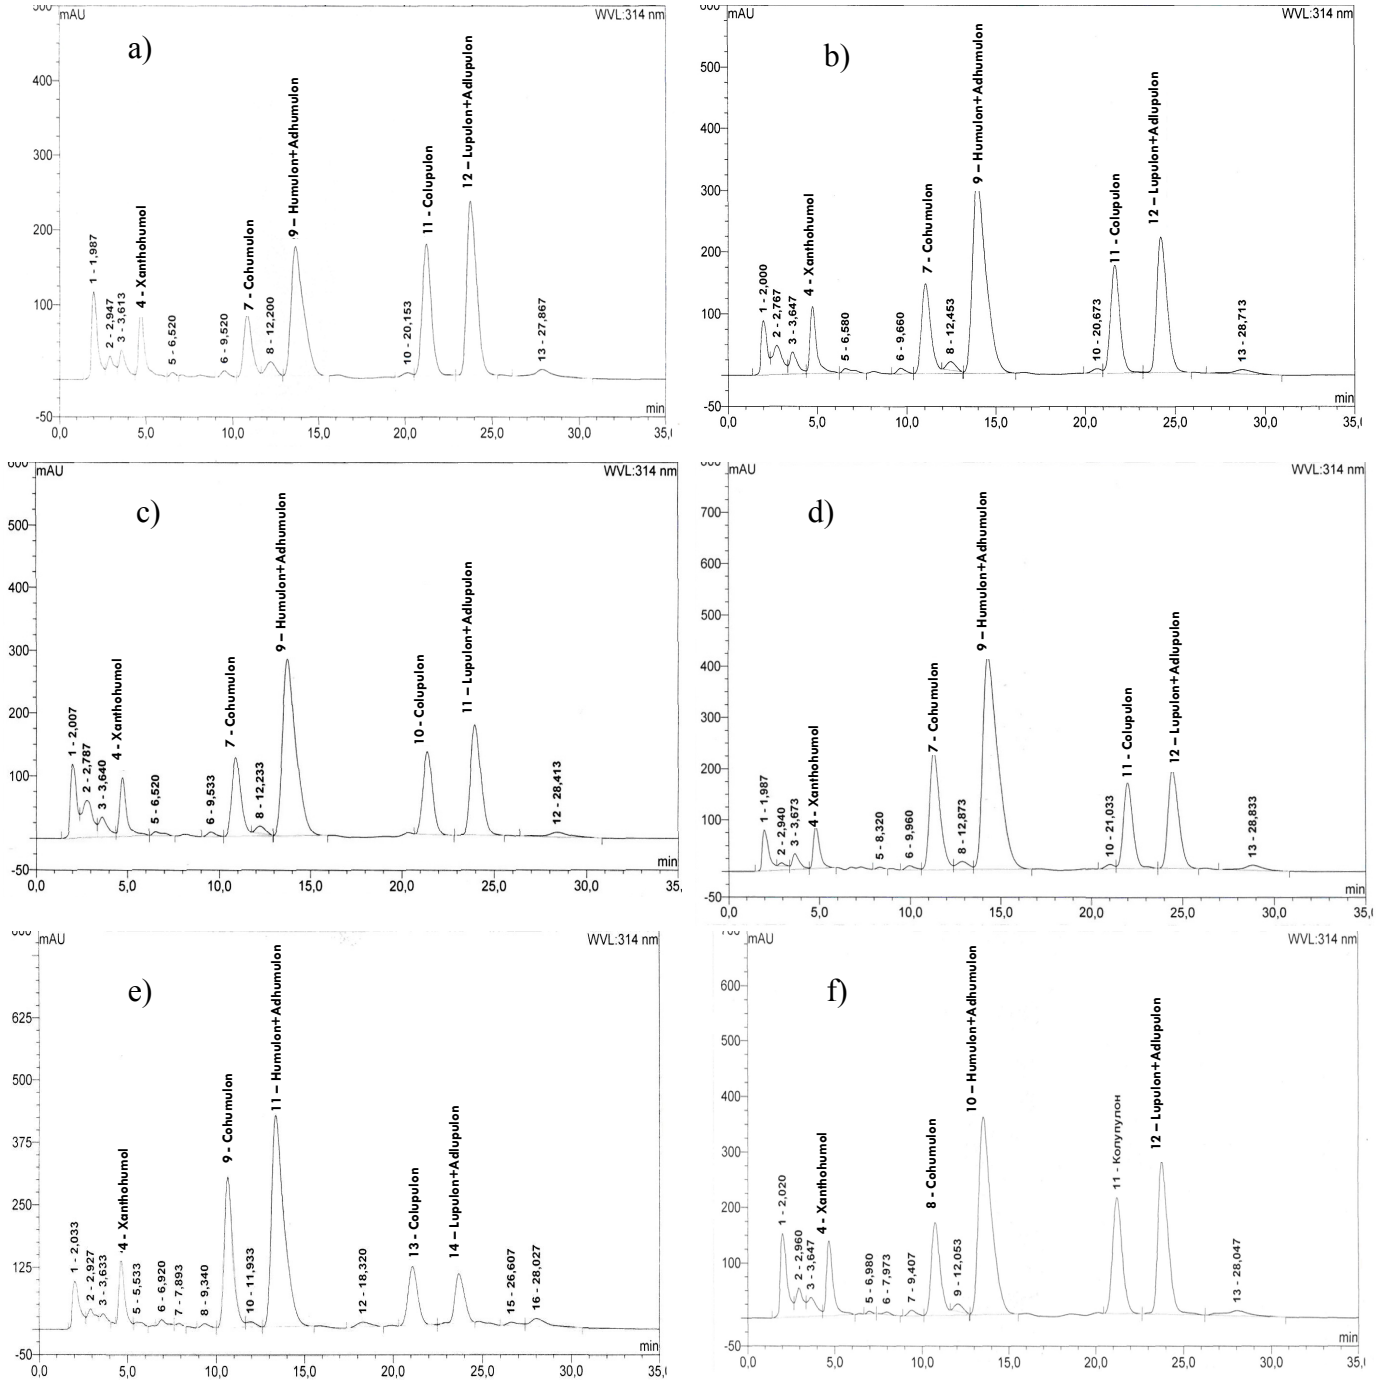

Figure 2 Chromatograms of the composition of bitters substances of pellets of hops: **a)** Pellets of type 90 Slavyanka variety; **b)** Pellets of type 90 Nationalny variety; **c)** Pellets of type 90 Zagrava variety; **d)** Pellets of type 90 Alta variety; **e)** Pellets of type 90 Hercules variety; **f)** Pellets of type 45 Tradition variety.

According to the results of the conducted researches (Table 1), the content of essential oils in the hop products was from 0.22 till 2.5 mg.100 g^{-1}. The highest content of essential oils was found in the CO_2 extract of hop of the Hercules variety. However, in brewing, in addition to the content and qualitative composition of essential oils have quantity of essential oil per 1 g of α-acids since the quantity of hops applied to beer calculated taking into account the content of α-acids.

On the contrary pellets and extracts, in cones of hops it is possible to see more quantity of essential oil per 1 g of α-acids, which provides more aromatic beer. For obtain the beer with a good hop flavour, it is necessary to use hops with content of essential oil at least 0.2 mL or about 50 μL sesquiterpenes per 1 g of α-acids **(Lyashenko, 2002; Pavlovič et al., 2012; Michałowska, 2017)**.

The organoleptic properties of beer made from different hop products also affect the different content of polyphenolic compounds. Along with the bitter substances, polyphenols have an important role in the forming of completeness and purity of the taste of the beverage, and also directly affect the freshness and stability of beer during storage. Hop polyphenols interact with high molecular proteins of wort, form complexes that fall into the precipitate and thus improve the clarification of wort and beer **(Goiris et al., 2014)**.

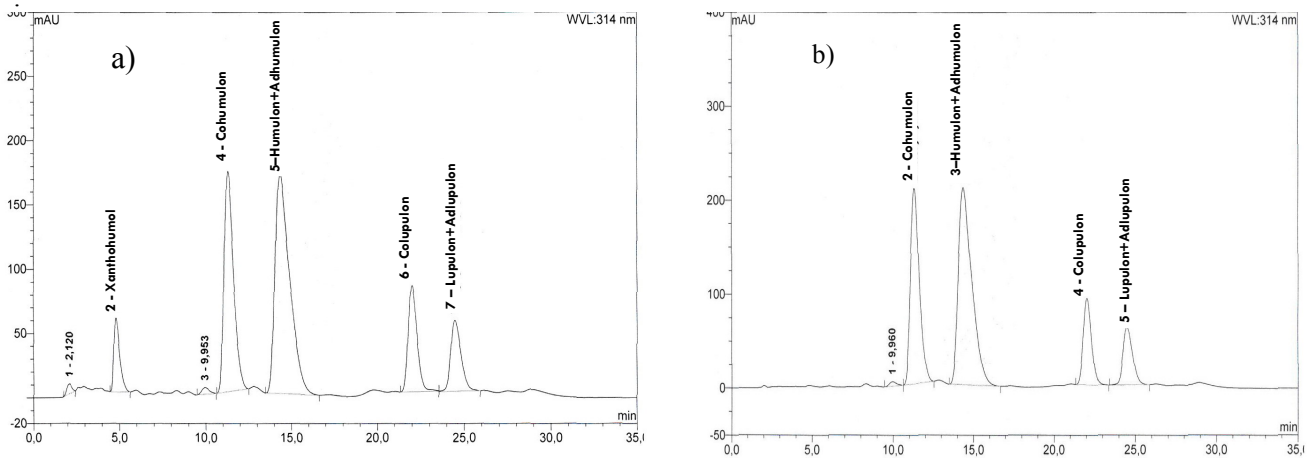

Figure 3 Chromatograms of the composition of bitter substances extracts of hops: **a)** Ethanol extract hops of the Hercules variety; **b)** CO_2-extract hops of the Hercules variety.

Always the best quality has beer which made from hops with a content of polyphenols do not less than 4.5 % **(Goiris et al., 2014)**.

The content of general polyphenols in the hop products according to Table 1 changed from 4.21 till 11.03 %. However, the main property of the hop products for this indicator determined do not by their general content, but by common quantity polyphenols per 1 g of α-acids. If in the cones of hop of aromatic varieties this value ranges from 1.0 till 1.3, hop pellets type 90 from 0.8 till 1.3, but in hop pellets type 90 bitter varieties from 0.3 till 0.4, that less on the 2.5 – 3.0 times. The studies showed that polyphenolic compounds were absent in ethanol and CO_2 extracts. Our studies confirmed investigations other scientists, which indicate the absence or insignificant content of polyphenolic compounds in these hops products.

In connection with this, for normal implementation of the brewing process and obtaining a full-fledged beer, it is necessary to add a certain quantity of cones or pellets of hop. Complex biochemical researches of hops and hop product of diffrent varieties with the used of modern biochemical methods give possible to established that hops and hop products of different varieties have different biochemical composition and hence different brewing value. This testified the fact that at the norms of different hop products of individual varieties with the same content of a-acids in the wort added different quantity of valuable for brewing components of hops. Consequently, the quality of beer produced by the same technology, but with the use of hops and hop products of different varieties can differ significantly.

Therefore, along with studies on the biochemical composition of pressed cones of hop and hop products of different varieties of domestic and foreign production, studies of their influence on the quality of the finished beer were conducted.

As the results of the researches, all obtained samples of beer were produced according the classical technology of light unfiltered beer which requirements of method described in state standard of Ukraine 3888:2015 **(DSTU 3888:2015)**. The physical and chemical indexes of the beer samples from the researches varieties of pressed cones of hop and different hop products presented in Table 2.

The analysis of physical and chemical indicators of beer quality shows that the degree of using of complex of valuable substances of hops and hop products was significantly higher in pellets and extracts than in native hop cones (Table 2). From the data which were presented we can see if used hop pellets type 90 of the Ukrainian bitter Alta variety in the hopped wort and beer, there were higher general indicators of bitterness and polyphenols than we using hops pellets type 90 of bitter Hercules type of German production. The norm at the same time was the same, taking into account only the content of alpha acids. Consequently, such results were due to the higher content of the beta fraction and polyphenols in pellets of the bitter Alta variety. The maximum amount of bitterness of beer provided pellets of hop type 45 of the Tradition variety, and the maximum amount of polyphenolic compounds in the wort and beer obtained with using hops cones and pellets of type 90 Slavianka and Zagrava varieties. Since there are not polyphenols in the extracts therefore in the wort and the finished beer which were produced from them obtained the least quantity of polyphenolic compounds.

In the process of basic and additional fermentation of beer the amount of bitter substances and polyphenols decreased **(Lyashenko, 2002; Pavlovič et al., 2012; Michałowska, 2017)**. Thus, the amount of bitterness from wort to finished beer decreased in the range of 14.5 – 23.3 % and total polyphenols 15.2 – 20.9 %.

The organoleptic assessment of the quality of the beer samples which were determined by the tasting commission, showed that was significantly different in taste, in the character of bitterness and aroma (Table 3).

All samples of beer (Table 3) were good or excellent quality and did not significantly differ. Each sample of beer had different taste, aroma or quality and fullness of bitterness. The quantity of pressed cones of hop (hop products) for adding to the wort calculated depend on the content of alpha acids in accordance with the branch Instruction TI 10-04-06-136-87 **(TI, 1998)**.

Hops and hop products added at the rate 50 mg of bitter substances per 1 dm^3 of wort. However, the taste of beer and the quality of bitterness in different samples were different. As indicated results researches of biochemical composition, the reason of this difference in the content of bitter substances and other components in the varieties of hops and hop products that added to wort. At the beer boiled added various hops products with the same content of alpha acids but different content of other valuable brewing components of hop. The quality of beer which was produced by one technology, but using different types of hop products was significantly differ. Our studies were correlation with other researches of the domestic and foreign scientists **(Lyashenko, 2002; Sheiko et al., 2019)**, which established that beer made from hops of various varieties was significantly different in character of bitterness, taste and aroma. The reason of this the peculiarity of the biochemical composition of bitters substances, polyphenolic compounds and essential oils of hop of aromatic and bitter varieties. Different ratio of components of these compounds differently affects on the taste and aromatics of beer. With taking into account, for determine the suitability of hops and hop products for beer making need carry out their complex comprehensive technological assessment of biochemical composition of the hops products.

According to the results of the tasting (Table 3), all samples of beer had a pleasant fresh beer flavor. The hop flavor was well presented in the beer with hopped wort by cones of pressed hop and pellets of hop type 90 varieties Slavyanka, Nationalny, Zagrava and Alta. In the samples of beer made from ethanol extract and CO_2-extract of hop of the Hercules variety, the aroma of hops was almost absence. The beer made from cones of pressed hop and pellets of hop type 90 varieties Slavyanka and Nationalny for bitterness and taste quite similar to each other. The bitterness was very light, delicate, soft, but in the beer made from pellets of hop type 90 varieties Slavyanka and Nationalny somewhat excess. The taste of this beer was full, harmonious. Beer obtained by adding to the wort pressed cones and pellets of type 90 of hop variety Zagrava for the quality of bitterness and taste similar. The beer has little harmonious taste and delicate, pleasant, balanced bitterness. But the bitterness of beer with added to the wort pellets type 90 of the Zagrava variety was more intense. When added to the wort pressed cones of hop of the Alta variety, pellets of hops type 90 varieties Alta and Hercules beer had rough bitter. Fullness of taste not detected.

Table 3 Organoleptic (tasting) evaluation of beer, depending on the characteristics of the hops and hop products, points.

No.	Grade of beer Variant of the experiment	Names of quality indicators: Taste: Transparency	Colour	Foaming	Flavour	fullness	hop bitterness	Total evaluation, points	Evaluation
1	Cones of hop of the Slavyanka variety	3.0	3.0	5.0	3.7	4.5	4.4	23.6	excellent
2	Cones of hop of the Nationalny variety	3.0	3.0	5.0	3.8	4.0	4.2	23.0	excellent
3	Cones of hop of the Zagrava variety	3.0	3.0	5.0	3.4	3.9	4.0	22.3	excellent
4	Cones of hop of the Alta variety	3.0	3.0	5.0	3.5	3.5	3.3	21.3	well
5	Pellets of type 90 Slavyanka variety	3.0	3.0	5.0	3.9	4.2	4.3	23.4	excellent
6	Pellets of type 90 Nationalny variety	3.0	3.0	5.0	3.8	4.2	4.2	23.2	excellent
7	Pellets of type 90 Zagrava variety	3.0	3.0	5.0	3.6	3.9	4.1	22.6	excellent
8	Pellets of type 90 Alta variety	3.0	3.0	5.0	3.5	3.5	3.5	21.5	well
9	Pellets of type 45 Tradition variety	3.0	3.0	5.0	3.7	4.0	4.0	22.7	excellent
10	Pellets of type 45 Spalt Select variety	3.0	3.0	5.0	3.8	4.1	4.5	23.4	excellent
11	Pellets of type 90 Hercules variety	3.0	3.0	5.0	2.2	2.9	2.9	19.0	well
12	Ethanol extract hops of the Hercules variety	3.0	3.0	5.0	3.0	3.3	3.5	20.8	well
13	CO_2-extract hops of the Hercules variety	3.0	3.0	5.0	3.1	3.0	3.4	20.5	well

The beer made from pellets of hop type 45 varieties Tradition had bound, balanced bitterness with a pleasant hops aroma. Adding to the wort the pellets of the hops type of the 45 variety Spalt Seleck provided the beer with fresh hop flavor, full harmonious taste and bound, pleasant, balanced bitterness.

Beer produced for the ethanol and CO_2-extracts of the Hercules variety of taste and bitterness were almost indistinguishable. The bitterness was rough, exceed. Beer was empty, without fullness of taste.

CONCLUSION

Complex researches of hops and hop products of various varieties with used of modern biochemical methods allow was established that hops and hop products of different varieties have different biochemical composition and hence difference brewing value. Differences depend on the absolute values of such parameters as the mass fraction of α-acids, β-acids and their composition, xanthohumol, general polyphenols, essential oils, the ratio of their valuable components of hops: β-acids to α-acids, and also the general quantity of polyphenols and essential oils per unit of α-acids.

Hops pellets of type 90 of domestic production contain the whole complex of necessary for brewing substances which were equivalent to hop cones. Characteristic feature of pressed cones of hop and hop pellets of type 90 and type 45, in particular of aromatic varieties, were high positive coefficient of aromatics between the content of β- and α-acids, ranging from 0.9 till 1.8. In opposite in pellets and extracts in hop cones presented more essential oils per 1 g of α-acids, which provides obtained more aromatic beer.

Hops pellets of the type 45 of foreign production enriched in the content of α-acids in their composition contained less amount of essential oil than hop cones and hop pellets type 90, which associated with the technology of obtaining pellets of this type.

Ethanol and CO_2 extracts had concentration of α-acids up to 50 % or more, which ensured the benefits of these products during storage, transportation and using in brewing. But these extracts do not had the required quantity of polyphenolic compounds of hops necessary for the normal implementation of the brewing process and obtaining full-fledged beer. They contained less quantity of essential oil, but it did not enough for the optimal ratio with alpha acids. Therefore, when making

beer, it is necessary to add certain quantity of cones or hops granules.

Technological assessment of the selection varieties of pressed cones of hop and hop products showed that all presented thin-aromatic and aromatic hops types Slavianka, Nationalny, Zagrava and pellets type 90, made from them and also pellets of type 45 varieties Tradition and Spalt Select were suitable both for self-use in brewing and for improve the taste of beer in combination with other processed products. Beer made from hops pellets, especially the Zagrava variety, had an excess of bitterness, therefore to norm pellets for beer production due to with an economy of up to 10 %. The individual used of pressed cones of hop and pellets of the bitter variety Alta and Hercules does not allow obtained the bitterness of beer of excellent quality. Ethanol and CO_2 extracts for self-use in brewing were not suitable. It was possible to recommend their using in combination with cones and pellets of aromatic varieties, while adhering to certain technology.

THE INFLUENCE OF LIFESTYLE ON CONSUMER BEHAVIOR AND DECISION MAKING IN RESEARCH AIMED AT PROTEIN BARS

Andrej Géci, Alexandra Krivošíková, Ľudmila Nagyová, Dagmar Cagáňová

ABSTRACT

We live in an era when all circumstances on the market are changing rapidly, which leads consumers (even, if they are not aware of it) to certain behaviour that affects their daily activities. Lifestyle can be described as someone's way of living or the things that a person or a particular group of people usually do. It is included among the modern elements of consumer behaviour and also affects an individual´s decision-making process. The concerns over obesity and dangerous food ingredients have prompted a "healthy lifestyle" to become the latest trend in marketing. Therefore, the regular exercising, the reduction of stress, drinking enough water, and eating nutritious food takes on its importance. The main objective of the paper is to assess the consumer behaviour on the market of a selected food commodity. For this purpose, protein bars, which are part of diet not only of athletes but also of ordinary consumers, have been chosen. To achieve this main goal, a questionnaire was designed and data were collected from the respondents of the different age groups in the Slovak Republic. Based on the primary results, the authors of the paper can claim that more than 60% of the respondents try intentionally to choose better options of food as they want to live healthy. For a deeper analysis, the assumptions were formulated and subsequently verified by the Pearson Chi-square test of independence and Kolmogorov-Smirnov test. The paper provides useful information on consumer behaviour that can help not only producers and retailers but also to consumers themselves.

Keywords: consumer; consumer behavior; lifestyle; food market; protein bar

INTRODUCTION

Recently, the psychosocial aspects of health have held interest. The constructs such as health perception and health-related quality of life are included in a broader domain because they pertain to positive health **(Grao-Cruces, Fernandez-Martinez and Nuviala, 2014)**. Individuals frequently face a "want-should" conflict between taking unhealthy food or activities and maintaining a healthy lifestyle. Such conflict is in nature a trade-off between a smaller immediate reward and a larger delayed reward **(Van Beek et al., 2013)**. An immediate oriented individual would choose an immediate reward over longterm benefits and thus make a less healthy decision **(Li and Hu, 2019)**. HA healthylifestyle includes taking physical exercise, keeping dietary eating and quitting smoking **(Adams and Nettle, 2009; Joireman et al., 2012)**. There are many benefits of the healthy lifestyle. It can increase a person's resilience and mental well-being **(Cairns et al., 2014)**. Understanding the factors that contribute to the healthy lifestyle behaviour is critical to the development of the interventions needed to promote the positive behaviour that can prevent the negative physical and mental health outcomes, which may have lifelong implications **(McGovern et al., 2018)**.

Lifestyle, but what is more a dietary pattern and has been changed rapidly by the development of urbanization, industrialization of societies and increased economic growth in the last decades **(Bolori et al., 2019)**. According to the World Health Organization, a healthy diet contains fruit, vegetables, legumes, nuts and whole grains, while also containing the limited amount of free sugars, salt and fat, and an amount of calories, which is in balance with energy expenditure **(World Health Organization, 2018a)**. By **Forshee et al. (2018)** the diets rich in fruits and vegetables and low in sugary foods and drinks were found to be associated with a lower-body mass index (BMI) **(Mytton et al., 2014; Ebbeling et al., 2012)**, but over 1.9 billion adults worldwide were overweight in 2016, resulting in higher prevalence of chronic diseases such as cardiovascular disease and diabetes **(World Health Organization, 2018b)**. In rodent models, changing the typical diet to one characterized by high-saturated fat, salt, and sugar consumption (often referred to as a"Western diet") reliably increases abdominal fat, insulin resistance,

atherosclerosis, and inflammation. Consuming this type of diet, has been linked to chronic, low-grade inflammation and associated diseases such as cancer, heart disease, and diabetes **(Christ et al., 2018; Huang et al., 2013; Thorburn et al., 2014)**.

High-protein foods are popular among the consumers seekingsatiety, increase muscle mass, or decreased risk of sarcopenia **(Sloan, 2012)**. Hence, protein bars have received growing attention in sports nutrition, musclebuilding, health supplement and weight reduction markets in recent years **(Kelly et al., 2019)**. The consumers are turning to the high-protein nutrition bars to add conveniently more protein to their diet. The high-protein nutrition bars have used new, trendy protein sources (e.g., insects), but have traditionally relied on dairy and soy ingredients such as concentrates, isolates, and hydrolysates **(McMahon et al., 2009; Imtiaz et al., 2012)**. These bars contain mainly protein (20 – 50%), carbohydrate (e.g. high-fructose corn syrup), fat (e.g. palm oil) and some humectants with a water activity of 0.5 – 0.8.

Scientific hypothesis

Assumption No. 1: We assume that there is no relationship between particular sex and the purchase of healthy food.

Assumption No. 2: We assume that there is no dependence between the respondent's sex and how often they engage in the sports activity.

Assumption No. 3: We assume that there is a relationship between particular sex and the consumption of protein bars.

Assumption No. 4: We assume that there is no correlation between the respondent's age and the preferred flavor of protein bars.

Assumption No. 5: We assume that there are differences between the influence of individual factors on the purchase of protein bars.

MATERIAL AND METHODOLOGY

The methodology of the paper was constructed through a questionnaire survey. The implementation was carried out both physically and using the Google Forms platform. The questionnaire survey was carried out in the Slovak Republic. The survey sample consisted of 627 respondents. The age structure was focused on the whole population. The survey was divided into three parts. The first part dealt with the demographic structure, the second one was generally focused on the respondents' lifestyle. The third part examined the consumer behavior of the selected food commodity. The main objective of the paper is to map a certain lifestyle of the respondents. The survey was used to find out consumers` behavior, preferences and decisions in everyday activities – buying of the selected food commodity.

The basic demographic data are given in Table 1. As far as the economic status is concerned, most surveyed are students (60.29%), followed by the respondents who are employed (30.94%). Almost half of the respondents (49.92%) completed the secondary education with the school-leaving examination as the highest achieved education, followed by students of grammar schools (18.98%) and then university graduates (15.95%).

Table 1 Characteristics of respondents.

Category of Respondents	%
Male	40.83
Female	59.17
Place of Residence	**%**
City	47.21
Village	52.79
Age Structure	**%**
Less than 20 years	47.21
21 – 30 years	34.45
31 – 40 years	4.94
41 – 50 years	9.09
51 years and more	4.31
Number of household members	**%**
1 – 2	16.75
3 – 4	62.68
5 and more	50.75

Statistical analysis

Before the questionnaire investigation, the scientific assumptions were established, whose testimony was verified by the means of a selected statistical method – Pearson Chi-square test of good conformity and Kolmogorov-Smirnov test. The authors of the paper have also used pivot tables whose application was realized on the obtained primary data. The authors determine the probability level - alpha ($\alpha = 0.05$), which will be compared with the level of significance (p-value). Based on alpha (α) it is possible to evaluate the hypothesis with a comparison of the p-value. If the p-value is less than alpha (α), we reject H_0. If the p-value is greater than alpha (α), we do not reject H_0.

RESULTS AND DISCUSSION

627 respondents participated in the questionnaire survey. The primary data were obtained to a greater extent from women (59.17%). In this survey 256 male respondents (40.83%) took part. The respondents were divided into five groups based on their age. The largest representation was the age structure under 20 years (47.21%). This was followed by an interval from 21 to 30 years (34.45%). These two age categories were the most important for the authors of the paper as we assume that the consumption of protein bars in the above age structures is the greatest. The age range from 41 to 50 years was 9.09%. Almost half of the respondents cited as the highest education a secondary school with a school-leaving certificate (49.92%). This was followed by grammar school leavers (18.98%) and university graduates (15.95%). The most frequently reported economic status was a student (60.29%). The second most frequently chosen option was the economic status - employed (30.94%). The authors of the paper also considered the family status, more than 2/3 of the respondents declared they were single. Only 14.51% of the participants stated that they were married. The last and also a very important question of the demographic survey was the net monthly income of the respondents (Figure 1).

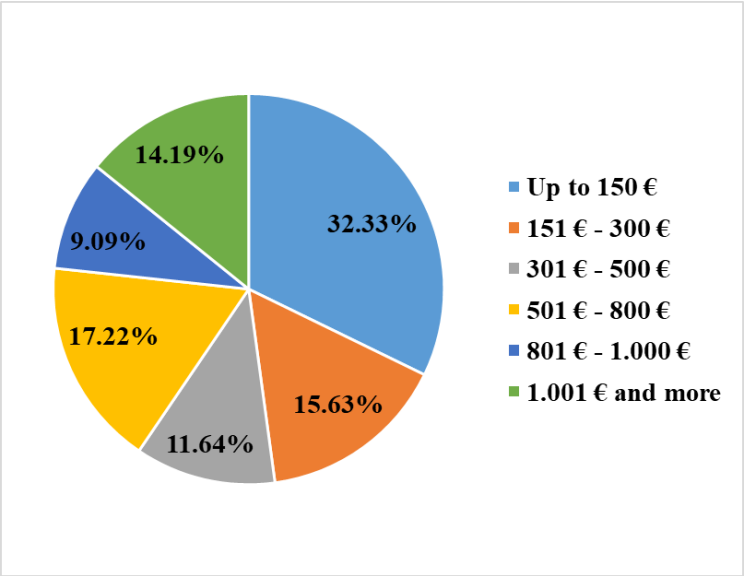

Figure 1 Monthly income of respondents.

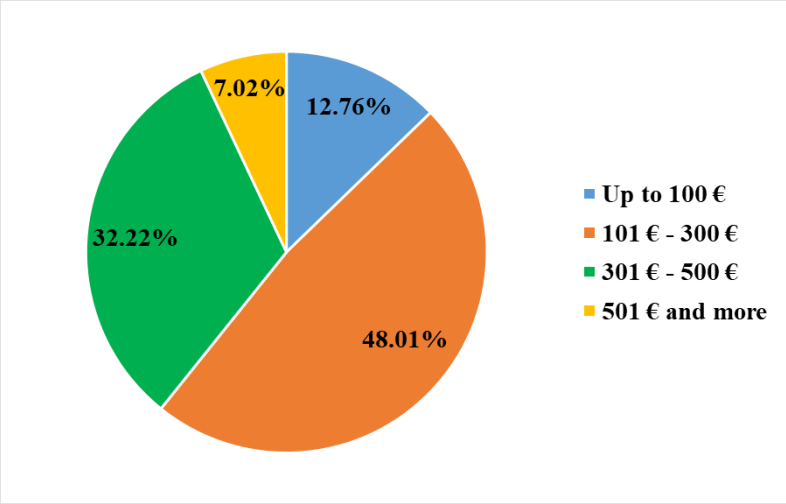

Figure 2 Monthly food expenses.

It follows from Figure 1 that the biggest interval up to 150 € constituted 32.33%. This was mainly because the maximum age limit was up to 20 years, and therefore, this age group does not have a big income opportunity. In the second place, there was an income from 501 € to 800 € with a percentage of 17.22%. An interesting feature of this survey, however, is the income interval above 1.001 €, which marked 14.19%. This was followed by a group of questions that dealt generally with consumer purchasing behavior. In this group of questions there were also formulated questions about the lifestyle of respondents. The authors of the paper have also considered the preferences and individual consumer impact factors. The first question focused on buying daily food consumer frequency. The observed values are given in Table 2.

The table shows that the respondents most often do shopping once or twice a week (42.11%). The second most frequent interval (three to four times a week) was 41.74%. Interestingly, up to 64 respondents buy daily groceries every day (10.21%).

Table 2 Frequency of shopping.

Frequency of shopping	Count	%
1 – 2x per week	264	42.11
3 – 4x per week	260	41.74
5 – 6x per week	39	6.22
Every day	64	10.21

Within this group of questions the authors of the paper have asked the respondents what was the decisive factor of their choice when buying food. In this case, the respondents identified quality as the most important factor (62.04%). Quality was also critical in surveys by **Grunert (2005)**. In the second place there was the price (25.68%), which is constantly placed in the leading position among the influencing factors on consumer purchasing decisions **(Gilbert, 2010; Ubreživá et al., 2019)**. This was followed by the origin of the particular foodstuff purchased (5.90%) and finally in the last place there was the package size (3.35%). The remaining 3.09% was divided among several factors that consumers had to choose (design, hunger, smell, composition, etc.).

This was followed by the related question, how much on average the whole family spends on food per month. The data are shown in Figure 2.

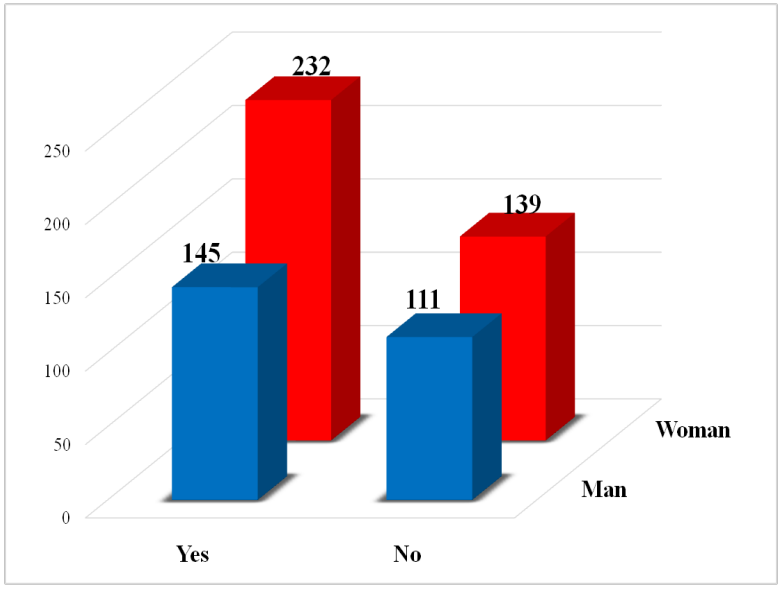

Figure 3 Confirmation of statistical assumption.

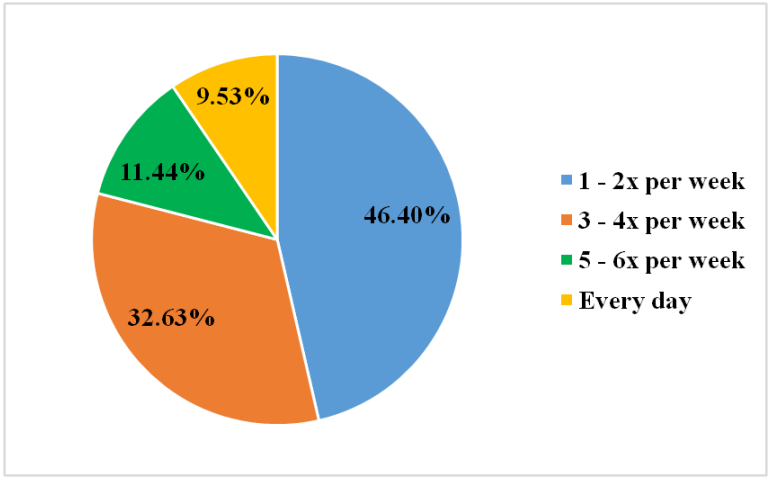

Figure 4 Sport activity.

From Figure 2, it is clear that the largest interval a family gives monthly to buy food is from 101 € to 300 €. Almost half of the respondents (48.01%) chose this option. Furthermore, the interval of 301 € to 500 € occurred. Spends only 7.02% spends on food more than 501 €.

Furthermore, the authors of the paper have concentrated their attention on respondents' lifestyles. They were asked if they were deliberately buying healthy food. Most of the respondents stated that they were deliberately buying healthy food (60.13%). 250 respondents (39.87%) answered negatively. If the respondents replied´yes´, they were asked what was the reason for such a purchase. More than half (51.89%) of the respondents stated that they want to live more healthy as a reason for purchasing **(Sjöberg et al., 2003; Kubicová and Habánová, 2012)**. The second most common answer was the possibility of self-belief (39.04%). Health reasons took last place (9.07%).

Based on the factors, the statistical observation was made on the presumption - whether there is a relationship between sex and the purchase of healthy food.

H_0: There is no relationship between sex and the purchase of healthy food.

H_1: There is a relationship between sex and the purchase of healthy food.

The *p*-value of Pearson's Chi-square good-fit test is used to verify the hypotheses. Testing will be carried out at the selected level of 5% significance, i.e. alpha will be 0.05. In this case, the *p*-value = 0.0941, which means that we reject the null hypothesis. We accept the alternative hypothesis and declare that 95% reliability is the relationship between sex and the purchase of healthy food. Based on the test results, the assumption is incorrect. Subsequently, the authors of the paper have also presented the results in Figure 3, which confirms the statistical testing.

Figure 3 shows that women buy healthy food more often. In general, women buy more often than men **(Beardsworth et al., 2002; Géci et al., 2017)**. Men in this case buy much less healthy food than women do.

Then, the respondents were asked whether they considered their lifestyle as healthy. Most respondents consider their lifestyle to be healthy, 74.80%. The remaining 158 respondents are not interested in a healthy lifestyle. For better clarity, we have made a comparison based on gender. The above question shows that both genders have the same values (positive and negative) when

compared. The female sex lives healthy at 74.66% and the male sex at 75.00%. This was followed by a related question, which dealt with the reason why a healthy lifestyle is a part of their lives. The vast majority responded that their own beliefs (84.58%) were a factor in a healthy lifestyle. **Moreno et al. (2008)**, achieved almost identical results. Then it was followed by family and friends (8.13%) and finally various health problems (7.29%).

A certain type of exercise (sports activity) is also closely related to a healthy lifestyle. Therefore, the authors of the paper have asked the respondents, if they were doing any sport (active or passive at least twice a week). 69.70% of the respondents gave a positive answer to the question. The authors have wondered how often they practice sport activities (Figure 4).

More than 46% of respondents claimed that they practice sport activities once or twice a week. More often, 32.63% carries out sporting activity. Interestingly, 45 respondents reported daily physical activity.

Based on the factors, the statistical observation was made on the presumption - whether there is a dependence between gender and frequency of sports activity.

H_0: There is no relationship between gender and frequency of spsportsctivity.

H_1: There is a relationship between gender and frequency of sports activity.

To verify the established hypotheses, the authors of the paper have used the *p*-value of the Kolmogorov-Smirnov test of good conformity. Testing was carried out at the selected level of 5% significance, i.e. alpha as 0.05. In this case, the *p*-value = 0.0154, which means that we reject the null hypothesis. We accept the alternative hypothesis and declare that 95% reliability is the relationship between the sex and frequency of sporting activity. Based on the test results, the authors of the paper have considered the assumption to be correct.

Finally, the authors came to the researched issue, which is a consumption and consumer behavior when buying a selected market commodity - protein bars. For this group of questions, the authors of the paper mainly deal with the reason and time of consumption, the preferred flavor, and the factors of choice for this food snack.

The first and main question of this section was concerning the consumption of protein bars (Table 3).

The authors of the paper have asked whether the respondents generally consume protein bars.

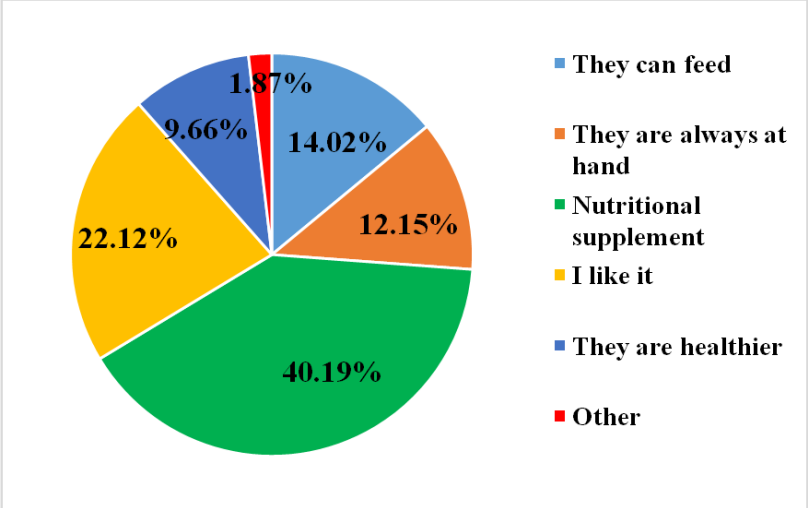

Figure 5 Reasons for consumption.

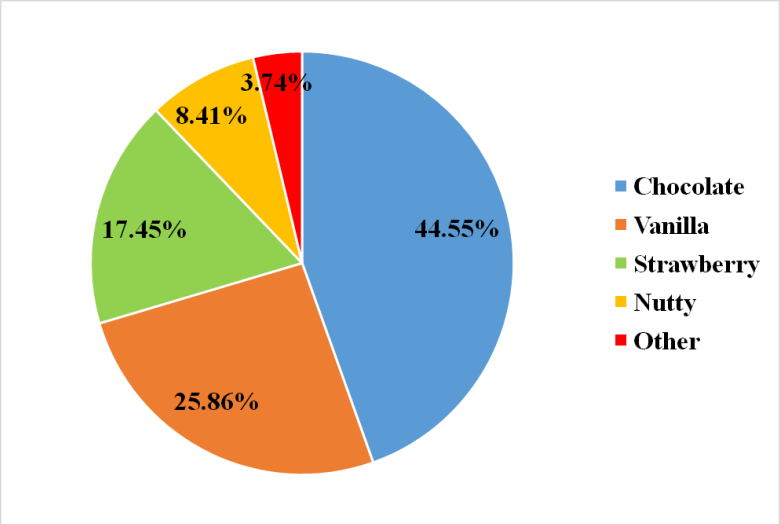

Figure 6 Preferred flavors.

Table 3 Consumption of protein bars.

Consumption	Count	%
Yes	321	51.20
No	306	48.80

The table clearly shows that the majority of the respondents do not consume the selected food commodity (51.20%). We have assumed such a result as protein bars are specialized food and not everyone knows and looks for this kind of food. Here the survey for some respondents is over. The authors of the paper have filtered out the respondents who do not consume protein bars so that testing can continue to evaluate the primary data obtained. From the original number of 627 respondents, only 321 respondents continue to be evaluated.

Based on the factors, the statistical observation was made on the presumption - whether there is a relationship between a sex and protein bar consumption.

H_0: There is no relationship between sex and protein bar consumption.

H_1: There is a relationship between sex and protein bar consumption.

The *p*-value of Pearson's Chi-square good-fit test is used to verify the hypotheses. Testing was carried out at the selected level of 5% significance, i.e. alpha as 0.05. In this case, the *p*-value = 0.0257, which means that the authors of the paper have rejected the null hypothesis. The authors accept the alternative hypothesis and declare that p 95% reliability is the relationship between sex and protein bar consumption. Based on the test results, the authors of the paper consider the assumption to be correct.

This was followed by a question about the frequency of protein bar consumption among the respondents. Most respondents (46.73%) declare they only consume protein bars occasionally. In this case, this means that eating this food does not have a regular place in the respondents' menus. The consumption was admitted once or twice a week (38.94%). In this case, the authors of the paper can assume that such consumers engage in some kind of sports activity. The last most frequently reported option was an interval of three to four times a week (11.21%). The authors of the paper have discussed the reason for buying this food commodity. This type of food belongs to specific and low-demand food for the majority of the population. The reasons for buying this specific type of food are shown in Figure 5. The chart shows that the respondents consume protein bars based on their nutritional value (40.19%). In this case, however, not all protein bars have the appropriate nutritional values **(Fernan et al., 2017)**. The research has evaluated and tested this type of food, sensory testing or, laboratory testing for these ingredients and nutritional values. It was concluded that not each protein bar should be called a protein bar. Some of them contain much more sugar than proteins and in this case they should not be categorized as protein bars **(Imtiaz et al., 2012; Zhou et al., 2013)**. The original protein bar should contain as little sugar as possible and the protein content should exceed the sugar value **(Li et al., 2008)**. The taste came in the second (22.12%) as the reason for the choice. As part of this response, the respondents declare they like protein bars and therefore buy them. In this case, they do not pay attention to the reasons for purchasing this specific commodity. 39 respondents said they buy protein bars mainly because they are always on hand when they get hungry. With this possibility, however, it should be kept in mind that protein bars are only a nutritional supplement **(Maughan et al., 2007)**. They do not replace a full-fledged and mainly nutritious meal in any way**(Singh et al., 2008)**. In the last place (1.87%) there were various other reasons for the consumption and purchase of protein bars, such as consumption is fashionable.

The authors of the paper have also asked the respondents when they consume protein bars most often. So whether they have a daily ritual of consuming these special kinds of food or do not solve it during the day. Most respondents stated that they do not need any special reason to consume sticks, and therefore they consume them at any time of the day when they feel like eating it (53.89%). Then followed the possibilities of consumption, which are already a daily ritual. The second most marked place was consumption after sports activity (31.46%). This was followed by consumption before sports activity (9.35%). According to **Corrado et al. (2003)**,sportst activity refers to any physical activity related to sport (training, exercis,e and various types of sport). In this case, the consumption before and after sports activity is due to the nutritional composition of various substances that have a positive effect on the stressed body **(Thiansilakul et al., 2007)**.

Another essential question of protein bar consumption was the question of preferred protein bar flavor. These flavor preferences are shown in Figure 6.

It follows from Figure 6 that the respondents prefer the consumption of chocolate protein bars (44.55%). Vanilla flavor (25.86%), strawberry flavor (17.45%), and hazelnut flavor (8.41%) followed. In the last place, there was the possibility of other flavors (3.74%). In this case, the respondents had in mind various other flavors such as lemon cake, coconut flavor, or various other fruit flavors in the limited editions.

Based on the factors, the statistical observations were made on the assumption - whether there is a relationship between age and the preferred flavor of protein sticks.

H_0: There is no relationship between age and preferred flavor of protein bars.

H_1: There is a relationship between age and preferred flavor of protein bars.

To verify the established hypotheses, the authors of the paper have used the *p*-value of the Pearson Chi-square test of good conformity. Testing was carried out at the selected level of 5% significance, i.e. alpha as 0.05. In this case, the *p*-value = 0.0358, which means that the authors have rejected the null hypothesis. The authors of the paper have accepted the alternative hypothesis and confirm that 95% confidence is the relationship between age and preferred flavor of protein bars. Based on the test results, the authors of the paper have considered the assumption to be correct. For better clarity, see figure 7.

It is clear from Figure 7 that the age structure influences the flavor decisions. This was followed by a question about the choice of protein selection factor. The respondents had a choice of five factors affecting their purchase. These factors were arranged from the most important to the least important factor. The numbers from 1 to 5 were assigned to each factor, with a score of 1 being the least important factor and the value of 5 being the most important factor. These values are shown in Figure 8 for clarity. The figure shows that the most important factor in the selection of protein bars is their particular flavor. Up to 45.18% of the respondents claimed the importance of the flavor. The flavor itself is a very important factor in the choice of any food **(Guichard, 2007)**. Interestingly, the selection factor nutritional supplement – 25.00% ended in the second place. This was followed by a brand, which is one of the basic factors for choosing a particular product. Subsequently, the price was placed (9.04%) and packaging was the least important factor. In very few cases the packaging itself is a decisive point in the choice of food **(Pollard et al., 2002; Pierański et al., 2017)**. This is due to the saturation of the market for this food commodity, as well as due to its specific location and respondents' attitude to its consumption **(Wells et al., 2007; Kozelová et al., 2014)**.

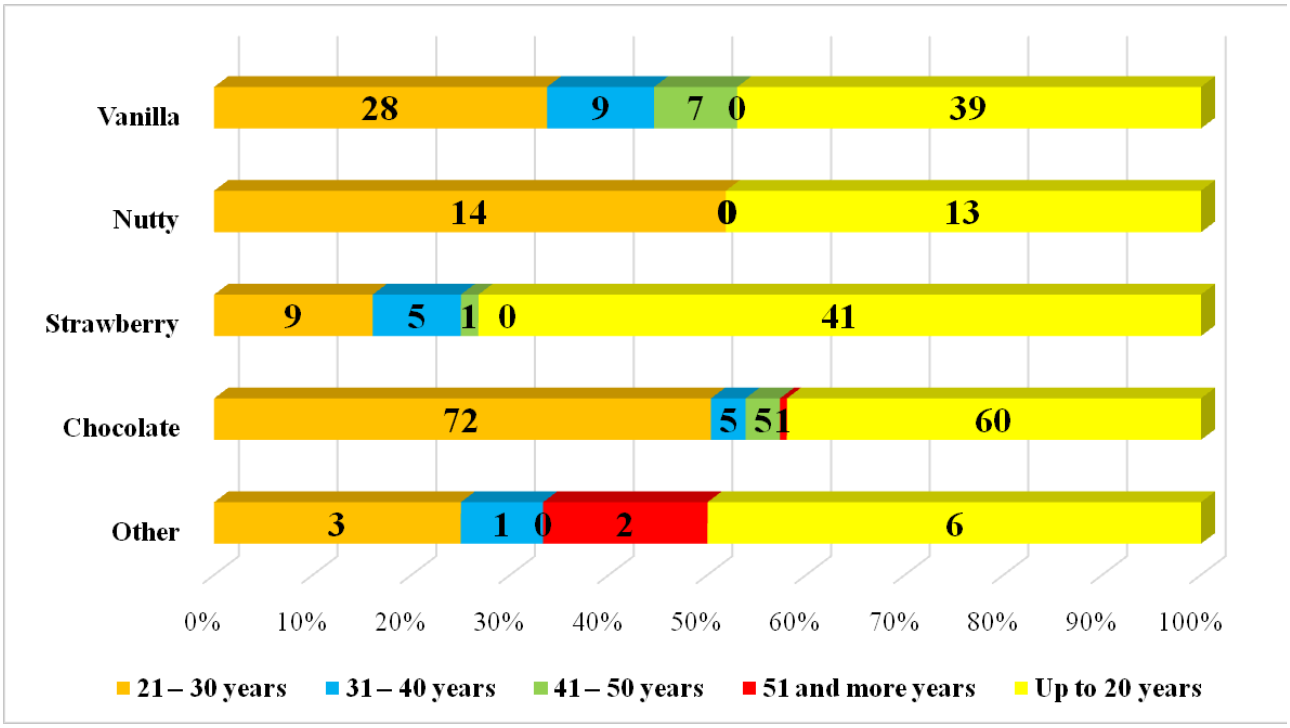

Figure 7 Preferred flavor by age.

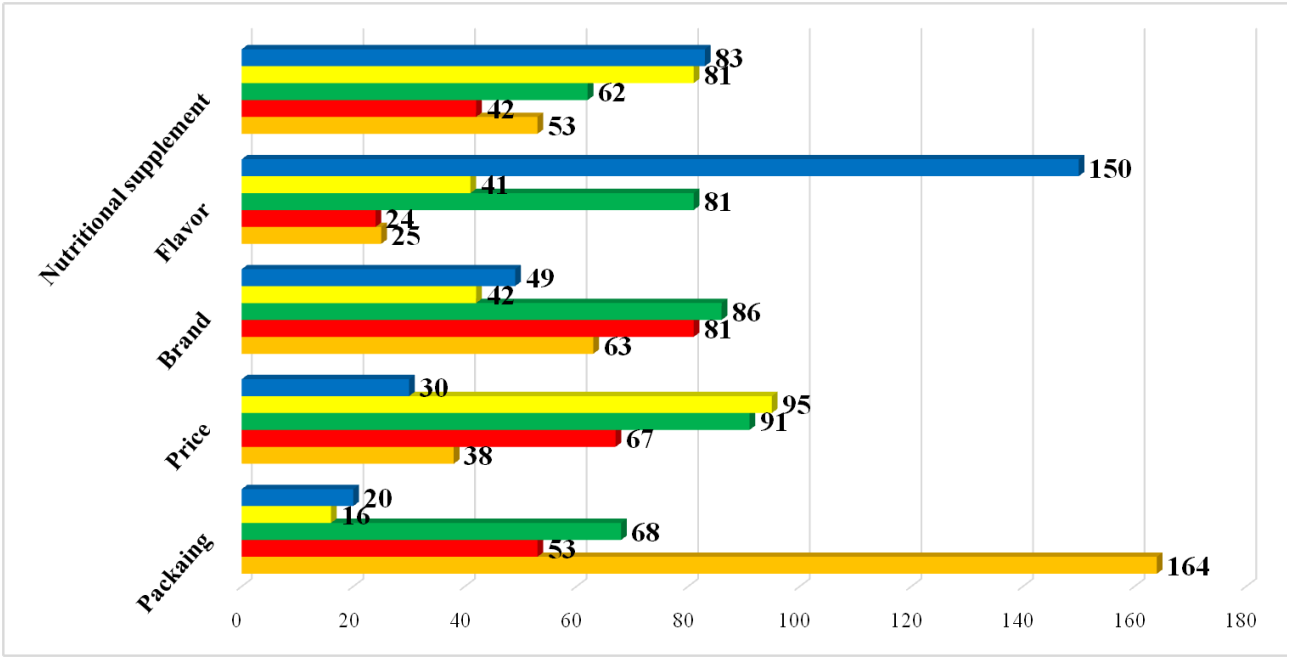

Figure 8 Protein flavor selection factor.

Based on the factors, the statistical observations were made on the assumption - whether there are differences between the influence of individual factors and the purchase of protein bars.

H_0: There are no differences between the influence of individual factors and the purchase of protein bars.

H_1: There are differences between the influence of individual factors and the purchase of protein bars.

The authors of the paper have used *p*-value from the Kolmogorov-Smirnov test of good conformity to verify the hypotheses. Alpha will be 0.05. In this case, the *p*-value = 0.0158, which means that the authors of the paper reject the null hypothesis. The authors accept the alternative hypothesis and declare that with 95% reliability, there are differences between the influence of individual factors and the purchase of protein bars. Based on the results, the authors of the paper consider the assumption to be correct.

The last question of the questionnaire survey focused on one of the most important factors, which plays an essential role in the purchase of food – and that is a price. The authors of the paper asked the respondents how much they are willing to spend on a protein bar. General weight of 100 grams was set for this question. Most respondents chose between 1.1 € and 2 € (73.52%). In the second place, there was a sum from 2.1 € to 3 € (17.76%). 6.85% of respondents indicated the price value up to 1€. In the last place, there was an interval of more than 3 €, which was chosen only by 6 of the surveyed consumers.

CONCLUSION

The paper analysed the consumer behaviour on the market of the selected food commodity – protein bars, which can be classified as healthy food. The survey was carried out on the selected sample of the respondents with the different gender, age, and lifestyle to be in accordance with the main sample of citizens of the Slovak Republic. The results showed that more and more consumers are becoming interested in the quality of products they purchase, as up to 62.04% of respondents stated the quality as a decisive factor when purchasing food and the price, which has always been at the forefront of the factors, reaching the second place (25.68%). The survey focused also on the healthy lifestyle of the respondents and buying healthy food. In this case, more than half of the respondents stated that they intentionally buy healthy food (60.13%), as they want to have healthy, full-featured, and longer life (51,69%). As far as the healthy lifestyle is concerned, up to 74.80% of the respondents were convinced that they can describe their lifestyle as healthy, and more than half of them reported practicing sport activities once or twice a week. Subsequently, the questions related to the purchase and consumption of protein bars followed. The most responses (51.20%) do not choose this food commodity, however, these results were expected as the protein bars are classified as specific food. The respondents, who purchase them, do it for their nutritional value (40.19%), but paradoxically they choose among them according to the flavor (45.18%) and not nutritional value (25.00%), and only 31.46% of the respondents consume this type of food after sports activity.

When buying the different food commodities, the consumers behave individually, and therefore, there is no general formula that can describe fully this daily shopping behaviour. Ultimately, the authors of the paper can conclude that consumer behaviour is unpredictable in all respects and the marketers can just work with their assumptions.

ISOLATION AND IDENTIFICATION OF ACTIVE COUMPOUND FROM BENGLE RHIZOME (*ZINGIBER CASSUMUNAR* ROXB) AS A STIMULANT IN PHAGOCYTOSIS BY MACROPHAGES

Muhamad Fauzi Ramadhan, Nurkhasanah Mahfudh, Nanik Sulistyani

ABSTRACT

Immunomodulators are pharmacological agents that modify or regulate the immune system through stimulating the functioning of the immune system and, at the same time, inhibiting excessive immune responses. This study was conducted to determine the active compound in *Z. cassumunar* that is responsible for increasing the immune system based on the parameters of phagocytic activity. The isolation method began with fractionation, which involved extraction with ethanol and successive fractionation with hexane and chloroform. *Z. cassumunar* extract, hexane fraction, and chloroform fraction were tested on mice macrophage cells for their phagocytic functions. The phagocytic activity of macrophages was measured by active phagocytic cells (averagely 39.194 ±1.597, 27.923 ±2.941, and 62.090 ±6.947) and phagocytic index (in a row, averagely 47.513 ±2.844, 41.129 ±7.195, and 101.527 ±10.555). The results showed that the *Z. cassumunar* extract, hexane fraction, and chloroform fraction exhibited more significant phagocytic activities of macrophages (p <0.05) compared with the normal group. Since the chloroform fraction showed the best result, this fraction was further separated by column chromatography. This procedure yielded five sub-fractions, namely F1, F2, F2C, F3, and F4. Based on the phagocytic activity testing, the results were as follows: (1) the active phagocytic cells of F1, F2, F2C, F3 and F4 were 18.860 ±3.191, 27.077 ±4.482, 15.749 ±3.026, 64.333 ±1.780, and 44.943 ±2.944, respectively, and (2) the phagocytic indices were 30.0249 ±3.4231, 44.5969 ±8.3646, 24.5597 ±5.4487, 102.7447 ±1.0806, and 76.5007 ±4.7293. Because F3 produced the best result, this subfraction was then identified using 1H-NMR and 13C-NMR. The identification results showed that F3 was (*E*)-4-(3,4-dimethoxyphenyl)but-3-en-1-ol as an active compound.

Keywords: *Zingiber cassumunar*; phagocytosis macrophage; (E)-4-(3,4-dimethoxyphenyl)but-3-en-1-ol

INTRODUCTION

Through various studies on effects and efficacy, traditional medicine has been increasingly developed for its use in overcoming health problems. Around 59.1% of the Indonesian population use traditional medicine, and 95.60% of which claim to perceive the benefits. This figure is supported by the abundant natural resources in Indonesia and the willingness to start following WHO's recommendations to incorporate natural ingredients in treatment and lifestyle. To substitute for immune enhancers, people tend to prefer traditional medicine **(Indonesian Health Ministry, 2013)**. The immune system consists of organs, tissues, cells, and chemical compounds that are used by the body to protect it from the danger of foreign objects or cells that potentially cause abnormal internal changes. The immune system is divided into two types, namely specific and non-specific. The non-specific immune system is the body's first defense against the attacks of foreign bodies because it responds directly to antigens. whereas, a specific immune system is a system that can recognize foreign substances that enter the body and can stimulate the development of specific immune responses to these substances **(Baratawidjaja and Rengganis, 2014; Hooper, Littman, and Macpherson, 2015; Shiland, 2014)**. In this system, macrophages play the most crucial role. They act as effectors on therapeutic bodies in the immune system against pathogens using the phagocytosis mechanism, either directly or indirectly, by releasing ROI and cytokines. These functions can be influenced by immunomodulators **(Baratawidjaja and Rengganis, 2014; Gabrilovich and Nagaraj, 2009)**. Immunomodulators are drugs that enhance immune systems with low function (immunostimulants), suppress excessive immune function (immunodepressant), and increase vaccine efficacy (Immunoadjuvant). In other terms, immunomodulators help the body to optimize the role of its immune system. One of the natural ingredients that have the potential to modulate the immune system is *Z. cassumunar* **(Baratawidjaja and Rengganis, 2014; Bascones-Martinez et al., 2014; Chairul, 2009; Nair, Chattopadhyay, and Saha, 2019)**.

Z. cassumunar is a type of rhizome from the Zingiberaceae family. It contains several chemical compounds, namely essential oils, starch, resin, tannins, flavonoids, and phenylbutanoic acids. This rhizome is often used as a medicine to treat various diseases, including fever and headache, and to increase immunity **(Hartati et al., 2013; Utami, 2008)**. In previous research, *Z. cassumunar* has been reported as an effective adjunctive therapy in malaria **(Hermansyah and Utami, 2015)**.

Several studies have succeeded in isolating phenylbutanoid derivatives from *Z. cassumunar*, namely (E) -4- (3 ', 4'-dimethoxyphenyl) but-3-en-1-ol; (E) -4- (2 ', 4', 5 '-trimethoxyphenyl) but-3-en-1-ol; (E) -4- (3 ', 4', 1-trimethoxyphenyl) but-3-en-1-ol; (E) -4- (3 ', 4'-dimethoxyphenyl) but-3-en-1-il-acetate, and methoxy-8-(3,4-dimethoxyphenyl) -1,4-napthoquinone **(Chairul, 2009; Hartati et al., 2013; Kuroyanagi et al,. 1980)**.

Scientific hypothesis

Z. cassumunar has compounds that are responsible for the phagocytic activity of macrophages.

MATERIAL AND METHODOLOGY

Plant Material

Bengle rhizomes (*Z. cassumunar*) were purchased from the Beringharjo Market, Yogyakarta, Indonesia. Before use, these materials had been identified in the biology laboratory, University of Ahmad Dahlan, with an identification number 036/Lab.Bio/B/IV/2018.

Material

Ethanol 96% (E-Merck, pro-analysis quality), Etanol 70% (E-Merck, pro-analysis quality), n-Hexane (E-Merck, pro-analysis quality), Dichloromethane (E-Merck, pro-analysis quality), Chloroform (E-Merck, pro-analysis quality). TLC plate with silica Gel GF_{254} (Merck), Silica powder for Column (Merck), NMR JNM-ECX500R (JEOL ltd) and Complete medium (MACS® media)

Procedure

Animal Preparation

The animal care procedure in this study has been approved by the research ethics committee of the University of Ahmad Dahlan, with approval number 011804063. The test animals were male BALB mice aged eight weeks old.

Extraction and Fractionation

The rhizomes of *Z. cassumunar* were washed with water, then dried in an oven at 50 °C. The produced *simplisia* (i.e., natural ingredients used as a medicine that have not been exposed to any processing and, unless stated otherwise, are in the form of dried materials) were ground into a powder and subsequently macerated using 96% ethanol at a ratio of 1:4. Afterward, the produced macerate was evaporated in a rotary evaporator to obtain a thick extract. Fractionation was carried out by successive fractionation. Thirty grams of the ethanol extract of *Z. cassumunar* were fractionated with n-hexane until no more compounds were dissolved in n-hexane. Then, the non-soluble part was fractionated with chloroform. The fractions obtained were further examined by thin-layer chromatography (TLC).

Macrophage Isolation

After fasted for 12 hours, the test mice were anesthetized using chloroform. The abdominal skin was cut open, and the peritoneal was cleaned using 70% ethanol. Ten ml of complete medium was injected into the peritoneal cavity, which was then massaged for 3 – 5 minutes. The cavity was pressed by two fingers to remove the peritoneal fluid; this fluid was aspirated using a syringe injection (by selecting parts that had no fat and far from the intestine). The number of cells were counted and added with complete medium to adjust the number of macrophages to 2.5 x 10^6 mL^{-1} cells.

Testing of Phagocytic Activity

Cells in 200 μL suspension were grown in each well and incubated using an incubator that was set at 5% CO_2 and a temperature of 37°C for 24 hours. The medium was removed and added with 50 μL latex and, then incubated using an incubator at 5% CO_2 and a temperature of 37 ° C for 1 hour. The suspension was removed and fixed with methanol for 3 minutes, then the methanol was removed. This mixture was colored with 10% Giemsa for 30 minutes and the coverslips were washed in distilled water. Finally, the cells were viewed under a microscope with 400x magnification (Nurkhasanah, Santoso, and Fauziah 2017).

Column Chromatography

Column chromatography was performed using silica powder with 230 – 400 mesh particle size in combination with the elute of n-hexane: dichloromethane (1:1). One gram of the chloroform fraction was ground with 5 grams of silica powder and stored at the top of the silica column. This process involved gradient elution for the mobile phase (i.e., a mixture of n-hexane: dichloromethane) and was examined using thin-layer chromatography.

Identification

The subfraction that showed the best phagocytic activity of macrophages was then prepared for 1H-NMR and 13C-NMR analyses. This procedure used a JNM-ECX500R spectrometer operated at 500MHz Superconducting Magnet.

Analysis

The macrophage activity was observed from the cells exhibiting active phagocytosis and the phagocytic index. Active macrophage cells are the percentage (x100%) of the number of latex cells among the total macrophages in the field of view **(Chairul, 2009)**, while the index is the percentage of a total number of macrophages that phagocyted latex particles among the total macrophages in the field of view **(Hartini, Wahyuono, and Widyarini, 2013)**.

$$\text{Active phagocytic cells (\%)} = \frac{Number\ of\ active\ macrophage\ cells}{total\ of\ macophage\ cell} \text{ x } 100\%$$

$$\text{Index of phagocytosis} = \frac{total\ antigen\ phagocyted}{total\ of\ active\ macophage\ cell}$$

Statistical analysis

The results were analysed statistically using Normality, Homogeneity, ANOVA, and LSD (Least Significant Differences); all of which were processed in SPSS version 22. The normality test result is accepted if the *p*-value is >0.05, which means that the data are normally distributed. The homogeneity test result is accepted if the *p-value* is >0.05, which represents homogeneously distributed data. The ANOVA result is accepted if the *p*-value is <0.05, which signifies a significant difference in the treatment group. Meanwhile, the LSD test is a test performed as a reference to determine whether or not the averages of two treatments are statistically different.

RESULTS AND DISCUSSION

An immunomodulator is a drug or a pharmacological agent that regulates the immune system. The ethanol extract of *Z. cassumunar* has been reported to exhibit immunomodulatory activity by increasing the secretion of ROI. ROI secretion shows the increased activity of macrophage cells. Macrophages with their phagocytosis mechanism are the main phagocytic cells that ward off or deflect pathogens **(Abbas, Litchman and Pillai, 2012; Akrom, 2013; Baratawidjaja and Rengganis, 2014; Hartini et al., 2013; Nurkhasanah et al., 2017)**.

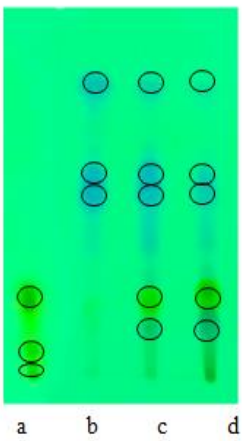

Figure 2 Profile TLC using the mobile phase chloroform: dichloromethane and stationary phase silica gel F254: a. curcumin b. n-hexan fraction c. bengle extract d. chloroform fraction.

Z. cassumunar extract, hexane fraction, and chloroform fraction significantly increased the active phagocytic cells and phagocytic index (p <0.05). Of the five test results, the highest increase in phagocytic activity was exhibited by the chloroform fraction, as indicated by active phagocytic cells (SFA) = 62.090 ±6.947 and phagocytic index (IF) = 1.638 ±0.079. Meanwhile, the lowest increase was shown by the hexane fraction, with SFA = 27.923 ±2.941 and IF = 1.476 ±0.227. These results are influenced by differences in the compounds of the fractions and *Z. cassumunar* extract. For instance, the hexane fraction only produced three spots with RF values = 0.522, 0.577, and 0.844 during the TLC procedure. Meanwhile, the extract and the chloroform fraction each had five spots with RF values= 0.15, 0.244, 0.522, 0.577, and 0.844.

The increase in phagocytic activity can occur in two ways, namely by the process of oxidative and non-oxidative. Oxidative processes increase the use of oxygen, myeloperoxidase, hydrogen peroxide, and hexose monophosphate that destroy bacteria. Hydrogen peroxide, superoxide anion, and nitric oxide secreted within the phagolysosome generate toxic oxygen metabolites that can be used to kill bacteria. Non-oxidative processes occur due to the influence of various proteins, such as hydrolytic enzymes, cationic proteins, lysozyme, lactoferrin, and nitric oxide synthase (NOS). Nitric oxide synthase can increase NO production from macrophages in the spleen with the help of IFN-γ and TNF-α **(Bermudez and Young, 1989; Ferrari, 2011; Ishimoto et al., 2008)**.

Z. cassumunar is a Zingiberaceae family that has curcumin. Curcumin is known to give antioxidant and immunostimulant effects by increasing T-cell proliferation, natural killer (NK) cell activity, and the activity of NO. One compound marker of *Z. cassumunar* is phenylbutanoid, which contains a phenyl group that initiates antioxidant effects and can support the immune system. Anti-oxidants are often associated with the immunostimulatory potential **(Ak, 2008; Chairul, 2009; Jayaprakasha, Jaganmohan, and Sakariah, 2006; Lu et al., 2008; Taechowisan, Suttichokthakorn, and Phutdhawong, 2018; Yadav et al., 2005)**.

Table 2 The phagocytic activity of the extract and fractions of *Zingiber cassumunar*.

Group	Active Phagocytic Cells (%)	Phagocytic Index
Control	8.731 ±4.080	1.641 ±0.387
n-Hexane Fraction	27.923 ±2.941*	1.476 ±0.227
Chloroform Fraction	62.090 ±6.947*	1.638 ±0.079
Z.cassumunar Extract	39.194 ±1.597*	1.215 ±0.105*

Note: *Showing a significant difference (p <0.05).

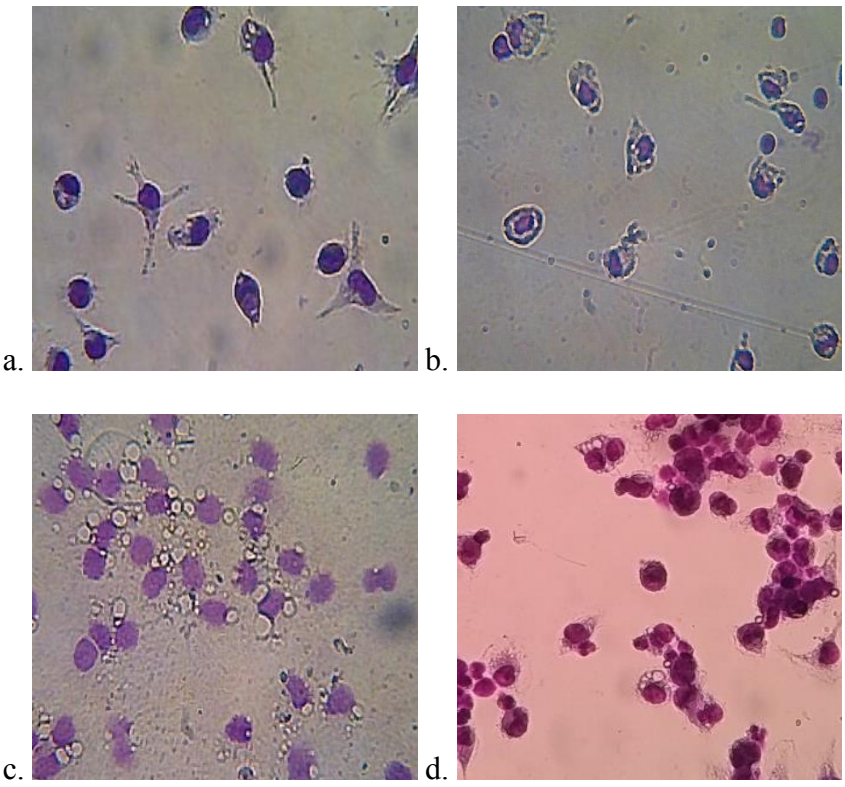

Figure 3 The Phagocytic activity of macrophage cells treated with: a. Normal group, b. Fraction of n-hexane, c. Fraction of Chloroform, d. Bengle extract.

The chloroform fraction was separated using column chromatography, and it produced five subfractions, as shown in Figure 4. These subfractions were then tested for their phagocytic activities, and the results are presented in Table 3. Table 3 shows that F1, F2, F2C, F3, and F4 influenced the phagocytic activity of macrophages. The highest activity was exhibited by subfraction F3 with SFA= 64.333 ±1.780 and IF= 1.598 ±0.059, followed by F4, with SFA= 44.943 ±2.944 and IF= 1.702 ±0.043. Meanwhile F1, F2 and F2C exhibited poor phagocytic activities, as evidenced by their SFA (18.860 ±3.191, 27.077 ±4.482, and 15.749 ±3.026, respectively) and IF (1.608 ±0.19,0 1.646 ±0.113, 1.557 ±0.167.

Table 4 shows that F3 is an active compound that is responsible for the immunomodulatory activity, which increased the activity of the murine macrophage cells. Increased macrophage activity is influenced by the production of NO, the ROI of intra phagosome killer, phagosome acidification, the fusion of phagosomes, and Fe supply reduction. The activation of macrophages can increase phagocytosis due to the increased expression of the gene transcription. The gene of macrophages has specific functions that the same cells cannot perform while in the rest position. Phagocytosis is affected by ROS. Through the ROI, ROS kills antigens that enter macrophages. Superoxide radicals, hydrogen peroxide, hydroxyl radicals, and singlet oxygen belong to the group of ROS. ROS is a highly reactive species that can kill bacteria and destroy the cells. Nitric Oxide Synthase molecules bind the cofactor tetrahydrobiopterin, then this NOS-cofactors bond produces NO, which is highly toxic to bacteria. This pathway is activated by INF-γ and is triggered by the presence of TNF-α, which increases the production of NO in the spleen **(Abbas et al., 2012; Baratawidjaja and Rengganis, 2014; Ismail, Stevenson, and Walker, 2006; Parslow et al., 2001; Tzianabos, 2000)**.

IFN-γ is a potential cytokine macrophage activator. IFN-γ will increase phagocytosis and stimulate the expressions of MHC-I and MHC-II and costimulator APC. IFN work on B cells in the transfer of IgG subclasses that enable FcyR in phagocytes and activate complement. IL-10 inhibits macrophage activity and controls non-specific immune responses and cellular immunity. The main function of IL-10 is to inhibit the production of several cytokines (TNF, IL-1, chemokines, and IL-12) and the function of macrophages in helping the activation of T cells **(Brummer, Hanson, and Stevens, 1988; Lo et al., 2019; Ravindran et al., 2019; Salim, Sershen, and May 2016)**.

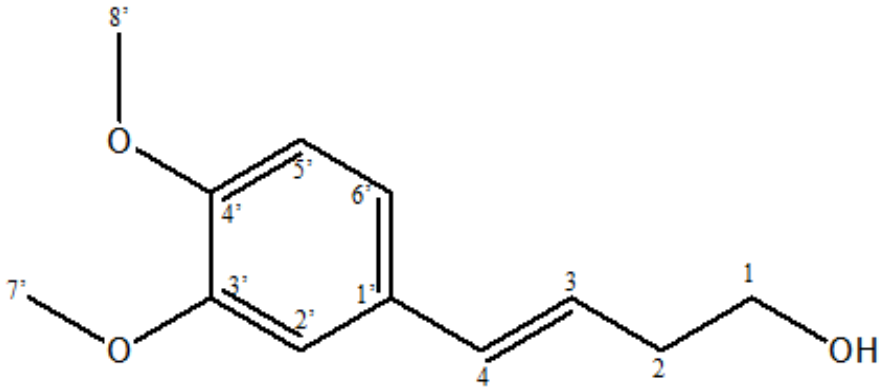

Figure 5 [(*E*)-4-(3',4'-dimethoxyphenyl)but-3-en-1-ol].

TNF is the main mediator in response to a variety of antigens that cause infections. Macrophages are a major source of TNF. TNF has a biological effect that activates neutrophils, macrophages, and monocytes to eliminate the antigen and then trigger vascular cell adhesion molecule, stimulate macrophages to secrete chemokines, induce chemotaxis, leukocyte deposition, and the apoptosis of the inflammatory cells. IL-12 is a major mediator of the early nonspecific immunity against intracellular antigens. The main source of IL-12 is mononuclear phagocytes and activated dendritic cells. The biological effects of IL-12 cause the NK cells and T cells to secrete IFN **(Cavalcanti et al., 2012; Engwerda et al., 2002; Ismail et al., 2006; Salim et al., 2016)**.

The compound [(*E*)-4-(3',4’-dimethoxyphenyl)but-3-en-1-ol] is a form of light green oil with the molecular formula C12H16O3 and C6-C4 carbon framework. Table 4 shows two methoxy groups (-OCH3) at δ 3.85 (s) and 3.87 (s), which were strengthened by the presence of carbon spectra at δ 55.9 and 55.8 ppm. Moreover, aromatic carbon with ortho and meta couplings appeared as three benzene substitutions at δ 6.87 (d, J = 8, 2), 6.77 (d, J = 8) and 6.85 (d, J = 2) and was amplified at the carbon spectra δ 108.8, 111.3, and 119.1 ppm. The protons in H-7 and H-8 showed a high constant coupling of 16, which indicates a trance configuration.

Chairul (2009) suggest that the compound isolated from the identified phenylbutanoid group [(*E*)-4-(3’,4’-dimethoxyphenyl)but-3-en-1-ol] induces a more significant increase in phagocytic activity in in vivo experiments on Swiss Webster male mice than [(*E*)-4-(2', 4',5'-tri-methoxyphenyl)but-3-en-1-ol] and [(*E*)-4-(3',4',1-trimethoxyphenyl)but-3-en-1-ol].

CONCLUSION

Bengle (*Zingiber cassumunar*) has the potential as immunomodulators that significantly increase phagocytic activity. The chloroform fraction has been proven to exhibit the highest phagocytic effects. Meanwhile, the subfraction that has the most substantial phagocytic effect is sub-fraction 3, which is identified as [(*E*)-4-(3',4'-dimethoxyphenyl)but-3-en-1-ol].

AN ANALYSIS OF THE USE OF MARKETING 4.0 PRINCIPLES FOR MANAGING CUSTOMERS RELATIONSHIPS IN MICROBREWERIES IN THE CAPITAL CITY OF PRAGUE

Vendula Kolářová, Eva Kolářová

ABSTRACT
Technological progress also affects the development of marketing, currently known as Marketing 4.0, which is characterized by digitization and indicates a connection with Industry 4.0. With digitization, companies can use a variety of tools and methods to collect useful customer data and then use it. Marketing 4.0 is mainly characterized by the fact that the customer wants to be part of the product development and wants to share her information and opinions and experience on the product. Thanks to the Internet, customers can get all the information from other customers. The aim of this analysis was to verify that microbreweries in Prague use Marketing 4.0, use digitization and adapt to the latest trends in marketing and define what methods they use to manage customer relations. The analysis is suitable for long-term monitoring of the development of this issue. Corresponding conclusions and recommendations for the future were drawn from the research findings.

Keywords: CRM; Marketing 4.0; Microbreweries; Czech Republic; Prague

INTRODUCTION
The trend today is digitalization, which has reached both marketing and other fields. In connection with the fourth technological revolution, i.e. Industry 4.0, Marketing 4.0 was created. Thanks to digitization, many new activities and procedures have been introduced into marketing, mainly thanks to the development of the Internet and social networks, which gave the customer access to information and opinions of other customers. Customers want to be part of the process and share their experiences. **(Jara et al., 2012)**. The number of microbreweries in the Czech Republic is growing every year. At the end of the 19th century, 800 to 1,000 breweries brewed beer in Bohemia and Moravia. A study on microbreweries and tourism marketing was published in 2017, where the author **Dunn and Kregor (2017)** states that the new era of marketing, i.e. the marketing era 4.0, introduced in 2017, was also reflected in the brewing industry. It is mainly thanks to social networks that made microbrewery's communication with customers is important, and this caused strengthening loyalty, sharing information and engaging customers in the brewing process. Moreover, microbreweries should also focus on different alternatives to delivering beer to customers and address the specific needs of their customers **(Dunn and Kregor, 2017)**. In the area of Prague there are 46 microbreweries that are located throughout the city. Some of these microbreweries are in the very center of Prague near Wenceslas Square, such as the Two Cats Brewery, Na Národni Brewery, or U Fleků. Other breweries are located on the outskirts of Prague, such as the Počernický Brewery. Most of these microbreweries have an on-site restaurant where meals are served together with their beer. One of the microbreweries, the Lajka microbrewery, is also unusually connected with coffee. Each of these microbreweries brews its original beer with its original name and original ingredients. As Prague is a frequent tourist destination, microbreweries also use a variety of ways to attract tourists. This especially applies to microbreweries in such destinations where there are many tourists. These tourists are attracted by microbreweries for originally crafted beer, various tastes, and mainly the possibility to buy beer in a PET bottle, in a glass bottle, buy a souvenir, or attend interesting events.

The trend of microbreweries in the Czech Republic is still on hold. In 2018, there were already 451 microbreweries in the Czech Republic and according to current trends the number will increase **(Stratilík, 2018)**. In 2015, there were 330 microbreweries in the Czech Republic experiencing a boom in the field. The top level of the Czech beer boom is out of sight and beer producers themselves claim that they do not compete with each other, and as there is a high demand for beers from microbreweries on the market, these microbreweries can still exist. There is a rather friendly atmosphere among the breweries, and they can also help each other. The only thing that can stop this boom in the field of microbreweries is the lack of hops, which is ordered more than a year in advance **(Ekonom, 2015)**. Compared to Europe, the number of microbreweries is the highest in the

UK, with up to 2378 microbreweries in 2018. The Czech Republic holds the top ten in the number of microbreweries **(Brewersofeurope, 2019)**. There are also large industrial breweries in the Czech Republic, including Plžeňský Prazdroj, Budějovický Budvar, Staropramen, and Zlatopramen **(Pivní.info, 2019)**. Beer as such is one of the most consumed alcoholic beverages in the Czech Republic. 141 litres of beer per citizen were consumed in 2018 **(Kolářová and Kolářová, 2019)**.

To support customer relationship management, microbreweries need to realize the importance of increasing customer loyalty and strengthening their business image. Today, unpredictable customer trends may occur. It is necessary to respond to these trends to keep the company interesting for its customers. This is also crucial for microbrewery businesses **(Porter and Donthu, 2008)**.

Marketing 4.0

The technological development of digital media is a historical necessity. These developments have affected cultural, educational, social and political dimensions, which also affect digital media **(Priyowidodo et al., 2019)**. Developments in technology that have occurred in recent decades have greatly changed the world and also the marketing industry. Thanks to this development, you can be labeled as participants in the age of Marketing 4.0. Today's customers require something EXTRA; they want more to satisfy their needs. Customers are looking for values that are defined by Marketing 3.0 and want to be part of marketing and to be directly integrated with the product. These customers use information technology to share their experience and that is why marketing is not focused on the product but the customers **(Łukowski, 2017)**. Marketing has evolved from Marketing 1.0 to 4.0. Marketing1.0 was focused on the product and on increasing its sales only **(Łukowski, 2017)**. These products were manufactured in rather small numbers and were intended for a large group of customers. The best example is the Ford T strategy designed by Henry Ford **(Fuciu and Dumitrescu, 2018)**. Marketing 2.0 already addressed the needs of customers. There were more products on the market and the customer could choose from and be getting well informed about the products **(Łukowski, 2017)**. Marketing 4.0 was based on technology development and can be defined as meeting the needs and wishes of customers **(Fuciu and Dumitrescu, 2018)**. **Kotler, Kartajaya and Setiawan (2017)** described Marketing 2.0 as being focused on customer and marketing. A turning point occurred in Marketing 3.0, when customers were already people with specific feelings and desires **(Kotler, Kartajaya and Setiawan, 2017)**. Emotions and a kind of emotional marketing were also included in this era of marketing. This was to place consumers on the level of thinking and sentient beings that have certain wishes and values **(Kotler, Kartajaya and Setiawan, 2010)**. Thus, the term Marketing 4.0 is related to the fourth industrial revolution. You can also see this designation in Industry 4.0 **(Drath, Horch, 2014)**. This Marketing 4.0 was introduced in 2017 and according to **Kotler, Kartajaya and Setiawan (2017)**, it combines offline and online marketing. It is a combination of existing marketing and digital elements. These digital elements represent social networks, for example, which can be used as a tool for communication with customers, but also for evaluating and sharing customer opinions **(Nowacki, 2014)**.

Marketing of the new era is also reflected in the marketing of breweries. In the study published by **Dunn and Kregor (2017)** stated that in order to support and develop the brewery, there must be support breweries via social networks, having different alternatives of supplying beer to its consumers, and address the needs of their visitors to secure their reputation and build awareness of the brand in tourism **(Dunn and Kregor, 2017)**.

Customer Relationship Management

There are many definitions in the literature and scientific articles of what Customer Relationship Management means. Customer Relationship Management can also be defined as a method or strategy to increase customer loyalty through communication and information gathering by the company **(Swift 2000)**. Customer Relationship Management is an effective marketing strategy that is a key process that is needed to sustain growth and maintain existing and attract potential customers **(Ližbetinová et al., 2019)**. According to **Parvatiyar and Sheth (2002)**, Customer Relationship Management is considered to be a strategy. This strategy targets particular potential customers that the company wants to acquire. This strategy works only with the support of marketing, customer center and sales. The aim is to bring more added values to the customer.

Payne and Frow (2005) point out that Customer Relationship Management is seen as a direct mail rather than a targeted customer loyalty strategy. With this view, the correct use of Customer Relationship Management may be compromised, as managers often think of loyalty programs or the database created in the Call Center. Thanks to digitization and progress, it is also important to keep in mind the social networks, which today play an important role in terms of customer loyalty **(Holsing and Olbrich, 2012)**.

Microbreweries

The brewery can be distinguished from one another according to the amount of beer that the brewery brews. Breweries can be divided into five categories, which vary according to the annual beer production. Domestic breweries have up to 10 litres of beer per batch.

Table 1 Number of microbreweries in Europen countries **(Brewersofeurope, 2018)**.

Country	No. of microbreweries	Country	No. of microfreweries
Great Britain	2,378	Spain	502
France	1,000	Sweden	332
Germany	824	Denmark	157
Switzerland	818	Austria	129
Italy	693	Portugal	115

These amateur beer enthusiasts are very important in microbreweries, since many of these amateurs may eventually become founders of microbreweries. Other breweries are also microbreweries that have an annual beer production of up to 10,000 hl, a brewery with a restaurant of up to 200,000 hl, regional breweries of up to 500,000 hl and industrial breweries of over 500,000 hl of annual beer production **(Kozák, 2017)**.

The number of microbreweries in the Czech Republic has varied over the years. At the end of August 2018, there were 451 microbreweries **(Stratilík, 2018)**. In comparison with the Czech Republic, in 2017, there were microbreweries in the following European countries (Table 1). Compared to European countries, the Czech Republic was placed 7th in 2017 with 402 microbreweries **(Brewersofeurope, 2018)**.

Like other industries, brewing is developing. Most Czech mini-breweries brew bottom-fermented beer, but there are also many mini-breweries where they experiment in beer production. One of these experiments is spontaneous fermentation, where the spontaneous process requires a completely different approach from microbreweries and puts more emphasis on hygiene **(Stratilík, 2018)**. As such, brewing contributes significantly to the economy. In the EU between the years 2008 and 2013, excise duty on beer of around EUR 10 billion was levied. Compared to the US in 2014, total excise tax and VAT revenues were $ 11 billion **(Ignacio and Higgins 2016)**. In the Czech Republic, the income from an excise tax on beer was CZK 4,775,528 thousand **(State Treasury, 2019)** and in comparison, with the USA in 2014, the Czech Republic's income from excise duty on beer was CZK 4,593,399 thousand **(State Treasury, 2019)**.

Scientific hypothesis

Hypothesis H_0 – More than 80% of microbreweries in Prague use Marketing 4.0 to manage the customer relationship.

Hypothesis H_1 – Less than 80% of microbreweries in Prague use Marketing 4.0 to manage customer relationships.

In view of the fact that a small amount of specific information has been processed on the subject under consideration yet, great attention needs to be paid to the collection and processing of basic data.

Research questions:

- Do microbreweries have their restaurant?
- Do microbreweries use SEO?
- Do microbreweries use social networks?
- Do microbreweries use content marketing?
- Do microbreweries have websites?

MATERIAL AND METHODOLOGY

The article deals with the marketing of microbreweries in Prague. The basic questions dealt with whether microbreweries in Prague have their restaurant, use SEO and other analytical methods, whether they use social networks, have websites, use content marketing, customize products, sell souvenirs, provided restaurant reservations, delivery and whether they use loyalty programs. From a theoretical point of view, microbreweries should also use Marketing 4.0 as part of customer relationship management.

The data were collected using qualitative research, structured interviewing, and interviewing in person at microbreweries in Prague. Thanks to the chosen research methods, the data were obtained, analysed and statistically processed, followed by conclusions and recommendations. The main aim of this work was to find out whether microbreweries in Prague are using Marketing 4.0. for customer relationship management. The research was conducted in October 2019 in microbreweries in the city of Prague.

There are 46 microbreweries in Prague, all of which were included in the research. And this makes this sample complete. Statistical methods were used for complex research sample.

Microbreweries in Prague:

Bubeneč Praha, Cobolis Praha, Dva Kohouti Praha, Hostivař H1 + H2 Praha, Jihoměstský pivovar Praha, Kail Praha, Kbelský pivovar Praha, Klášterní pivovar Strahov, Kolčavka Praha, Ladronka Praha, Lajka Praha, Libocký pivovar Praha, Loď Pivovar Praha, Lužiny Praha, Marina Holešovice, Moucha Praha, Na Lochkově Praha, Pivovar Národní, Nedomlel Praha, Novoměstský pivovar Praha, Ossegg Praha, Pivo Karlín Praha, Pivovar Kunratice – muflon, Pivovar Uhříněves, Pivovarský dům Praha, Počerňák Praha, Počernický pivovar Praha, Řeporyjský pivovar Praha, Spojovna Praha, Suchdolský Jeník, Šedivák Praha, Třebonický rukodělný pivovar, Trilobit Praha, U Bansethů Praha, U Bulovky Richter Pub Praha, U Dvou koček Praha, U Fleků, U Medvídků, U Supa Praha, U tří růží, Victor Praha, Vinohradský pivovar Praha, Vojanův Dvůr Praha**.**

Statistical analysis

Another method we used to reject or not reject the hypothesis H_0 is Pearson's Chi-Squared test. The basic assumption was that 80% of microbreweries use 4.0 marketing to manage customer relationships, focusing on research questions and significance level $\alpha = 0.05$ and conducting a significance test. The critical value of the chi-square at a number of freedoms 4 is 9.49. The calculated chi square value is 9.21. This value is less than the critical value and therefore we do not reject our hypothesis H_0 and reject the hypothesis H_1. For statistical analysis was used Social Science Statistics, the year 2020.

RESULTS AND DISCUSSION

In a complete sample of microbreweries, data were collected concerning the restaurant itself, the use of SEO and other analytical tools, the use of content marketing, product customization, souvenir sales, distribution and the use of loyalty programs.

The first research question was whether microbreweries run a restaurant. Some microbreweries have their restaurant where they brew very well and have a microbrewery only as a supplement.

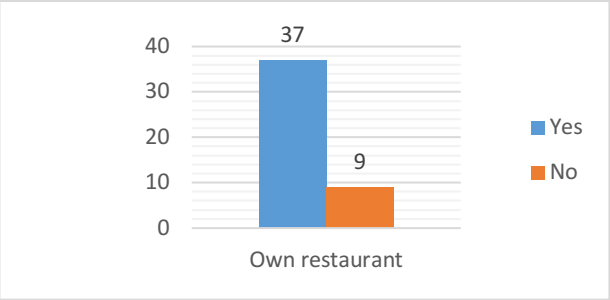

Figure 1 Own restaurant.

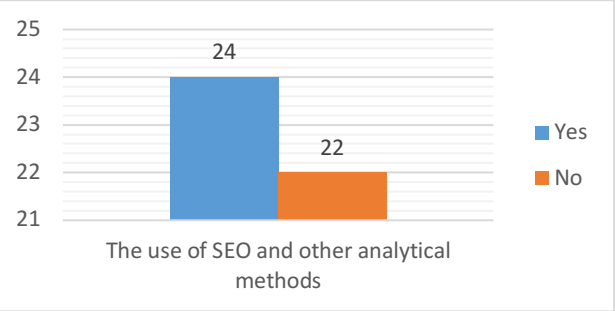

Figure 2 The use of SEO and other analytical methods.

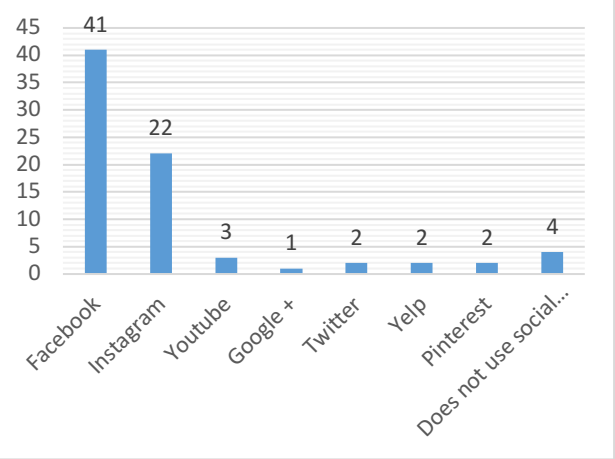

Figure 3 The use of various kinds of social networks.

Some microbreweries only brew beer and do not have a place or restaurant where they can tap their beer. Results are presented in Figure 1. 80.4% of microbreweries have their restaurant where they top their beer and only 19.6% of microbreweries do not own the restaurant or there sell their beer to other restaurants where they top their as well as types of beer.

The use of SEO sites in microbreweries is almost even. Results are presented in Figure 2. 52.1% responded positively that they use SEO on their webpages and also use other analytical methods such as Google Analytics. 47.9% of microbreweries do not use these analytical methods at all. Microbreweries should use these analytical methods to find out important information regarding their customers. SEO is a necessary system for every business owner who has a website **(Berman, Katona, 2013)**. Thanks to SEO, it is possible to improve your website and also have an overview of consumer behavior **(Yang and Ghose, 2010)**. This allows microbreweries to find out what customers are doing and looking for on the web.

Another part of the research concerned social networks, i.e. what social networks microbreweries use. The results are presented in Figure 3. Most microbreweries use social network Facebook. The second most used social network is Instagram. Four of the microbreweries surveyed do not use social networks at all. For these microbreweries, the website is also at a poor level. Some microbreweries also use a social network to share YouTube videos. Most microbreweries combine social networks Facebook and Instagram. According to **(Clark et al., 2017)** if social networks are maintained and communication is maintained, social networks are very beneficial for business. Here you can give events that happen in microbreweries but also photos and more. It is therefore important that microbreweries communicate via social networks.

As for the use of social networks it was also examined whether microbreweries use content marketing. The results are presented in Table 2. The research found that five microbreweries do not use content marketing at all. Other microbreweries as for the use of this type of marketing, hire a special person to take care of their social networks or manage to create this content that is of interest to their customers themselves. The use of content marketing was evaluated on a five-point scale, with 1 - not fully utilized and 5 – fully utilized. **Rowley (2008)** argues that content marketing is particularly important for strategy and marketing communications. Thanks to this content marketing we can use it well in communication with customers. According to research, most microbreweries use content marketing, which is good for their communication with the customer.

The statistical processing shows that the arithmetic mean is 3.217 and occurs in the range of "neither use nor uses" and "rather uses". On a scale of 1 to 5, the median is 3.

Table 2 Using content marketing on scale.

	1 - not fully used	2 - rather not used	3 - neither uses nor uses	4 - rather uses	5 - fully utilized
Content marketing	5	8	15	8	10

Table 3 Microbrewery websites rated on scale.

	1 - completely outmoded	2 - rather outmoded	3 -neither modern nor modern	4 - rather modern	5 - completely modern
Website	5	8	10	13	10

The standard deviation is 1.478 and indicates that most microbreweries do not deviate from the average 1.478. Another part of the research dealt with the website. All microbreweries surveyed have websites. The results are presented in Table 3.

The research analysed web pages of microbreweries in terms of modernity and suitability for customers. The website was ranked on a five-point scale, with 1 – completely non-modern and 5 – completely modern. For microbreweries that lively communicate on social networks, the website was "very" or "completely" modern. For microbreweries that do not communicate so often on social networks, or their posts are not of interest to users, the website is more neutral or out of fashion.

The statistical processing shows that the arithmetic mean is 3.326 and occurs in the range of "neither modern nor modern" and "rather modern". On a scale of 1 to 5, the median is 4. The standard deviation is 1.857 and indicates that most microbreweries do not deviate from the average by 1.857. 21.8% of microbreweries on the scale were rated as "completely modern" and "neutral". Most microbreweries, namely 28.2% of microbreweries, were rated as rather modern. All websites provide contacts, opening hours on where the microbrewery can be found, and in many cases, a menu is also provided.

The graph shows the evaluation of the other questions examined.

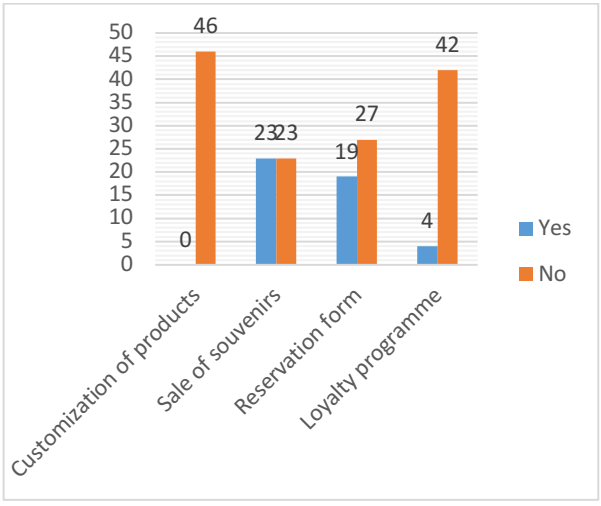

Figure 4 The evaluation of the remaining questions.

In the last part of the inquiry, the microbreweries were asked whether they customize products, sell souvenirs, whether they have a reservation form for a restaurant and whether they offer a loyalty program. The results are presented in Figure 4. None of the microbreweries responded positively to the customization of their products. The brewing process depends on the demand and the brewer, but microbreweries do not include services such as customized labels or beer on the client's request. 50% of microbreweries sell their souvenirs. The most interesting souvenir is a cycling jersey of the microbrewery Hostivař H1, which is sold in the style of beer with the logo of the microbrewery. The most frequented souvenirs are glasses with the brewery logo, as well as trays, pencils, or baseball caps. Restaurants having a microbrewery as a supplement to the restaurant do not usually have such souvenirs; people can only buy their beers bottled into PET bottles. Souvenirs in the travel industry have a strong symbolic value associated with pleasant travel experiences and memories **(Baizerman et al., 1994)**. As beer tourists can buy a souvenir, they can also take away something that reminds them of a microbrewery. According to **(Collins-Kreiner and Zins, 2011)**, souvenirs can affect the tourist experience and enhance the emotion that can affect the tourist.

A reservation form is a form that can be used to make a restaurant reservation on a website without having to call the restaurant just by filling in the name, time, contact and number of people and the microbreweries arrange a table for the hour. If the restaurant is already full, they call the contact person to inform that the reservation is no longer possible to be made. None of the microbreweries have an interactive restaurant map where the customer could choose the specific place they wish to have. Only four microbreweries use the loyalty program. The loyalty programs for all these microbreweries work on the principle of points. They earn points for the beer they drink, and they can either buy a souvenir or beer for those points. To support customer relationship management, microbreweries need to realize the importance of increasing customer loyalty and enhancing its business image. Today, unpredictable customer trends can occur. It is necessary to respond to these trends to keep the company interesting for its customers. This is also crucial for microbrewery businesses **(Porter and Donthu, 2008)**. Microbreweries in Prague use various possibilities to increase customer loyalty. In particular, the sale of souvenirs. These loyalty programs have only 4 microbreweries. Youjae Yi and Hoseong Jeon report in the Journal of the Academy of Marketing Science that loyalty programs are important for perceived value and brand loyalty **(Yi and Jeon, 2003)**. According to **(Zakaria et al., 2014)** is an important relationship between loyalty program and customer satisfaction, loyalty, and customer satisfaction, and they also work against the customer's transition to competition. As already mentioned, microbreweries do not prefer these loyalty programs yet.

The trend of microbreweries is still growing and as **Stratilík et al. (2018)** said, microbreweries will continue to grow. Because the microbreweries can feed themselves and there is a demand for the beer that is brewed in microbreweries, this boom has no end. The only thing that can stop microbrewery is the lack of hops, which is ordered more than a year in advance **(Ekonom, 2015)**. There is also a boom in microbreweries in the United States; from 8 to 2768 **(Moore, Reid and McLaughlin, 2016)**. The boom of microbreweries is not limited to Europe, but also other countries. As in Britain, where the number of micro-breweries is increasing, and microbreweries gain a larger market share **(Cabras and Bamforth, 2016)**. It can be argued whether microbreweries with such growth rates compete with large breweries in the future.

When the research questions are included in the statistical processing, we get to the average use of Marketing 4.0 at 84.88%, thus not rejecting the hypothesis H_0. To not reject or reject the hypothesis H_0, it is assumed that more than 80% of microbreweries use Marketing 4.0 and $\chi 2$ chi-square statistic has been used. The critical value of the chi-square $\chi 2$ at the number of freedoms 3 is 9.21. This value does not reject our hypothesis H_0 and rejects the hypothesis H_1.

Recommendation

Today, there is a boom in food delivery applications. Some microbreweries, but a relatively small part, use the option of delivery via the Dámejidlo.cz or Uber applications, but through these applications only food from the restaurant can be ordered. Microbreweries should extend their offer to the distribution of beer products. For example, in the Damejidlo.cz application, customers can only order a beer in PET bottles, or special large sets, such as a celebration.

Several microbreweries have poor website status. In today's digital era, the microbrewery web presentation should be a calling card for a new potential customer and an existing customer, too. For these microbreweries, it would be advisable to have a professional form of the website with SEO for search engines.

Three of the microbreweries bought an application for their smartphones, where the current menu, phone contacts, and information about the microbrewery are available. In some applications, there are also updates and links to social networks. None of these microbreweries have loyalty points that could be maintained in the mobile app. The users would log in to this app and be able to monitor the status of their points which they would receive for drinking beer and could choose their reward either in the form of free beer or souvenirs directly in the application.

The microbreweries, which are in the center of tourism in Prague, offer tours of their microbreweries. However, the microbreweries that are located in parts of Prague where tourists do not travel much do not organize these tours or organize them in exceptional cases only. For local customers who drink beer from the local microbrewery, it might be interesting to look at the microbrewery, or link it to, for example, a newly brewed type of beer.

CONCLUSION

The article was focused on the application of Marketing 4.0 in microbreweries in Prague. In the introduction, literary research was conducted, which was an introduction to the issues of Marketing 4.0, microbreweries, and CRM. The research surveyed 46 microbreweries located in Prague by personal interviewing, structured interviewing, and interviewing data. These data were processed, analysed and subsequently recommendations and formulated conclusions were made.

The article set out scientific questions that were answered by microbreweries about their restaurant, the use of SEO, social networking, content marketing, and websites. Over 80% of the microbreweries have their restaurant where customers can order something to drink or eat.

Over 52% of the microbreweries use SEO and other analytical methods. Microbreweries use social networks, especially Facebook and the second most used social network is Instagram. Two of the microbreweries also use the social network Pinterest. On these social networks, microbreweries post messages containing photographs of food, events that are going to be in the microbrewery, or photographs from the microbrewery background.

All microbreweries have websites that have been rated on a five-point scale. Some microbreweries have outdated and old websites. Other microbreweries have very modern and new websites. Three microbreweries have purchased mobile applications for their customers, where they can find out the current menu and news.

When the research results are included in the statistical processing of research questions, we get to the average use of Marketing 4.0 at 84.88%, thus not rejecting the hypothesis H_0. Not to reject or reject hypothesis H_0, it is assumed that more than 80% of microbreweries use Marketing 4.0 and a chi-square statistic has been used. The critical value of the chi-square at the number of freedoms 3 is 9.21. This value rejected the H_0 hypothesis and rejects the H_1 hypothesis.

CONSUMPTION OF FOOD IN THE EU BY THE DEGREE OF URBANIZATION: DATA VISUALIZATION AND CLUSTER ANALYSIS OF THE EU SAMPLE

Lenka Maličká

ABSTRACT

This paper examines the consumption of one of the COICOP classes – food and non-alcoholic beverages – by the degree of urbanization on the sample of EU countries in three periods – 2005, 2010, and 2015. The share of this class in total consumption of cities, towns, and suburbs and rural areas presents the second largest item of the total consumption of all structures in question. They examined the key variable creates an input to the analysis stated in the paper. First, the data visualization is realized by creating maps of scaled consumption of food and non-alcoholic beverages in cities, towns, and suburbs and rural areas in the three periods – 2005, 2010, and 2015. The spatial distribution of data shows, that higher shares of consumption of food and non-alcoholic beverages are obtained in CEE and southern countries in all structures and all periods. Considering that consumption of food and non-alcoholic beverages is negatively correlated with GDP per capita or household expenditure per capita it is possible to conclude that countries with lower levels of GDP per capita spend more on goods of daily use. Second, based on k-means clustering, cluster analysis is stated. Similarities between EU countries in the consumption of food and non-alcoholic beverages by the degree of urbanization and with respect to socio-economic conditions are investigated. Clusters are made for all three monitored periods. In 2005 and 2010 five clusters were identified, in 2015 their number has been reduced to four. Similarities between EU countries in the consumption of food and non-alcoholic beverages by the degree of urbanization change through time. The delayed effect of the financial crisis may explain observed changes. The obvious relocation of countries is evident when comparing clusters in the period 2010 and 2015. Besides it, the most stabile cluster is the cluster, which contains core EU countries.

Keywords: city; suburb; rural area; cluster analysis; COICOP

INTRODUCTION

Currently, tendencies towards the growth of cities, towards the urbanization in the European Union (EU) countries and global terms are evident. The importance of cities relies on the concentration of GDP, work places, and social and cultural infrastructure. On the sample of EU countries, the paper compares a very important part of consumption – consumption of food and non-alcoholic beverages by the degree of urbanization in EU countries. Consumption of food is an inevitable part of human consumption. In EU countries, in 2005, 2010 and 2015 it creates in average 16.1% of the total consumption of cities, 17.6% of the total consumption of towns and suburbs and 19.4% of the total consumption of rural areas (respecting the classification of consumption known as the Classification of individual consumption by purpose, abbreviated as COICOP, for more details see Table 1) **(European Commission, 2019a)**. Besides consumption related to housing, water, electricity, gas, and other fuels, it presents one of the highest items of consumption at all degrees of urbanization. Noticeably, it varies by the degree of urbanization.

Currently, the field of urbanization is widely examined by empirical evidence. **Balk et al. (2018)** mention that most of the future population growth will take place in cities. However, the movement to the cities and their attraction is discussed in an earlier paper of **Yap (1977)**. Since then, cities became a focus of research. The size and prosperity of cities are stressed by **Batty (2011)**, the "New science of cities" is presented in **Batty (2013)**.

However, the urbanization is often examined in connection with economic performance. According to **Bertinelli and Black (2004)**, urbanization and economic growth are positively linked to each other. But as **Poelhekke (2011)** stresses, the urbanization can accelerate even under the worsening economic conditions due to rural-urban migration. Similarly, **Chen et al. (2014)** conclude that expected economic benefits from accelerated urbanization are not obtained in certain cases. They identify a group of countries where the relationship between the economic growth and growth of urbanization is not statistically significant. **Jedwab, Christiaensen, and Gindelsky (2017)** focused on such terms as rural push and urban pull factors in connection with the rural-urban migration. They deliberate over the third factor influencing

the rapid urbanization, urban push factor, which covers the rapid internal urban population growth. The large body of scientific papers is dedicated to the impact of further urbanization on the environment, e.g. **Borck and Pflüger (2019)**, **Yazdi and Dariani (2019)**, **Raheem and Ogebe (2017)** or **Marlier et al. (2016)**.

The European Commission (2019b) monitors the urbanization at the global and EU levels. Expected results of urban sprawl (continuing urbanization) describe a situation, when the urban population reaches 60% by 2030 and 68.4% by 2050. The economic power of cities is broadly discussed because it is estimated that they generate 80% of all economic growth. However, the topic of urbanization in Europe has been a point of interest for a long time. **Enyedi (1990)** mentions that East-Central European countries (socialistic countries) replicated the global process of urbanization, but it was influenced by specific factors related to their history and partisan ideology. Urban sprawl in the European Union was investigated by **Patacchini et al. (2009)**. Urban population trends are discussed in **Kabisch and Haase (2011**). Growth of cities in EU countries in the period of 1990 – 2000 and 2000 – 2006 was investigated by **Haase, Kabisch and Haase (2013)**.

Consumption of food in EU countries is an object of many papers, and it is monitored by the European Commission. The convergence of consumer attitudes to food in the EU was examined in **Trail (1998)**. Since then, many research papers with research objects related to food consumption in EU countries were published (e.g. **Dudek and Koszela, 2013**; **James, Lomax and Birkin, 2019)**. European food consumption databases are under scrutiny in **Le Donne et al. (2011)**. European Food Safety Authority **(EFSA, 2019)** collects data on food-related data. Household expenditure by the consumption purpose (COICOP) is provided by Eurostat **(European Commission, 2019c)**. Thus, even though consumption of food and non-alcoholic beverages by the degree of urbanization is monitored in EU countries (e.g. in the **European Commission, 2019a)**, it is not under the systematic surveillance of empirical evidence.

The paper's motivation is driven by the evidently increasing role of urbanized structures. The paper aims to elicit, if there are any differences in food consumption in differently urbanized structures of EU countries. Correspondently, using the cluster analysis, EU countries are divided into more homogenous groups based on consumption of food by the degree of urbanization and by selected macroeconomic variables in the three periods (2005, 2010 and 2015), from which one is linked to the period immediate to a recent financial crisis.

Paper is organized in the following manner. After the part Introduction, scientific hypotheses of research are listed. Next, the chapter Material and Methodology explains the data and instrumentation used in the paper. Results and Discussion present and discuss results obtained in the provided analysis. The paper is ended by Conclusion and References.

Scientific hypotheses

Consumption of food and non-alcoholic beverages increases with the decrease in the degree of urbanization.

In cities, the share of consumption of food and non-alcoholic beverages in total consumption is lower than in other structures.

Similarities between EU countries in the consumption of food and non-alcoholic beverages by the degree of urbanization change in respect of the recent financial crisis.

The financial crisis in 2009 influenced the consumption of all structures at all degrees of urbanization. Correspondently changes contain clusters.

Table 1 Consumption shares of EU countries (in %) on the basis of COICOP classification and by the degree of urbanization.

COICOP	Cities	Towns and suburbs	Rural areas
Food and non-alcoholic beverages	16.1	17.6	19.4
Alcoholic beverages, tobacco and narcotics	2.5	2.6	2.7
Clothing and footwear	5.3	5.3	5.0
Housing, water, electricity, gas and other fuels	29.5	27.2	26.7
Furnishings, household equipment and routine household maintenance	5.0	5.3	5.3

Note: Averages are computed for 2005, 2010 and 2015 employing all EU countries; light grey indicates the lowest values, dark grey indicates the highest values, unknown consumption is excluded.

MATERIAL AND METHODOLOGY

The research involved various types of data, but all of them are extracted from the Eurostat database. The three degrees of urbanization are distinguished. The most urbanized are cities. The degree of urbanization diminishes in towns and suburbs and the rest is concerning rural areas. Data related to consumption by the degree of urbanization are covered in **(European Commission, 2019a)**. Data mentioned hereinbefore are classified according to the COICOP. Here, data are collected in five-year intervals. Hence, years 2005, 2010 and 2015 are employed in research. This is mainly influenced by the incomplete database in previous years and thus the aim to minimize the occurrence of missing data in the panel. For the research purpose, the most important of them are data on the share of food and non-alcoholic beverages consumption in total consumption of all types of urbanization structures. The socio-economic conditions of EU countries are expressed employing the data on GDP, household expenditure, unemployment rate, inflation rate and country size (population). These data are covered in **(European Commission, 2019d)** and **(European Commission, 2019e)**. GDP at market prices is expressed in per capita terms. Final consumption expenditure of households is expressed in per capita terms, too. The annual average of the unemployment rate is expressed as the percentage of the active population. Inflation is based on the food price monitoring tool, expressed as Harmonized Index of Consumer Prices (HICP, 2015 = 100) for the COICOP class of Food in the last month of the respective period (2005M12, 2010M12 and 2015M12). Country size employs the variable of the total population on 1 January.

Statistical analysis

Respecting the paper goal, two main scientific instruments are used to provide the analysis of food and non-alcoholic beverages consumption in EU countries.

First, the creation of maps serves to a visualization of the differences in the spatial distribution in food consumption by the degree of urbanization in EU countries. Maps are created using the R program for statistical computing and graphics **(R Development Core Team, 2019)**. It is a free software environment. The latest R version 3.6.1., released on July 5, 2019, is employed in the research. Packages rgdal, shape and map tools serve to the map creating.

Second, cluster analysis is realized to find similarities/differences between the consumption of food and non-alcoholic beverages by the degree of urbanization in EU countries in 2005, 2010 and 2015. Cluster analysis is provided in the R version 3.6.1, packages class, cluster, pvclust, mclust, stats, graphics, maps, LLAhclust and shapefiles. In general, the method of clustering objects into groups (clusters) is based on the principle of obtaining the highest possible similarity inside the group and the lowest similarity between different groups. In this paper, the method of k-means clustering, introduced by **MacQueen (1967)**, is used. It is an iterative optimization method, which starts from an initial division of object into *k* clusters. In a k-means clustering, the number of centroids is defined in the expertise of the author. Consequently, the number of centroids, which present a real or imaginary center of cluster, reduces the number of clusters. After the definition of the number of centroids, Euclidean distances between each object and centroids are computed. The object is allocated to the nearest initial centroid. In the next step, a new centroid for each cluster is computed. In a stepwise procedure, distances between each object and each centroid are computed again. In case a certain object is closer to another centroid, as it was in the previous step, it is shifted to another cluster. Thus, objects in clusters are rearranged. The aforementioned procedure is repeated until the rearrangement of clusters stops. The k-means clustering depends on the order of the object, thus the locally optimal solution is achieved. The k-means clustering is in details processed e.g. in **Rokach and Maimon (2005)**, **Stankovičová and Vojtková (2007)** or **Řezánková, Húsek and Snášel (2009)**.

RESULTS AND DISCUSSION

Analysis based on data visualization (maps)

The expectation that in cities the share of consumption of food and non-alcoholic beverages in total consumption is lower than in other structures has been confirmed. The combination of data extracted from **(European Commission, 2019a)** and **(European Commission, 2019c)** is projected in Figure 1. It contains nine maps created for the three degrees of urbanization and three periods.

In 2005, results show that the share of consumption of food and non-alcoholic beverages on total consumption of cities is similar to towns and suburbs, but is lower than in rural areas. It is more evident in the case of Central and East European countries (CEE) of the EU and southern countries of the EU (e.g. Italy, Spain and Portugal).

In 2010, the difference between cities and lower degrees of urbanization becomes more obvious. Higher shares of consumption of food and non-alcoholic beverages are observed in towns and suburbs and rural areas. Again, as it is in a previous period, this is observable in CEE and southern countries of the EU (including France).

In 2015, the distinction between cities, towns and suburbs and rural areas is the most obvious. The given hypothesis has also been confirmed in this case when the share of consumption of food and non-alcoholic beverages in total consumption of cities is lower than in towns and suburbs, and also than in rural areas. Consumption of food and non-alcoholic beverages increases with the decrease in the degree of urbanization. The spatial distribution of consumption of food and non-alcoholic beverages intensity emulates the results reached in 2005 and 2010.

In general, results point to the current advanced socio-economic development of cities described in **Bertinelli and Black (2004)**, **Patacchini et al. (2009)**, **Kabisch and Haase (2011)**, **Haase, Kabisch and Haase (2013)** or **Balk et al. (2018)**. Supposing that the economic activity concentrated in cities leads to higher living standards of the city population, the share of COICOP items on total consumption (see Table 1) emulates the expected behavior of developed societies. In comparison with lower degrees of urbanization, they spend more money on recreation, education, hotels and restaurants and housing including fuels.

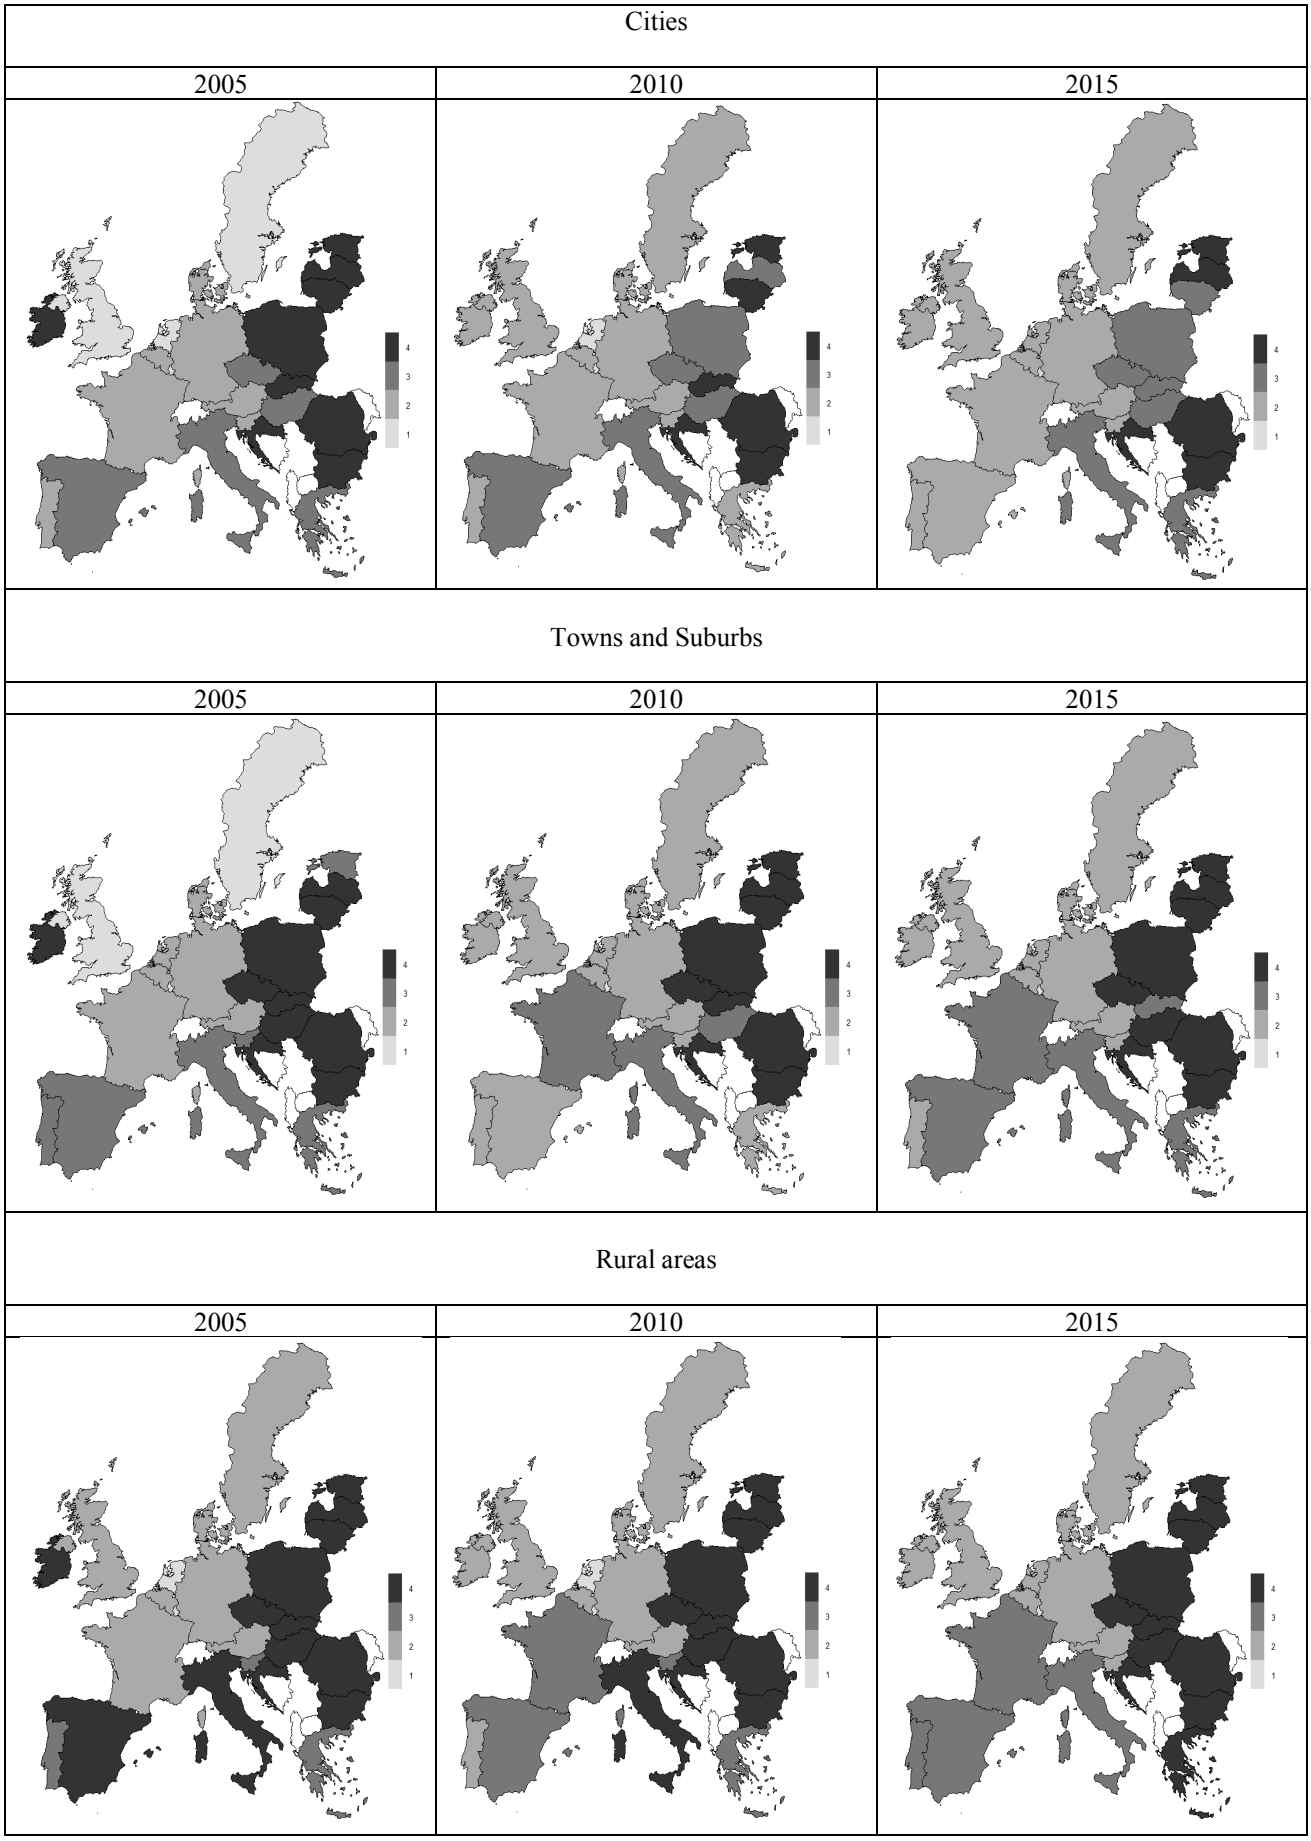

Figure 1 A comparison: Intensity of food consumption by the degree of urbanization in 2005, 2010 and 2015. Note: Scale: (1) the lightest shadow of grey refers to values lower than 0.1 (or 10%), (2) refers to 0.1 – 0.15, (3) refers to 0.15 – 0.2, (4) the darkest shadow of grey refers to values higher than 0.2.

Besides it, certain other common tendencies may be recognized. The intensity (share in total consumption) of food and non-alcoholic beverages consumption is higher in CEE countries. It may be explained by GDP, income and living standards in CEE countries, which, in fact, overcame the transition in the last decades. As mentions by **Enyedi (1990)**, CEE countries "replicated" the trend of urbanization. The urban sprawl mentioned in **Patacchini et al. (2009)** or the growth of cities, examined by **Kabisch and Haase (2011)** and **Haase, Kabisch and Haase (2013)** are present in these countries, too. However, a certain delay in the level of economic development in comparison with the core EU countries is evident. Higher values of the food and non-alcoholic beverages consumption in mentioned countries are still preferred to goods and services of no daily pattern consumption.

Cluster Analysis

Results of cluster analysis present clusters of EU countries, which are homogenous in consumption of food and non-alcoholic beverages by the degree of urbanization (cities, towns and suburbs and rural areas), GDP per capita, household expenditure per capita, unemployment rate and inflation on food. Table 2 displays the correlation coefficients of the mentioned variables.

Using the k-means clustering, EU countries are clustered into five clusters in 2005 and 2010 (see Figure 2 and Figure 3) and into four clusters in 2015 (see Figure 4).

The content of clusters in 2005 is the following:

1) Poland, Slovakia, Croatia, Romania, Latvia, Lithuania, Bulgaria.
2) Czechia, Estonia, Hungary, Malta, Slovenia.
3) Germany, France, Italy, United Kingdom.
4) Belgium, Netherlands, Sweden, Finland, Austria, Cyprus, Denmark, Luxembourg.
5) Spain, Portugal, Greece, Ireland.

The content of clusters in 2010 is the following; relocated countries are highlighted in italics:

1) Poland, Slovakia, Croatia, Romania, Latvia, Lithuania, Bulgaria, *Estonia.*
2) Spain, Portugal, Greece, Ireland.
3) Belgium, Netherlands, Sweden, Finland, Austria, Cyprus, Denmark, Luxembourg.
4) Germany, France, Italy, United Kingdom.
5) Czechia, Estonia, Hungary, Malta, Slovenia.

The content of clusters in 2015 is the following; relocated countries are highlighted in italics:

1) Belgium, Netherlands, Sweden, Finland, Austria, Denmark, Luxembourg, *Ireland.*
2) Spain, Portugal, Greece, *Slovenia, Cyprus.*
3) Poland, Slovakia, Croatia, Romania, Latvia, Lithuania, Bulgaria, *Malta, Czechia, Estonia, Hungary.*
4) Germany, France, Italy, United Kingdom.

The hypothesis that similarities between EU countries in the consumption of food and non-alcoholic beverages by the degree of urbanization change through time has been confirmed. The most significant differences are observable comparing the years 2010 and 2015. The influence of the financial crisis in 2009 may be observed in the following period of 2015 when the economic recovery brings certain rearrangements in comparison with the period before the financial crisis (2005). Correspondent changes in the content of clusters reflect the reorganization of results.

Table 2 Correlation matrix of food consumption by the degree of urbanization (cities, towns and suburbs, rural areas) and selected macroeconomic indicators.

	Cities	**Towns and suburbs**	**Rural areas**	**GDP pc**	**Household Expenditure pc**	**Unemployment rate**	**Inflation on food (HICP)**
Cities	1	0.9535	0.9504	-0.7614	-0.8415	0.2729	-0.2269
Towns and suburbs		1	0.9695	-0.7692	-0.8566	0.2548	-0.1737
Rural areas			1	-0.7549	-0.8439	0.2737	-0.2241
GDPpc				1	0.9185	-0.3657	0.2800
Household Expenditure pc					1	-0.3422	0.3166
Unemployment rate						1	0.1512
Inflation on food (HICP)							1

Note: Correlation coefficients; using the observations 1:1 – 28:3; 5% critical value (two-tailed) = 0.2146 for n = 84.

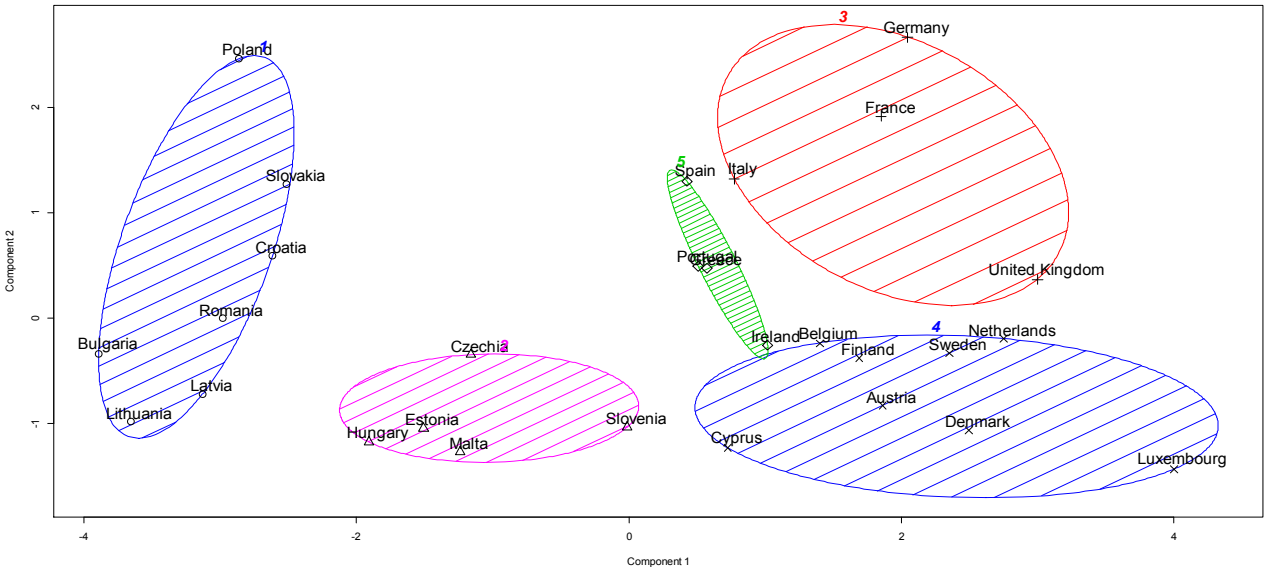

Figure 2 Clustering EU countries in 2005. Note: k-means clustering.

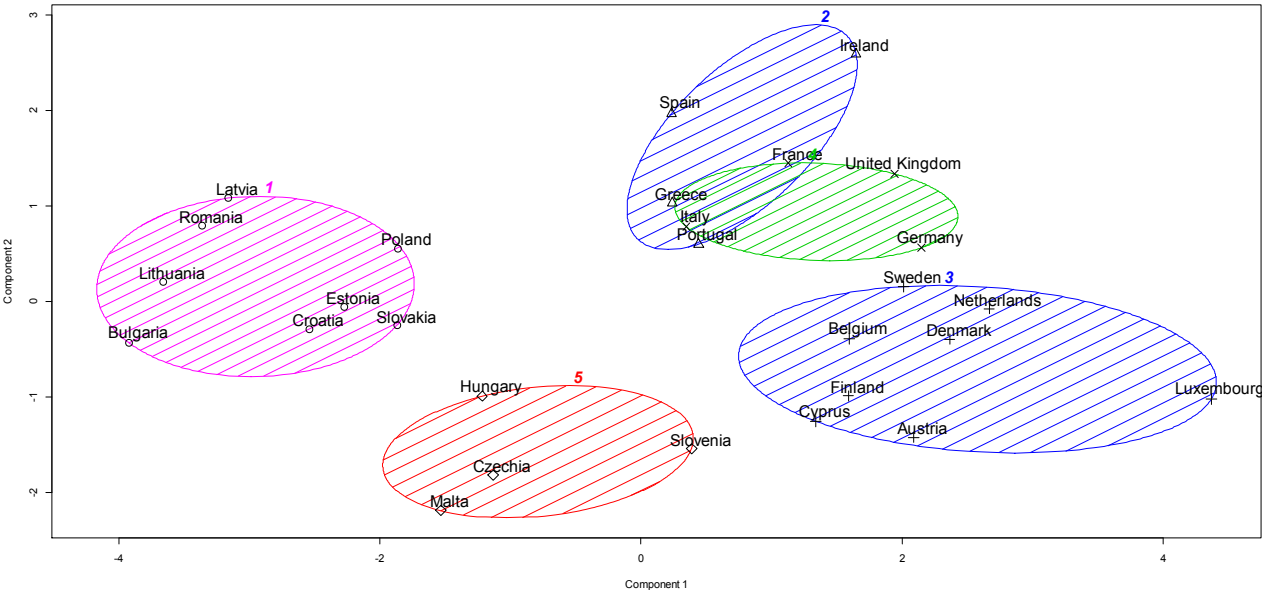

Figure 3 Clustering EU countries in 2010. Note: k-means clustering.

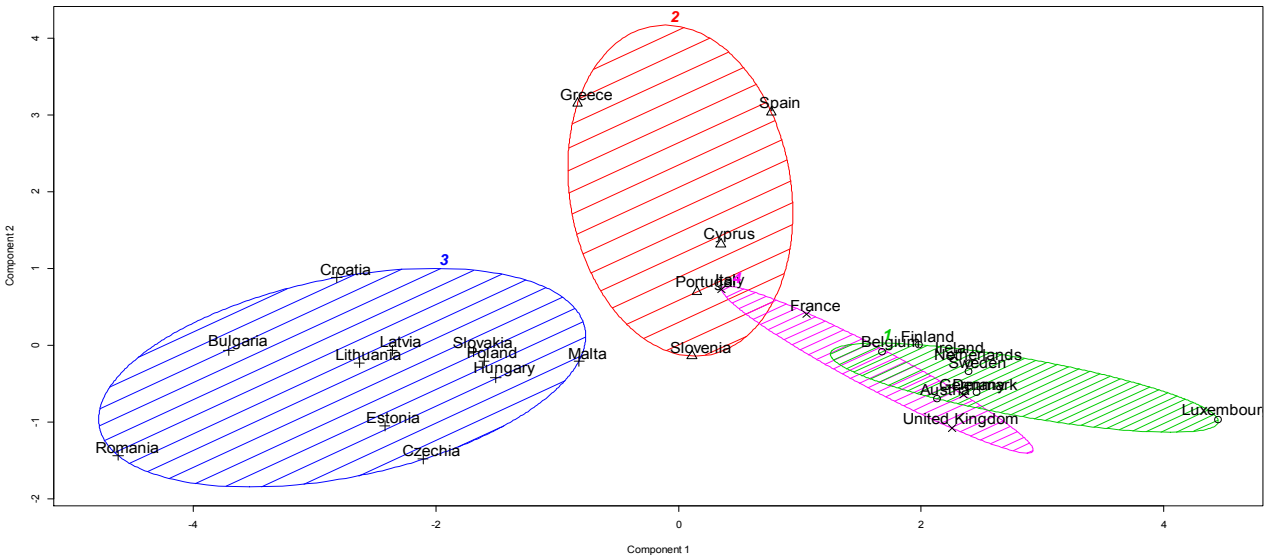

Figure 4 Clustering EU countries in 2015. Note: k-means clustering.

Comparing periods 2005 and 2010, clusters seem to be stable, without evident relocation of countries. Only Estonia moved from the cluster of Czechia, Estonia, Hungary, Malta and Slovenia (2005, cluster 2) to cluster of Poland, Slovakia, Croatia, Romania, Latvia, Lithuania and Bulgaria in 2010 (2010, cluster 1).

In 2015 obvious relocation of countries may be observable. First, contrary to periods 2005 and 2010, four clusters are created. Hence, in 2015 two clusters joined to one (2015, cluster 3). The rest of the clusters stayed almost unchanged.

The most stable cluster is cluster, which contains core EU countries (Germany, France, Italy and the United Kingdom). It remains without any changes.

Ireland moved from the cluster of Spain, Portugal, Greece and Ireland (2010, cluster 2) to cluster of Belgium, Netherlands, Sweden, Finland, Austria, Denmark and Luxembourg (2015, cluster 1).

Slovenia moved from the cluster of Czechia, Estonia, Hungary and Malta (2010, cluster 5) to cluster of Spain, Portugal and Greece (2015, cluster 2).

Cyprus moved from the cluster of Belgium, Netherlands, Sweden, Finland, Austria, Cyprus, Denmark and Luxembourg (2010, cluster 3) to the cluster of Spain, Portugal and Greece (2015, cluster 2).

Clusters presented in Figure 2, Figure 3 and Figure 4 correspond approximately to 77% of the variability of the analysed problem.

Chen et al. (2014) examined the worldwide urbanization by comparing the year 1980 and 2011. According to their results, current EU member countries did not overcome a dramatic wave of urbanization when comparing e.g. to China or Central Africa. At the base of Figure 1, it is obvious that the intensity of the consumption of food and non-alcoholic beverages changed in the cities predominantly. This is observable in 2015. The relocation of countries in the cluster analysis (see Figure 2, Figure 3 and Figure 4) is thus importantly influenced by other variables of macroeconomic nature extracted from **(European Commission, 2019d)** and **(European Commission, 2019e)**. As many of the created clusters are sensitive to changes in macroeconomic conditions, the stabile cluster of core EU countries resists external shock in the form of a financial crisis.

Research on household consumption in EU countries provided by **Dudek and Koszela (2013)** points to certain accordance with the results of the cluster analysis. These authors mention similarities between the Czech Republic and Estonia (in this research both involved in cluster 3 in 2015), Cyprus, Greece and Portugal (cluster 2 in 2015) or Poland, Hungary and Slovakia (the cluster 3 in 2015). Although the field of food consumption is not so rarely employed to the researches (mainly as the COICOP element, e.g. **Dudek and Koszela, 2013** or **James, Lomax and Birkin, 2019**), the connection of the consumption of food and degree of urbanization stays unique.

CONCLUSION

Tendencies towards urbanization are observable all over the world. The increased role of cities is evident also in the EU. This paper examines the consumption of the COICOP class – food and non-alcoholic beverages by the degree of urbanization on the sample of EU countries. As data shows, the share of an examined class of COICOP in total consumption of cities, towns, and suburbs and rural areas presents the second largest item of the total consumption of all structures in question.

This paper examines two scientific hypotheses. First, the consumption of food and non-alcoholic beverages increases with the decrease of urbanization degree. For this purpose, data visualization is employed. Maps are created based on scaled consumption of food and non-alcoholic beverages in cities, towns, and suburbs and rural areas in the three periods – 2005, 2010, and 2015. Nine maps are created. The spatial distribution of data shows that higher shares of consumption of food and non-alcoholic beverages are obtained from CEE and southern countries in all structures and all periods. Considering that consumption of food and non-alcoholic beverages is negatively correlated with GDP per capita or household expenditure per capita, it is possible to conclude that countries with lower levels of GDP per capita spend more on goods of daily use. Finally, in this case the hypothesis has been confirmed. In cities, the share of consumption of food and non-alcoholic beverages in total consumption is lower in comparison with other structures.

Second, the scientific hypothesis stresses the potential change of similarities between EU countries in the consumption of food and non-alcoholic beverages by the degree of urbanization in respectthe of recent financial crisis. To this purpose, the cluster analysis is provided in the research based ons of k-means clustering, similarities between EU countries in the consumption of food and non-alcoholic beverages by the degree of urbanization and with respect to socio-economic conditions are investigated. However, the inter-period comparison of cluster constitution (clusters are made for the all three monitored periods) is made. Obtained results show that similarities between EU countries in consumption of food and non-alcoholic beverages by the degree of urbanization change through the time. Also in this case the scientific hypothesis has been confirmed. The delayed effect of financial crisis may explain observed changes. Obvious relocation of countries is evident when comparing clusters in period 2010 and 2015. Besides it, the most stabile cluster is a cluster, which contains core EU countries (Germany, France, Italy and the United Kingdom).

SHELF LIFE OF TEMPEH PROCESSED WITH SUB-SUPERCRITICAL CARBON DIOXIDES

Maria Erna Kustyawati, Filli Pratama, Daniel Saputra, Agus Wijaya

ABSTRACT

Tempeh, a fermented soybean-based food originally from Indonesia, is a remarkably nutritious functional food with health benefits. Unfortunately, tempeh is highly perishable, with a shelf life of 24 – 48 hours. The goal of this research was to evaluate the possibility of a sub-supercritical CO_2 technique to increase the shelf life of tempeh by measuring the changes in the L^* (lightness) value and texture of tempeh via application of a kinetic approach and, based on the observations, to estimate its shelf life. Tempeh was processed with sub-supercritical CO_2 at 6.3 MPa for 10 min, then together with unprocessed tempeh (control), stored for 5 days at temperatures of 20, 30 and 40 °C. The Accelerated Self-Life Test (ASLT) with the Arrhenius model was used to measure the shelf life of processed and control tempeh. The calculated shelf life of processed tempeh using the ASLT by the Arrhenius method was 2.43 days at 20 °C, 3.7 days at 30 °C and 1.4 days at 40 °C, and the shelf life of unprocessed tempeh was 3.33 days at 20 °C, 2.90 days at 30 °C and 2.56 days at 40 °C. The conclusion was that the use of sub-supercritical CO_2 at 6.3 MPa for 10 min increased the shelf life of tempeh stored at 30 °C.

Keywords: sub-supercritical CO_2; kinetic change; shelf life; tempeh

INTRODUCTION

At present, consumers demand fresh food that is not only of high quality and safe but also has a long shelf life. High-pressure carbon dioxide (HPCD) technology has been developed as a food processing technology with the advantage of minimizing the loss of heat-sensitive nutrients. Carbon dioxide in the supercritical state has the dual properties of a gas with high diffusivity and a liquid with high solubility **(Ferrentino et al., 2010)**. These properties allow HPCD to diffuse easily through complex matrices, causing modification in either macromolecular or micromolecular substrates **(Garcia-Gonzales et al., 2007; Liao et al., 2010; Ferrentino, Balzan, and Spilimbergo, 2012; Guo et al., 2011)**. Many researchers have shown that HPCD could extend the shelf life of food by killing microbes and enzymes at a relatively low temperature whilst preserving the nutritional and sensory qualities of vegetables and food products. HPCD could inactivate *Salmonella*, *Listeria monocytogenes* and *Escherichia coli* **(Bourdoux et al., 2018; Liao et al., 2010)**, as well as the natural microbial flora **(Li et al., 2012; Cappelletti et al., 2015)**. HPCD has also been proven capable of inactivating the enzymes that cause food spoilage and lowering food quality, such as pectin methyl esterase, poly galacturonase, peroxidase, polyphenol oxidase and lipoxygenase **(Niu et al., 2019; Illera et al., 2018; Briongos et al., 2016; Liu et al., 2010; Hu et al., 2013)**.

Tempeh is an Indonesian fermented food made from soaked, hulled and cooked soybeans inoculated with the fungus *Rhizopus oligosporus*. Tempeh is a remarkably nutritious functional food with health benefits; however, it is highly perishable, with a short shelf life of 36 – 48 hours at room temperature **(Sparringa and Owens, 1999; Nout and Kiers 2005; Djunaidi et al., 2017)**. Several researchers have reported on methods of extending the shelf life of tempeh. Frozen storage (-18 °C) of tempeh resulted in loss of taste and texture which softened after thawing, while refrigerated storage caused discoloration and spoilage after 72 hours **(Witono et al., 2015)**. Meanwhile, tempeh kept under modified atmosphere packaging (15% O_2, 30% CO_2 and 55% N_2) spoiled in 24 hours **(Muslikhah, Anam and Andriani, 2014)**. A previous study performed by the author found that processing of tempeh with high pressure CO_2 at a pressure of 6.3 MPa for 10 min reduced the number of bacteria, yeasts and moulds in tempeh to 4.1, 5.1 and 4.3 log CFU g^{-1}, respectively. This discovery led us to study the effect of HPCD on the shelf life of tempeh. The objective of this research was to study the degradation kinetics of the quality parameters of tempeh processed with sub-supercritical CO_2 and to determine the shelf life of such tempeh.

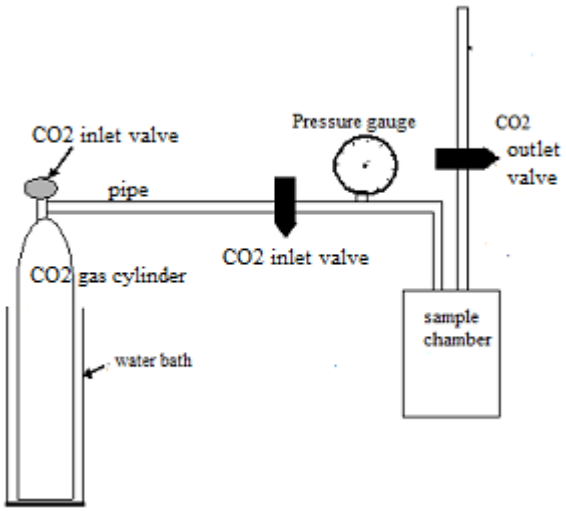

Figure 1 The set-up of the experimental apparatus **(Saputra, 2006)**.

Scientific hypothesis

The shelf life of tempeh stored at 20, 30, and 40 °C can be extended by treatment with CO_2 at sub-supercritical pressure.

MATERIAL AND METHODOLOGY

Treatment of tempeh with supercritical CO_2

Tempeh, in the form of a cylinder with a diameter of 35 mm and a length of 100 mm, fermented for 36 hours at 30 °C, was obtained from the Center of Home Industry Tempeh Making Palembang, Indonesia, placed in a cooler box and carried to the laboratory for direct processing **(Kustyawati et al., 2018)**.

The high-pressure CO_2 installation used for experimental treatments, consisting of a CO_2 gas cylinder, a cylindrical pressure chamber, pressure gauges, and a water bath at a constant temperature, is shown in Figure 1 **(Saputra, 2006).** Fresh tempeh was placed in a pressure chamber and then closed tightly. When the designated temperature in the water bath reached a constant 25 °C, and all pipe connections were secured, commercially available CO_2 was injected through the gas inlet valve from the gas cylinder into the pressure chamber, within 1 minute, until it reached the desired pressure of 6.3 MPa (sub supercritical CO_2 condition), which was indicated by the pressure gauge. After 10 min of treatment with sub-supercritical CO_2, the pressure was lowered to atmospheric pressure within 2 minutes by slowly opening the gas outlet valve. The tempeh was then collected aseptically from the pressure chamber using sterilized tongs, placed in a sterilized container, and stored in a refrigerator for further study. The processed and unprocessed tempeh (control) were analysed further for colour and texture, before and during the storage period.

Storage study

Tempeh processed with sub-supercritical CO_2 (6.3 MPa, 25 °C for 10 minutes) and unprocessed tempeh were employed as the treatment and control, respectively, in this experiment. All of the tempeh was stored for 5 days. Tempeh was stored as follows: tempeh samples were placed on a Styrofoam plate and covered with plastic film then stored at 20, 30 and 40 °C with the same relative humidity. Observations on quality parameter changes (*C*) were carried out by measuring the quality attributes represented by *L** and texture. Observations were made daily. A storage time of 5 days was chosen considering that the shelf life of fresh tempeh is normally around 24 – 48 hours at room temperature (28 – 30 °C).

The Accelerated Self Life Test (ASLT) with the Arrhenius model was used to determine the shelf life of tempeh, in which, if the food product deteriorates faster, then the shelf life is determined based on extrapolation to storage temperature. Changes in the quality factor were used to determine the degree of decrease in quality. Data were transformed into a kinetic plot, and an appropriate kinetic parameter model was obtained. The quality decrease in food is given by equation (1).

$$\frac{dQ}{dt} = k.Q^n \qquad (1)$$

Where: Q is the quality factor, t is time, k is a rate constant that depends on temperature, n is a degree factor or reaction order and $dQ\ dt^{-1}$ is the change in the Q factor per unit of time.

Most of all, a decrease in food quality includes zero-order (order 0) and first-order (order 1) reactions. The Arrhenius correlation chart was generated by evaluating the rate constant (k) at three different temperatures. The rate constant (k) was predicted by extrapolating the correlation between $ln\ k$ and 1/T at three temperatures. Shelf life is determined on the basis of the most influential factors on the product. One of the factors that can affect a product's shelf life is temperature. The Arrhenius kinetic approach was used to determine the shelf life and temperature limit factor. The equation for the Arrhenius model is shown in equation (2).

$$k_T = k_o e^{\frac{-E_a}{RT}} \qquad (2)$$

Where: k_T was the reaction rate constant of quality degradation, k_o was a constant (frequency factor, not dependent on temperature), E_a was activation energy, T was absolute temperature (K) and R was the gas constant (8.341 $J.mol^{-1}.K^{-1}$).

The zero-order and first-order quality reaction was measured by using equation (3) and equation (4), respectively **(Labuza and Szybist, 2001)**.

Zero order: $$t = \frac{(C_1 - C_o}{k} \quad (3)$$

First order : $$t = \frac{ln\frac{C_1}{C_o}}{k} \quad (4)$$

Where: C_o was the initial quality value of storage, C_t was the quality value at the storage time t, k was the reaction rate constant and t was the storage time (days). The determination of the order of the most suitable reaction was performed by selecting the equation with the highest R^2.

Colour and texture measurement

The surface colour analysis of tempeh was evaluated as the *CIE L*a*b** value and *LCH* colour scale using a colour difference meter (TC-1500, Tokyo, Japan). Results were expressed as L^* (Lightness), a^* (redness) and b^* (yellowness).

The total colour difference (ΔE^*) between the control and the processed tempeh was obtained using the following equation (5):

$$\Delta E^* = \sqrt{\Delta L^{*2} + \Delta a^{*2} + \Delta b^{*2}} \quad (5)$$

Where: ΔL^*, Δa^* and Δb^* were the differences between L^*, a^* and b^* after treatment and the L^*, a^* and b^* values of the standard colour. The standard colour used in this experiment was the L^*, a^* and b^* values of the unprocessed tempeh (control), which was L^*=76.6, a^*=3.1 and b^*=7.5.

Texture analysis

The texture analysed was tempeh hardness. The greater the value, the harder the sample being analysed. The LFRA Texture Analyzer (Brookfield AMETEK CT3-100-115), type A 7.1 was used to measure tempeh texture. The texture of the tempeh in this study was the quality of compactness of tempeh when sliced, because compact and dense soybean strands produce tempeh that is easily sliced. Tempeh has a non-homogeneous texture because it consists of woven soybean seeds arranged mycelia. This arrangement gives rise to varying angles/areas of penetration of the probe, for example, the possibility of probes piercing right into the soybean seeds or the soft areas between soybeans strands. Therefore, a Brooke-type probe blade was used in this study. The Brooke-type blade presses right in the centre of the sample. The peak load and final load numbers in units of gram force (gf) listed on the display were recorded. Measurements were performed in three replicates.

Statistical analysis

Statistical analysis was carried out using Microsoft Excel 2003 and Statistica 8.0 StatSoft software. Analysis of variance (ANOVA) was used to study differences between samples. A software program using Duncan's multiple range test was used to compare treatment means. A value of p <0.05 was considered statistically significant. All experiments were performed with at least three replicates.

RESULTS AND DISCUSSION

Kinetics of quality degradation

Processed and unprocessed (control) tempeh were used as the models in this experiment. Colour is very important to the sensory nature of tempeh because it is the first characteristic observed by the consumer. The colour of tempeh produced by the growth of mould was influenced by changes in the chemical composition of the tempeh and storage temperature. The lightness (L^*) value of the control was high, approximately 75.7 on the initial day, and then the lightness darkened to 57 at the third day of storage. The initial L^* value of the tempeh processed with sub-supercritical CO_2 glimmered to 74.4 and decreased to dark (69.3) by the fifth day (Table 1 and Table 2).

The data obtained from the experiments were plotted on a graph of the relationship between the degradation in the quality of L^* and texture, and the storage time at various temperatures. Based on the correlation coefficient (R^2) of texture and L^* (Table 3), the rate of change in the quality of tempeh followed the first-order reaction model. A higher correlation value indicates a faster decline in reaction product quality. This was in agreement with the findings of **Ahmed, Shivhare and Raghavan (2001)** that the degradation of betanin, a natural colour compound in beets induced by heat, followed a first-order reaction.

Figure 2 shows that the lightness value (L^*) weakened during storage at various temperatures, where it developed from light to dark. The colour of fresh tempeh is brownish yellow, due to the compounds furosine, hydroxymethylfurfural (HMF) and acrylamide, which are the products of the Maillard reaction in beans **(Zilic et al., 2014)**. Tempeh is made from cooked soybeans which have been heated to boiling temperature. In addition, during the depressurization process of the high-pressure CO_2 treatment, the mycelia of the mould are wiped from the surface of the tempeh, resulting in a brownish-yellow colour appearing on the beans. Moreover, a study performed by **Handoyo and Morita (2006)** found that over-fermentation of tempeh that occurred during storage could bring about protein depletion and produced a blackish-brown colour.

The hard texture of tempeh increased significantly during storage (p <0.05) (Table 1 and Table 2). The texture of tempeh is dense, compact and sliceable. It is formed by soybean cotyledons intertwined with the mycelia of moulds. As mould grows, it produces fluffy white mycelia which bind the beans, squeezing and penetrating the cell walls to create a cake texture and simultaneously producing enzymes that cause softening of the beans due to hydrolysis of various compounds during fermentation **(Duniaji et al., 2019; Jones et al., 2017; Wati et al., 2020)**.

Shelf-life prediction

The influence of temperature on the reaction rate was described using the Arrhenius equation. The regression equation and value of the R^2 data for tempeh at 20, 30 and 40 °C are shown in Table 3. The lightness (L^*) decreased faster than the texture, which was indicated by the slope values. Plotting *ln k* against *1/T* produced a linear regression of the Arrhenius model in which the slope represents the E_a value (Table 4). The E_a values of L^* and texture were 12.27 and 25.59 kcal.mol^{-1}, respectively, indicating that lightness was more sensitive to temperature. The sensitivity of quality parameters to changes in temperature can also be evaluated based on the value of the correlation coefficient R^2, where the greater the value of R^2, the greater the relationship between changes in the rate constant (*k)* and temperature. The dates on which characteristic limits for processed tempeh were attained with respect to lightness characteristic criteria were 2.43, 4.88 and 9.36 days at storage temperatures of 20, 30 and 40 °C, respectively, while those with respect to texture characteristic criteria were 8.6, 3.7 and 1.4 days at storage temperatures of 20, 30 and 40 °C, respectively. The shelf life was defined as the earliest date of all the dates on which characteristic limits were attained when each characteristic criterion reached its limit. Therefore, the shelf life of processed tempeh was estimated to be 2.43 days at 20 °C, 3.7 days at 30 °C and 1.4 days at 40 °C. The dates on which characteristic limits were attained for the control (unprocessed tempeh), with respect to lightness characteristic criteria, were 3.33 days, 2.90 days, and 2.56 days at 20, 30 and 40 °C, respectively, while those with respect to texture characteristic criteria, were 6.89 days, 4.47 days and 2.99 days at 20, 30 and 40 °C, respectively. Therefore, the shelf life of unprocessed tempeh was estimated to be 3.33 days at 20°C, 2.90 days at 30 °C and 2.56 days at 40 °C. Summarizing the results, the shelf life processed tempeh was longer than that of unprocessed tempeh at 30 °C. However, the shelf life estimated in this study cannot be applied to all tempeh, because many factors including consumer palatability and consumer perspective, also play vital roles.

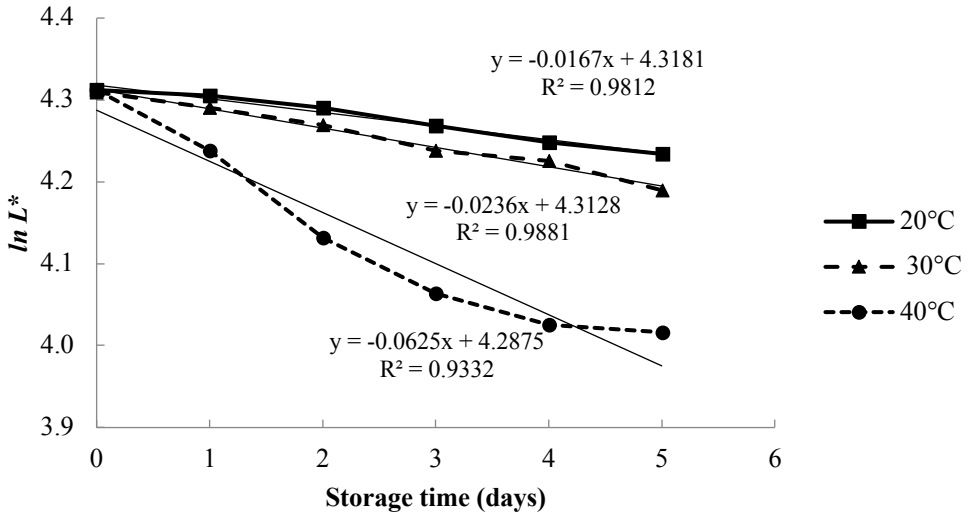

Figure 2 The correlation between lightness (*L**) of processed tempeh and time according to a first-order reaction.

Table 4 Regression equation of tempeh stored at 20, 30 and 40 °C.

	Quality parameter	T, °C	Regression equation	Reaction order	E_a, [1] kcal.mol-1	K,[2] day-1	R^2	C_o[3] - C_t[4]	Shelf - life (days)

Note: [1] Activation energy in kcal.mol^{-1}; [2] Rate constant; [3] Initial value of quality parameter; [4] Data of quality parameter as t time passes; [5] Processed tempeh; [6] Control (unprocessed tempeh).

All food expiration dates could be established as self-applied safety factors by each producer. For tempeh, expiration dates may not be mandatory because tempeh categorized as a fresh food product has a very short shelf life, and the spoilage of tempeh is easily detectable by looking at the colour, texture and aroma. Therefore, an expiration date is not necessary. From the point of view of microbial safety, tempeh, fermented soybean, is a reliably safe food because bacteria, yeasts and moulds that grow in tempeh have their own specific role. *R. oligosporus*, an important fungus in tempeh, is known to produce antibiotics against bacteria **(Kobayasi, Okazaki and Koseki, 1992; Wang et al., 1969)**. *Bacillus subtilis*, the most common bacteria in tempeh, contribute to the production of fatty acids and isoflavones **(Barus et al., 2017; Kanghae, Eungwanichayapant and Chukeatirote, 2017)**. The role of yeast in tempeh is not clear **(Nout and Kiers, 2005; Pleva et al., 2018)**; however, the authors' previous results show that co-culturing *Saccharomyces cerevisiae* with *R. oligosporus* in soybean fermentation produced tempeh with a pleasant yeast/tapai aroma that was liked by panellists **(Kustyawati, Nawansih and Nurdjanah, 2017)**. Further studies on the role of yeast in tempeh production are needed.

CONCLUSION

Sub-supercritical CO_2 processing at 6.3 MPa for 10 min increased the shelf life of tempeh at a storage temperature of 30 °C. The shelf life of processed tempeh was 2.43 days at 20 °C, 3.7 days at 30 °C and 1.4 days at 40 °C, and the shelf life of unprocessed tempeh was 3.33 days at 20 °C, 2.90 days at 30 °C and 2.56 days at 40 °C.

IMPACT OF HUMIC ACID AS AN ORGANIC ADDITIVE ON THE MILK PARAMETERS AND OCCURRENCE OF MASTITIS IN DAIRY COWS

František Zigo, Milan Vasiľ, Zuzana Farkašová, Silvia Ondrašovičová, Martina Zigová, Jana Maľová, Jana Výrostková, Jolanta Bujok, Ewa Pecka-Kiełb

ABSTRACT
Given growing concerns about the use of antibiotics in the treatment of animals, identifying organic alternatives as feed additives to improve animal health and the development of immune responses has become of interest in dairy farming. Humic acids (HA) seem to be a suitable alternative with a favorable impact on the health and production parameters of animals. This study aimed to determine the effects of an HA supplemented diet on milk parameters as well as the effects on somatic cell count (SCC) and the occurrence of mastitis in dairy cows during the peripartum period. Twenty dairy cows in the last stage of pregnancy were selected from a herd of 140 cows. The selected cows were randomly divided into two groups: control (C) and experimental (E). The two groups were fed the same feed mixture and group E was additionally supplemented with HA at a total dose of 100 g per cow per day during the last 50 days of pregnancy. The milk parameters (dry matter, lactose, fat, crude protein, casein and milk urea) and SCC of every cow, and the presence of mastitis, were checked on days 10 and 30 during the first month of lactation. The results of the study show that dietary supplementation with HA significantly reduced the milk urea (MU) content and SCC on the 10th day after calving but did not affect the other milk compositions. In addition to the decreased MU and SCC, the number of positive quarters detected by the California Mastitis Test was reduced by 20.0% and the occurrence of mastitis caused by coagulase-negative staphylococci (CNS). Based on the obtained results we can conclude that the addition of HA stabilizes the nutrient digestion, as was confirmed by a reduced MU content in the supplemented group. Their indirect beneficial effects improved the development of immune responses, resulting in decreased SCC and the occurrence of mastitis caused by CNS.

Keywords: dairy cows; supplementation; humid acid; mastitis; milk urea

INTRODUCTION
The health-safety and nutritional quality of raw milk are influenced by many factors. One of the main factors that affect the health of and milk production by dairy cows is mastitis. Mastitis is an inflammation of the mammary gland characterized by physical, chemical, bacteriological, and cytological changes in the milk. Changes in the quality and quantity of milk, as well as pathological changes in the glandular tissues of the udder have been observed **(Pyörälä and Taponen, 2009)**.

Mastitis is mainly caused by microorganisms. These are usually bacteria, including gram-negative and gram-positive bacteria, mycoplasmas, yeasts, and algae **(Zadoks et al., 2011)**.

The majority of mastitis cases are caused by a few common bacterial pathogens involved: *Staphylococcus* spp. (*S. aureus, S. warneri* and *S. chromogenes*), *Streptococcus* spp. (*Str. agalactiae, Str. dysgalactiae, Str. uberis* and *Str. bovis*), coliforms (mainly *E. coli* and *Klebsiella pneumoniae*) and *Actinomyces pyogenes* **(Idriss et al., 2013)**. Although some pathogens from the group of coagulase negative staphylococci (CNS) and *Corynebacterium bovis*, are historically considered to be of limited importance and are therefore often described as minor pathogens. In the last decade the impact of CNS has increased probably because the prevalence of major pathogens has decreased **(Pyörälä and Taponen, 2009)**.

Mastitis and other diseases are common problems in dairy herds, resulting in increased costs and decreased production. Most diseases in dairy cows occur at or just after calving, which is a period associated with immune suppression, resulting in increased susceptibility to infections. Prepartum immune suppression is multifactorial but is associated with endocrine changes and destabilization of intestinal flora, leading to impaired digestion and utilization of nutrients from animal feed **(Xiaowang, Shaohua and Lixia, 2010; Zigo et al., 2014)**.

During the past few decades the use of organic feed additives to improve health, wellbeing, and production has been investigated in some areas of animal husbandry. Humic substances (HS) are one such additive **(Marcinčáková et al., 2015; Semjon et al., 2020)**.

Humic substances (HS) are geological deposits made of a complex mixture of acids that arise from the natural decomposition of plant and animal material by soil microorganisms occurring in water, soil, carbon and other sources. They are heterogeneous high molecular weight organic substances and their composition differs according to the geographic region **(Jaďuttová et al., 2019; Mudroňová et al., 2020)**.

A yellow to brown-coloured seam (brown seam) may contain high concentrations of fulvic acid, whereas a dark brown to black-coloured seam (black seam) may contain high amounts of humic acid and humin. Humic acids (HA) are considered to be adsorbent, because of various binding sites present in their structure. It has been assumed that humic acids could reduce the absorption and systemic availability of bacterial endotoxins, which could be of great importance in the protection of animal and human health **(Trckova et al., 2005; Galip, Polat and Biricik, 2010)**.

Moreover, many positive effects on the performance and health of animals have been attributed to humic acids. They inhibit the growth of pathogenic bacteria and moulds and decrease the level of mycotoxins and thus may lead to improved gut health **(Marcinčáková et al., 2015)**.

Humic acids stabilize the intestinal flora, and in this way, improve the utilization of nutrients from animal feed, which affects the composition of dairy cows' and goats' raw milk **(Potůčková and Kouřimská, 2017)**.

Scientific hypothesis

Previous studies reported that the addition of HA to the diet of cows stimulated the fermentation products with improved nutrients digestion, growth and development of immune responses, but there is no data on the effect of its use on cow milk parameters and mammary health. Therefore, the aim of this work was to evaluate the effects of a humic acid supplemented diet on the main milk parameters and composition as well as the occurrence of mastitis in dairy cows during the peripartum period.

MATERIAL AND METHODOLOGY

Animal care

The practical part of the study was carried out in a dairy herd of 140 crossbred Slovak Pied cattle x Red Holstein. Dairy cows from the monitored herd were kept in a free housing system with a separate calving barn, equipped with individual boxes with bedding and were allowed ad libitum access to water. Cows were cow according to the Nutrient Requirements of Dairy Cattle **(NRC, 2001)**.

During the lactation, period cows were milked twice a day at 4:30 a.m. and 4:30 p.m. in the fishing-milking fed twice a day with feed mixture formulated for a 650 kg parlour (FarmTec) 2x10 pcs (Figure 1). First, water was used to remove impurities from the udder and teats. Subsequently, the udder was thoroughly wiped with disposable paper wipes. The first milk from each quarter was hand-drawn into a dark-bottomed pot, and the milk was subjected to sensory analysis. During the milking process, the pulsation ratio was 60:40 at a rate of 52 $c.min^{-1}$ and milking was automatically terminated when the milk flow dropped to 0.2 $L.min^{-1}$. After milking, the teats were disinfected by teat-dipping. Before drying an intramammary antibiotic preparation Orbenin Dry Cow a.u.v. (Pfizer, IT) was applied to every quarter of the udder in pregnant cows.

Experimental design, animals and diets

The experimental conditions were designed in accordance with the Guide for the Care and Use of Agricultural Animals in Research and Teaching **(FASS, 2010)**. Twenty gravid cows in the last stage of pregnancy were selected from the herd. Fifty days before the expected calving date the cows were randomly divided into two groups, control (C) and experimental (E). The 10 animals per group were housed on a deep litter divided into two separate stables with *ad libitum* access to water and feed.

Selected cows from each group were fed twice a day with a total mixed ration (TMR) containing corn silage (65%), grass hay (12%), barley straw (10%), bean (11.7%) and concentrate (1.3%) with the content of extracted rape and soy meal according to the current **NRC (2001)** during the dry period (Table 1). The mean daily intake for the dry period under study was 9.6 kg of DM per cow per day.

The experimental group (E) was supplemented into the diet with humid acids at a dose of 100 g per cow per day. The humic acids (product Humac Nature AFM) used in the experiment were obtained from Humac ltd. the company, SR. According to the producer, Humic Nature as an organic additive in the diet of animals contains: total humic acids 65% and minerals 15%, of which accounted for free humic acids 60%.

The experimental period lasted 50 days before the expected parturition and ended immediately after calving. Subsequently, the calves were separated from cows that were then milked into individual containers. Five days after calving the cows from the control and experimental group were milked twice a day together with all lactating cows.

Udder health examination and milk sampling

Udder health was evaluated and milk samples were taken from each selected cow on days 10 and 30 of the first month of lactation. A thorough evaluation of udder health included clinical examination, sensory analysis of milk from forestripping of each udder quarter followed by the assessment of CMT (Indirect Diagnostic Test, Krause, Denmark). Milk from every quarter was mixed with the reagent and the result was scored as negative, trace, or positive (score 1 – 3) depending on the formation of gel in the milk sample according to **Jackson and Cockroft (2002)**.

Next, we collected a milk sample from one quarter for bacteriological cultivation and two mixed milk samples for measurement of the milk components and SCC from each cow aseptically in accordance with the guidelines of the **National Mastitis Council (2001)**. The samples were cooled to 4 °C and immediately transported to the laboratory and analysed on the following day.

Analytical methods

TMR chemical composition

A 1 kg sample of TMR was analysed for dry matter (DM), crude protein, crude fat, ash neutral detergent fibre

(NDF) and acid detergent fibre (ADF) according to **AOAC** methods **(2012)**. The net energy (NE) contents were obtained by calculation **(NRC, 2001)**.

Determination of milk parameters

The raw milk samples were analysed for dry matter (total solids), non-fat dry matter (SNF; solids non-fat), lactose, fat, proteins content and pH using the Milk analyzer Lactoscan MCCW (Milkotronic, Bulgaria) according to **Potůčková and Kouřimská (2017)**. Milk urea (MU) content was measured on a CHEMSPEC apparatus (Bentley Instruments Inc.) according to **Pecka et al. (2012)**. All measurements were performed twice for each sample.

Determination of SCC

The somatic cell count (SCC) is one of the internationally recognized standards for milk quality control and is also a useful indicator of mastitis presence.

The Somatic Cell Counter Lactoscan SCC (Milkotronic, Bulgaria) is based on direct fluorescent, low magnification microscopic somatic cell counting. Lactoscan SCC uses a very sensitive fluorescent dye (Sofia Green) and LED optics (CCD technologies) in order to make the cell analysis more accurate, reliable and fast.

Laboratory analyses

Bacteriological examinations were performed according to commonly accepted rules **(Malinowski et al., 2006)**. Milk samples (10 μL) were cultured at the respective veterinary practice according to routine procedures, usually employing Columbia Blood Agar Base with 5% of defibrinated blood, Staphylococcal medium N° 110, Baird-Parker agar, Edwards Medium, Mac Conkey Agar (Oxoid, OXOID Ltd., Basingstoke, Hants, UK), and incubation at 37 °C for 24 h.

As well as evaluating bacterial growth characteristics other assays were used to identify bacterial species: pigment and coagulase production, catalase activity, haemolysis, Gram staining and other virulence factors. *Staphylococcus* spp. were selected for the tube coagulase test (Staphylo PK, ImunaPharm, SR). Suspected colonies of *Staphylococcus* spp., *Streptococcus* spp. and *Enterobacteriacae* spp. were isolated on blood agar and cultivated at 37 °C for 24 h and identified biochemically using the Staphy test, Strepto test and resp. Entero test using the software TNW Pro 7.0 (Erba-Lachema, CZ) according to the manufacturer's instructions.

Statistical analysis

A one-way ANOVA with an F-test on the arithmetic means (M) from 10 parallel measurements with standard deviation (SD) of dry matter (total solids), SNF (solids non-fat), lactose, fat, protein content, pH, MU and SCC was performed by Microsoft Excel 2003. Statistical significance was set at $p < 0.05$. The differences in the prevalence of mastitis and distribution of bacterial pathogens among monitored groups of cows were statistically analysed using the Chi-square test. The dependence of the individual signs was tested at a significance level $\alpha = 0.05$, with critical value = 5.991.

RESULTS AND DISCUSSION

Table 2 illustrates the effect of the supplementation of HA on the milk components and SCC in dairy cows. The two groups of animals, control and experimental, were fed with TMR (Table 1) during the 50 days prior to parturition. In addition to this feed, the experimental group was supplemented with HA at a dose of 100 g per cow per day. Changes of MU content (Figure 2) and SCC on the 10th day after calving in HA supplemented group was reported. No changes in the composition of dry matter, SNF, lactose, fat, protein content, or pH in raw milk were noted during the monitoring period (Table 2).

The observed decreased level of MU in cows fed diet with HA can be explained by lower blood urea nitrogen (BUN) level which resulted from lower ruminal ammonia nitrogen (NH_3-N) concentration indicated by more efficient utilization of dietary crude protein (CP).

The same trend was observed in the study by **Van Soest (1994)** who supplemented dairy cows with HA during lactation. In HA treated cows, lower blood urea nitrogen (BUN) value was indicated by more efficient utilization of dietary CP for microbial protein synthesis associated with nitrogen-binding capabilities of HA. This low value of BUN is usually associated with a lower ruminal NH_3-N flux to the bloodstream. Thus, a reduction in MU result can be explained with the reduction of BUN supported by lower ruminal NH_3-N concentration.

Similar results were observed by **Degirmencioglu (2014)** after supplementation of HA to ruminants for 90 days of lactation, with no improvements in milk composition (non-fat dry matter, lactose, fat and protein content). The effect on milk yield was inconsistent.

Other studies have reported positive effects of HA on milk production, milk fat **(Thomassen and Faust, 2000)** and milk protein **(Potůčková and Kouřimská, 2017)** in dairy cows. Another study showed that the use of HA as an animal feed supplement leads to increased milk production and increased butterfat percentage in dairy cows **(Islam, Schumacher and Gropp, 2005)**.

However, it is difficult to compare the effects of HS across studies due to the different sources and preparations of HA used, as well as because animals reared in various regions of the world are exposed to different climates and environmental conditions.

Milk SCC is a useful tool for measuring milk quality, the health status of the mammary gland and changes in milk composition. In the European Union the legal limit for cows is 400 000 cells.mL^{-1} **(Zajác et al., 2012)** and in the USA the legal limit established by the Food and Drug Administration for cows is 750 000 cells.mL^{-1} **(Paape et al., 2007)**.

In our study, the control group shoved increased SCC value above the legal limit on the 10th day after calving (Figure 2). However, the HA supplemented group had lower SCC values on the 10th day after calving (Table 2) and positive quarters according to the CMT (Table 3).

A score of 1 to 3 in the CMT indicates an increased SCC over the legal limit, most commonly caused by the presence of pathogenic bacteria. The penetration of pathogenic bacteria into the teat canal irritates the delicate mammary tissue causing an inflammatory response and changes in milk quality and composition **(Sharma, Singh and Bhadwal, 2011)**.

In particular, differences were found by comparing the positive quarters in both groups with CMT score 1 and 3. According to our results the number of positive quarters detected by the CMT on the 10th day after calving was reduced by 20.0% in the group of cows supplemented with HA (Table 3).

Similar to our study, **Thomassen and Faust (2000)** reported that HA supplementation significantly decreased the SCC in milk. They reported that a diet containing 3 g.HA.kg^{-1} decreased the SCC level in milk dairy by about 50%.

Similarly, **Xiaowang, Shaohua and Lixia (2010)** reported that a lower (by 40.1%) SCC was observed in their humate-supplemented group compared to the control.

Intramammary bacterial invasion occurs immediately after calving and leads to glandular damage in parenchymatous tissue. The glandular tissue damage leads to increased SCC and reduced milk production. The cellular presence in milk is one of the important protective mechanisms of the mammary gland **(Sharma, Singh and Bhadwal, 2011)**.

The addition of HA at a dose 100 g per cow per day in our study had a positive nutraceutical effect that stimulated neutrophil activity, which may protect against bacterial pathogens and reduce mortality during acute bacterial infection. The results show that in addition to reducing SCC the number of positive quarters infected with CNS was reduced by 12.5% during the first 30 days of lactation (Figure 3). On the 10th day of lactation, 15 and 9 quarters were infected in the control and experimental group, respectively. The same trend was observed on the 30th day of lactation. A large proportion of CNS (40%) was noted in the control group from infected quarters.

In recent years CNS have become increasingly important in udder infections. They are normal inhabitants of the skin and teat canal and are frequently isolated from milk samples **(Taponen et al., 2006)**. *S. chromogenes, S. haemoyticus* and *S. warneri* were pathologically important in intaramammary infection with increased SCC. The addition of humates to the feed reduced the incidence of staphylococcal infections by 5%.

According to **Dabovich et al. (2003)** the use of HA increases the body's defenses by stimulating neutrophil activity in response to the onset of inflammation. Testing of milk during field trials often indicates an increase in the number of microbes in the milk, an indication to the dairyman of impending mastitis.

As a result of feeding humates, mastitis cases within the milking herd dropped from an average of 3 to 4 cases daily to 4 cases in a month **(Islam, Schumacher and Gropp, 2005)**.

Table 1 Chemical composition of feed mixture.

Component	Content
DM (g.kg^{-1})	408.8
CP (g.kg^{-1}DM)	53.3
Fat (g.kg^{-1} DM)	14.5
NDF (g.kg^{-1} DM)	182.4
ADF (g.kg^{-1} DM)	129.4
Ash (g.kg^{-1} DM)	38.9
Starch (g.kg^{-1}DM)	40.8
NE^{1}, MJ.kg^{-1}	5.65

Note: DM – dry matter, CP – crude protein, NDF – neutral detergent fibre, ADF – acid detergent fibre, NE^{1} - net energy, obtained by calculation.

2	850 – 1.200 (±200)	Subclinical/clinical mastitis[3]	10.0	10.0	12.5	15.0
3	1.500 – 5.000 (±300)	Clinical mastitis	7.5[a]	0.0[b]	7.5	2.5

Note: N (neg.) – negative CMT score (healthy quarters); Exper. – experimental group supplemented with HA; [ab]Significant differences; p <0.05; Latent mastitis[1] – normal milk consistency, but infection is present in samples of raw milk without changing the SCC and a negative CMT score; Subclinical mastitis[2] – no symptomps are observed, the udder and milk appear normal, but infection is still present with positive CMT score and increased SCC; Clinical mastitis[3] – signs range from mild to severe with a positive CMT score, high level of SCC, positive bacteriological cultivation, changing the consistency of the milk with the presence of flakes, clots or pus and reduction or loss of milk production with clinical signs.

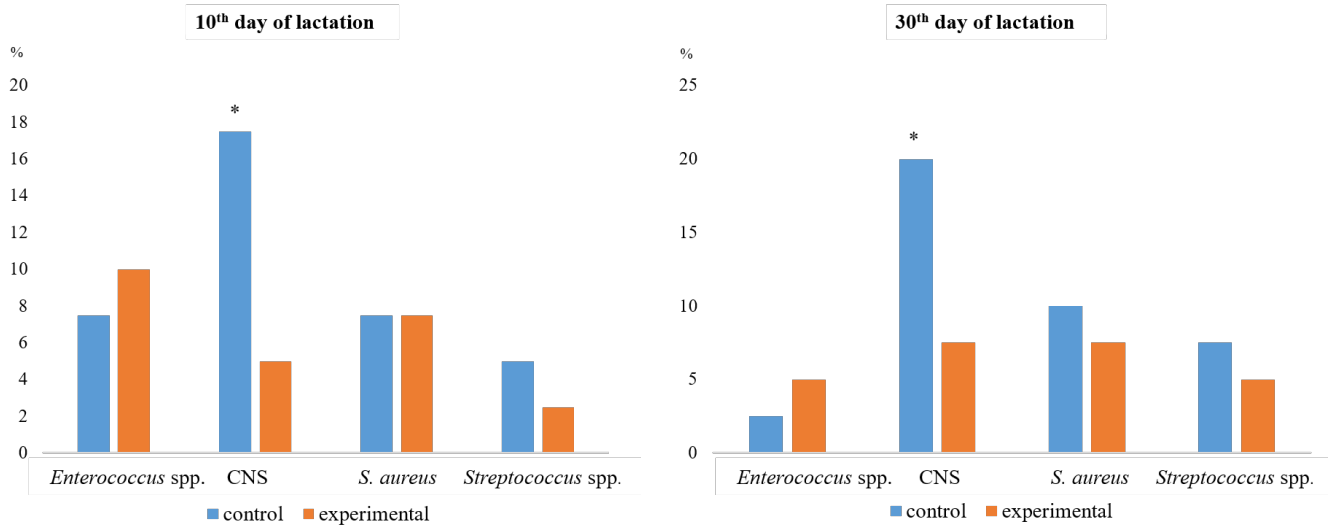

Figure 3 Distribution of bacterial pathogens causing mastitis in monitored groups (%). Note: Experimental – experimental group supplemented with HA, control – group without supplementation of HA, CNS – coagulase negative staphylococci, *Significant difference p <0.05 when significance level α = 0.05 (5%); critical value $\chi 2$= 5.99.

CONCLUSION

According to our results dietary supplementation with HA significantly reduced the MU content, SCC and the number of positive quarters detected by the CMT on the 10th day after calving but did not affect the others milk parameters. Although the mechanism by which HA supplementation affects milk synthesis and mastitis reduction has not been fully described, its indirect beneficial effects could improve the immunity of the mammary gland. Based on the information above, further research into the use of humates for the prevention of mastitis during the peripartum period and early lactation will be needed.

POLYPHENOLS AND ANTIOXIDANT ACTIVITY IN PSEUDOCEREALS AND THEIR PRODUCTS

Soňa Škrovánková, Dagmar Válková, Jiří Mlček

ABSTRACT
Pseudocereals are important as gluten-free crops that could be utilized as functional foods. They contain proteins with high biological value and also bioactive compounds such as phenolic compounds, flavonoids, vitamins, and minerals that can possess positive health effects on the body. Three types of pseudocereals (amaranth, buckwheat, and quinoa) were evaluated for polyphenols and antioxidant activity. Spectrophotometric methods were used for the determination of free phenols amount with Folin-Ciocalteu reagent, and total antioxidant capacity (TAC) with DPPH and ABTS reagents. Free phenols, the predominant part of polyphenols, were in pseudocereals in the range from 12.4 to 678.1 mg GAE.100g^{-1}. The highest content of FP was found in buckwheat products (146.8 – 678.1 mg GAE.100g^{-1}); quinoa and amaranth products reached much lower values (up to 226.1 mg GAE.100g^{-1}). Antioxidant activity was in an agreement with the FP amounts order, the highest TAC values were again for buckwheat products (167.3 – 473.9 and 876.9 – 3524.8 mg TE.100g^{-1}), followed by quinoa (78.2 – 100.6 and 738.9 – 984.5 mg TE.100g^{-1}) and amaranth ones (25.0 – 69.7 and 118.2 – 431.4 mg TE.100g^{-1}). A high positive correlation between FP amount and TAC values was evaluated for analyzed pseudocereals. The highest content of free phenols and the best antioxidant potential showed buckwheat wholemeal flour, so buckwheat could be characterized as a great source of free phenols with high antioxidant activity.

Keywords: pseudocereal; free phenol; antioxidant activity; DPPH; ABTS

INTRODUCTION
Pseudocereals are important gluten-free crops where belong especially amaranth, buckwheat, and quinoa. Their great nutrient properties and also suitability for the preparation of gluten-free foodstuffs **(Alvarez-Jubete et al., 2010)** predestinate them for the utilization as functional foods. They are known to have good nutritional value, specifically because of proteins with high biological value. It is due to the presence of essential amino acids (especially lysine and tryptophan) in a higher content **(Kocková and Valík, 2011)**. Due to their starch content they are also sources of energy. They contain also natural antioxidants, high levels of flavonoids (e.g. rutin, hyperoside, vitexin, isovitexin, orientin, isoorientin, catechin and epicatechin gallate in buckwheat), vitamins and minerals **(Salehi et al., 2018; Tomotake et al., 2007; Kiprovski et al., 2015)**.

Amaranth (*Amaranthus* spp.) is a rich source of proteins, with well-balanced amino acid composition and good bioavailability. It has higher lysine content than other cereal grains **(López et al., 2019; Tovar-Pérez, Lugo-Radillo and Aguilera-Aguirre, 2019)**. Amaranth is known also due to some potential health benefits (decreasing plasma cholesterol levels, reducing blood glucose levels and anemia) that have been conducted in experimental animal models **(Caselato-Sousa and Amaya-Farfán, 2012)**. Its seeds contain a good amount of polyphenols such as flavonoids with quite high antioxidant activity **(Vollmannová et al., 2013)**. To the important phenolics, there belong caffeic acid, ferulic acid and *p*-hydroxybenzoic acid **(Klimczak, Małecka and Pachołek, 2002)**.

One of the most important pseudocereal sources for functional foods is common buckwheat (*Fagopyrum esculentum* Moench). To the functional substances in buckwheat belong flavonoids, phytosterols, fagopyrins, fagopyritols, phenolic compounds, resistant starch, dietary fiber, lignans, vitamins, minerals and antioxidants **(Ahmed et al., 2014)**. Middling and bran buckwheat flours could be used to develop functional foods due to phenolic compounds presence. Phenolics are present there in the free and bound form. They are concentrated mainly in the outer layer (hull and bran) as the hull is removed before the milling of the buckwheat **(Martín-García et al., 2019)**. The study of **Li et al. (2013)** showed that rather than buckwheat flours, hulls and brans are a better source

of antioxidants. The health-promoting properties of buckwheat are expressed due to the content of antioxidants such as phenolic acids, rutin (quercetin-3-rutinoside), and fagopyrin, and specific proteins **(Ölschläger et al., 2008; Sytar et al., 2016)**. To the other health benefits belong, similarly as for amaranth, plasma cholesterol level reduction, antidiabetic properties, and also anti-inflammatory effect and improvement of hypertension conditions **(Giménez-Bastida and Zieliński, 2015)**.

Quinoa (*Chenopodium quinoa* Willd.) is a plant of the *Chenopodiaceae* family. It is also a gluten-free crop that is suitable for coeliac patients because it contains very little or no prolamin **(Jancurová, Minarovičová and Dandár, 2009)**. It is exceptionally high in lysine that is not overly abundant in the vegetable kingdom. Quinoa seeds contain also phytohormones that have a good impact on human nutrition **(Vega-Gálvez et al., 2010)**.

Processing of crops (procedures, extraction methods, used temperature, type of present compounds) can modify the polyphenol content of foods in several ways **(Manach et al., 2004; Inglett et al., 2011)**.

This study aimed to assess differences in antioxidants of pseudocereals, concretely amaranth, buckwheat and quinoa, by comparison of free phenols content and total antioxidant capacity.

Scientific hypothesis

The scientific hypothesis of this study was to examine the differences and relations between free phenolic content and antioxidant capacity measured by two methods (DPPH with IC50, and ABTS tests) in three types of pseudocereals (amaranth, buckwheat, and quinoa), and also differences between samples themselves.

MATERIAL AND METHODOLOGY

Pseudocereal samples

Three types of pseudocereals and their products (13 samples), bought from food markets of different origin, were analyzed. There were amaranth, buckwheat, and quinoa. Amaranth (4 samples of Indian, Hungarian, Czech and German origin; grains (AG), flour (AF), wholemeal flour (AWF) and particles (AP)); buckwheat (6 samples of Poland, Czech and Latvia origin; grains (BG1, BG2), flour (BF1, BF2), wholemeal flour (BWF) and groats (BGR)); and quinoa (3 samples of Peruvian and Bolivian origin; different types of grains (white QGW, red QGR, black QGB)).

Determination of Free Phenolic Content

For the determination of free phenolics content (FP) in the pseudocereals modified spectrophotometric method with Folin-Ciocalteau reagent **(Vollmannová et al., 2013)** was used.

The extracts of pseudocereal samples were prepared from 1 g of homogenized pseudocereal sample and 25 mL of methanol (80% (*v/v*); Penta Chemicals, CZ) with stirring in a shaker for 8 h at room temperature. The extract was afterward filtered through a paper filter and used for the analyses of FP.

To extracts (1 mL) with 5 mL of distilled water, Folin-Ciocalteau reagent (2.5 mL; Penta Chemicals, CZ), was added and after agitation, it was left for 3 min in the dark at room temperature. Then sodium carbonate solution (7.5 mL, 20% (*w/v*); Penta Chemicals, CZ) was added to a mixture and mixed again. The content was then filled up to 50 mL. After 2 h of the extract standing in the dark at room temperature the absorbance of samples was measured at wavelength 765 nm (Libra S6 Biochrom spectrometer, GB) against blank. As a standard a gallic acid was used. FP values were expressed as gallic acid equivalents (GAE), $mg.100g^{-1}$ sample. Determinations were made in triplicate.

Determination of Antioxidant Activity

Antioxidant activity of pseudocereals was assessed as a total antioxidant capacity (TAC). It was evaluated by a modified spectrometric method with DPPH reagent **(Vollmannová et al., 2013)** and also with ABTS reagent **(Škrovánková et al., 2018)**.

For both determinations there was used the same extraction process for analyzed samples. 1 g of homogenized pseudocereal sample was mixed with 25 mL methanol (80% (*v/v*); Penta Chemicals, CZ) with stirring in a shaker for 8 h at room temperature. The extract was afterward filtered through a paper filter and used for the analyses.

DPPH method: To pseudocereal extract (0.1 mL) a DPPH (1,1-diphenyl-2-picrylhydrazyl) solution in methanol (3.9 mL; 1 mM; Sigma Aldrich, CZ) was added. The mixture was shaken vigorously on a Vortex mixer in capped glass and left in the dark for 10 min. (room temperature). The absorbance of samples (A) and absorbance of control samples (AC) was measured on the spectrometer (Libra S6 Biochrom, GB) at λ = 515 nm against a blank. The pseudocereal inactivations (I) were calculated from the decrease of absorbance (%) according to relation (1) and the results were then expressed, using the calibration curve of standard (trolox), as trolox equivalents (TE) in $mg.100g^{-1}$ sample. Average results were obtained from three parallel determinations.

$$I = \frac{AC-A}{AC} . 100 \quad (1)$$

IC50 method: For the determination of 50% antioxidant inactivation, to scavenge 50% of DPPH free radicals, the most effective pseudocereal type, buckwheat, was used. For IC50 method there were prepared five diluted methanolic buckwheat extract solutions for each sample, in the range 1 – 10 $mg.mL^{-1}$. The reaction mixtures were made the same way as for TAC (DPPH) determination. From the results of inactivation for these extract concentrations the IC50 values were quantified by linear regression.

ABTS method: To 50 µL of pseudocereal extracts 4 mL of the reactive radical mixture composed of ABTS (2,2′-azino-bis-3-ethylbenzthiazoline-6-sulphonic acid; Sigma Aldrich, CZ) (12 mL; 3.5 mM) with $K_2S_2O_8$ (0.06 M; Lukes, CZ) and acetic buffer (pH 4.3), was added. The solution was shaken vigorously on a Vortex mixer and left to react without light exposure for 30 min at room temperature. Pseudocereal samples absorbance (A) and absorbance of control samples (AC) were then measured by a spectrometer (Libra S6 Biochrom, GB) at wavelength 734 nm against a blank. Inactivations (I) were

calculated from the decrease of absorbance (%) according to relation (1). Results of TAC (ABTS) were calculated from inactivation using a calibration curve with trolox as a standard. It was expressed as trolox equivalents (TE) in the mg.100g^{-1} sample. Average results were obtained from three parallel determinations.

Statistical analysis

All data were expressed as mean values ± standard deviation (SD), every determination was made in triplicate. Statistical analysis of the results was made by Statistica program, StatSoft version 9.0 (Dell, USA) using parametric test comparing mean values of two independent assortments (Student *t*-test). Differences at a 95% confidence level (p <0.05) were considered statistically significant. Correlations between the evaluated parameters were obtained using Pearson's correlation coefficient (r).

RESULTS AND DISCUSSION

Content of phenolics

Antioxidants that could donate electrons, such as polyphenols, vitamin C (ascorbic acid), and vitamin E (tocopherols), were evaluated by the method with Folin-Ciocalteau reagent.

As **Li et al. (2013)** found out predominant polyphenols in pseudocereals, such as buckwheat, are free phenolics (FP), accounted for about 94.07% of whole polyphenol content.

The amounts of FP in the pseudocereal samples in our study (Table 1) ranged from 12.4 to 678.1 mg GAE.100g^{-1} with the average 208 mg GAE.100g^{-1} pseudocereal sample. There were marked differences between individual pseudocereals (p <0.05, Student *t*-test).

The highest content of FP was analyzed for the buckwheat products; quinoa and amaranth products reached much lower values. These findings are in agreement with **Alvarez-Jubete et al. (2010)** results for pseudocereal seeds determination. Also **Vollmannová et al. (2013)** and **Gorinstein et al. (2008)** detected for pseudocereals this order of polyphenols amount.

The average FP value for buckwheat seeds and products in our research was 357 mg GAE.100g^{-1}, that is up to 3 times higher than in quinoa (average 141 mg GAE.100g^{-1}) and up to 10 times than in amaranth (average 34 mg GAE.100g^{-1}) seeds and their products. The highest amount was analyzed for buckwheat wholemeal flour followed by other types of buckwheat flours.

In **Alvarez-Jubete et al. (2010)** study polyphenol amount for buckwheat seeds was 323 mg GAE.100g^{-1}, for amaranth 21.2 and for quinoa it was 71.7 mg GAE.100g^{-1}. Buckwheat values of our determination were similar also to the contents of **Salehi et al. (2018)** study that were in the range from 265 to 430 mg of caffeic acid equivalents per 100g.

In a study of **Gorinstein et al. (2007)**, the total phenol content in amaranth and quinoa reached similar values (40.5 – 43 and 91.2 mg GAE.100g^{-1}, respectively) as in our study, for buckwheat it was much less, 60 mg GAE.100g^{-1}. **Vollmannová et al. (2013)**, however, found in seeds of selected pseudocereals a higher amount of phenolics than evaluated in our study for buckwheat; quinoa, and amaranth seeds and their products.

Antioxidant activity

To evaluate the antioxidant potential, the antioxidant activity of all selected pseudocereal seeds and their products was measured. Two methods, DPPH and ABTS tests were used. The results of total antioxidant capacity (TAC) are summarized in Table 1.

The TAC values for the DPPH method were in the range from 25 to 473.9 of trolox equivalents per 100 grams of pseudocereal sample with an average 166 mg TE.100g^{-1}. Results of ABTS test were from 118.2 to 3524.8 mg TE.100g^{-1}, the average 1280 mg TE.100g^{-1}. For the results of both methods there were marked differences between pseudocereals (p <0.05, Student *t*-test), similarly as for free phenols.

From the evaluation of the results it can be seen that the pseudocereal type with higher antioxidant values is buckwheat, followed by quinoa and amaranth. It is the same order as for FP values. These findings are in agreement with the values previously reported by **Alvarez-Jubete et al. (2010)** for pseudocereal seeds. The studies of **Gorinstein et al. (2007)**, **Gorinstein et al. (2008)** and **Vollmannová et al. (2013)** introduced for pseudocereals the same order for antioxidant capacity results.

Buckwheat samples for DPPH and ABTS test in our study reached 2 – 19 and 2 – 30 times higher values than in quinoa samples (average 92 and 860 mg TE.100g^{-1}, respectively) and 2 – 6 and up to 5 times, respectively, than in amaranth (average 41 and 263 mg TE.100g^{-1}) seeds and their products. As for particular samples, the best product with the highest antioxidant activity, measured by both methods, was buckwheat wholemeal flour followed by other types of buckwheat flours and buckwheat grain (BG1).

A similar trend of buckwheat samples is shown for IC50 values in Figure 1. IC50 expresses the concentration of buckwheat extracts requisite for 50% inhibition, therefore the highest antioxidant capacity is showed by the lowest IC50 value. IC50 concentrations of buckwheat extracts were in the range 2.391 – 6.520 mg.mL^{-1}, the average 4.218 mg.mL^{-1}. Wholemeal flour (BWF) had the lowest IC50, nearly 3 times lower than the sample with the highest IC50 value (buckwheat grain BG2). So wholemeal flour has the highest antioxidant activity what could be seen also from DPPH and ABTS tests.

Alvarez-Jubete et al. (2010) reported analogous order of antioxidant capacity for pseudocereal seeds, determined by DPPH assay, the value of 620 mg TE.100g^{-1} for buckwheat, 57.7 for quinoa, and 28.4 mg TE.100g^{-1} for amaranth, respectively. In the study of **Salehi et al. (2018)** TAC results (DPPH test) in buckwheat seed samples varied from 268 to 628 mg TE.100g^{-1}. **Zielińska et al. (2012)** determined TAC in buckwheat seeds 215 mg TE.100g^{-1}.

Despite some variations in exact values of antioxidant potential in our research and other studies, they are comparable, and buckwheat could be reported as the greatest source of polyphenols with the highest antioxidant activity amongst pseudocereals and also some other cereals too **(Gorinstein et al., 2007; Gorinstein et al., 2008; Gallardo, Jiménez and García-Conesa, 2006; Zieliński and Kozlowska, 2000)**.

Table 1 The content of free phenols (FP) and values of total antioxidant capacity (TAC) in pseudocereals.

Pseudocereal sample	FP (mg GAE.100g^{-1} ±SD)	TAC (DPPH) (mg TE.100g^{-1} ±SD)	TAC (ABTS) (mg TE.100g^{-1} ±SD)
AG	12.4 ±0.7^{a}	26.4 ±1.3^{a}	118.2 ±8.3^{a}
AF	31.5 ±1.2^{a}	25.0 ±0.9^{a}	173.0 ±13.8^{b}
AWF	19.2 ±1.6^{a}	69.7 ±1.8^{b}	431.4 ±25.0^{c}
AP	71.6 ±3.5^{c}	44.2 ±3.5^{c}	327.9 ±17.9^{d}
BG1	292.5 ±10.8^{d}	280.0 ±11.5^{d}	2031.6 ±78.7^{e}
BG2	146.8 ±3.2^{e}	167.3 ±5.1^{e}	876.9 ±65.2^{f}
BF1	347.2 ±16.9^{f}	266.1 ±13.9^{f}	2287.4 ±90.4^{g}
BF2	354.9 ±18.0^{f}	291.6 ±14.2^{d}	2795.7 ±81.2^{h}
BWF	678.1 ±21.3^{g}	473.9 ±22.4^{g}	3524.8 ±121.6^{i}
BGR	321.4 ±10.1^{f}	242.0 ±9.1^{h}	1528.3 ±60.8^{j}
QGW	226.1 ±9.4^{d}	100.6 ±7.7^{i}	984.5 ±51.3^{k}
QGR	97.3 ±4.8^{h}	78.2 ±6.2^{b}	826.1 ±41.8^{f}
QGB	100.5 ±5.6^{h}	97.4 ±2.8^{i}	738.9 ±37.2^{l}

Note: Means within a column with at least one identical superscript are not significantly different by Student's t-test (p <0.05).

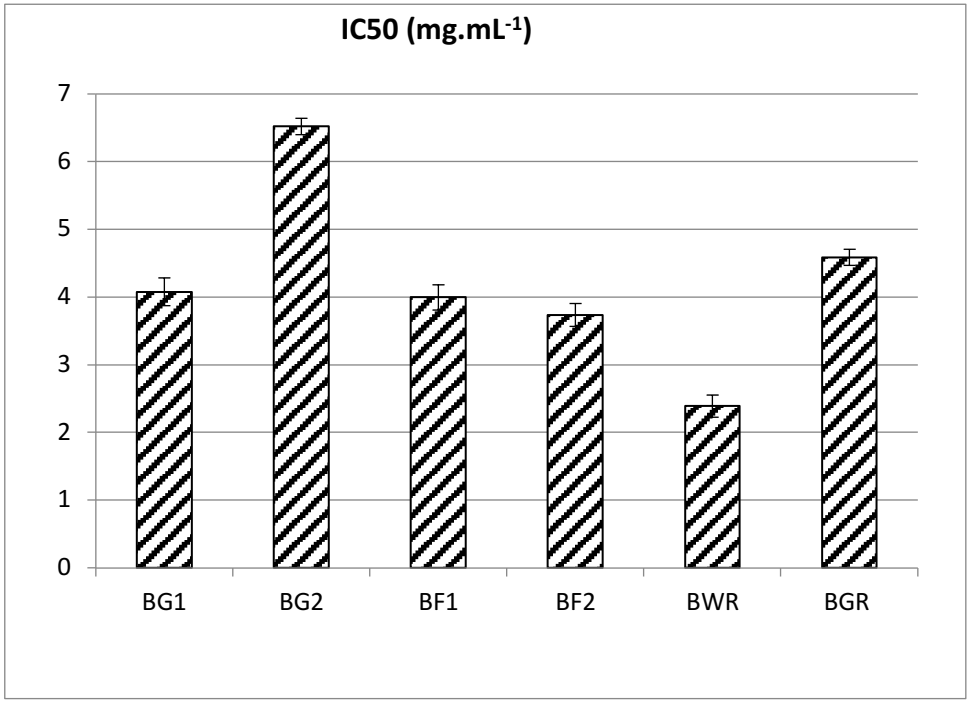

Figure 1 IC50 values (DPPH test) (mg.mL^{-1}) of buckwheat samples.

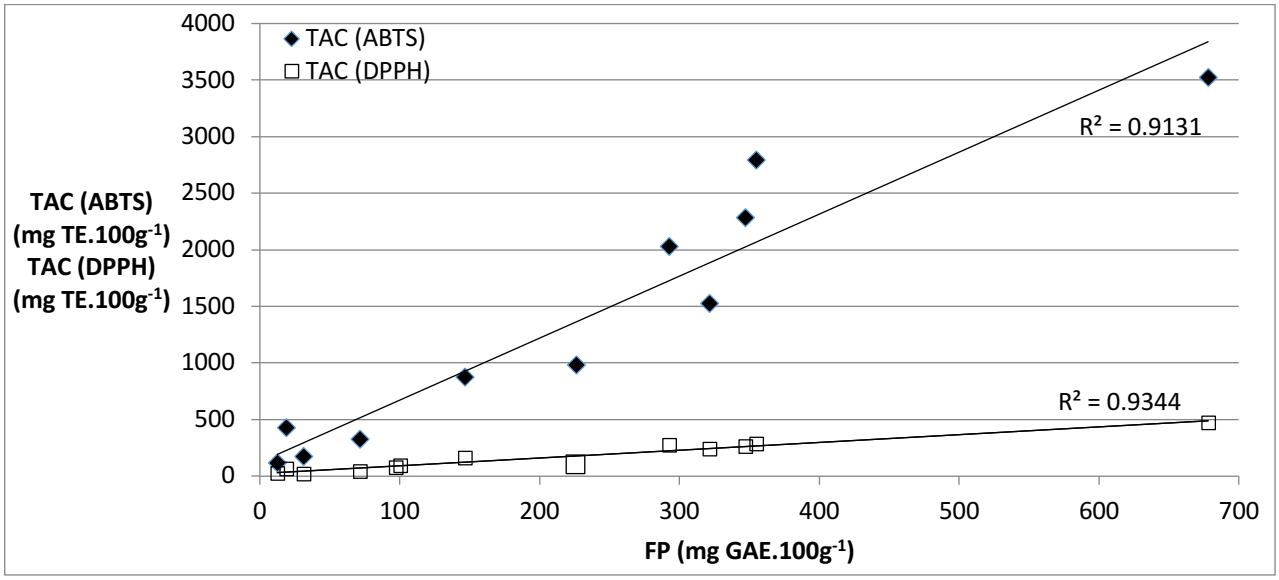

Figure 2 Correlations between FP and TAC values (DPPH, ABTS tests) of pseudocereals.

Pseudocereal samples exhibited similar order of samples for FP and TAC values (DPPH and ABTS assays). The relationships between them are shown by the correlations in Figure 2. They are strongly related to a correlation factors $r = 0.9666$ and 0.9565, respectively. In the research of **Sun and Ho (2005)** there was also found a significant correlation (0.96) between polyphenols content and antioxidant activity (DPPH method), in buckwheat extract. In amaranth and quinoa extracts there were reported weak correlations between polyphenols content and antioxidant activity by **Nsimba, Kikuzaki and Konishi (2008)** study.

CONCLUSION

Pseudocereals contain bioactive compounds such as phenolic compounds, flavonoids that can possess positive health effects on the body.

Amaranth, buckwheat, and quinoa were evaluated by spectrophotometric methods for the determination of free phenols amount and total antioxidant capacity. Free phenols in pseudocereals were in the range from 12.4 to 678.1 mg GAE.100g^{-1}. The highest contents of FP were found in buckwheat products; quinoa and amaranth products reached much lower values (up to 226.1 mg GAE.100g^{-1}). Evaluated antioxidant activity, the highest TAC values were determined again for buckwheat products (up to 473.9 (DPPH test) and 3524.8 (ABTS test) mg TE.100g^{-1}), followed by quinoa (up to 100.6 and 984.5 mg TE.100g^{-1}, respectively) and amaranth ones (up to 69.7 and 431.4 mg TE.100g^{-1}, respectively). Antioxidant capacity values by two evaluation methods (DPPH, ABTS) are in agreement with polyphenols content order. The highest content of free phenols, and also the best antioxidant potential, showed buckwheat wholemeal flour. Our study is generally in agreement with the findings of previously reported researches focused on pseudocereals. Buckwheat therefore could be characterized as a great source of free phenols with high antioxidant activity and thus could be used as seed for production of high nutritional quality products, especially for people who do not could eat cereal products due to the gluten presence. Buckwheat seeds could be also added to other cereal products to heighten their nutritional quality.

INFLUENCE OF PACKAGING ATTRIBUTES ON PERCEPTION OF JUICE: EYE-TRACKING STUDY

Ján Nemergut, Stanislav Mokrý

ABSTRACT

Today, consumers are increasingly aware of the impact that the fast and stressful way of life has on their health. They focus not only on physical activity, but also on a diet filled with fruits and vegetables. As a result, they often choose a tasty alternative which is one of the main sources of vitamins and nutrients - fruit juices. However, these products are often labeled as drinks with high amounts of sugar. Therefore, it is very important for these drinks to be perceived by the consumers as healthy and tasty, which is one of the most important features of their packages. Their goal is to appeal to customers, catch their attention and make them buy the product. One of the most convenient methods to study how packages appeal to customers is the eye-tracking method. The aim of this article is to find out how different attributes of packages can influence customers' perception of the juice. The research was carried out in a form of eye-tracking experiment (A/B testing), which involved 38 participants at the age from 20 to 29 (generation Y). Results showed that lower color saturation significantly reduces the attention of individual packages and also reduces the influence of craving the juice as opposed to brighter colors. The importance of information on the back side was also confirmed, since moving the information from back to the front side did not show any significant decrease of the back side's attention span. Last but not least, it has been found out that the image type used on the orange juice package holds importance too, since photography of oranges led to a higher craving of the juice in comparison to the illustration of oranges. However, it was not proven that photographs of oranges held a higher attention span compared to the illustrations. The article contains demonstrable proof of individual package attributes' influence on how generation Y consumers perceive the juice.

Keywords: consumer; attribute; juice; eye-tracking; package

INTRODUCTION

In recent years, the consumers' attention is focusing on a healthy lifestyle, which is also related to a healthy diet. There is a permanent trend among global and state institutions which recommend higher consumption of fruit and vegetable due to positive effects on the organism. This is one of the reasons why the vast majority of consumers perceive juices as beneficial for health **(Nicoli, 2012)**. Their popularity confirms the fact that while in the past, they were created as a result of the overproduction of fresh fruit, nowadays the fruit (mostly citruses and apples) is in many areas grown specifically for juicing **(Robertson, 2009)**. Fruit juices contain mainly vitamins and minerals but also saccharides prevailing in the solid component. Even though the fruit contains only a small amount of proteins and fats, there are higher concentrations of iron, calcium, and vitamins B and C **(Ashurst, 2016)**.

The area of drinks, and more specifically juices, belongs to a group of products that are bought impulsively (habitually) by consumers **(Mruk-Tomczak, Jerzyk and Wawrzynkiewicz, 2019)**. This means that during the decision process, they create little to no conscious effort, they don't search for information beforehand and as a result, they're often tempted to buy impulsively **(Solomon, 2009)**. The product's packaging design plays a crucial role in this form of shopping **(Cahyorini and Rusfian, 2012; Hubert et al., 2013; Waheed, Khan and Ahmad, 2018)**.

In recent years, there have been countless researches about the influence on the decision making of consumers during shopping for groceries. One of the researched attributes was the shape and overall package design. According to **Burgess (2016)**, the shape of a specific product package is very important for the consumer, since people are visually driven beings and therefore the color and overall package design have a much bigger influence on expectations and consequential experience of the consumer compared to holding the product itself in their hands as such. Nowadays, there is a lot of research carried out on the so called "crossmodal correspondence". It stands for cross sense associations, e.g. between letter shapes and taste **(Velasco**

et al., 2014), package shape and perceived health safety **(Fenko, Lotterman and Galetzka, 2016; Ooijen et al., 2017)**, smell and shape **(Hanson-Vaux, Crisinel and Spence, 2012),** etc. where consumers imagine a certain taste, smell and so on based on a certain shape. The importance of packaging colors has also been proven within impulsive shopping **(Bone and France, 2001)**. The research focused on color harmony **(Wei et al., 2014; Hurley et al., 2017)**, color hues **(Ampuero and Vila, 2006)**, but also the influence of colors on product's taste itself **(Piqueras-Fiszman and Spence, 2011; Karnal et al., 2016; Rompay, Deterink and Fenko, 2016)**. Within the products, consumers are now also focusing on the health side of the products, and therefore the impact of the information on the perception of the health acceptance of the product is being examined increasingly. On that account, the subject of the research was, for example, the presentation of health claims on the packages **(Liem, Aydin and Zandstra, 2012; Sütterlin and Siegrist, 2015)**, the presentation of nutrition claims **(Talati et al., 2017)** or the impact of images on the packaging on consumer's perception **(Mizutani et al., 2010)**.

It is necessary to realize that these researches are not only a mere theory, but it is indeed possible to implement gained conclusions in practice. As one of the examples may serve the redesign of the orange juice package of one of the world's largest fruit juice processors, Tropicana. When changing the package of Tropicana's pure orange juice, the typical feature of the juice packaging - an orange with a straw - was removed. This has made it impossible for consumers to find this particular feature, which means that they cannot identify the new package and, of course, do not buy it. The new juice packaging resembled a private brand. The change in the company's packaging resulted in a significant drop in sales by 20% between December 2008 and February 2009, which is an estimated loss of 27.3 million dollars. The redesign of the new packaging cost Tropicana about 35 million dollars and is considered to be the most important event in the beverage industry **(Lee, Gao and Brown, 2010)**.

Many other researches have been, are and will continue to be conducted within the design of packages, to reveal some links between packaging attributes and consumer's perception. The goal of this study is to test certain assumptions of the impact of packaging on the perception of Y-generation consumers in the field of fruit juices by using eye-tracking technology and thereby also contributing to further progress in this field of research.

Scientific hypothesis

H_0: Color saturation of juice package has no impact on the package's attention span.

This hypothesis is based on the assumption that the higher the package color saturation is, the higher level of attractiveness and expectations for its consumers it has **(Velasco and Spence, 2018)**.

H_0: Additional information on the front side of the juice package has no impact on the inspection duration of the back side of the juice package.

This hypothesis is formulated based on the general assumption that the consumers will spend less time looking at the back side of the juice package after moving the information from the back side to the front side.

H_0: Type of package image has no impact on the length of observation of the juice package.

This hypothesis includes the assumption that consumers prefer photography of a certain object over its illustration **(Kovač et al., 2019)**, therefore they should spend more time looking at the package with photography compared to the package with an illustration.

MATERIAL AND METHODOLOGY

The research consisted of two parts, where the first part was eye-tracking research and the second part was an in-depth interview. The research was held from the 14th to 18th of October 2019 in eye-tracking laboratory ETLab of the department of economics at Mendel University in Brno. The respondents applied for this research via Google Docs application shared through social media Facebook. Requirements for participation in the research were age between 20 to 30 years and consumption of fruit juices. 38 respondents have participated in the research, during which none of the respondents experienced loss of signal or incorrect calibration, which could significantly influence the eye-tracking research. Half of the participants were in the age between 20 to 24, the other half belonged to the age group between 25 to 29. The average age of the participants was 24.53 years. 58% of the respondents consisted of women (22) and the remaining 42% of men (16). The largest representation consisted of Slovak nationality (25), which is roughly 65%. The second largest representation was one of Czech nationality (12), which is roughly 33%. One of the participants was of Ukrainian nationality and has been living in the Czech Republic for the last 5 years and speaks fluent Czech. Table 1 shows the estimated monthly juice consumption in liters among individual respondents.

Table 1 Estimated monthly juice consumption in liters among individual respondents.

1 – 2 L	15 respondents	39.47%
2 – 5 L	16 respondents	42.10%
5 – 7 L	6 respondents	15.80%
7 – 10 L	1 respondent	2.63%
More than 10 L	0 respondent	0%

The research was in a form of experiment and A/B testing, where 19 respondents in group A were presented with one variant of stimuli, and the other 19 respondents in group B were presented with another variant of stimuli with variations. This research used a static eye-tracker SMI RED 250 produced by SensoMotoric Instruments GmbH (hereinafter referred to as SMI), which was placed under screen's monitor with resolution 1680×1050 px. Eye-tracking reading was carried out on a frequency of 120 Hz. The software used for eye-tracking research was Experiment center SMI, as well as SMI iView X, which was used to control the eye-tracking. First, a 5-point calibration was performed, followed by validation, which provided information about the deviation from the calibration point. For this thesis, a maximum deviation of 0.5 degrees was determined on both the x-axis and y-axis. Calibration and validation were performed multiple times while choosing the best value. The eye-tracking research consisted of several blocks. At the beginning of each block, instructions were given, after which the respondents continued by pressing the spacebar on a keyboard. After

each task description (before displaying each stimulus), a so-called "fixation cross" was displayed for 800 ms. The goal of this cross was to direct the participant's eyes to the center of the screen, therefore allowing each stimulus to be viewed from the same place. All stimuli (juices) were displayed in the background with RGB color: 192, 192, 192. Respondents answered a specific question each time an image was displayed. Respondents could view each stimulus indefinitely and press the spacebar to continue to the next image. After the eye-tracking research, an in-depth interview took place, where the participants were asked several questions regarding the eye-tracking, as well as general questions about the consumption of juices.

For the processing of the eye-tracking research data, SMI BeGaze software was used to create individual areas of interest (AOI). These were the individual parts of the packaging that, in certain cases, differed in groups A and B and were the subjects of research. These areas of interest contained metrics also known as key performance indicators (KPIs). These KPIs may for example indicate how many participants viewed each element, in which order and with how many repetitions. Based on the data, heat maps were also created, where red indicates the areas with the most attention, while blue indicates the least attention.

The hypotheses were tested using paired *t*-test and Mann-Whitney test using IBM SPSS Statistics 25 statistical software.

Stimuli

The research used pictures of fruit juice packages of foreign brands, but also of juice brands sold in Czech and Slovak markets (Figure 1). In the case of the first hypothesis, which concerns the effect of the color saturation, the color saturation of each alternative was reduced by 50%. In the second stimulus, the information from the back side of the juices was added to the front side of the juices in a form of leaves that fitted the entire package design better. In the case of the third hypothesis, packages with illustrations of oranges were created in addition to the juices with images of real oranges. The effect of the image type was observed in the case of the packages, where the image was a small part of the package, as well as in the case where it created a larger part of the package. All graphic edits were done with Adobe Photoshop CC2018 software.

RESULTS AND DISCUSSION

The first stimulus consisted of a selection of 4 juices, 2 of which were colored normally and the remaining two had their color saturation reduced by 50%. Based on the data of individual metric, it has been recorded that the color saturation had an impact on the number of returns to a certain juice. The largest difference has been recorded in juice brand Tropicana, where the respondents looked back 3 times at the version with lower color saturation, while the normally colored version caught their attention more than 5 times. In case of juices Minute Maid and Tropicana, the most observed area of interest was the brand, while for the remaining two juices Del Monte and Dimes it was the flavor labeled 100%.

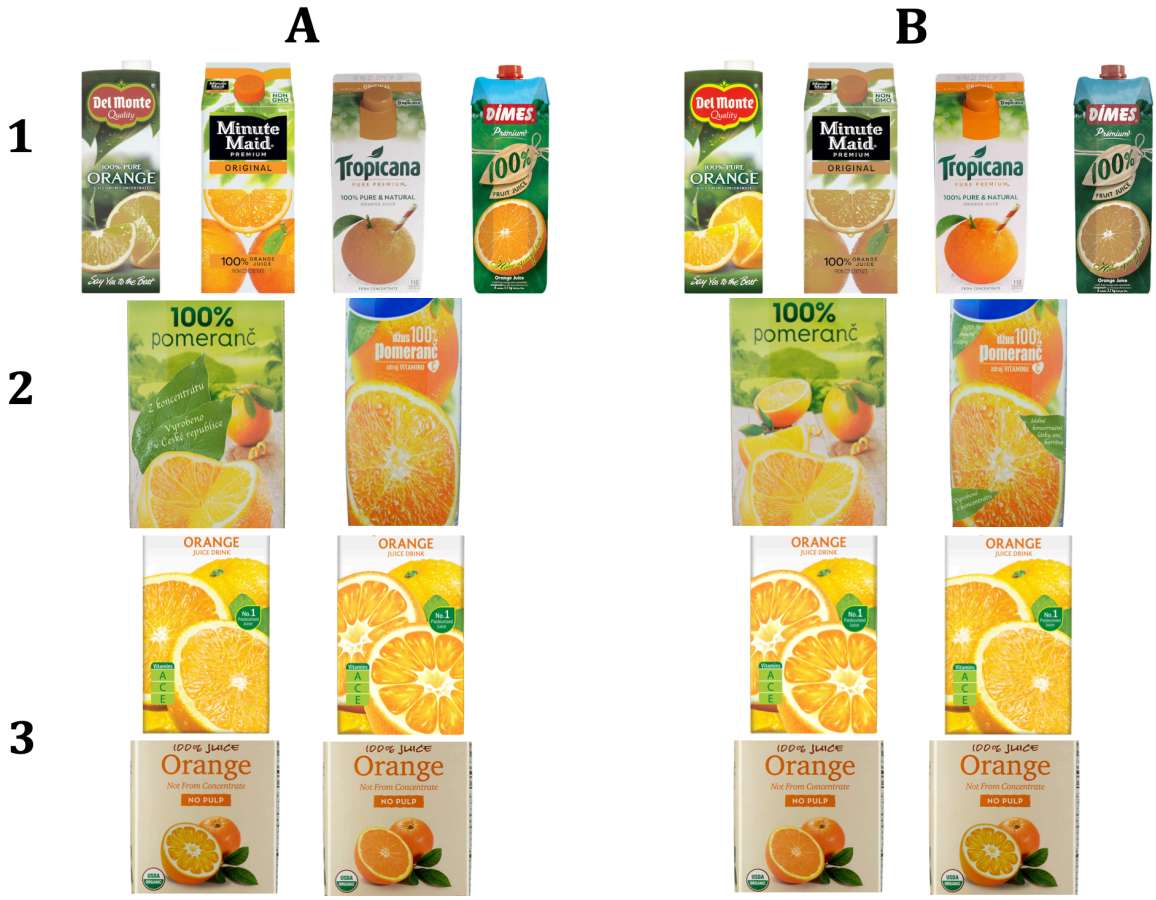

Figure 1 Variants of stimuli used for A/B test.

Table 2 Average dwell time of selected AOIs of juices from the first part of eye-tracking research.

		Normal saturation	Lower saturation
Del Monte	Brand	4.1%	4.9%
	Picture	5.9%	4.3%
	Flavor + 100%	9.3%	5.0%
Minute Maid	Brand	20.0%	13.1%
	Picture	5.7%	4.6%
	Flavor + 100%	3.1%	1.8%
Tropicana	Brand	10.4%	7.4%
	Picture	6.0%	2.5%
	Flavor + 100%	3.1%	2.0%
Dimes	Brand	4.2%	1.7%
	Picture	4.9%	4.1%
	Flavor + 100%	5.9%	6.6%

Table 2 shows the average dwell time in the percentage of selected areas of interest at lower and higher color intensities. Based on these numbers we're able to conclude that higher saturation positively impacts the attention paid to the selected areas of interest. This impact of saturation has been statistically tested with the first hypothesis, which has been observed individually at each juice. Table 5 shows that the *p*-value of tests is lower than the significance value $\alpha = 0.05$ in three out of four tests, therefore the null hypothesis is rejected and the alternative hypothesis is accepted instead. Therefore, it can be concluded that most of the offered juices showed a statistically significant effect of color saturation on the specific juice's attention. In the case of the juice Del Monte where the null hypothesis of the nonexistence of color saturation impact on dwell time was not rejected, Table 5 shows higher average dwell time in the case of higher color saturation. We are therefore able to observe the positive impact of color saturation in this juice, even though it has not been confirmed as statistically significant. **Kovač et. al (2019)** also observed the same impact of brighter colors during his research, which confirmed that brighter colors are more attractive to consumers. Brighter colors not only impacted the dwell time of consumers but also their selection of the juice. During the eye-tracking research, they were asked to choose one of the four juices they fancied the most. Within group A, it was very clear since 18 respondents (95%) chose juice Minute Maid, while 1 respondent (5%) chose juice brand Dimes. Both brands had fully colored packaging. Group B was less clear. Juice Minute Maid was fancied the most by 4 participants (21%) despite the lowered color brightness in packaging. The remaining participants would choose juices with higher package color saturation, more specifically 5 (26%) would choose Del Monte and 10 respondents (53%) would choose juice Tropicana. We can conclude that the packaging colors are being subconsciously perceived by consumers who may be influenced by more saturated colors in the form of fancying the juice more. This fact has also been clarified in a study by **Wei et al. (2014)** who explains that saturated colors create a new expectation of a fresh fruit product in consumers. Juice package with bright colors may create an impression of a freshly squeezed juice. The higher presence of orange color on juice packages Tropicana and Minute Maid may have caused higher dwell time with these brands. **Wei et al. (2014)** and **Ježovičová, Turčinková and Drexler (2016)** state that it is appropriate to use a color in the background of the juice package that corresponds to the fruit from which the juice is prepared. **Schloss and Palmer (2010)** found in their research that the evaluation of color preferences and harmony was highest for colors that have the most similar hues. This could also have resulted in a successful selection of these juices by the respondents. The mentioned fact may have also contributed to the choosing of these juices by the respondents. On the other hand, **Hurley et al. (2017)** did not confirm the significance of color harmony on package preference in his study. He stated that designers have creative freedom in package design and are not required to follow this rule.

In the second part, we researched whether an edit of the front side of juice packaging can impact the reviewing process of the juice by the respondent. Two Czech juice brands Hello and Relax in tetrapack package were chosen as the stimuli. The front sides of the packages were edited with additional information from the back sides in the form of texts placed in leaves. In the case of the juice Hello, the added information were "z koncentrátu" (from concentrate) and "Vyrobeno v České republice" (Made in Czech Republic). In case of the juice Relax, the added information was "100% obsah ovocné složky" (100% fruit content), "Žádné konzervační látky ani barviva" (No preservatives, no artificial colors) and "Vyrobené z koncentrátu" (Made from concentrate). The choice of this information was made regarding the study results by **Gadioli et al. (2013), Mohebalian, Cernusca and Aguilar (2012)** and **Romano, Rosenthal and Deliza (2015)**.

Based on the heat maps in Figure 2, it is clear that the graphic edit of the front side of the packaging drew significant attention from the respondents. Figure 2 also shows that attention paid to additional information increased at the expense of the sign "100% pomeranč" (100% orange) and the image of an orange. The most viewed part of the front side was leaves with information (37.5%), while with the original package without any edits it was the brand name (21.9%). Great attention while viewing the front side of the package was also paid to juice flavor along with the 100% sign, which the respondents in

Figure 2 Heat maps of tested variants juice Hello with and without additional informations.

group A paid attention to for about 16% of viewing time, while in group B they spent about a quarter of it.

However, the method of viewing the back side of the juices was the same in both variants. In both groups, participants spent more than 50% of the time reading the juice composition in the Czech and Slovak languages. Only 2% of viewing time was spent on each of the other areas of interest such as producer, volume, producer's website label, etc.

Similar to the Hello juice, the Relax brand can be seen in Figure 3, where we can observe the attention of the respondents with accompanied information on the front side. With the front page without additional information, the areas of greatest attention are flavor along with 100% (46.3%), brand (24.9%) and orange image (14.4%). In case of the front page with information, the flavor along with 100% (30.3%) and brand (19.7%) are also the main areas of interest but are followed by "no preservatives or artificial colors" (14.3%) and "100% fruit content" (9.5%). Only then follows the orange picture (4.6%). The label "made from concentrate" received less than 3% attention. This lesser attention could also be due to the position of this label, as it was found out that consumers prefer the upper part of the package **(Juravle et al., 2015; Rebollar et al., 2015)**.

Even in the case of the back of the Relax Juice, the most observed part was the juice composition, at which participants spent up to 40% of their time. However, there were two other areas of interest in this juice, where the participants spent a certain amount of time. Those are the nutritional values, that group A respondents went through for about a quarter of the time, while in group B the participants spent a little less time there (only about 15%). The respondents' attention was also drawn to the graphic element located in the center of the package, which spoke of shaking the juice before opening. Participants in group A spent 13.9% of the time and group B spent 11.6% of the time in this area of interest.

In this case of the eye-tracking research, we tested the assumption that when placing additional information from the back of the juice package to the front, the respondents spend less time looking at the back of the juice package. The hypothesis was tested for both juices, but in neither case the *p*-value of the tests did fall below the significance level of 5% (Table 5) and therefore the null hypothesis cannot be rejected. Thus, there is no statistically significant difference between the time of observation of the back side for additional information on the front side of the juice. With Relax juice, the *p*-value (0.0597) is relatively close to the rejection of the null hypothesis. This is also shown by the average back side viewing time, which is significantly lower if the front page information is added, although this has not been confirmed statistically. From Table 5, it can also be noted that the average back side viewing time is even longer in the case of Hello juice if there is additional information on the front side in comparison to its absence. This could also be due to the number of information added to the front, which was higher in the case of Relax, but specific information could also have an impact. Indeed, Relax juice had information about vitamin C on the front and according to **Gadioli et al. (2013)**, this information is very important for young people and students. Therefore, along with additional information, the front of Relax juice could have had a more meaningful value than Hello juice.

Figure 3 Heat maps of tested variants juice Relax with and without additional informations.

However, these incentives have confirmed the importance of the back juice packaging, which is significant for consumers. This was also confirmed in an in-depth interview where up to 32 (84%) of respondents said they always or frequently read the back of juice containers while the remaining 6 (16%) do not read this information.

Recent packages of fruit juices in this research have been examined for the perception of different types of presented oranges. For each pair of juices, the respondents were to choose the one that makes them fancy orange juice the most.

For the first stimulus, juice 365 Everyday Value, it is clear from the heat maps (see Figure 4) that respondents were primarily driven by orange images during the decision process. This is also confirmed by the authors **Simmonds and Spence (2017)**, who confirms that food images can evoke hunger or craving for food in the consumers' minds. The average percentage values of dwell time for individual areas of interest are shown in Table 3, which shows that the participants spent most of their time looking at pictures of oranges on the juice packaging. They spent up to 30% of their total viewing time by looking at orange images.

Figure 4 Heat maps of tested variants juice 365 Everyday Value with photo and illustration of oranges.

Table 3 Average dwell time of selected AOIs of juice 365 everyday value.

	Photo of oranges	Illustration of oranges
Opening system	1.35%	1.45%
Brand	8.45%	7.40%
Flavor + 100%	11.10%	9.25%
Picture	15.10%	16.10%
Additional information	2.40%	2.00%

In both groups, although the oranges in the form of illustrations were viewed longer, the difference was only 1%. The second most viewed part of the package was the 100% composition label along with the flavor, which is also confirmed by the heat map on which the area is colored as well. Juice brand viewing ranked third. The respondents paid the least attention to the uppermost part of the package (opening system) as well as the lowermost part of the package, where the volume and health claims were stated.

In the second stimulus, the package also differed in the form of oranges (graphic/real), but in this case the oranges covered a larger package area than the 365 Everyday Value juice. With the Peel Fresh juice, however, it is not possible to speak of a clear way of monitoring the juice package as it was with the first stimulus. From Figure 5 it can be stated that in this juice, the participants checked the package from top to bottom, which was due to a relatively small number of elements on the package. Table 4 shows the average percentage times of viewing specific areas of interest in Peel Fresh juice. In the case of both juices, the respondents spent about 50% of their total viewing time looking at oranges. With the brand, the average was about 13% of the viewing time. When comparing the juice packages (Figure 5), it is shown that some attention is also paid to the vitamin elements and the "No. 1 Pasteurised Juice" label. This could be because when comparing the appearance of oranges, the respondents looked from one package to another with the aforementioned elements, and therefore the respondents' eyes were focused on them for a certain amount of time.

Table 5 also shows the results of the last third tested the hypothesis, which examined the assumption that the photographs of oranges placed on the package will draw the

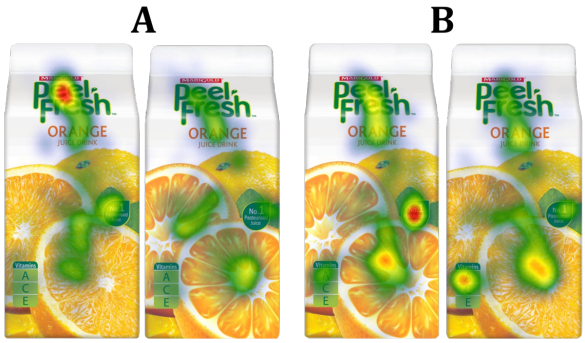

Figure 5 Heat maps of tested variants juice Peel Fresh with photo and illustration of oranges.

respondents' attention more than the illustrated oranges. However, the *p*-values of both tests did not reject the null hypothesis, thereby confirming an alternative hypothesis that suggests statistical insignificance of the image type for attention to packages. However, Table 5 shows that higher average attention was recorded in both cases of juices with a genuine depiction of orange.

Although the type of image did not have a significant effect on the length of attention, it affected fancying the orange juice. The respondents' answers about evoking the biggest appetite for juice when choosing from two versions of 365 Everyday Value juice packages clearly say that respondents prefer photographs of oranges over illustrations.

Up to 35 out of 38 respondents (92%) chose the real orange option, while only 3 participants (8%) had a greater appetite for juice when looking at the graphic version. A similar result can be observed with Peel Fresh juice.

Up to 33 participants (87%) fancied a juice package with real oranges more, while 5 respondents (13%) fancied a package with a graphic version of oranges. These results

Table 4 Average dwell time of selected AOIs of juice Peel Fresh.

	Photo of oranges	Illustration of oranges
Brand	7.30%	5.50%
Flavor	3.85%	3.85%

are in line with the results of other studies that have shown that food product photography gives consumers feel of a healthier and more natural product **(Kovač et al., 2019; Smith, Barratt and Sørensen, 2015; Abrams, Evans and Duff, 2015; Pensasitorn, 2015)**.

This study has shown interesting results in the graphic design of juice packages, but it can also provide resources for further research. Research of the form of the fruit's presentation on the juice package proves to be suitable. The way of fruit processing has already been studied by **Machiels and Karnal (2016)**, but it would also be useful to find out what type of fruit serving produces the greatest appetite for juice (sliced, whole…).

A certain extent of limitation of this study can be seen in the unequal distribution of men and women, as the majority of the sample were women. This could have had an impact on the overall data obtained. Indeed, in some studies **(Orquin and Scholderer, 2011; Abdi Sargezeh, Tavakoli and Daliri, 2019; Sammaknejad et al., 2017)**, it has been confirmed that there are certain differences in the monitoring of men and women. The weak point of this study could also be the low number of respondents. The limitations of this study can also be seen when creating heat maps. The heat maps were created separately for Group A and Group B with each group containing 19 participants. However, **Pernice and Nielsen (2009)** recommend a minimum of 30 respondents for the creation of heat maps. Therefore, the resulting heat maps shown above may be slightly distorted.

CONCLUSION

The eye-tracking research has shown that color saturation of the fruit juice package has a significant impact on the attention of Y-generation consumers since the *p*-value in three out of four tests of color saturation of the juice package was lower than $\alpha = 0.05$. The lesser attention paid to the juice as the result of a lower saturation effect has been confirmed in up to three out of four juices. This claim is also reinforced by the fact that the vast majority of respondents chose the package with the highest color saturation as the packaging which evoked the highest appetite for orange juice. Adding information to the front side of the juice packages did not significantly reduce the viewing time of the back of the juice packages. Therefore, the importance of reading information on the back sides of juice packages, which is sometimes or occasionally read by up to 85% of the respondents, has been confirmed. The respondents spent most of their time reading the juice composition while viewing the back side. In the case of an image type, its impact on respondents' observation time was not confirmed. It however did have an impact on fancying the orange juice, as up to 90% of respondents evoked the appetite by looking at the images of real oranges. It has also been found out that when deciding on the induction of appetite, the long-term focus was on fruit images on the juice package.

ANTIOXIDANT ACTIVITIES OF SNAKEHEAD (*CHANNA STRIATA*) FISH SKIN: PEPTIDES HYDROLYSIS USING PROTEASE TP2 ISOLATE FROM SWAMP PLANT SILAGE

Ace Baehaki, Indah Widiastuti, Citra Nainggolan, Nuni Gofar

ABSTRACT
The purpose of this research was to study the antioxidants activities of peptides from skin fish of snakehead (*Channa striata*), using hydrolysis of protease TP2 isolate from swamp plant silage. This research 5 treatments hydrolysis time (0, 30, 60, 90, 120 min, respectively), with two replicates, which included several stages of preparation and pre-treatment of the snakehead fish skin production of protease enzymes which were isolated from swamp water, preparation of protein hydrolysates, measurement of hydrolysis degrees, analysis of peptides content and analysis of the antioxidant activity. Results showed that the treatment had given a significant effect on the 5% level of the degree of hydrolysis production (13.98% – 27.08%), with peptides content of 2.73% – 3.78% and antioxidant activity (10.75% – 20.7%). The results of the degree of hydrolysis indicate that the longer the hydrolysis time, the percent degree of hydrolysis will increase. Peptide content and antioxidant activity were increased with increasing hydrolysis time.

Keywords: hydrolysis time; protein hydrolysates; skin; snakehead (*Channa striata*); antioxidant

INTRODUCTION
Snakehead fish in South Sumatra is generally used as basic ingredients of the typical Palembang food industry, namely pempek, kerupuk, and kemplang. The processing process produces waste, one of which is skin waste. The waste is still underutilized due to lack of technological equipment, low commercial value, and a lack of application to the waste **(Blanco et al., 2007)**.

Unused waste contains very important nutritional compounds such as protein content (collagen and keratin) and mineral composition **(Moller et al., 2008)**. This waste has the potential to be used as a protein hydrolysate containing bioactive peptides. Several studies have shown that fish protein hydrolysates have functional properties as antihypertensive, anticancer, antimicrobial, and antioxidant. Bioactive peptides can be obtained by several methods of hydrolysis, namely hydrolysis with digestive enzymes and hydrolysis by proteolytic enzymes produced by microorganisms or plants **(Korhonen, 2009)**.

The bioactive activity of peptides is very diverse and is determined by the sequence of amino acids that make up it. Some bioactive peptides can be precursors of proteins or peptides that will be active when hydrolysed from natural proteins through enzymatic hydrolysis in the digestion, fermentation, and processing processes **(Korhonen, 2009)**. Bioactive peptides have several mechanisms of antioxidants, among others: as radical scavenging (free radical deterrent), a mineral chelating, metal-reducing agents and protectors **(Elias et al., 2008)**. The antioxidant activity of bioactive peptides is strongly influenced by the natural nature and composition of the relevant peptide fragments **(Phelan et al., 2009)**. This is very much determined by the specificity of the protease enzyme used **(Korhonen and Pihlanto, 2006)**. The potential for peptides as antioxidants is not only limited to the prevention of risk factors for degenerative diseases, but also for cosmetic composition and food preservation **(Samaranayaka and Li-Chan, 2011)**.

Proteases are hydrolytic enzymes that can break down peptide bonds between amino acids. Protease enzymes hydrolyse peptide bonds specifically from their original proteins, then produce peptides with sequences and diverse functional properties **(Gonzalez-Rabade et al., 2011)**. One source of proteases are some microorganisms that have been known to produce proteases for commercial applications are *Bacillus, Lactobacillus, Pyrococcus, Termonospora, Rhizopus, Mucor, Endothia* and *Aspergillus* **(Rao et al., 1998)**. In this study using TP2 isolates from swamp plant silage which had a high protease enzyme activity **(Baehaki et al., 2018)**. Protease enzymes are used to hydrolyse proteins in snakehead fish skin and then the hydrolysates produced are tested for antioxidant activity. Antioxidants are known to inhibit the work of free radicals so that the search for antioxidants

from snakehead fish skin is an effort to optimize the use of natural materials in Indonesian waters.

Scientific hypothesis

Protease from swamp plant silage isolates can be used for hydrolysis of snakehead fish skin (*Channa striata*) to produces peptide with antioxidant activity. Degree hydrolysis, peptide content and antioxidant activity increase with increasing hydrolysis time.

MATERIAL AND METHODOLOGY

Materials

The materials used in this study were snakehead fish (*Channa striata*) size ±500 g (weight), TP2 isolate, trichloroacetic acid (Merck, Germany), NaOH (Merck, Germany), DPPH and nutrient Agar (Merck, Germany). The tools used include pH meter, OHAUS analytical balance, incubator, micropipette (Single Channel Capp 10-100 Ul, USA), autoclave (Hirayama, Japan), hotplate (Cimarec, United Kingdom) and spectrophotometer.

Methods

Preparation of Snakehead fish Skin

The preparation of snakehead fish skin is done according to the method of **Liu et al. (2015)**. Preparation is done by separating the skin from other parts such as scales and the rest of the meat. The skin is cut to the size of approximately 1 x 1 cm^2 using scissors. The first stage is the pre-treatment process with NaOH solution which aims to eliminate non-collagen proteins and other impurities such as fat, minerals, pigments, and odours. The fish skin of *Channa striata* is soaked in NaOH solution with a concentration of 0.05 M for 6 h and every 2 h the NaOH solution is replaced with the ratio between the skin and NaOH solution is 1:10 (w/v). The fish skin of *Channa striata* immersed in selected NaOH is washed to near neutral pH.

Refresher Culture

The way the culture of refresher works is as follows: The culture used in this study was in the form of culture stored in the refrigerator. Therefore, the culture must be refreshed first. Approximately 1 ose was scratched after being transferred into a test tube containing 10 mL of sterile NB media, then incubated at 37 ℃ for 24 h. Furthermore, 0.1 mL of the test tube containing the culture was taken and put in another test tube containing 10 mL of sterile LB media to be incubated at 37 ℃ for 24 h. Incubated cultures are ready for use.

Protease Production from TP2 Isolate

The production of protease enzymes uses the method of **Baehaki, Rinto and Budiman (2011)** modified, carried out as follows: TP2 isolates were inoculated on 10 mL of Luria Bertani Broth (LB) media with 1% tripton composition, 1% NaCl, and 0.5% yeast extract. LB media taken 10% of the amount of media then added to the new Luria Bertani Broth (LB) media as a medium for producing proteases. The media is then incubated in the shaker incubator for 45 h, at 37 ℃ at a speed of 120 rpm. The extraction of the protease enzyme was carried out by centrifuging the medium of bacterial growth at a speed of 3000 rpm for 15 min at 4 ℃. The supernatant is an enzyme extract that will be used to hydrolyse protein.

Hydrolysates Production

The preparation of protein hydrolysates was carried out according to the method of **Bhaskar et al. (2008)**. The raw material in the form of fish skin pre-treatment has been mixed with a pH 7 buffer until homogeneous by comparison (1:10). The protease enzyme is added with a concentration of 20% (v/v). The mixture is then hydrolysed at 55 ℃ for 0, 30, 60, 90, and 120 min using a water bath shaker, during the hydrolysis process the sample is stirred regularly. The results of hydrolysis are included in the water bath to inactivate the enzyme at a temperature of 85 ℃ for 20 min. Samples were centrifuged for 20 min at 10 ℃ with a speed of 6000 rpm to separate the dissolved fraction (supernatant) and the non-soluble fraction (pellet). The protein hydrolysate of snakehead fish skin (*Channa striata*) produced was frozen, before being used analysed.

Degree of Hydrolysis.

The degree of hydrolysis is calculated based on the percentage ratio of trichloroacetic acid (TCA) according to the method of **Hoyle and Merritt (1994)**. 20 mL of protein supernatant/hydrolysate added 20% TCA (w/v) as much as 20 mL. Then was centrifuged at a speed of 8,000 rpm at 4 ℃ for 10 min. The resulting supernatant was analysed for protein content. The degree of hydrolysis can be calculated using the following formula:

$$\% \text{ DH} = \frac{\text{100 x dissolved nitrogen in TCA 10\%}}{\text{Total nitrogen in the sample}}$$

Analysis of Peptide Content

Analysis of extract peptide levels was carried out using the formol titration method **(Wikandari and Yuanita, 2016)**, as follows: A total of 5 mL extracts of the sample are put in 100 mL Erlenmeyer. Then extract the sample added 10 mL aqua bides and ±0.5 mL PP indicator. Then the sample was titrated with 0.1 N NaOH until it is pink. Samples added 1 mL of 40% formaldehyde solution and titrated with NaOH.

$$\%N = \frac{a}{B \times 10} \times \text{NaOH} \times \text{Ar N} \times \text{FP}$$

Where:
a = Titration Volume Formol; b = Sample Weight; fp = Dilution Factor

Analysis of Antioxidant Activities with DPPH Method

Testing of antioxidant activity using the DPPH method which refers to **(Shimada et al., 1992)** is as follows: The samples tested for determining the highest antioxidant activity were protein hydrolysate filtrate which was diluted 20 times with ethanol solvent p.a. The sample solution and the comparative antioxidant solution that was made each were taken as much as 1.5 mL and reacted with 1.5 mL of 0.1 mM DPPH solution in a test tube. The mixture is then vortexed and incubated at 37 ℃ for 30 minutes and the absorbance is measured at a wavelength of 571 nm to determine its inhibitory percent. The results of absorbance

measurements and to determine antioxidant activity are expressed in the formula:

$$\% \text{ Inhibition} = \frac{\text{blank absorbance - sample absorbance}}{\text{blank absorbance}} \times 100$$

Statistical analysis

All experiments were carried out in triplicate and the results are reported as means with standard deviations. The experimental data were subjected to analysis of variance (Duncan's test), at the confidence level of 0.05 using the SPSS software (IBM, USA).

RESULTS AND DISCUSSION

Degree of Hydrolysis

The degree of hydrolysis is a parameter that shows the ability of proteases to break down proteins by comparing amino nitrogen with total nitrogen, the degree of hydrolysis can be used as an indicator of the success of the hydrolysis process **(Hasnaliza et al., 2010)**. Hydrolysis conditions are generally influenced by substrate concentration, enzyme concentration, temperature, pH, and time **(Muchtadi et al., 1992)**. Different hydrolysis times will produce different types of free amino acids and peptides which can be seen from the percentage of hydrolysis. The value of the degree of hydrolysis changes during the hydrolysis process. The percentage value of the hydrolysis degree of snakehead fish skin (*Channa striata*) can be seen in Figure 1.

The results of the degree of hydrolysis indicate that the longer the hydrolysis time, the percent degree of hydrolysis will increase. The smallest hydrolysis degree found in the treatment the 0 min hydrolysis time was 13.98% and the highest value of hydrolysis degree in the treatment 90 min hydrolysis time was 27.08%. The degree of hydrolysis of snakehead fish skin increased faster in the first 30 min, however, after hydrolysis time of 30 to 90 min there was an increase but not significant (p <0.05). This might be due to the hydrolysis time that was used not long. In the study of **Gomez-Guillen et al. (2010)**, the hydrolysis level of gelatine hydrolysate of tuna skin and squid skin using alkalase has a maximum hydrolysis degree value of 47.52% incubated for 150 min and 43.46% after incubation for 110 min.

In this study, there was a decrease in the value of hydrolysis degrees in the treatment of 120 min hydrolysis time with a percentage of hydrolysis degree of 24.97%. This is in line with the research of **Khirzin et al. (2015)**, on the hydrolysis of collagen protein peptides from gamma sea cucumber using the pepsin enzyme, decreasing the degree of hydrolysis starting from the treatment when hydrolysis 180 min at 54.54%. Decreasing the degree of hydrolysis was caused by several conditions including a decrease in the concentration of available peptide bonds to be hydrolysed, decreased enzyme activity, and the inhibition of the substrate hydrolysis process by the products produced **(Guerard et al., 2001)**. Literature studies show that there was a relationship between the degree of hydrolysis and its bioactivity, generally its antioxidant activity **(Klompong et al., 2007**) and ACE inhibitors **(Chen et al., 2012)**.

Peptide Content

Peptides are composed of two or more amino acids that form a bond. If the number of amino acids below 50 molecules are called a peptide if more than 50 molecules are called proteins. Bioactive peptides have extensive biological functions and are beneficial for health, which can function as antimicrobial, antihypertensive, antioxidant, anticytotoxic, and mineral transporting activities **(Korhonen and Pihlanto, 2006)**. Fish skin contains collagen which has three polypeptides (α-chains) in the form of triple helix and can be a source of protein needs animal for the body **(Gelse et al., 2003)**. Peptide level analysis was carried out by the formol titration method **(Wikandari and Yuanita, 2016)**.

The purpose of this hydrolysis was to produce peptides with lower molecular weights to produce peptides with higher antioxidant activity. The average value of the peptide content contained in snakehead fish hydrolysate was shown in Figure 2. The results of the research on the determination of peptide content, the average value of protein hydrolysate peptide content of snakehead fish skin produced ranged from 2.73 to 3.78%. The hydrolysis time treatment of 0 min was not significantly different from the hydrolysis time treatment of 30 and 60 min but it was significantly different from the hydrolysis time treatment of 90 and 120 min. This shows that hydrolysis time that was not long (30 and 60 min) produces the same peptide content as without hydrolysis (0 min), but the use of 90 and 120 min of hydrolysis time results in increased peptide content.

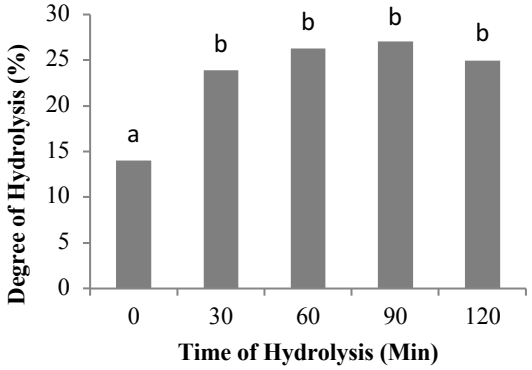

Figure 1 Degree of Hydrolysis of Snakehead Fish (*Channa striata*) Protein.

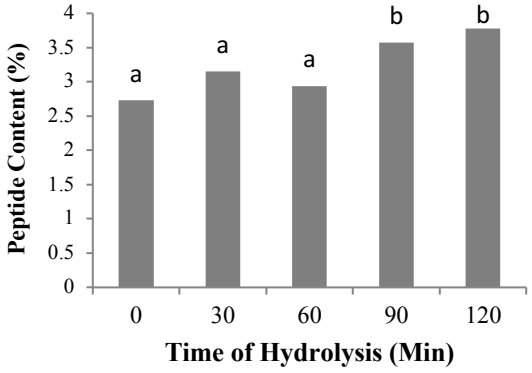

Figure 2 Peptide Content of Hydrolysis Protein from Snakehead Fish (*Channa striata*).

Determination of peptide content was carried out using formol titration, the end point of the titration if the colour changes to pink colour. Peptide bioactivity was influenced by molecular size and amino acid composition **(Gomez-Guillen et al., 2011)**. **Putalan (2018)** states that the hydrolysis time can increase the concentration of peptide content in the selar fish hydrolysate protein. **Nielsen et al. (1997)** also state that peptide content increase as the degree of hydrolysis increases, this was because during the process of hydrolysis the protein was broken down into simpler peptides.

Antioxidant Activity with DPPH Method

In this study, the antioxidant activity of protein hydrolysate of snakehead fish skin was measured using the DPPH method. DPPH which has the molecular formula $C_{18}H_{12}N_5O_6$ and molecular mas was 394.33, DPPH was a stable free radical that can react with other radicals to form more stable compounds **(Molyneux, 2004)**. DPPH can also react with hydrogen atoms to form a stable reduced DPPH (diphenyl picrylhydrazine). A compound can be said to have antioxidant activity if the compound is able to donate its hydrogen atom **(Molyneux, 2004)**. The DPPH method can be used to test solid or liquid samples and is not specific to certain antioxidant components **(Baehaki et al., 2015)**. Percent of DPPH free radical inhibition of snakehead fish skin protein hydrolysate was shown in Figure 3.

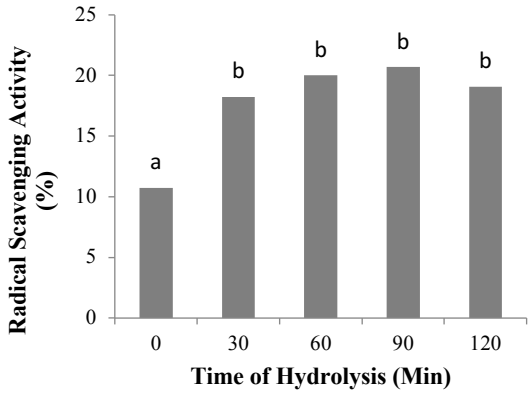

Figure 3 Radical scavenning activity of hydrolyze from Snakehead Fish (*Channa striata*).

The results of the study showed that the highest antioxidant activity produced had a percentage of 20.7% in the treatment of 90 min hydrolysis time. Figure 3 shows the difference between radical scavenging activity (antioxidant activity) without hydrolysis (0 min) and hydrolysis (30 to 120 min). The hydrolysis time used (30 to 120 min) produces radical scavenging activity that was not significantly different (p <0.05), this may be due to the hydrolysis time was used not long and the enzyme was used crude enzyme from TP2 isolate.

Several studies on the antioxidant activity of proteins have been carried out such egg yolk protein **(Park et al. 2001)**, Alaska Pollack skin gelatine hydrolysate **(Kim et al. 2001)**, pork protein **(Carlsen et al. 2003)**, yellowfin fish protein **(Jun et al. 2004)** and collagen from skin fish **(Baehaki et al., 2016)**.

CONCLUSION

Protease from swamp plant silage isolates can be used for hydrolysis of snakehead fish skin (*Channa striata*) to produces peptide with antioxidant activity. The difference in hydrolysis time in the preparation of snakehead fish skin hydrolysates has a significant effect on the degree of hydrolysis, peptide content, and antioxidant activity (p <0.05).

EFFECT OF INOCULATION ON THE CONTENT OF BIOGENIC ELEMENTS IN THE WHITE LUPINE AND GRASS PEA

Erika Zetochová, Alena Vollmannová, Ivana Tirdil'ová

ABSTRACT

The aim of this work was to determine the influence of the inoculant on the content of biogenic elements in ten foreign varieties of white lupine (*Lupinus albus*) and three varieties of grass pea (*Lathyrus sativus* L.) of Slovak origin. Rizobine was used as the inoculum before sowing. Dried and homogenised seed samples were mineralised using concentrated HNO^3 using the MARS X – Press 5 instrument. Analytical determination of macro- and microelements in all samples was performed using ARIAN DUO 240FS/240Z atomic absorption spectrometer. The determined values of biogenic elements content were expressed as $mg.kg^{-1}$ of dry matter. The average content of Cu was lower for both crops in variant A compared to variant B. The addition of the inoculant increased the content of Cu in both crops in lupine by 3.7% and grass pea by 10.94%. The Zn content of variant A in lupine was 19.14% higher than that of the grass pea. Grass pea seeds contained 97.76% less Mn than white lupine seeds in both variants. The Cr content of white lupine was 67.74% higher in variant A than in grass pea. The inoculant also increased the content of Cr in lupine by 25.0%. Lupine contained 30.02% less Fe in variant A and 41.27% less Fe in variant B than the grass pea. The results we have obtained show that Ca, K, and P are the predominant elements in the seeds of grass pea in both variants. By comparing selected types of legumes we found that the grass pea features a higher content of Cu, Fe, K, and P. The analysed seeds of white lupine had a higher content of Zn, Mn, Cr, Ni, Co, Na, Ca, and Mg. In conclusion, inoculation does not significantly affect the content of biogenic elements of selected legume species.

Keywords: lupine; grass pea; inoculation; biogenic elements; analysis

INTRODUCTION

Legumes are the mature, dry seeds of annual and perennial plants of the *Fabaceae* family. Even though legumes have been in our diet for more than a thousand years, studies in recent years have pointed to their unique composition. They are a source of plant proteins, containing a complex of saccharides, soluble and insoluble fibre, essential vitamins, minerals, and polyphenols. The content of these substances advises them among functional foods with a beneficial effect on human health. In combination with cereals, they provide the body with full-value proteins.

Legumes are largely consumed by humans worldwide. Human diets are mostly insufficient in mineral elements like zinc (Zn), iron (Fe), iodine (I) and they may also be deficient in selenium (Se), copper (Cu), calcium (Ca), and magnesium (Mg) mostly in less developed countries **(Welch and Graham, 2002; White and Broadley, 2005)**. Minerals are present in greater quantities in legumes than in cereals. The most represented macroelements are potassium, phosphorus, and calcium. Legumes are rich in iron, zinc, manganese, copper, nickel, cobalt, and molybdenum **(Tichá and Vyzínová, 2006; Velíšek, 1999)**.

Essential elements, including the main elements and a number of trace elements, make up electrolytes, enzymes, vitamins and hormones **(Gruchow, Sobucinski and Barboriak, 1988; Kirbaşlar et al., 2012)**. The importance of mineral composition is due to their nutritional properties and beneficial health effects, as well as their meeting dietary guidelines required for a healthy diet **(Welna, Klimpel and Zyrnicki, 2008; Kirbaşlar et al., 2012)**.

The demand of the ever-growing world population for protein foods is no longer sustainable through animal products alone. To compensate for this deficiency, soya bean has become the prevalent source of plant protein for food and feed.

During recent years, human consumption of lupine seeds has increased worldwide as lupine seeds are a good source of nutrients, not only of proteins but also lipids, dietary fibre, minerals, and vitamins. There are variations in the protein content between species, cultivars, the growing conditions, and soil types **(Martínez-Villaluenga, Friás and Vidal-Valverde, 2006)**. Although lupine belongs to the legumes and is not described as an oilseed crop, it has a considerable amount of oil in its seeds **(Uzun et al., 2007)**. Lupine seeds are a good source of macro- and

microelements **(Ehsan et al., 2015)**. Some *Lupinus* species are able to accumulate Zn, Cd, Mg, Al, Hg **(Esteban et al., 2008)**, Pb, and Cr **(Ximénez-Embún et al., 2001)**; therefore new species of lupine should be examined before its application for food.

Grass pea (*Lathyrus sativus* L.) is an annual plant of the *Fabaceae* family, commonly used for feed or feed components. Grass pea is high in protein (26 – 32%), highly adaptable to extreme conditions, resistant to disease, and has a low moisture requirement for growing. *Lathyrus sativus* L. is cultivated worldwide as a resistant leguminous plant showing tolerance to various biotic and abiotic factors **(Vaz Pato et al., 2006; Nagati et al., 2015)**.

One of the most beneficial characteristics of legumes is their ability to fix atmospheric nitrogen in symbiosis with soil bacteria called rhizobia which form several species **(Peix et al., 2015)**. These bacteria induce nodules in legume roots or stems where the nitrogen fixation takes place after the infection process. This process requires several steps.

After nodule formation, the rhizobial cells are released into the plant cells, and they are transformed into bacteroids which are able to fix atmospheric nitrogen. This process involves plant and bacterial proteins such as leghemoglobins and nitrogenases **(Peix et al., 2010)**. Therefore, the inoculation of a legume with rhizobia induces metabolic changes in the plant. The most studied changes have been the increase in nitrogen and protein contents, which have been exploited in agriculture to improve the crop yield of several legumes **(Morel, Braña and Castro-Sowinski, 2012)**. Also, in the last decades, the increase of other plant components, such as phosphorous, has been studied after the inoculation of phosphate solubilising rhizobia **(Dahale, Prashanthi and Krishnaraj, 2016)** and currently, the increase of potassium by using K-solubilising bacteria is starting to be analysed **(Kumar et al., 2016)**.

It is apparent that the studied legumes are meaningful sources of all the necessary elements in the human diet. The aim of this work was to determine the influence of inoculant on the content of biogenic elements in selected varieties of white lupine (*Lupinus albus*) and grass pea (*Lathyrus sativus* L.).

Scientific hypothesis

We hypothesize that the content of inoculant will have an effect on the content of macro and microelements in white lupine and grass pea.

MATERIAL AND METHODOLOGY

The analysed plant material was sown in field trial plots (GPS coordinates 48.5917973 and 7.827155) at the National Agricultural and Food Center – Research Institute of Plant Production in Piešťany (Figure 1, Figure 2, Figure 3, Figure 4). Piešťany belongs to the corn production area, which is located at an altitude of 162 m.n.m. In this area, the average annual temperature is around 9.2 °C, and long-term precipitation average is 625 mm. The climate is typically lowland, slightly dry, and slightly windy. The average number of sunny days is 265 per year.

The evaluated material consisted of two types of legumes: white lupine (*Lupinus albus*) and grass pea (*Lathyrus sativus* L.). From the selected types of legumes, we analysed 11 genotypes of foreign origin *(Lupinus albus)* and three genotypes of Slovak origin (*Lathyrus sativus* L.) (Table 1), which belong to the gene pool of legumes in the Gene Bank of the Slovak Republic. The weight of each legume average sample was 200 g.

Two variants were sown from each genotype control variant (A) and the variant with inoculant (B). The experimental plot had dimensions of 5.2 x 1.5 m. Rizobin was used to inoculate the legume seeds. It has a high content of live bacteria (5*109). An organic polymer was used as a binder in the formulation. Seed inoculation was performed by simple mixing directly in the seed drill. The advantage of seed inoculation is an increase of 13 – 25% of the crop, but also an increase of some qualitative indicators, such as the content of crude protein and oil. Samples were taken at full maturity, dried, and then cleaned.

Analytical methods used

For the analysis, we used dry seeds of selected types of legumes, 1 g from each genotype. Samples were analysed in two phases. In the first phase, the material was decomposed in a wet way with the addition of 10 cm^3 of oxidised HNO_3.

Mineralisation of the samples was performed by microwave digestion in the Mars X-Press 5 (CEM Corp., USA). In the second phase, after the mineralisation, the residue was filtered and filled with distilled water in a 50 cc volumetric flask to the exact volume. The analytical endpoint of the determination of the heavy metal content in the plant material was atomic absorption spectrometry using the VARIAN DUO 240FS/240Z (Varian. Australia) instrument. All risk metal content values were expressed as $mg.kg^{-1}$ of dry matter in order to assess the safety of the monitored plant food raw materials as objectively as possible. Eachl analysis was done in 4 repetitions.

Statistical analysis

The measured data were statistically evaluated using the statistical package STATGRAPHICS Centurion XVI.II. The t-test was used to compare means, F-test to compare standard deviations, Mann-Whitney (Wilcoxon) W-test to compare medians, and Kolmogorov-Smirnov test to compare the distributions of the two samples.

RESULTS AND DISCUSSION

Legume seeds are known to contain important nutrients like Mn, Cu, P, Zn, Mg, Ca, and K **(Glew et al., 1997; Tharanathan and Mahadevamma, 2003)**. The average values for the content of select macro- and microelements of lupine and pea in the control variant (A) and in the variant with inoculum addition (B) are given in Table 2 and Table 3.

We found that the average content of Zn, Mn, Cr, Ni, and Co was higher in lupine in both variants (Table 2). On the other hand, the content of Cu and Fe were higher in grass peas in both variants (Table 2). Zinc plays a central role in many biochemical and immunological functions **(Fell and**

Lyon, 1994; O´Dell and Sunde, 1997). The Zn content of variant A in lupine was 19.14% higher than that of the grass pea. The addition of the inoculant reduced the Zn content by 16.40% in grass pea. White lupine seeds contained Zn in variant A by 2.87% more than in variant B. Many metabolic processes require magnesium, iron, and potassium.

Similarly, the content of microminerals in the evaluated leguminous plant seeds was dependent on variety too, and the greatest differences were noted for manganese. Noteworthy, the white lupine seeds accumulated significant amounts of manganese **(Page, Weisskopf and Feller, 2006)**. The content of Mn in lupine seeds strongly depends on the field conditions and the species. **Hung et al. (1987)** examined 33 samples of seeds from two species of lupin and found that *L. angustifolius* had a much lower Mn content (61 $\mu g.g^{-1}$) than *Lupinus albus* (1316 $\mu g.g^{-1}$). The average Mn content was higher in white lupine in variant A (571.63 $mg.kg^{-1}$) and also in variant B (588.20 $mg.kg^{-1}$) in comparison to the results of other types of lupine seeds. Generally, the Mn content of *Lupinus albus* L. 2277.16 $mg.kg^{-1}$) was found to be higher than other legume seeds **(Özcan, Dursun and Al Juhaimi, 2013)**. Grass pea seeds contained 97.76% less Mn than white lupine seeds in both variants. The Mn content in variant A was 8.11% lower than in variant B. According to **Trumbo et al. (2001)** the greatest levels of this element were noted in the white lupine seeds (especially in the Butan cultivar – 370 $mg.kg^{-1}$ DM), compared with only 13 – 20 $mg.kg^{-1}$ DM in the lentil, grass pea, common bean, and broad bean seeds ($p < 0.05$) (Table 2). In these investigations, the average content of manganese was 252 $g.kg^{-1}$ DM, while the adequate intake (AI) of this element is 1.8 mg per day^{-1}.

In humans and animals, Cr is an essential nutrient that plays a significant role in the metabolism of glucose, fat, and protein through potentiation of insulin action. There is limited data on which to base tolerable daily intakes for chromium. The Cr content of white lupine was 67.74% higher in the variant A than in grass pea. The addition of the inoculant also decrease the content of Cr in lupine by 25.0%. We also noticed significant differences in Cr content by comparing both variants in lupine. Variant A contained 52.69% more Cr than variant B. It is the highest difference observed in the comparison of variants A and B for all monitored elements. The average content of Cu was higher for both crops in the A variant compared to the B variant (Table 2). The addition of inoculant increased the content of Cu in both crops of lupine by 3.7% and grass pea by 10.94%. Iron is compulsory for haemoglobin and myoglobin synthesis **(Saleh-E-In et al., 2008)**. The Cu content was increased by 27.1% for grasspea in variant A and by 17.47% in variant B. We found that the content of Fe was higher in the seeds of the grass pea in both variants. Lupine contained 30.02% less Fe in variant A and 41.27% less Fe in variant B than the grass pea. The difference in Fe content of variants A and B was 1.64% for white lupine.

Nickel promotes iron absorption and protects against anemia. Nickel is considered synergistic to Fe by promoting its intestinal absorption. The highest content of Ni was found in seeds of white lupine for the A variant (3.99 $mg.kg^{-1}$). The addition of the inoculant reduced the content of Ni in white lupine by 6.02%. Compared to grass pea, the content of Ni was lowered by 56.64% in the variant A and 58.13% in variant B.

Macroelements such as Na, Mg, K, and Ca are essential for a wide variety of metabolic and physiological processes in the human body; therefore they should be included in daily diets to prevent chronic diseases **(Williams, 2006; Alsafwah et al., 2007)**. Sodium and potassium influence acid-base balance and nerve transmittance. Calcium and phosphorus are necessary for the development and appropriate functioning of bones muscles and teeth **(Saleh-E-In et al., 2008)**. Sodium, potassium, and calcium also impact heart functions. Calcium increases heart shrinkage **(Rajurkar and Damame, 1997)**.

The results we have obtained show that K and P are the predominant elements in the seeds of grass pea in both variants. The higher content of P was determined for the variant B in grass pea (Table 3). The content of K in lupin seeds is 11% lower than that in grass pea in both variants with the addition of an inoculant.

Özcan, Dursun and Al Juhaimi (2013) reported a P content in seeds (*Lupinus albus* L.) of 2.719 $mg.kg^{-1}$ and a Ca content from 1.309 $mg.kg^{-1}$ (*C. arietinum* L.) to 2.781 $mg.kg^{-1}$ *(Lupinus albus* L.). According to our results, the P content of lupine is 1999.04 $mg.kg^{-1}$ for variant A, and the addition of the inoculant increased it to 2596.87 $mg.kg^{-1}$.

The results of our analyses show that the Ca content in the white lupine is 2822.60 $mg.kg^{-1}$ for variant A and 3053.51 $mg.kg^{-1}$ for B variant. By comparing selected types of legumes, we found that the grass pea features higher content of K and P. According to **Grela et al. (2017)**, the seeds of the grass pea contain 8.75 – 9.23% K, 1.14 – 1.24% Mg, 0.97 – 1.03% Ca, 4.68 – 5.13% P, 6.98 – 7.95% Cu, 43.52 $mg.kg^{-1}$ Fe, 29.57 – 31.24 $mg.kg^{-1}$ Zn, and 13.29 – 15.31 $mg.kg^{-1}$ Mn. This data suggests that seeds of the grass pea can be a good source of minerals due to the high content of calcium and magnesium.

The analysed white lupin seeds had a higher content of Na, Ca, and Mg (Table 3). The content of Na in variant A was 37.88% higher in the seeds of white lupine compared to the grasspea seed. Variant B (white lupine) contained 68.41% more Na than variant B (grasspea). There was a significant difference between of Ca content of the crops. The lupine contained 90.56% more Ca than the grasspea in variant A. Variant B contained 120.22% more Ca in the lupine compared to the grasspea. By comparing these two crops the Mg values were not significantly changed.

The measured data were statistically evaluated using the statistical package STATGRAPHICS Centurion XVI.II (Table 4 and Table 5).

A statistically significant difference between lupine variant A and lupine variant B was detected for chromium, sodium, and calcium. A statistically significant difference between grass pea variant A and grass pea variant B was not detected for any element.

Figures 4 Grass pea – our regional variety.

Cabrera et al. (2003) and **Özcan, Dursun and Al Juhaimi (2013)** reported that the levels of macroelements in *Fabaceae* were present in the following ranges: 7426 – 16.558 mg.g^{-1} K; 269.75 – 445.81 mg.kg^{-1} Na; 2719 – 5556 mg.kg^{-1} P; 1309 – 2781 mg.kg^{-1} Ca; and 2083 – 2900 mg.kg^{-1} Mg. According to our analyzes, the values of macroelements were lower for Ca, Mg, P in both crops. The pea had a lower Na content and a higher K content than the stated values as stated **Cabrera et al. (2003)** and **Özcan, Dursun and Al Juhaimi (2013)**. White lupine contained more Na. The levels of microelements were as follows: 2.1 – 22.0 mg.kg^{-1} Cu; 22.5 – 152.80 mg.kg^{-1} Fe; 31 – 109 mg.kg^{-1} Zn; and 17.53 – 2277.16 mg.kg^{-1} Mn **(Cabrera et al., 2003; Özcan, Dursun and Al Juhaimi, 2013)** which is consistent with the values obtained in this study.

CONCLUSION

Despite the fact that the inoculation with bacteria of the Rhizobium did not significantly affect the content of biogenic elements in the selected leguminous species, it is a significant part of legume cultivation. Biologically fixed nitrogen positively affects the harvest as well as improving the nutritional status of the next crop. The effectiveness of seed inoculation is dependent on the common interaction of Rhizobii and the soil moisture, temperature, and the nitrate content of the soil.

COMPARATIVE ANALYSIS OF ANTIOXIDANT ACTIVITY AND PHENOLIC COMPOUNDS IN THE FRUITS OF *ARONIA* SPP.

Yulia Vinogradova, Olena Vergun, Olga Grygorieva, Eva Ivanišová, Ján Brindza

ABSTRACT

Chokeberry (*Aronia* Medik.) is a non-traditional fruit plant known as a rich source of biologically active compounds and inhibits the numerous biological activities. We compared the antioxidant activity and phenolic compounds of fruits between widely cultivated *Aronia mitschurinii* (AM-TCH, from Tchekhov district; AM-D, from Dmitrov district; AM-OZ, from Orekhovo-Zuevsky district of Moscow region, Russia) and introduced North American Aronia species (*Aronia arbutifolia* (AA-M), *A. melanocarpa* (AML-M), *A.* × *prunifolia* (AP-M), which have not been planted yet in the arboretum of Main Botanical Garden of the Russian Academy of Sciences (Moscow). Studying samples were collected in their secondary distribution range. Ethanolic extracts were determined for antioxidant capacity (antioxidant activity by DPPH and phosphomolybdenum methods, the total content of polyphenols, flavonoids, phenolic acids) and measured spectrophotometrically. As standards were used Trolox (TE) for antioxidant activities, gallic acid (GAE) for polyphenol content, quercetin (QE) for flavonoid content, caffeic acid (CAE) for phenolic acid content. The antioxidant activity by DPPH method in ethanol extracts of investigated plants was from 6.96 (AM-D) to 8.89 (AM-OZ) mg TE.g^{-1} DW. Reducing the power of investigated extracts exhibited activity from 151.47 (AM-OZ) to 297.8 (AA-M) mg TE.g^{-1} DW. The content of polyphenol compounds determined from 25.98 (AM-TCH) to 54.39 (AA-M) mg GAE.g^{-1} DW, phenolic acids content was from 7.76 (AP-M) to 11.87 (AM-D) mg CAE.g^{-1} DW and the content of flavonoids detected from 8.12 (AM-OZ) to 16.62 (AM-D) mg QE^{-1} DW. Obtained data showed a strong correlation between the content of polyphenol compounds and reducing the power of extracts (r = 0.700), between flavonoids and phenolic acids (r = 0.771) and also between phenolic acids and reducing power (r = 0.753) in Aronia ethanol extracts. Fruits of investigated species of Aronia can be propagated as a source of polyphenol compounds with antioxidant activity and obtained results may use for farther pharmacological study.

Keywords: *Aronia* spp.; antioxidant activity; polyphenols; flavonoids; phenolic acids

INTRODUCTION

The last studies demonstrated that fruit plants are rich in antioxidants and their use can promote human health **(Widén et al., 2012)**. *Aronia mitschurinii* A. K. Skvortsov and Maitul are one of the most famous sources of food polyphenols and antioxidants, its juice has long been used in clinical practice. The natural distribution range of Aronia is located in the eastern part of North America. According to a later nomenclature **(Hardin, 1973)**, the genus Aronia consists of three species: *A. arbutifolia* (L.) Rers., *A. melanocarpa* (Michx.) and their hybrid *A.* × *prunifolia* (Marshall) Rehder. All three species have been introduced in European gardens since the beginning of the XIX century. At the end of the XIX century, *A. melanocarpa* from Germany has been grown in the nursery of I. V. Mitchurin (Tambov province, Russia). There, by the method of "screening in three generations", a man-made *A. mitschurinii* was born **(Vinogradova and Kuklina, 2014)**. It is still unclear whether this taxon arose as a result of macro mutation, or is it a hybrid between *A. melanocarpa* and *Sorbus* spp. Undoubtedly, however, that *A. mitschurinii*, both by morphological and by genetic characteristics, differs so much from the parental *A. melanocarpa*, which is quite correctly described as an individual species **(Skvortsov and Maitulina, 1982; Skvortsov, Maitulina and Gorbunov, 1983)**. Also, based on the morphological properties of *A. mitchurinii* selection work with this species can be successful **(Vinogradova et al., 2017)**. At first, *A. mitschurinii* has been grown as a fruit crop enriched in vitamins and minerals. In the 1960s, the discovery of high content of P-vitamin substances in its berries led to the using of Aronia juice in medical institutions for the treatment of hypertension **(Vinogradova and Kuklina, 2012)**. Now this species began to be tested as a source of antioxidant activity due to the high content of polyphenols **(Mayer-Miebach, Adamiuk and Behsnilian, 2012; Bräunlich, 2013; Taheri et al., 2013; Žlabur Šic et al., 2017)**.

Previous reports about *Aronia melanocarpa* showed that its fruits contain powerful antioxidants (anthocyanidins,

phenolic acids, quercetin glycosides) with different pharmacological activities such as anti-cancer **(Jeong, 2008; Kulling and Rawel, 2008; Olas et al., 2008)**, cardio-protective **(Olas et al., 2010)**, antimutagenic, lipid-lowering, antihypertensive, hepatoprotective, gastroprotective, antimicrobial, radioprotective, immunomodulatory **(Kokotkiewicz, Jaremicz and Luczkiewicz, 2010)**, anti-inflammatory, anti-allergic, antiatherogenic, antidiabetic **(Banjari et al., 2017)**. Fruits of Aronia species contain flavonoids anthocyanins **(Brand et al., 2017)**. In the fresh fruits of *Aronia* spp. was identified carbohydrates (sorbitol, fructose, glucose, sucrose), organic acids (quinic acid, malic acid, ascorbic acid, shikimic acid, citric acid, etc.) **(Sidor and Gramza-Michałowska, 2019)**, polyphenols (neochlorogenic acid, chlorogenic acid, epicatechin, quercetin-3-rutinoside, quercetin, etc.) **(Šnebergrová et al., 2014; Denev et al., 2018)**. Biochemical composition of fresh fruits it's also sugars (10 – 18%), pectin (0.6 – 0.7%), fat (0.14%), ash (0.44%), mineral compounds (high content of K, Zn, Na, Ca, Mg, Fe) **(Kokotkiewicz, Jaremicz and Luczkiewicz, 2010)**. Some results showed that the fruits of *Aronia* spp. rich in antioxidants such as polyphenols, flavonoids, anthocyanins **(Widén et al., 2012; Kapci et al., 2013)**. According to **Kapci et al (2013)**, chokeberry fruits contain four major anthocyanins such as cyanidin-3-galactoside, cyanidin-3-arabinoside, cyanidin-3-glucoside and cyanidin-3-xyloside. Polyphenols in *A. mitschurinii* 'Viking' have been found to consist of cyaniding anthocyanins, proanthocyanidins, flavonols, chlorogenic acid, and neochlorogenic acid **(Oszmianski and Wojdylo, 2005; Slimestad et al., 2005; Koponen et al., 2007)**.

The study of **Suvajdžić et al. (2017)** demonstrated that *Aronia* × *prunifolia* juice and ethanol extracts showed antialgal activity. Moreover, a higher concentration of selected biochemical compounds was identified in the extracts than in juice. The juice from fruits of *A. mitschurinii* has an antimutagenic activity **(Gasiorowski et al., 1997)**, gastroprotective effect **(Matsumoto et al., 2004)**, hepatoprotective activity **(Valcheva-Kuzmanova and Belcheva, 2006)**, cardioprotective and anti-diabetes effect **(Kulling and Rawel, 2008; Denev et al., 2012; Gralec, Wawer and Zawada, 2019)**, anticancer activity **(Sharif et al., 2012)**, anti-inflammatory effect **(Martin et al., 2014)**, antiatherogenic activity **(Daskalova et al., 2015)**. In addition, fruits of *A. melanocarpa* characterized by antioxidant, antimicrobial, and neutrophil-modulating activity **(Denev et al., 2019)**. Production containing chokeberry fruits also characterized. As reported by **Nguyen and Hwang (2016)**, yogurt with *Aronia melanocarpa* juice had high antioxidant activity.

However, there is little information on the polyphenol contents in the other wild species of Aronia. As reported **Denev et al. (2018)**, in *A. melanocarpa* fruits identified organic acids (quinic, malic, ascorbic, shikimic, citric, oxalic, succinic), polyphenols (neochlorogenic acid, chlorogenic acid, epicatechin, quercetin-3-rutiniside, quercetin-3-glucoside, quercetin, anthocyanins, proanthocyanidins), carbohydrates (the main component is sorbitol).

In Europe, these species are not yet cultivated and are only available in collections of botanical gardens **(Vinogradova and Kuklina, 2014)**, although, according to the latest data, they possess economically valuable traits **(Kokotkiewicz, Jaremicz, and Luczkiewicz, 2010)**. In the USA, native *A. melanocarpa*, *A. arbutifolia,* and *Aronia* × *prunifolia* have unique polyphenol profiles warranting further investigation of their comparative nutraceutical and commercial values **(Taheri et al., 2013)**.

Antioxidant properties of *Aronia* spp. can be useful as well in human life as an animal. Investigation of **Bolser et al. (2013)** showed that autumn-migrating birds selected certain of wild-growing plant fruits among which were *Aronia* × *prunifolia* and *A. melanocarpa*. These two species, along with others, had a high concentration of antioxidants as reported in this study.

The purpose of this study was to investigate the antioxidant capacity of Aronia fruits of different origins.

Scientific hypothesis

The first, we assumed (based on the Vavilov's Law about homological rows) that the closely related North American species of the genus Aronia will have the same high levels of antiradical activity as the widely cultivated *A. mitschurinii*. The second, we assumed that native species (from North America) have the same polyphenol contents as plants in the secondary distribution range (from Moscow).

MATERIAL AND METHODOLOGY

Plant materials

In this study, we investigated fruits of plants of *Aronia arbutifolia* (L.) Pers. (AA-M), *A. melanocarpa* (Michx.) (AML-M), *Aronia* × *prunifolia* (Marshall) Rehder (AP-M) in the arboretum of Main Botanical Garden of the Russian Academy of Sciences (Moscow, Russia), which were brought from the USA in the 1980s. Also, we used to study samples of cultivated *A. mitschurinii* A. K. Skvortsov and Maitul from the Tchekhov (AM-TCH) and *A. mitschurinii* from Dmitrov (AM-D) districts of the Moscow region and one sample of naturalized *A. mitschurinii* from the Orekhovo-Zuevsky (AM-OZ) district of the Moscow region.

Chemicals

All chemicals were analytical grade and were purchased from Reachem (Slovakia) and Sigma Aldrich (USA).

Sample preparation

0.2 g of dried plant raw material was extracted with 20 mL of 80% ethanol for 2 hours. After centrifugation at 4000 g (Rotofix 32 A, Hettich, Germany) for 10 min, the supernatant was used for the next measurements: antioxidant activity, polyphenols, and flavonoids.

Antioxidant activity

Radical scavenging assay

The radical scavenging activity of samples was measured using 2.2-diphenyl-1-picrylhydrazyl (DPPH) **(Sanchez-Moreno, Larrauri and Saura-Calixto, 1998)**. The extracts (0.5 mL) were mixed with 3.6 mL of radical solution (0.025 g of DPPH in 100 mL ethanol). The absorbance of the sample extract was determined using the

spectrophotometer Jenway (6405 UV/VIS, England) at 515 nm. Trolox (6-hydroxy-2,5,7,8-tetramethylchroman-2-carboxylic acid) (10 – 100 mg.L^{-1}; R^2 = 0.988) was used as the standard and the results were expressed in mg.g^{-1} Trolox equivalents.

Molybdenum reducing power

Reducing the power of extracts was determined by the phosphomolybdenum method of **Prieto, Pineda and Aguila (1999)** with slight modifications. The mixture of a sample (1 mL), monopotassium phosphate (2.8 mL, 0.1 M), sulfuric acid (6 mL, 1 M), ammonium heptamolybdate (0.4 mL, 0.1 M) and distilled water (0.8 mL) incubated at 90 °C for 120 min, then rapidly cooled and detected by monitoring absorbance at 700 nm using the spectrophotometer Jenway (6405 UV/VIS, England). Trolox (10 – 1000 mg.L^{-1}; R^2 = 0.998) was used as the standard and the results were expressed in mg.g^{-1} Trolox equivalents.

Total polyphenol content

Total polyphenol content extracts were measured by the method of **Singleton and Rossi (1965)** using Folin-Chiocalteu reagent. 0.1 mL of each sample extract was mixed with 0.1 mL of the Folin-Chiocalteu reagent, 1 mL of 20% (w/v) sodium carbonate and 8.8 mL of distilled water. After 30 min. in darkness the absorbance at 700 nm was measured using the spectrophotometer Jenway (6405 UV/VIS, England). Gallic acid (25 – 250 mg.L^{-1}; R^2 = 0.996) was used as the standard and the results were expressed in mg.g^{-1} gallic acid equivalents.

Total flavonoid content

Determination of total flavonoids content was conducted using the modified method of **Shafii et al. (2017)**. 0.5 mL of sample extract was mixed with 0.1 mL of 10% (w/v) ethanolic solution of aluminum chloride, 0.1 mL of 1 M sodium acetate and 4.3 mL of distilled water. After 30 min. in darkness the absorbance at 415 nm was measured using the spectrophotometer Jenway (6405 UV/VIS, England). Quercetin (0.01 – 0.5 mg.L^{-1}; R^2 = 0.997) was used as the standard and the results were expressed in mg.g^{-1} quercetin equivalents.

The total phenolic acid content

Determination of total phenolic acid content of extracts was carried out using the method of **Farmakopea Polska (1999)**. 0.5 mL of sample extract was mixed with 0.5 mL of 0.5 M hydrochloric acid, 0.5 mL Arnova reagent, 0.5 mL of 1 M sodium hydroxide (w/v) and 0.5 mL of distilled water. Absorbance at 490 nm was measured using the spectrophotometer Jenway (6405 UV/Vis, England). Caffeic acid (1 – 200 mg.L^{-1}, R^2 = 0.999) was used as a standard and the results were expressed in mg.g^{-1} caffeic acid equivalents.

Statistical analysis

The statistically treated data are given in tables as the arithmetical mean values and their standard errors. Data were submitted ANOVA and differences between means compared through the Tukey-Kramer test (α = 0.05). Correlation analysis was performed using Pearson's criterion.

RESULTS AND DISCUSSION

Numerous biologically active compounds act as powerful antioxidants, among which different groups of polyphenol compounds that are determined in fruits and berries **(Szopa et al., 2017; Aly, Maraei and El-Leel, 2019; Rodriguez-Werner, Winterhalter and Esatbeyoglu, 2019)**.

Antioxidant activity

As reported **Oszmiański and Wojdylo (2005)**, antioxidant activity level decreased in the following order: juice, fruits, pomace. There are numerous methods to determine antioxidant activity in plant extracts among them radical scavenging assay by DPPH and phosphomolybdenum method (reducing power of extracts) **(Alam, Bristi and Rafiquzzaman, 2013; Moharram and Youssef, 2014; Pisoschi et al., 2016)**. DPPH scavenging activity is the most popular assay to determine antioxidant capacity **(Gralec, Wawer and Zawada, 2019)**.

Radical scavenging assay by DPPH

Our preliminary data show that the DPPH scavenging activity of extracts for all specimens of Aronia was 83.25 – 93.30% (methanol extracts), 78.07 – 93.23% (ethanol extracts) and 59.87 – 88.36% (aqueous extracts). Alcoholic and aquatic extracts of fruits have almost equal antioxidant activity. The lowest antioxidant activity in alcohol extracts was shown by cultivated *A. mitschurinii*, and the highest one by invasive plants of *A. mitschurinii*. Conversely, aqueous extracts have the lowest antioxidant activity in invasive plants of *A. mitschurinii* and the highest one in cultivated samples **(Vinogradova et al., 2018)**. Also, in another study, the Aronia extract was tested for various antioxidative potentials and inhibitory effects. Thus, high polyphenol and flavonoid content suggests that Aronia extracts may be useful for the prevention or treatment of allergic disease **(Jeong, 2008)**. In study **Jakobek et al. (2012)** antiradical activity of wild chokeberries was higher than cultivars (besides one cultivar).

In our study radical scavenging activity of the ethanol extracts of investigated Aronia species was screened against DPPH radical which is the most used to determine the antiradical activity of several natural compounds and was from 6.96 (AM-D) to 8.89 (AM-OZ) mg TE.g^{-1} (Figure 1). **Strugała and Gabrielska (2014)** determined that significantly higher antioxidant activity was found at the start of storage for Japanese quince and chokeberry extracts than the same of hawthorn and quince. **Tolić et al. (2015)** found that antioxidant activity by DPPH method in dried fruits of *A. melanocarpa* was 183.52 – 191.31 mg TE.L^{-1}. Antioxidant activity by DPPH-method, according to **Wangensteen et al. (2014)**, in methanol extracts of *A. melanocarpa* cultivars and *Aronia* × *prunifolia* was higher than in ethanol extracts. **Yang, Kim and Shin (2019)** measured antioxidant activity by DPPH method of fruit extracts with ascorbic acid (AA) as equivalent and obtained values 4144.44 – 4565.28 mg AA.100 g^{-1} FW.

Molybdenum reducing the power of extracts

We determined the reducing power of Aronia extracts by phosphomolybdenum method that is also widely used to determine the antioxidant capacity **(Alam, Bristi and Rafiquzzaman, 2013)**. We found that reducing the power of ethanol extracts of Aronia samples in our study was from 151.47 (AM-OZ) to 297.8 (AA-M) mg TE.g^{-1} (Figure 2).

It is very difficult to compare data with other reviews because were used different methods of measure and various units. So, **Rugină et al. (2012)** determined reducing the power of extracts by the FRAP method and found a correlation between this parameter and total flavonoid content. The same method of reducing power determination used by **Tolić et al. (2015)** and a strong correlation found between reducing power and flavonoid content. **Oszmiański and Lachowicz (2016)** also used the FRAP method for the determination of reducing the power of extracts and determined a strong correlation between phenolic acids and FRAP and total phenolics and this parameter. Our preliminary results about another species *Asimina triloba* (L.) Dunal. showed molybdenum reducing the power of extracts from 97.25 to 275.41 mg TE.g^{-1} DW **(Brindza et al., 2019)**.

Total polyphenol content

The polyphenols contained in fruits are of great interest for their antioxidant and anti-inflammatory properties **(Chrubasik, Li and Chrubasik, 2010; Montrose et al., 2011)**. Previous data showed that Aronia pomace had higher content of polyphenols than juice and fruits. Polymeric proanthocyanins are the major class of phenolic compounds of fruits of these species **(Oszmiańsky and Wojdylo, 2005)**. As emphasized by **Jurikova et al. (2017)**, the content of total polyphenol compounds and their selected groups of *A. melanocarpa* depends on some factors, among which is the temperature of storage. So, after six months of storage at 3 ℃ content of polyphenols decreased by 30%.

The antioxidant capacity of plant extracts has been attributed to their phenolic contents that were determined by Folin-Ciocalteu reagent. The amount of total polyphenol content of investigated extracts was from 25.98 (AM-TCH) to 54.39 (AA-M) mg GAE.g^{-1} (Table 1).

According to **Denev et al. (2018)**, total polyphenol content was found from 1022.4 to 1795.5 μmol TE.g^{-1} FW. HPLC analysis identified total polyphenol compounds in crude extracts of *A. melanocarpa* fruits 53.5 mg.g^{-1} **(Denev et al., 2019)**. As reported **Gao et al. (2018)**, *A. melanocarpa* polyphenols showed no cytotoxic effect. Polyphenol compounds from *A. melanocarpa* demonstrated immunomodulatory and anti-inflammatory functions **(Ho et al., 2014)**. The main group of *A. melanocarpa* polyphenols is procyanidins **(Gralec, Wawer and Zawada, 2019)**.

According to **Brand et al. (2017)**, the highest concentration of total phenolic compounds identified in fruits of *Aronia* × *prunifolia*, whereas, for *A. arbutifolia* and *A. melanocarpa* this parameter was less. Comparing obtained data and previous results of yogurt with chokeberry juice (*Aronia melanocarpa*), it's should be noted that total polyphenol content of 1%, 2%, and 3% yogurts was 28.70, 41.30 and 54.05 mg GAE.g^{-1} DW respectively **(Nguyen and Hwang, 2016)**. Also, dried fruits of *A. melanocarpa* showed total phenolics content in the range from 2,000 to 8,000 mg per 100 g **(Kokotkiewicz, Jaremicz and Luczkiewicz, 2010)**. In our case, the content of polyphenol content of investigated fruits of *A. melanocarpa* was 40.06 mg GAE.g^{-1} DW. In the study of **Jakobek et al. (2007)** total polyphenol content of *A. melanocarpa* fruits was 10637.20 mg GAE.kg^{-1} and total flavanol content by HPLC method was 76.43 mg.kg^{-1}. Different cultivars of *A. melanocarpa* had polyphenol content from 11721.7 to 14350.3 mg GAE.kg^{-1} FW **(Jakobek et al., 2012)**. As identified by **Jurikova et al. (2017)**, the total polyphenol content of *A. melanocarpa* can vary from 690 to 2560 mg GAE.100g^{-1} FW. In the study of **Rugină et al. (2012)** total phenolic values were 1586.5 to 2059.5 mg GAE.100 g^{-1} FW.

In another study, represented that the total phenolic content of dried fruits of *A. melanocarpa* was 1954 – 2466 mg GAE.100 g^{-1} **(Tolić et al., 2015)**. Investigation of **Veljković et al. (2014)** demonstrated that *A. melanocarpa* tea diffusions, as well as dry or fresh fruits, had a high antioxidant activity due to the content of polyphenol content such as flavonoids and phenolic acids. **Wangensteen et al. (2014)** determined that the polyphenol content of *A. melanocarpa* cultivars was 98 – 148 mg GAE.g of extract and 1079 – 1921 mg GAE.g FW, and for *Aronia* × *prunifolia* this parameter was 175 mg GAE.g and 2996 mg GAE.g FW. **Yang, Kim and Shin (2019)** found that the phenolic content of fruits of Aronia cultivars was 3955.28 – 4393.50 mg GAE.100 g^{-1} FW.

The total phenolic acid content

Phenolic acids are a group of polyphenol compounds that are generally described as phenolic compounds that have one carboxylic acid group and possess higher antioxidant activity than vitamins and present in food mostly in bound form. These compounds exhibited the following activities: antioxidant, antimicrobial, anticancer, anti-inflammatory, anti-diabetic, neuroprotective **(Kumar and Goel, 2019)**. They determined in various berries and fruits such as saskatoon chokeberry, blueberry, dark plum, elderberry, cherry **(Mattila, Hellström and Törrönen, 2006; Jakobek and Seruga, 2012; Lachowicz et al., 2017; Horčinová Sedlačková et al., 2018)**.

The phenolic acid content of Aronia samples in our study determined from 7.76 (AP-M) to 11.87 (AM-D) mg CAE.g^{-1} (Table 2). *A. melanocarpa* is known as a rich source of anthocyanins and phenolic acids **(Oszmiańsky and Lachowicz, 2016)**. The phenolic acid concentration was higher in juice than in pomace of this species whereas total phenolic content is higher in pomace than in fruits and juice **(Oszmiańsky and Wojdylo, 2005)**. In selected cultivars of *A. melanocarpa* identifies high content of chlorogenic, caffeic, ferulic acids. During the process of pasteurization, the most unstable was hydroxycinnamic acid (**Jurikova et al., 2017**). According to **Jakobek and Seruga (2012)**, the phenolic acid content in chokeberry fruits was 266.9 mg.kg^{-1}.

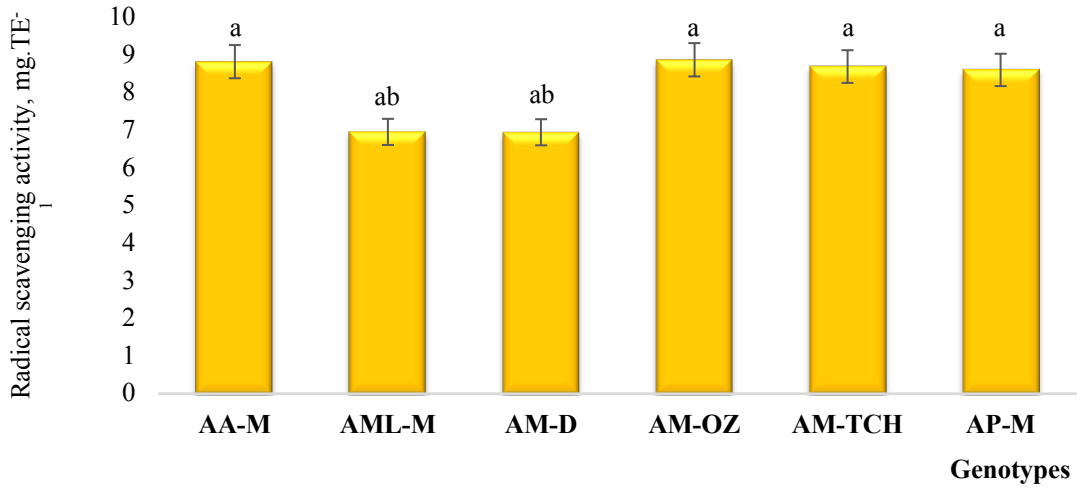

Figure 1 Antioxidant activity by DPPH-method of ethanol extracts of *Aronia* spp. Note: means in columns followed by different letters are different at $p = 0.05$; each value represents the mean of three independent experiments (±SD).

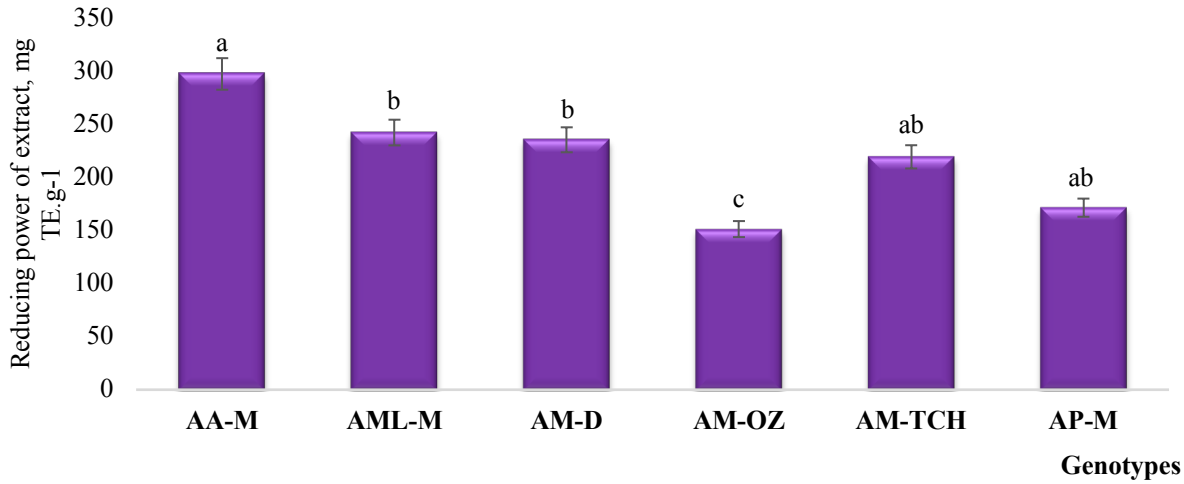

Figure 2 Reducing power of ethanol extracts by phosphomolybdenum method of *Aronia* spp. Note: means in columns followed by different letters are different at $p = 0.05$; each value represents the mean of three independent experiments (±SD).

Table 1 Total polyphenol, flavonoid and phenolic acid content in the fruits of Aronia specimens.

Plant sample	Total polyphenol content, mg GAE.g^{-1}	Total phenolic acids, mg CAE.g^{-1}	Total flavonoid content, mg QE.g^{-1}
A. arbutifolia **(AA-M)**	54.39 ±1.05a	11.06 ±0.79ab	10.88 ±0.41ab
A. melanocarpa **(AML-M)**	40.06 ±1.61b	11.54 ±0.09ab	13.16 ±0.15b
A. mitschurinii **(AM-TCH)**	25.98 ±1.28c	8.79 ±0.42b	11.05 ±0.21ab
A. mitschurinii **(AM-D)**	38.91 ±4.56ab	11.87 ±0.23a	16.62 ±0.50a
A. mitschurinii **(AM-OZ)**	28.80 ±2.75c	8.69 ±0.47b	8.12 ±0.17b
A.* × *prunifolia **(AP-M)**	40.39 ±1.78b	7.76 ±0.31c	10.02 ±0.56c

Note: Means in columns followed by different letters are different at $p = 0.05$; each value represents the mean of three independent experiments (±SD); GAE – gallic acid equivalents; CAE – caffeic acid equivalents; QE – quercetin equivalents.

Table 2 Coefficient of correlation between investigated parameters of *Aronia* spp. extracts.

Characters	Polyphenols	Phenolic acids	Flavonoids	Antioxidant activity (DPPH)	Molybdenum reducing power
Phenolic acids	0.495*	1			
Flavonoids	0.210*	0.771*	1		
Antioxidant activity (DPPH)	-0.098	-0.738	-0.870	1	
Molybdenum reducing power	0.700	0.753*	0.480*	-0.266	1

Note: Significant according to the t-test (p <0.05).

Total flavonoid content

The main groups of flavonoids of *A. melanocarpa* were anthocyanins, proanthocyanins, flavonols and flavanols **(Jurikova et al., 2017)**. Total flavonoid content was determined in the range from 8.12 (AM-OZ) to 16.62 (AM-D) mg QE.g^{-1}. Investigation of **Kapci et al. (2013)** reported that among different products from chokeberry dried fruits had the highest total flavonoids content and antioxidant activity values. But total phenolics and anthocyanins were found in chokeberry pomace. According to **Gralec, Wawer and Zawada (2019)**, the content of flavonoids of *A. melanocarpa* was from 7 to 11 g.100^{-1} DW. The study of **Rugină et al. (2012)** showed that the content of flavonoids ranged from 47.67 to 64.04 mg QE.100 g^{-1} FW. As reported by **Slimestad et al. (2005)**, the black chokeberries contained up to 71 mg flavonols per 100 g FW. **Tolić et al. (2015)** determined total flavonoids content in dried fruits of *A. melanocarpa* 867 – 1394 mg GAE.L^{-1}. According to **Yang, Kim and Shin (2019)**, the flavonoid content of three cultivars of Aronia was 3175.52 to 3577.7 mg CE.100 g^{-1} FW (catechin equivalent).

The antioxidant activity of investigated raw can be caused by the presence of different groups of compounds such as phenolics. In this case, we determined correlations between of investigated parameters. Correlation analysis found a strong correlation between the content of polyphenol compounds and reducing the power of extracts (r = 0.700), between flavonoids and phenolic acids (r = 0.771) and also between phenolic acids and reducing power (r = 0.753) of Aronia ethanol extracts (Table 2). The moderate correlation found between the accumulation of flavonoids and reducing the power of extracts (r = 0.480) and between polyphenol content and phenolic acids (r = 0.495). Weak relation was determined between the accumulation of polyphenol content and flavonoids of investigated extracts. Between rest, parameters were identified as a negative correlation.

As reported by **Gralec, Wawer and Zawada (2019)**, antioxidant activity by the DPPH test of *Aronia melanocarpa* positively correlated with the content of polyphenol compounds of both ripe and unripe fruits. **Yang, Kim and Shin (2019)** indicated a very strong correlation between flavonoid and phenolic content in fruit extracts (r = 0.991), between flavonoids and antioxidant activity by DPPH method (r = 0.997), between total phenolics and chlorogenic acid (r = 0.940). **Tolić et al. (2015)** found that the correlation between reducing power and total phenolic content of chokeberry juice was higher than between total antioxidant capacity and phenolic content.

CONCLUSION

Aronia species are non-traditional fruit plants, which are a rich source of polyphenol compounds with high antioxidant activity. In this study, cultivated plant species had the least values of polyphenol compounds as opposed to naturalized plants. However, the content of flavonoids and phenolic acids varied for all species. It was found that maximal values of polyphenol compounds were determined for *A. arbutifolia*, and total flavonoid and phenolic content for *A. mitschurinii* (from Dmitrov region). Thus, naturalizing plants of Aronia species (*Aronia arbutifolia*, *A. melanocarpa*, *Aronia* × *prunifolia*) can be an alternative source of antioxidants to widely cultivated species (*A. mitschurinii*). Thus, in the secondary distribution range, introduced species retain their biochemical characteristics.

Apparently, plants accumulate fewer biologically active substances in a comfortable culture environment than during forced adaptation to unfavorable ecological conditions. The determination of the polyphenol contents in the closely related species of the genus Aronia is necessary for the further use of the nutrient properties of this small fruit crop. Wild, still exploitable Aronia species could be selectively used to improve the nutritional and functional properties of cultivated *A. mitschurinii* fruits. In addition, interest in functional foods and food additives, which may support the protective mechanisms against diseases caused by oxidative stress, is increased currently.

RATIONAL AND IRRATIONAL BEHAVIOR OF SLOVAK CONSUMERS IN THE PRIVATE LABEL MARKET

Ingrida Košičiarová, Zdenka Kádeková, Ľubica Kubicová, Kristína Predanocyová, Jana Rybanská, Milan Džupina, Ivana Bulanda

ABSTRACT
Rational and irrational consumer behavior has already been the subject of several studies. Although their attention was mostly focused on traditional brands, these studies and their conclusions may also serve as a model for private label research, which is now increasingly coming to the forefront. Private labels are gradually becoming an adequate purchase alternative to traditional brands. The aim of the paper was to find out the influence of packaging and chosen marketing communication tools, on consumer purchasing decisions in the dairy segment. An anonymous questionnaire survey was chosen as the main research method, where participated 1,116 respondents from all over Slovakia; which was subsequently supplemented by the blind test involving 20 respondents under the age of up to 25 years. Seven chocolate-flavored yogurt samples were examined in the blind test; while the samples were such traditional brands by traditional producers as well as private labels. Interestingly, identical products were investigated – products from the traditional producer, both under its brand and under the retailer's private label. The results of our research proved some interesting findings – more than 28% of respondents buy private label products regularly and more than 53% buy them sporadically; whereas respondents do not buy private labels, mainly because of their lack of interest to try something new, assuming poor product quality and inadequate price; they buy them mainly because of lower prices compared to traditional product brands, comparable quality to traditional brands and good experience; respondents perceive private labels as good products of adequate quality and private labels evoke that products are adequate quality at a reasonable price. Although most respondents have no opinion on the packaging of private label products, more than 31% of them consider their packaging as unattractive and almost 36% think that their packaging does not affect them, but the results of the blind test partially refused this opinion.

Keywords: private label; traditional brand; marketing communication; packaging; consumer; blind test

INTRODUCTION
One of the modern and probably the most successful strategies of foreign as well as domestic retail chains and companies is to reach as many customers as possible, not only those customers for whom the price is decisive but also those who prefer high-quality products when purchasing. All these requirements are to be met by private labeled products, whose share of household spending in Europe, especially in Slovakia, is constantly increasing (Figure 1).

Private labels, also referred to as store brands, retail chain brands, custom brands, etc. are a traditional retailer branding strategy (whether in its name or wholly owned by the retailer) were firstly introduced in the US at the end of the 19th century **(Nagyová and Košičiarová, 2014)**.

Even though it is not an absolute "novelty", attention is drawn especially at present, when so-called global phenomenon **(Herstein and Gamliel, 2004; Smith and Bashaw, 2009)** and when traders are increasingly aware of their hidden advantage, which is the possibility of strengthening their competitive advantage, resp. higher profits at lower costs. Many studies point to the fact that private labels are more profitable than traditional brands themselves **(Heijn, 2012; Dulíková, 2012; De Wulf et al., 2005)**.

Private labels bring benefits to the retailer as well as to the manufacturer and the customer. The main advantages on the part of the retailer are in particular – strengthening its competitive advantage and achieving higher profits at lower costs. On the customer's side, the biggest advantage is that private labels are an alternative to traditional brand products at comparable, if not higher quality, but lower prices. As far as the manufacturer is concerned, the biggest advantage is the volume of sales and the resulting profits. However, it is necessary to add the fact that private labels also bring many disadvantages such as the possibility of damaging the company´s reputation by a lower-quality product, resp. of knowledge of the original producer, which in many cases

discourages the purchase itself **(Košičiarová, Holotová and Nagyová 2014)**.

Even though the United States (USA) is considered to be the "birthplace" of private labels, in the case of Europe and especially the Slovak Republic it is possible to view a later, but more extensive and faster development and establishment of private labels on the consumer market as in the USA, the share of private label purchases in household expenditures is 18% on average **(Košičiarová and Nagyová, 2015)**; in the case of Europe and the Slovak Republic, we notice three times higher share on average (Figure 1). The speed and rate of private label expansion in Europe, compared to the US, was not only supported by customers' interest, but also by the invention of retail chains that discover much more in private labels than just another commercial item that hides margin **(Augustín, 2005; De Wulf et al., 2005)** - private labels are becoming a source of competitive advantage and in particular, the means by which they can build resp. improve the company´s image. For the customer, on the other hand, private labels are an alternative to traditional brands, but this is no longer exclusively due to the price sensitivity of consumers, but to increasing the quality of private labels products and realizing of their hidden benefits.

This paper deals with the issue of the private labels in terms of their attractiveness for the customers themselves, as it was already indicated above, the private labels are the alternative to traditional brands. The paper intends to find out, to what extent the packaging affects the purchasing decision of the consumers and which communication tools could be used to reach customers´attention to purchase the private label products.

Scientific hypothesis

For a deeper analysis of the research objectives, the following hypotheses were formulated:

Hypothesis 1: We assume there is a correlation between the quality rating of private label products and the gender of respondents.

Hypothesis 2: We assume there is a correlation between the purchase of private label products and the gender of respondents.

Hypothesis 3: We assume there is a correlation between the purchase of private label products and the economic activity of respondents.

Hypothesis 4: We assume there is a correlation between the perception of private label packaging and the gender of respondents.

Hypothesis 5: We assume there is a correlation between the perception of facts that influence respondents to buy private label products and the gender of respondents.

Hypothesis 6: We assume there is a correlation between the perception of facts that influence respondents to buy private label products and the age of respondents.

Hypothesis 7: We assume there is a correlation between the decisive factor when buying private label products and the gender of respondents.

Hypothesis 8: We assume there is a correlation between the decisive factor when buying private label products and the age of respondents.

Hypothesis 9: We assume there is a correlation between the facts that discourage respondents from buying private labels and the gender of respondents.

Hypothesis 10: We assume there is a correlation between the facts that discourage respondents from buying private labels and the age of respondents.

MATERIAL AND METHODOLOGY

The paper aimed to find out how the packaging and selected marketing communication tools affect consumer purchasing decisions in the dairy segment. An anonymous questionnaire survey was chosen as the main research method, with a total of 1,116 respondents from all over Slovakia (Table 1). This sample of respondents can be considered as representative on the 95% confidence level and 3% error margin as $n \geq 1{,}067.12$. The questionnaire survey consisted of 10 questions formulated as closed ones with the possibility of one, resp. multiple responses; and 7 classification questions.

A blind test method was chosen as a complementary method of research, in which participated 20 respondents aged up to 25 years – respondents had to evaluate on a scale of 1 to 5, with 1 being the best and 5 the worst, the color, flavor, fragrance, consistency, and the chocolate ratio in the first round of testing; and color, flavor, fragrance, consistency, chocolate ratio, the attractiveness of the packaging and the grammage in the second round of testing. Total of seven chocolate-flavored yogurt samples were examined in two rounds. Thus, the samples represented traditional brands as well as private labels. Interestingly, identical products were investigated, i.e. products of a traditional producer, both under its brand and under the retailer's private label. Table 2 provides a more detailed overview of the examined yogurt samples.

Statistical analysis

The results of both the questionnaire survey and the blind test were verified by statistical verification of dependencies and the following methods: Pearsons´ Chi-Square Test, Mantel-Haenszel Chi-Square Test, Phi Coefficient, Cramer´s V Coefficient and correspondence analysis by statistical programs XL Stat, SAS Enterprise Guide and SAS 9.4.

In hypothesis testing, if the *p*-value is lower than a significant level, in our case 0.05, the null hypothesis is rejected and the alternative hypothesis is confirmed.

RESULTS AND DISCUSSION

Although rational resp. irrational behavior of consumers has already been studied by various researchers, resp. experts in the field, such as **Galbraith (1938)**, **Hanf and von Wersebe (1994)**, **Dean and Croft (2009)**, **Marsden and Littler (1998)**, **Hantula (2012)**, **Rybanská, Nagyová, and Košičiarová (2015)**, **Guziy, Šedík and Horská (2017)**, **Šedík et al. (2019)**, **Rybanská, Košičiarová and Nagyová (2019),** etc., resp. that the effect of packaging on shopping behavior or the attractiveness and effectiveness of the packaging has been examined by other researchers, e.g. **Horská et al. (2018)**, **Nagyová et al. (2018)**, **Bogdanovičová and Jarošová (2015)**, **Pavelková and Flimelová (2012)**,

Čanigová et al. (2018); it can still be stated that the present contribution represents an innovative approach to this issue since the effect of the packaging on the consumer's purchasing decision in the case of private labels has not been yet examined. In the field of private labels, attention has been, so far, focused primarily on whether consumers buy the products, what product categories do they buy and what benefits these products bring to them or whether consumers prefer traditional brand or private label products **(Hoch and Banerji, 1993; Narasimhan and Wilcox, 1998; Cotterill, Putsis and Dhar, 2000; Steenkamp, Van Heerde and Geyskens, 2010; Košičiarová, Holotová and Nagyová, 2014; Košičiarová and Nagyová, 2015; Košičiarová et al, 2018)**.

As stated in Table 1, the majority of respondents were represented by female gender (63.3% of respondents), aged up to 25 years (49.2% of respondents), with secondary education with A level (39.2% of respondents), employed (48% of respondents), with a net money income of households between 501 and 800 € per month (25%) and city as the residence of respondents (63.9%).

As the aim of the paper was to find out how the packaging and selected marketing communication tools affect the consumer purchasing decisions in the dairy segment, within the questionnaire survey were formulated questions related to the issue of private label products, followed by the blind test carried out in two rounds, to determine whether the packaging influence the purchasing decision of consumers.

In terms of purchasing the private label products, the current situation in Slovakia is favorable, as of total 1,116 respondents, up to 28.7% buy the products on a regular basis and 53.1% of respondents buy them sporadically. For specific reasons for purchasing or non-purchasing of the given products can be said that while our respondents do not buy private labels mainly because of *lack of interest to try something new* (32.3% of respondents), *assumed low product quality* (27.1% of respondents) and *unsatisfactory price* (13.5% of respondents); they buy them mainly because of *lower prices compared to traditional product brands* (31% of respondents), *comparable quality to traditional brands* (24.3% of respondents) and *good experience* (24.3% of respondents). Based on the above, it can be said that rational reasons prevail over irrational ones, and therefore in this case respondents behave rationally.

In terms of the frequency of private label products purchases, our respondents buy the products mainly once a month (27.7% of respondents) and multiple times a week (24.9% of respondents); they buy private brands the most often in the categories of *milk and dairy products, meat and fish* purchased every week, *savory snacks and mineral waters, lemonades, and juices*, which they buy on a monthly or weekly basis. For this reason, dairy products, namely yogurts, were further tested in the blind test.

These results largely correspond to those of research agencies TNS Slovakia **(TNS, 2015)** and GFK Slovakia **(TASR, 2010)**, resp. our previous study **(Nagyová and Košičiarová, 2014; Košičiarová et al., 2017**), which says that Slovaks buy private label products mainly several times a week, resp. once a week; they buy them mainly because of their cost-effectiveness, quality and confidence; and that every Slovak household has in its regular purchases a "favorite brand", for some categories of goods there is a stronger brand preference, when the brand is put before the price, mainly in dairy products that are purchased every third day on average; coffee and coffee specialties followed by margarine and butter, body and dental hygiene products, skin care, shampoos and other hair care products. The survey further shows that, while in a case of long-life milk the “less prestigious“, private label products make up almost 80% of total consumption, within the acidophilic milk, fresh milk and fresh cheeses dominate the traditional brand products **(TASR, 2010)**.

In terms of the perception of quality and evoked impression in consumer perception and consciousness, we can further say that our respondents perceive private labels as products of good resp. of adequate quality (48.7% of respondents), resp. private labels evoke that they are products of adequate quality at a reasonable price (59.8% of respondents).

As has been indicated before, the aim of the paper was also to find out how packaging affects consumers' purchasing decisions. For this reason, the questionnaire survey also formulated questions about how respondents perceive the packaging of products labeled with a private label and whether they think, that packaging influences them in their purchasing decision. The evaluation of the questions showed that although most respondents have no opinion on the packaging of private label products (up to 45.3% of respondents), up to 31.3% think that this packaging is unattractive and up to 35.8% believe that the packaging does not affect them. Following the findings, a correspondence analysis was created in SAS 9.4 to determine if the packaging affected our respondents' purchasing decisions. As can be seen in Figure 2, those respondents who reported that private label products buy regularly think that private labels have attractive packaging and that packaging does not affect them in their purchasing decisions; respondents who buy private labels sporadically think that their packaging is unattractive, resp. that the packaging affects them; and those respondents who do not buy private label products, do not have any opinion.

These findings are followed by a blind test conducted on a sample of 20 respondents from the category of young people (up to 25 years), as they represent potential regular customers of the products. Yogurts have become the subject of the blind test, as several studies proved that private label products are purchased primarily in the categories of milk and dairy products **(Košičiarová et al., 2018)**. The blind test took place in two separate rounds. While in the first round, respondents tasted yogurts without knowing what specific yogurt it was, in the second round they were already tasting yogurts by seeing their particular packaging.

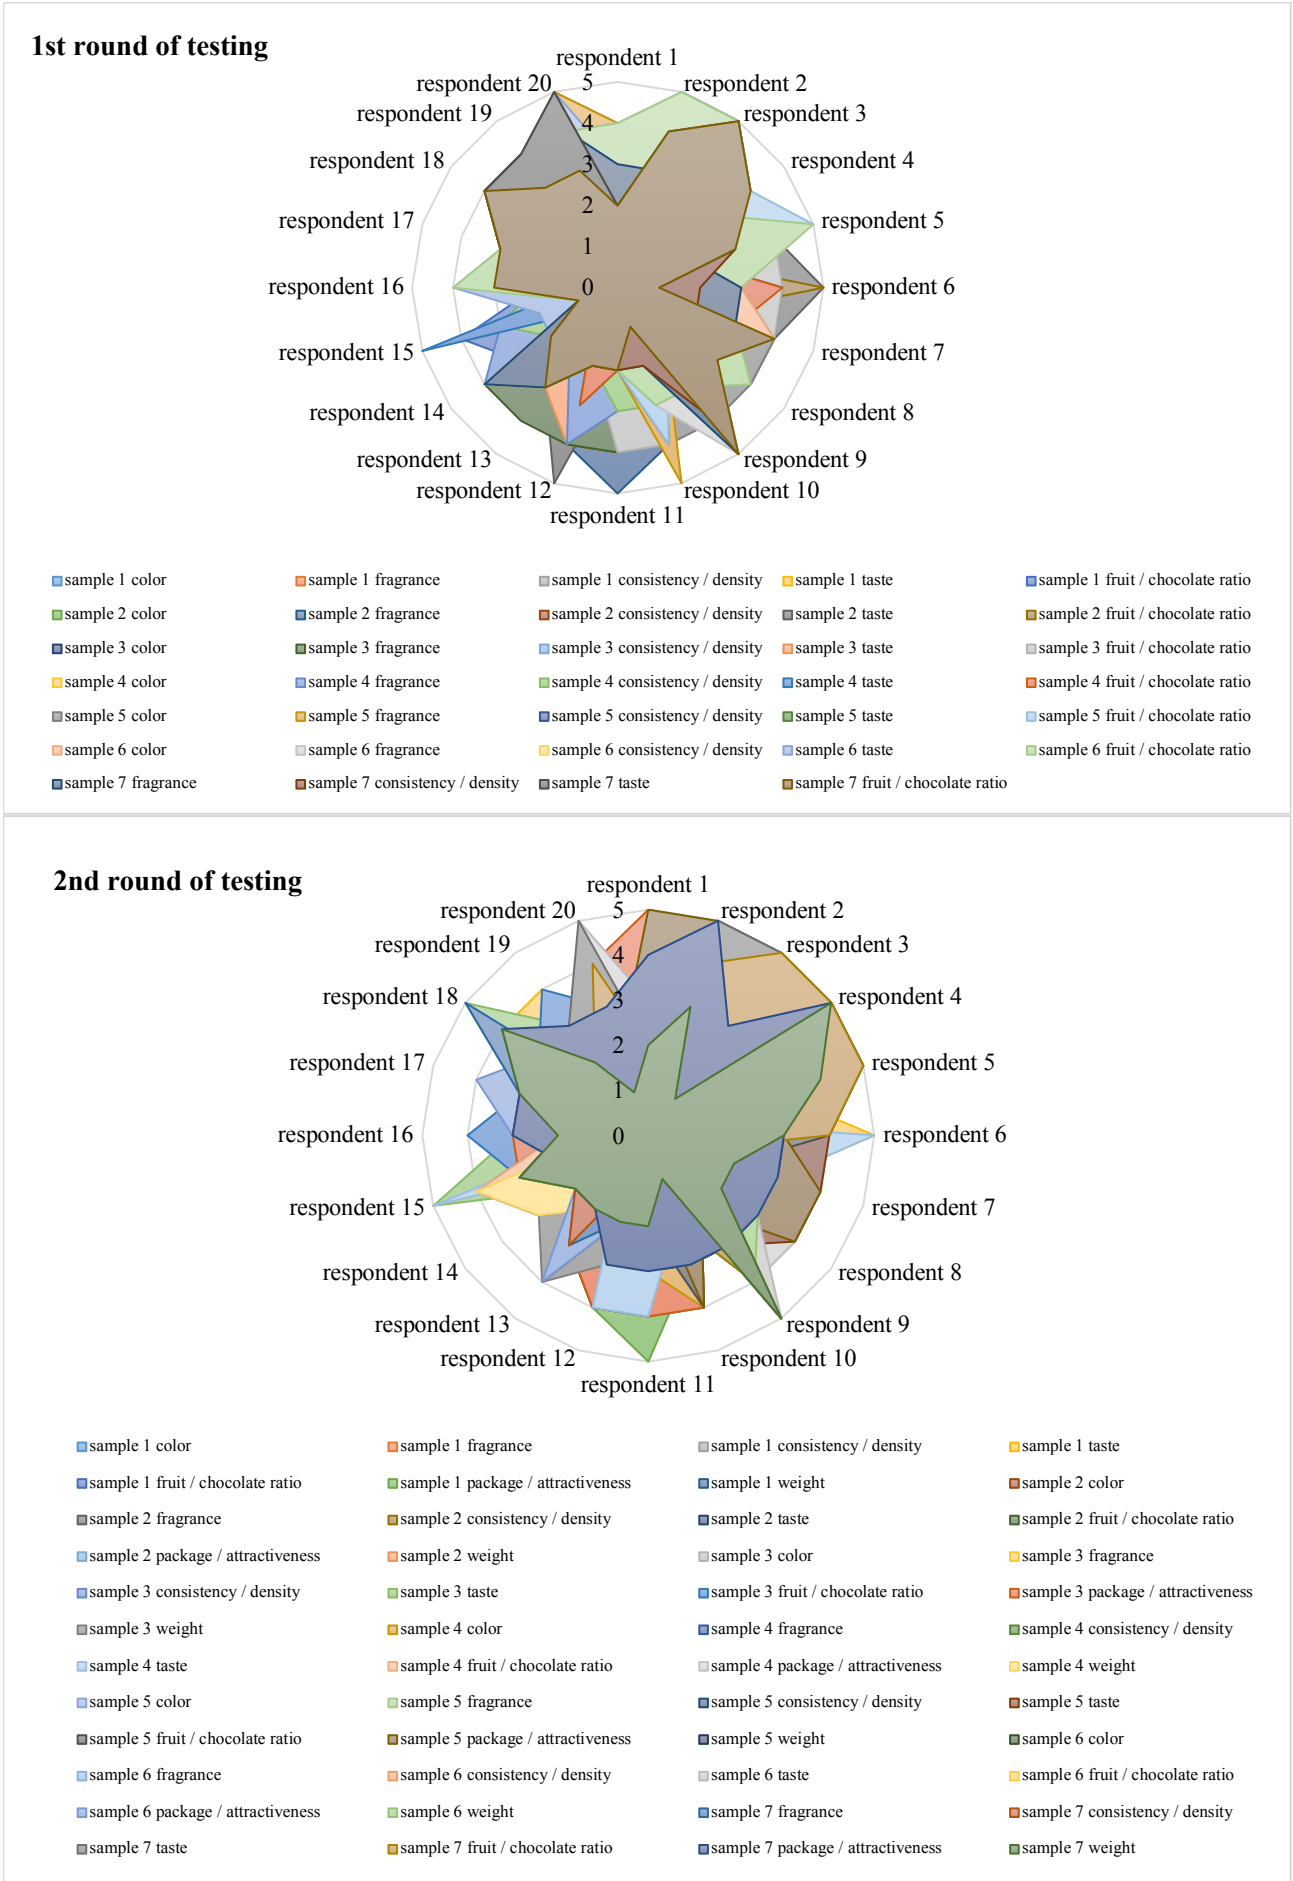

Figure 3 Comparison of Results of Two Rounds of Blind Testing. Note: Source: Results of own research.

The aim of this research, as it has been mentioned before, was to find out whether the packaging of a given product affects the consumer's purchasing decision. Respondents were tasked on a scale of 1 to 5, with 1 being the best rating and 5 the worst to evaluate selected attributes of the examined yogurts. These attributes were color in the first round of testing; aroma; consistency, resp. yogurt density; flavor and proportion of chocolate. In the second round of testing, the package size (i.e. whether it is suitable for respondents) and the attractiveness of the package was added to the attributes.

The results of both rounds of mentioned blind test point to many interesting findings – while in the first round of the blind test carried out in the overall evaluation of the respondents, as the best yogurt was evaluated the yogurt sample No. 5, in the second round there were the samples No. 7 and No. 6 (Figure 3).

If we look at the evaluation of the yogurt in more detail, we would find that while in the first round, when comparing samples No. 1 and No. 2 representing identical yogurt, the sample No. 1 was evaluated better, where respondents also perceived higher proportion of chocolate, even better taste of the yogurt. When comparing samples No. 3 and No. 4, representing identical yogurts than sample No. 4 was evaluated better only in color, the other attributes were perceived and evaluated in both samples the same way, except the taste, that was slightly better in Sample No. 3 and the smell that was better in Sample 4. In a comparison of samples No. 5, No. 6 and No. 7, respondents reported very similar ratings but based on the share of chocolate as the worst were evaluated the samples No. 6 and No. 7. In the second round of blind testing, when the respondents knew the specific yogurts and therefore could be influenced not only by the packaging but also a specific brand of yogurt, was in case of samples No. 1 and No. 2 better-evaluated sample No. 1 regarding the volume of packaging and sample No. 2 regarding the taste. When comparing the samples No. 3 and No. 4, sample No. 3 was better rated in terms of color and sample No. 4 in terms of taste and volume of the packaging; and when comparing samples No. 5, No. 6 and No. 7, the best rated for the attractiveness of packaging was sample No. 5, the best taste was rated in sample No. 6, and the best smell in sample No. 7. Consistency was evaluated as the best one in sample No. 6 and No. 7.

In terms of evaluation of packaging attractiveness and the impact of packaging on consumer behavior can be said that in this case, irrationality prevails, as already mentioned, identical yogurts were examined in the blind test but under different brands but respondents felt differences in taste, consistency, etc. Thus, the evidence indicates that the packaging can influence the consumer's decision and plays an important role in his purchasing decision and the evaluation of the en product.

The most attractive packaging in the case of our research was considered packaging with traditional "Slovak" motives and figures.

The last questions of the questionnaire survey focused mainly on factors leading and discouraging to and from the purchase of private label products, resp. what would affect our respondents to buy the products the most? Based on the evaluation of these questions, it can be said that while the most important factors leading to the purchase of private label products are *the combination of reasonable price and quality* (47% of respondents), *perceived quality* (13.2% of respondents) and *good experience* (11.4% of respondents) and not the price by itself how it was until recently **(Burt, 2000; Kumar and Steenkamp, 2007)**. The most important factors discouraging the purchase of private label products are *the expected low quality* (17.2% of respondents), *nonacquaintance of the producer* (16.8% of respondents), and *freshness* (14.9% of respondents).

Again, in terms of our respondents' purchase of private label products can be seen many interesting findings – as consumers are in an increasingly competitive and dynamic market environment in today's modern and globalized world **(Smutka et al., 2016; Polakevičová, 2015; Džupina, Hodinková and Kiková, 2016; Lorincová et al., 2018; Ližbetinová et al., 2019; Mach, Dvořák and Hošková, 2018)** characterized mainly by the online environment and the supersaturation of traditional communication tools, online communication, digital marketing, influencer marketing, etc. However, this assumption has not been confirmed as our respondents prefer more traditional forms of marketing communication, such as *word of mouth marketing and friends´ recommendations* (40.3% of respondents), *more interesting form of promotion* (15.9% of respondents), *tasting* (15% of respondents) *and free samples or buy 1 get 1 free* (14.8% of respondents).

Evaluation of tested dependencies

Hypothesis 1: We assume there is a correlation between the quality rating of private label products and the gender of respondents –confirmed.

Hypothesis 2: We assume there is a correlation between the purchase of private label products and the gender of respondents –confirmed.

Hypothesis 3: We assume there is a correlation between the purchase of private label products and the economic activity of respondents – rejected.

Hypothesis 4: We assume there is a correlation between the perception of private label packaging and the gender of respondents – rejected.

Hypothesis 5: We assume there is a correlation between the perception of facts that influence respondents to buy the private label products and the gender of respondents – rejected.

Hypothesis 6: We assume there is a correlation between the perception of facts that influence respondents to buy the private label products and the age of respondents – rejected.

Hypothesis 7: We assume there is a correlation between the decisive factor when buying private label products and the gender of respondents – confirmed.

Hypothesis 8: We assume there is a correlation between the decisive factor when buying private label products and the age of respondents – rejected.

Hypothesis 9: We assume there is a correlation between the facts that discourage respondents from buying private labels and the gender of respondents – confirmed.

Hypothesis 10: We assume there is a correlation between the facts that discourage respondents from

buying private labels and the age of respondents – confirmed.

CONCLUSION

Even though private labels are not a complete novelty in the market, they still represent a kind of uncharted territory that needs to be explored. The submitted paper dealt with the issue of private labels and their perception by Slovak consumers as well as with the influence of packaging and chosen marketing communication tools on consumer purchasing decisions in the dairy segment, as the results of several surveys proved that private labels are mainly purchased in this segment.

An anonymous questionnaire survey was chosen as the main research method, which was attended by total 1,116 respondents from all over Slovakia, and was subsequently supplemented by the blind test attended by total of 20 respondents aged up to 25 years. The results of our two researches have shown several interesting and key findings, which proved that while the reasons, resp. rationality prevails over irrational factors leading to and discouraging the purchase of private products, irrationality prevails in the perception and evaluation of packaging. As far as the marketing communication techniques and methods are concerned, based on the results of our research, it can be concluded that the "heart" rather than reason prevails, since it is still true that respondents prefer more traditional forms of marketing communication, such as *word of mouth marketing and friends´ recommendations, more interesting form of promotion, tasting and free samples or buy 1 get 1 free* and not the modern techniques and forms of addressing customers, which we have expected before.

EFFECTS OF PROCESSING METHODS ON NUTRITIONAL COMPOSITION OF FISH *PAMPUS ARGENTEUS* (WHITE POMFRET) IN IRAN

Ali Aberoumand

ABSTRACT

The effects of different processing methods (Frying cooking, brining and boiling) on the proximate composition of fish species (*Pampus argenteus*) were investigated. The objective of this work is to know the best processing methods, the effect of processing on nutritional values of fish products. The result of the proximate composition of the fish species showed that the highest protein content (38.17%) was in *P. argenteus* processed with the frying process. The result of moisture content indicated that boiled samples were consistently the least (25.20%) while for fried sample had the highest moisture percentage. The lipid was reduced to the least value of 9.94% in the brined fish. In cooking, the important factors for consideration are moisture, lipids, and protein, though low moisture would ensure a fish product with extended shelf life. To have a longer shelf life, high protein is desirable, a low lipid is equally desirable as to reduce oxidation and rancidity in the samples which causes off-flavor and bad taste in fish products. In conclusion, all the processing methods are good and could extend the shelf life of the products with an exception of boiling method; they could keep the fish fillet free from spoilage and microorganisms attack for some period. This study showed that the proximate values obtained could be of help in choosing fish based on nutritional values.

Keywords: frying; brining; boiling; processing; *Pampus argenteus*

INTRODUCTION

Fish and seafood are a source of good quality protein which is essential for health **(Kim and Lall, 2000)**. Fish is usually cooked in different ways such as boiling, smoking, baking, frying, and grilling. These cooking methods result in enhancing flavor, taste, and improve the digestibility and inactivate the pathogenic microorganisms and enzymes **(Kocatepe et al., 2011)**.

During cooking of fish, some chemical and physical reactions take place such as protein denaturation that increases its digestibility and improves the nutritional value. However, the contents of fat-soluble vitamins or polyunsaturated fatty acids are often reduced **(Alizade et al., 2009)**.

Deep Fat Frying (DFF) is a major cooking method and is considered to be one of the oldest methods of food preparation. It is a cooking method of immersing foods in hot oil at a temperature above the boiling point of water. The oil temperature usually varies from 130 to 200 °C. During frying, there are many chemical reactions such as browning, gelatinization, and denaturation due to the elevated temperature of the product **(Tangduangdee, Bhumiratana, and Tia, 2003)**.

Pampus argenteus (White pomfret) is one of the most preferred indigenous aquaculture species in Iran due to better growth. Nutritional information is only available for fresh fish (Figure 1). The study was carried out to determine nutritional composition (protein, fat, ash, moisture, and energetic values) of brined, boiled, and fried *Pampus argenteus*.

These cooking methods result in enhancing organoleptic properties and improve the digestibility and inactivate the pathogenic microorganisms **(Kocatepe et al., 2011)**. Method cooking of fish, lead to some chemical and physical reactions take place such as protein denaturation that increases its digestibility and improves the nutritional value. Meanwhile, the contents of fat-soluble vitamins or polyunsaturated fatty acids are often reduced **(Alizade et al., 2009)**. Deep fat frying is a major cooking method and is mentioned as one of the old methods of food preparation. It is a cooking method of immersing foods in plant hot oil at a temperature above the boiling point of water. The oil temperature usually is around 180°C. During frying, there are many chemical reactions that take place such as browning, gelatinization, and denaturation due to the elevated temperature of the product **(Tangduangdee, et al. 2003)**.

Salting is the oldest, applied, and commonly used processing technique for fish preservation all over the world because of the simplicity of the process and low production cost **(Martínez-Alvarez and Gómez-Guillén, 2013)**. Salt is effective as a preservative compound because it reduces the

Figure 1 Fish *Pampus argenteus* (White pomfret).

water activity of fish fillets, consequently, microorganism growth and enzymatic spoilage are inhibited. Also, the aim of salted fish is to improve sensory properties more than preservation **(Mujaffar and Sankat, 2005)**.

Scientific hypothesis

The different processing methods will affect the composition and energetic values of the Pampus argenteus fish fillets.

MATERIAL AND METHODOLOGY

Raw materials

This study was carried out in the Department of Fisheries, Behbahan Khatam Alanbia University of Technology in November 2019. *Pampus argenteus* (White pomfret) fresh fish, similar sizes (54 – 66 cm) and weights (3.456 – 3.234 kg), were purchased from the fish market of the city of Behbahan, Iran, they were immediately stored in containers with ice and transported to the fish analysis laboratory of the Behbahan Khatam Alanbia University of Technology for processing and analysis.

Sample preparation and cooking methods

White pomfret fish were caught from the southern waters of Iran during September 2019. A homogeneous lot of fish was kept in a cold iced box and transported to the laboratory within 20 min. Samples were then filleted and then fish fillets were divided into 3 groups. The first group was uncooked (raw samples); the other 2 groups were cooked by different heat treatments (boiling and frying) and the third group was brine salted treated.

Boiling

The fillets were uniformly placed forming a thin layer on a stainless steel steamer above a stainless steel pot of boiling water and cooked with the lid on for 20 min.

Frying

The fillets were uniformly placed forming a thin layer in a wire mesh basket and immersed in Sunflower oil in a deep fryer for 10 min at 180 °C.

Brine salting

In the brine salting method, the cleaned fish were placed inside plastic jars of 5 liters, and brine was added until the fish was completely covered and brined in 30% salt solution, fish fillet to salt solution ratio is 1:1. were placed for 15 min in a special container **(Binici and Kaya, 2018)**. The producer and purity of chemicals used for experiments were according to a standard method by **Binici and Kaya (2018)**.

Analytical procedures

The heat treatment methods were performed in triplicate. After all heat treatments, the samples were cooled to 25 °C temperature. Each sample of raw or cooked fish fillets was crushed using a kitchen blender (made in Iran) and the fish powder was used to determine proximate chemical composition.

Proximate chemical composition

The moisture content of cooked and uncooked fish fillets was dehydrated by an oven at 115 °C until a constant weight was obtained **(AOAC, 2005)**. Crude protein content was calculated by converting the nitrogen content determined by Kjeldahl's method (6.25 × N). Fat content was determined according to the Soxhlet method **(AOAC, 2005)** by using chloroform as an extraction solvent. Ash content was determined by incineration in a muffle furnace (Made in Iran) at 600 °C for 2.5 h **(AOAC, 2005)**. The total caloric value was calculated from the corresponding caloric coefficients for proteins, lipids, and carbohydrates, respectively 4, 9, and 4 kcal.g^{-1} **(USDA, 2015)**.

Statistical analysis

Statistical analysis was performed using SPSS for Windows version 16.0. Software for Difference in the means between the groups was analyzed using the T-test. Duncan's multiple range tests were applied to do multiple means comparison. Statistical significance was set at $p < 0.05$.

Table 1 Proximate composition (g.100g^{-1}) and caloric value of fresh,brined, fried and boiled fish *Pampus argenteus*, on a dry basis.

	Moisture	Protein	Lipids	Ash	Calories (Kcal.100g^{-1})
Fresh	24.60 ±0.28^{a}	13.60 ±0.38^{a}	55.80 ±0.23^{a}	6.00 ±0.07^{a}	556.60 ±1.9^{a}
Boiled	25.20 ±0.4^{b}	29.40 ±0.97^{b}	38.40 ±0.55^{b}	7.00 ±0.12^{b}	463.2 ±1.61^{b}
Brined	38.80	33.56	9.94	17.70	223.6
Fried	40.40	38.17	12.23	9.20	262.75

Note: Mean of samples analyzed in duplicate. The same letters in the column do not differ from each other at the 5% level of significance.

RESULTS AND DISCUSSION

Results for proximate composition analysis (protein, fat, moisture, and ash) for fresh, boiled, fried, and brined fish *Pampus argenteus* are presented in Table 1.

Determined protein content for *P. argenteus* was 13.60%, 29.40%, 38.17%, and 33.56% for fresh, boiled, fried, and brined fish respectively (Table 1). Protein content was significantly increased (p <0.05) is processed (boiled, fried, and brined) fish. Lowest protein levels were nevertheless observed in boiled fish. The highest and lowest levels of fat were recorded in brined (9.94%) fish and were significantly different from unprocessed (fresh) fish. Brined and fried fish had significantly high levels of ash (17.70% and 9.20%) (p <0.05). There were significant differences (p <0.05) in moisture content for *P. argenteus* where the lowest levels were recorded in boiled fish (25.20%).

Chemical composition of fish varies widely depending on the fish species, age, nutrition, size and sex, growth place, catching season, and the environmental conditions **(Manthey, Karnop and Rehbein, 1988)**. The increase in the fat content of the fried fish fillets is related to oil absorption during the cooking process. Also, reported that the increase in dry matter content was observed in the fried and grilled fish fillets. The decreased moisture content was noticed in all the cooking methods except for the boiled fillets. Increased ash content was noticed in all the cooked fillets when compared to raw fish fillets. That deep-fried fish had the highest protein value comparing other cooking methods. Water loss, occurring during cooking resulted in increasing protein content in the fried fish samples **(Gökçe et al., 2004; Gokoglu, Yerlikaya, and Cengiz 2004)**. The higher lipid content of fried fish than other methods is mainly due to the absorption of oil by the fish and losing moisture during frying process (the apparent higher ash content of a fried sample is due to more loss of moisture took place during deep-frying cooking comparing with another method **(Küçükgülmez et al., 2006))**. A higher level of protein in this study agrees with earlier reports **(Saguy and Dana, 2003)**.

Cooking methods that require heat can affect the nutritional composition of fish depending on the intrinsic composition, temperature, and time the product is exposed and the method used. The water loss may be attributed to the evaporation, dehydration of the fillet fibrils, and probably to some heat-induced protein denaturation during boiling, which causes less water to be entrapped within the protein structures **(Chukwu and Shaba, 2009; Costa et al., 2013)**.

Quality properties of processed fish at the time of consumption and eating greatly depends on different factors such as; the freshness and fish quality, the cooking methods, and the storage or preservation conditions followed before cooking. Fish spoilage is usually more rapidly than other animal muscle foods and this spoilage is primarily bacterial. Therefore, good preservation techniques must prevent the bacterial spoilage of fish without affecting its quality and nutritional value **(El-Lahamy et al., 2018)**.

Marimuthu et al. (2012) showed that the increase in dry matter content was observed in fried fish fillets. The highest moisture content (77.2%) was recorded in raw fillets. Increased ash content was noticed in all the cooked fillets when compared to raw fish fillets. Moisture loss was also found in baked fillets of snakehead fish. However, the dehydration rate comparatively was lower than during frying. These changes were similar to those reported by **Gokoglu, Yerlikaya and Cengiz (2004)** in rainbow trout and **García-Arias et al. (2003)** in sardines. Water losses, occurring during frying resulted in higher protein content in fried fish as compared to the raw fish fillets **(García-Arias et al. 2003)**. Accordingly, the increase in ash, protein, and fat content found in cooked silver catfish fillets is explained by the reduction in moisture. These results were similar to our present study.

Abraha et al. (2018) reported that generally fish processing methods (high and low-temperature treatments) including, chilling, freezing, canning, smoking, drying, salting and frying, and various combinations of these, to give the fish product a form which is attractive, fresh to the consumers and prolong and suitable storage life. These processing methods have different applications, techniques, and significant influences and effects on the chemical, physical, and nutritional composition of processed fish. This is because heating and exposure to a high concentration of salt lead to chemical and physical changes. Ultimately different quality could be obtained via these methods, hence subsequent effects on processed fish's shelf life also vary **(Magnussen et al., 2008; Díaz-Tenorio, García-Carreño and Pacheco-Aguilar, 2007)**.

CONCLUSION

The results obtained from this study showed that the highest protein (38.17%) and moisture (40.40%) contents found for fried fish *Pampus argenteus*, while lowest moisture content (25.20%) found for boiled fish. The least lipid content (9.94%) found for brined fish (p <0.05). Fish provides the most dietary animal valuable protein to people in Iran. Findings also confirm earlier reports that processing alters nutrients content in fish. Although fried fish are mostly liked by many people, results in this study have demonstrated that more nutritional benefits could be obtained when fish are processed through the boiling method.

Lower amounts of lipids in boiled samples were presumably the result of the spread of fat into stock during boiling. As far as fat is concerned, the loss introduced by heat treatment is not as explicit as in the case of water. Boiling, both with and without the addition of salt and, caused a substantial (10% on average) drop in the amount of fat. The loss of fat and nutrients in boiling was less than frying in oil. It has been shown also that boiled fish exhibit better storage properties due to low moisture retention

FOOD ADULTERATION AND SAFETY REGARDING DETECTED MARKET CASES AND CONSUMER OPINIONS

Martina Fikselová, Lucia Benešová, Peter Zajác, Jozef Golian, Jozef Čapla

ABSTRACT
Food fraud is one of the long-standing causes of scandals attracting particular attention for a long time. This study aimed to monitor food fraud in the European Union and to identify the relationships among the countries where the cases were reported, adulterated commodities (seafood, eggs, milk, meat, fish, and their products) and types of fraud. The secondary data were covered by the survey focused on consumer knowledge about fraudulent activities, ingredient substitution, masking of origin, mislabeling, placing on the market of foods not fit for human consumption within Slovak inhabitants. Primary and secondary data were used to achieve this aim. Primary data were obtained from the Food Fraud and Quality Knowledge Center (KCFFQ) and secondary data from the questionnaire survey from 354 respondents. During the period from 2017 to 2019, 163 cases of food fraud were reported, most of which originated from Italy and mainly concerned fish and fish products. Based on primary data and one-way ANOVA statistical tests, we confirmed five hypotheses. There was found no statistical impact of the country on the type of food fraud ($p = 0.0067$), but the significant effect was determined on which food was adulterated ($p = 0.000001$). There was no statistical correlation among years and countries where the cases were reported ($p = 0.110$), but the statistically significant correlation was confirmed among years and commodities ($p = 0.0043$) and types of fraud reported ($p = 0.009$). Based on the processed secondary data from the questionnaire, we can conclude some information or public interest in food fraud problems.

Keywords: food fraud; KCFFQ; consumers; adulteration; questionnaire

INTRODUCTION
Adulteration in food has been a concern since the beginning of civilization, as it not only decreases in the quality of food products but also results in several ill effects on health. Authenticity testing of food and adulterant detection of various food products is required for value assessment and to assure consumer protection against fraudulent activities. Concerns about food safety and regulation have ensured the development of various techniques such as physical, biochemical/immunological, and molecular techniques, for adulterations detection in food **(Bansal et al., 2017)**. Food fraud, the intentional misrepresentation of the true identity of a food product or ingredient for economic gain, is a threat to consumer confidence and public health and has received increased attention from both regulators and the food industry **(Everstine et al., 2018)**. Every European citizen has the right to know how the food he eats is produced, processed, packaged, labelled, and sold. The implementation of this integrated Food Safety policy in the EU involves various actions, namely to assure effective control systems and evaluate compliance with EU standards in the food safety and quality, animal health, animal welfare, animal nutrition and plant health sectors within the EU and in non-EU countries in relation to their exports to the EU; to manage international relations with non-EU countries and international organisations concerning food safety, animal health, animal welfare, animal nutrition, and plant health; to manage relations with the European Food Safety Authority (EFSA) and ensure science-based risk management **(European Commission, 2020a)**. Rapid alert system for the notification of a direct or indirect risk to human health deriving from food or feed was established in the EU. It involves the Member States, the Commission, and the EFSA **(Regulation (EC) No 178/2002)**. Starting from November 2015 a dedicated IT application known as the Administrative Assistance and Cooperation System (AAC) has been made available for the Member States. After a successful period of testing dealing with fraudulent practices in the agri-food chain, in 2016 the system was also opened to liaison bodies based on official controls. The AAC and RASFF (Rapid Alert System for Food and Feed) are working together in synergy to keep the high EU standards for food and feed **(EU, 2017; RASFF, 2018)**.

The Knowledge Centre for Food Fraud and Quality provides and shares up-to-date scientific knowledge on food fraud and food quality issues. It coordinates market surveillance activities and operates early warning and information system for food fraud. Collectively is operated by the European Commission's science and knowledge

service, the Joint Research Centre (JRC), and the Departments regulating the feed-food chain and protecting consumer rights. The Centre complements the activities of the EU Food Fraud Network, which is operated by the European Commission Department for Health and Food Safety **(European Commission, 2020b)**.

Scientific hypothesis

The first objective of this study was to monitor the food fraud focused mainly on the food of animal origin in member states of the European Union and to identify the most common reasons for these cases. The following hypotheses concerning food fraud were set up as follows:
Hypothesis 1: We assume no statistical evidence of the country's impact on food frauds, which were reported.
Hypothesis 2: We assume statistical evidence of the country's impact on counterfeit foodstuff.
Hypothesis 3: We assume no statistical evidence between the countries and year when the food fraud cases were reported.
Hypothesis 4: We assume statistical evidence between adulteration of food and the year of its occurrence.
Hypothesis 5: We assume statistical evidence between the type of food fraud and year of its occurrence.

The second objective was to find out consumer awareness in Slovakia regarding their knowledge and opinion on food fraud.

MATERIAL AND METHODOLOGY

The objective of this paper was achieved by using and processing of primary and secondary data. Primary data were obtained from the Knowledge Centre for Food Fraud and Quality (KCFFQ) which is hosted by the Joint Research Centre (JRC), during the period 2017 – 2019. The records were obtained using the portal contained information about:

- the reporting country,
- the food commodities,
- categories of food fraud,
- accurate case information.

The data obtained became the basis for confirming or rejecting hypotheses.

Secondary data were obtained using the survey focused on identifying consumers' awareness of food fraud in the Slovak Republic. The questionnaire was performed at a sample of 354 respondents in the 2019 year, using the Google Forms platform. The respondents were diversified into 2 categories in terms of gender and age. Women were represented by the amount of 278 (78.5%). The men were represented by 76 respondents (21.5%). Group was also divided into four groups based on their age. The age structure consisted as follows: from 16 to 21 years (13.3%), from 22 to 30 years (41.2%), from 31 to 45 years it was 27.1% and from 46 to 70 it was 18.4%. Questions about which commodities are most often adulterated, which types of food fraud occur most often, in which countries they think food fraud is the most commonly reported, and from what media they get this information was given to respondents.

Statistical analysis

The collected data were processed using the statistical program XLSTAT (Addinsoft, version 2019.1.2) The formulated hypotheses were tested using the one-way ANOVA statistical test. Hypotheses were tested: if the *p*-value is less than a significant level (0.05) the invalid hypothesis was rejected and an alternative hypothesis was confirmed.

RESULTS AND DISCUSSION

Analyzes of primary data from KCFFQ

Food safety is one of the crucial issues of public health protection **(Cieslik and Cieslik, 2012)**. If food is misdescribed, i.e. the information about the origin, composition, etc. provided to customers is not true and if this misdescription is done to deceive the customer for financial gain, food fraud, also known as economically motivated adulteration, is committed. Economically motivated adulteration of food is estimated to cause damage of around €8 to €12 billion per year **(Vaqué and Vidreras, 2018)**.

By evaluating food fraud notifications at KCFFQ during years from 2017 to 2019, we found 163 notifications reported to the KCFFQ system (Table 1a, 1b, 1c, 1d, 1e, and 1f). We evaluated the ten most common types of fraud, 12 reporting countries, 5 commodities that were most commonly adulterated. There were found 60 notifications in 2017, where in Slovakia was reported only one case. This notification involved meat originating from Brazil contaminated with *Salmonella*.

The next year 2018, showed the highest amount of notifications for the whole observed period, namely 72.
In 2019 there were found 31 reports. In Slovakia, no notification of food fraud was reported in the year 2018 and 2019. Reports of food fraud in each country from 2017 to 2019 in Europe are shown in Figure 1. Within this period, 92 reports were received from Italy, of which 37 concerned fish and fish products. Spain received 25 reports, also related to fish and fish products. 12 reports originated from the UK and 8 of them related to meat and meat products. 7 reports were reported from Belgium and Portugal, in both countries 6 cases related to meat and meat products, together 6 cases originated from France and 4 related to fish and fish products. 5 cases were reported from the Netherlands with 3 concerning the eggs. 3 cases from Ireland related to meat and meat products, Malta, Poland, and Slovakia reported one case of meat fraud and Germany reported one case of egg fraud.

Čapla et al. (2019) published a review on different types of foreign matter detected in food, reported by the RASFF during the period from 2016 to 2018. The presence of foreign bodies in food from different European regions showed differences. Plastic, glass, and metal were the most commonly reported in Western Europe, pests, and rubber in Northern Europe. As far as food commodities are concerned, bakery and confectionery products, fruit and vegetables, and convenience foods were the most frequently reported and the notifications originated often from Western Europe. Notifications from this part of Europe were made concerning other monitored commodities as well. Regarding the notification type, the most frequent one was an alert, and, in the case of a risk decision, serious risk constituted the largest part. Following updates to food safety certification standards and publication of new U.S. regulatory requirements, **Everstine et al. (2018)** undertook

a project to develop a scheme to classify food fraud-related adulterants based on their potential health hazard and apply this scheme to the adulterants listed in a database of 2,970 food fraud records. The classification scheme was developed by a panel of experts in food safety and toxicology from the food industry, academia, and the U.S. Food and Drug Administration. Results reinforce the importance of including a consideration of food fraud-related adulterants in food safety systems.

Regarding the particular problems found in our evaluation, we can see several kinds of foods reported as the problem with traceability (from Italy, Spain, Portugal, France, etc.). For example, Italy reported at 3.5 mil. eggs, that they were found to be untraceable.

Table 1a An overview of food frauds in 2017 – 2019 in the order in which they were reported.

Country	Commodity	Food fraud	Details
2017			
Italy	fish and fish products	mislabelling	incorrect labeling of fish during the Christmas period
Italy	fish and fish products	mislabelling	fish were not traceable
Italy	fish and fish products	artificial enhancement	dyeing low quality tuna to sell it as fresh fish
Italy	milk and milk products	counterfeit	counterfeiting of mozzarella (discovery of labels of a well-known dairy company stored along with cow milk from other companies)
UK	meat and meat products	substitution	selling turkey instead of halal lamb
Italy	milk and milk products	artificial enhancement	spoilt milk was treated with caustic soda to mask acidification and aging
Italy	milk and milk products	Substitution	replacement of buffalo milk for cow's milk
Italy	milk and milk products	artificial enhancement	smoked Provolone cheese with cardboard and printed and glued paper leaflets.
Spain	seafood	mislabelling	no records of octopus traceability
UK	meat and meat products	origin masking	claimed their lamb products had been 'Produced in Britain' but in fact contained traces of imported New Zealand meat
Italy	meat and meat products	origin masking	using inappropriate animals to produce the cured ham and forging documents to reconstruct the traceability of the meat
Netherland	meat and meat products	substitution	sold horse meat as beef
Netherland	fish and fish products	substitution	endangered shark found in several fish products
Italy	eggs	origin masking	declaration of origin and other labelling information were missing
Italy	fish and fish products	mislabelling	lack of or incomplete informations about traceability
Italy	fish and fish products	mislabelling	untraceable fish products
Italy	seafood	mislabelling	untraceable seafood products
Spain	fish and fish products	mislabelling	lack of traceability and proper labelling
Slovakia	meat and meat products	products not fit for consumption	meat coming from Brazil contaminated with *Salmonella*
Portugal	milk and milk products	mislabelling	untraceable fozen goat milk
Italy	fish and fish products	mislabelling	mislabelling and traceability problem
Italy	eggs	mislabelling	absence of labelling, making it impossible to determine the origin of the eggs
Italy	fish and fish products	mislabelling	mislabelling juvenile fishe
Italy	fish and fish products	illegal equipment	use of illegal equipment and catch of juvenile fishe
Spain	fish and fish products	mislabelling	lack informations or mislabelling of origin
Italy	milk and milk products	origin masking	doubts about the true origin of dairy products
Italy	meat and meat products	substitution	sale of pork sausages instead of advertised wild boar and deer sausages
Italy	fish and fish products	substitution	red tuna was substituted by Yellowfin tuna and grouper was replaced by cheaper Nile perch in restaurant
Spain	meat and meat products	substitution	adding pig meat, soy and bread to their beef burgers and meatballs

Table 1b An overview of food frauds in 2017 – 2019 in the order in which they were reported.

Country	Commodity	Food fraud	Details
2017			
Portugal	meat and meat products	products not fit for consumption	lack of veterinary controls; lack of traceability; expired food relabelled with a new expiry date
Italy	fish and fish products	mislabelling	mislabelling of fish
Italy	fish and fish products	substitution	bluefin tuna was sold as a cheaper Albacore fish
Spain	meat and meat products	products not fit for consumption	distributing horse meat (horses were too old or labelled as "unfit for consumption")
Belgium	meat and meat products	products not fit for consumption	distributing horse meat (horses were too old or labelled as "unfit for consumption")
Italy	food	mislabelling	selling frozen food in restaurant without properly informations on the menu
Italy	fish and fish products	products not fit for consumption	expired and/or unlabelled products
Italy	eggs	mislabelling	traceability problems
UK	meat and meat products	substitution	horse meat and regular beef were sold as 100% beef
Italy	eggs	contamination	high levels of fipronil detected
Netherland	eggs	contamination	high levels of fipronil detected
Belgium	eggs	contamination	high levels of fipronil detected
Germany	eggs	contamination	high levels of fipronil detected
United Kingdom	fish and fish products	mislabelling	labels of other companies were used to by-pass the Russian law limiting the number of UK exporters
Italy	milk and milk products	origin masking	cheese were produced in unregistered places, labelled with incorrect information and entered fraudulently the Fontina DOP production chain
Italy	fish and fish products	mislabelling	unlabelled fish products
Italy	milk and milk products	origin masking	dairy farms were not accredited for the production of cheese with a protected origin and re-used old labels to pass the product as authentic
Spain	fish and fish products	artificial enhancement	the nitrites contained in the vegetables give the tuna a bright red colour making it appear fresher
Italy	milk and milk products	origin masking	labelling rules concerning claims made on the geographical origin and/or being organic were falsed claims
Italy	fish and fish products	mislabelling	unlabelled fish and molluscs
Italy	food	mislabelling	food without any traceability
Italy	fish and fish products	mislabelling	problems of traceability and compliance to mandatory labelling
Spain	fish and fish products	mislabelling	untraceable and unlabelled tuna
Italy	meat and meat products	mislabelling	of poor hygiene and non-traceability distibuted to schools, hospitals and military canteens
Italy	eggs	mislabelling	3.5 million eggs were found to be untraceable
Italy	fish and fish products	mislabelling	fish were found with irregularities concerning the labelling and traceability
Spain	fish and fish products	artificial enhancement	dyeing low quality tuna to sell it as fresh fish
Italy	fish and fish products	mislabelling	mislabelling of fish
Italy	fish and fish products	substitution	Bluefin tuna was sold as a cheaper Albacore fish
Italy	fish and fish products	mislabelling	health inspection, origin, date of freezing and traceability documentation were missing
Italy	milk and milk products	mislabelling	untraceable products in the food chain

Table 1c An overview of food frauds in 2017 – 2019 in the order in which they were reported.

Country	Commodity	Food fraud	Details
Spain	seafood	mislabelling	the origin of the product could not be determined as the mandatory labelling was missing
2018			
Spain	fish and fish products	mislabelling	fish that could not be traced
Spain	fish and fish products	substitution	restaurants were selling other types than those on offer (replaced by sole, hake and bluefin tuna)
Italy	fish and fish products	mislabelling	sale of frozen foodstuffs as fresh food of incorrect Italian origin
Italy	meat and meat products	origin masking	sale of frozen foodstuffs as fresh food of incorrect Italian origin
United Kingdom	meat and meat products	substitution	lamb meat (animal <12 months) has been replaced by mutton meat (older animal)
Italy	fish and fish products	origin masking	the shellfish was not traceable and the documentation of origin was missing
Italy	milk and milk products	mislabelling	Untraceable food
Italy	fish and fish products	mislabelling	Untraceable food
Belgium	meat and meat products	mislabelling	minced meat witch the expiry dates of the products were falsified
Spain	seafood	origin masking	Portugal clams were sold as Galician clams
Belgium	meat and meat products	substitution	conventional meat were sold as organic meat
Italy	food	origin masking	the traceability documentation were missing
Spain	meat and meat products	products not fit for consumption	freezing products; adding warm water, viscera and pork blood to cows to increase body weight; the product has expired 3 years ago and products contaminated with S*almonella*
Italy	meat and meat products	origin masking	improper marketing of meat with registered trade mark
Ireland	meat and meat products	products not fit for consumption	horse meat imported from eastern countries were unfit for human consumption; sold without true evidence on the Irish market
Italy	fish and fish products	products not fit for consumption	distribution of expired ten tonnes of frozen fish
Italy	meat and meat products	counterfeit	Danish Duroc boars have been used instead of Italian pig breeds for insemination purposes to reduce the fat content of the hams produced
Italy	fish and fish products	mislabelling	lack of appropriate traceability documentation for tuna, salmon and other types of fish
Italy	fish and fish products	mislabelling	lack of appropriate traceability documentation for fish products
Italy	fish and fish products	products not fit for consumption	use low quality fish to prepare sushi and sashimi; offered frozen fish that have expired
France	fish and fish products	products not fit for consumption	fillets were sold as fresh fish, although they were actually frozen
France	fish and fish products	artificial enhancement	use of unauthorized additives to improve the red color of tuna
France	fish and fish products	artificial enhancement	salt, potassium lactate, potassium acetate, citric acid and polyphosphate were used to retaining water
Italy	milk and milk products	mislabelling	the product was not made with PDO cheese from Bergamo as indicated on the label
Belgium	meat and meat products	products not fit for consumption	poultry meat with a counterfeit expiry date were sold
Italy	meat and meat products	origin masking	counterfeiting ham with PDO San Daniele

Table 1d An overview of food frauds in 2017 – 2019 in the order in which they were reported.

Country	Commodity	Food fraud	Details
United Kingdom	eggs	mislabelling	the sale of eggs at high prices whilst they were free range eggs that did not actually meet the criteria
Italy	milk and milk products	substitution	false mozzarella di bufala DOP and other type of cheese were sold to tourists
Spain	meat and meat products	products not fit for consumption	ham and other types of meat that were expired, were re-labelled and re-introduced into the market
Italy	food	substitution	substitution of organic products by conventionally produced products; lack of hygiene and traceability of the products
Italy	food	products not fit for consumption	rotten foods, in some cases after the expiry date was relabelled and intended to be offered for sale
Spain	meat and meat products	mislabelling	the hams in the packages were sold with a changed expiration date or were rotten
Italy	fish and fish products	products not fit for consumption	defrosted fish placed on the market from a fishing shop that did not meet the hygiene conditions laid down by law were seized
Portugal	meat and meat products	products not fit for consumption	found rotten meat stored under unsuitable conditions
Italy	fish and fish products	products not fit for consumption	part of the fish was supposed to be sold fresh, but in fact it was rotten
Spain	fish and fish products	smuggling	endangered Spanish eel species smuggled into Japan via China
Italy	fish and fish products	mislabelling	fish were found without traceability documents
Spain	fish and fish products	artificial enhancement	fish that was caught by boats not equipped with the appropriate freezers were treated with additives to mimic the appearance of fresh fish
Spain	fish and fish products	counterfeit	canned tuna were sold as fresh tuna
Italy	fish and fish products	products not fit for consumption	fish in a restaurant was not fit for human consumption
Italy	food	mislabelling	mislabeling and missing food traceability documents
United Kingdom	meat and meat products	substitution	meat products were sold and produced from unspecified meat (the species was not mentioned on the label)
Italy	food	products not fit for consumption	meat and fish unfit for human consumption were sold in a restaurant
Italy	meat and meat products	counterfeit	ham was not produced according to the mandatory compliance process to be labelled as "Crudo di Parma"
Italy	fish and fish products	products not fit for consumption	non-compliance with hygiene regulations for the storage and handling of fish in markets and restaurants
Italy	milk and milk products	counterfeit	cheese sold with the false labels of the Pecorino Crotonese PDO cheese
Ireland	meat and meat products	mislabelling	minced meat without proper labelling
Ireland	meat and meat products	substitution	meat from species not declared on the label. Lamb was most frequently replaced by meat from other spices and cow was the most commonly undeclared species
United Kingdom	meat and meat products	mislabelling	selling meat labelled as the "Best of British" when actually it was sourced from abroad.
Italy	fish and fish products	mislabelling	found 500 kg of untraceable fish
United Kingdom	meat and meat products	substitution	selling beef as lamb in restaurant

Table 1e An overview of food frauds in 2017 – 2019 in the order in which they were reported.

Country	Commodity	Food fraud	Details
Italy	fish and fish products	mislabelling	restaurants were indicted for selling frozen fish as fresh.
Spain	meat and meat products	substitution	restaurants in Madrid did not correspond to the species indicated on the menu
Italy	fish and fish products	mislabelling	lack of traceability information
Italy	fish and fish products	products not fit for consumption	non-respect of the expiry date and lack of adequate storage conditions
Italy	milk and milk products	substitution	mozzarella, sold in Spain and claimed to be produced using buffalo milk was made mostly with cow milk
Belgium	meat and meat products	mislabelling	meat sold in Belgium under the quality mark Belbeef lacks traceability
Italy	food	substitution	conventional food were labelled as "organic"; in some fields the company produced food respecting the rules of organic production, while on other fields food was produced with the use of pesticides, herbicides, etc.
Italy	milk and milk products	counterfeit	"Grana Padano" and "Parmiggiano" were sold in Canada making fraudulent use of the label "made in Italy".
Italy	milk and milk products	substitution	sale of false mozzarella di bufala DOP
Italy	milk and milk products	substitution	mixing cow and buffalo milk to produce the popular Italian cheese and sold it under the label "mozzarella di bufala".
Italy	meat and meat products	origin masking	sold meat labelled as Italian which rather was the meat of animals grown in other countries, mostly Spain and France
Italy	fish and fish products	artificial enhancement	a large amount of bleach was found in a food production plant
Italy	seafood	products not fit for consumption	octopus, sepia and squid with expiry dates in 2010 were withdrawn from the market
2019			
Malta	meat and meat products	origin masking	Imported live animals were slaughtered but labelled as originating from Malta
Poland	meat and meat products	products not fit for consumption	captured meat from sick cows killed in a Polish slaughterhouse which was not fit for human consumption
United Kingdom	fish and fish products	substitution	fish and chips restaurants sold protected spiny dogfish and some other protected types of shark, which commercialization is forbidden in Europe
Netherland	eggs	products not fit for consumption	eggs contaminated with fipronil
Netherland	eggs	mislabelling	according to the labels the eggs came from a farm that produced "free range" eggs but this information turned out to be false
Italy	eggs	mislabelling	missing traceability information of 4 000 g eggs
Spain	meat and meat products	origin masking	hams which were not designated as PDOs were referred to as PDO hams
Spain	fish and fish products	mislabelling	sale of canned tuna as fresh tuna
Italy	eggs	mislabelling	sale of food commodities fraudulently labeled as organic
Italy	fish and fish products	mislabelling	selling cheaper fish at a much more expensive price to restaurants
Italy	eggs	mislabelling	lacking traceability information

Table 1f An overview of food frauds in 2017 – 2019 in the order in which they were reported.

Italy	food	origin masking	food was labelled as Italian but it came from another country
Italy	food	products not fit for consumption	food that did not meet the required hygienic conditions was on offer
United Kingdom	milk and milk products	substitution	buffalo mozzarella sold in restaurants and supermarkets, was made wholly or partly from cow's milk
Italy	milk and milk products	counterfeit	cheese was labelled as a Protected Geographical Indication (PGI) product without fulfilling the requirements; counterfeited cheese was found
Italy	milk and milk products	products not fit for consumption	the cheese was found after a few months, stored under inappropriate conditions
France	meat and meat products	substitution	meat patties made in Poland contained fat, skin, starch and soya which are not allowed for this type of product
Italy	eggs	products not fit for consumption	the eggs had an extended expiration date in the pack-house
Italy	meat and meat products	mislabelling	hams do not fulfil the requirements to bear the PDO label
Italy	meat and meat products	substitution	hams did not comply with the requirements to bear the PDO labels
Italy	seafood	mislabelling	lacked appropriate information to trace the product
United Kingdom	meat and meat products	mislabelling	some species were declared on the label but in reality were not present in the product, for instance, ham without pork
Belgium	meat and meat products	substitution	meat conventionally produced, and originating from the Netherlands was labelled and sold in Belgium as organic meat
Spain	meat and meat products	products not fit for consumption	meat was contaminated with *Listeria*
Spain	meat and meat products	mislabelling	meat producer sold contaminated meat to a second company, which in turn sold it without indicating on the label the name of the producing company
France	meat and meat products	dilution	fraudulent increase of the weight of chicken meat with water
Spain	meat and meat products	origin masking	meat sold as lamb in Burgos is from other countries
Italy	eggs	mislabelling	organic eggs were from hens in cages
Italy	food	products not fit for consumption	found rotten fish not fit for human consumption
Italy	meat and meat products	counterfeit	butcher sold regular beef as Japanese Kobe beef
Portugal	meat and meat products	products not fit for consumption	meat not fit for human consumption was sold
Portugal	meat and meat products	mislabelling	products that lacked traceability information and did not fulfil administrative requirements
Portugal	meat and meat products	products not fit for consumption	meat was not stored at the right temperature
Portugal	meat and meat products	artificial enhancement	samples contained sulphite, a substance which addition to meat is forbidden
Italy	fish and fish products	mislabelling	fish did not fulfil the legal traceability requirements
Italy	food	mislabelling	some items had a PDO labelling although they did not fulfil the required criteria
France	meat and meat products	products not fit for consumption	rotten meat without traceability
Italy	fish and fish products	mislabelling	sale of food commodities fraudulently labeled as organic

Food or feed which is launched to the market shall be adequately labelled or identified to facilitate its traceability, through relevant documentation or information in accordance with the relevant requirements of more specific provisions.

By the **Regulation (EC) No 178/2002** it is the ability to trace and follow a food, feed, food-producing animal or substance intended to be, or expected to be incorporated into a food or feed, through all stages of production, processing, and distribution.

In samples of eggs, fipronil contamination was reported from several countries. Fipronil is an insecticide of the phenylpyrazoles class and an active ingredient of one of the popular ectoparasiticide veterinary products. Fipronil is also formulated as insect bait for roaches, ants, and termites; as a spray for pets. In humans, poisoning is mainly due to accidental ingestions or suicidal attempts. In agriculture, fipronil is widely used for soil treatment, seed coating, and crop protection **(Ramesh and Milatovic, 2014)**. **EU Regulation (EC) 396/2005** set up the maximum levels for fipronil (0.005 $mg.kg^{-1}$ in chicken eggs) in several raw materials and foods. As consumers pay extra for perceived benefits of free-range eggs, this market sector presents profitable opportunities for producers with expertise in managing hens with enhanced behavioral freedom **(Newberry, 2017)**. According to the labels, some of our samples of eggs came from a farm that produced "free-range" eggs but this information turned out to be false. Several countries reported dyeing low-quality tuna to sell it as fresh fish or case of sulphite addition to meat. Unprocessed foods belong to the food in which the presence of a food dye may not be permitted **(Regulation EC no. 1333/2008)**. Conventional meat and other foods were sold as organic in several cases. Demand for organic meat is partially driven by consumer perceptions that organic foods are more nutritious than non-organic foods **(Średnicka-Tober et al., 2016)**.

The increasing consumer demand for organic products caused the organic food market has expanded in all continents of the world. Organic foods represent a specific segment of the food market **(Kozelová, Vietoris, and Fikselová, 2013b)**.

By our results found at the market, we can agree with the statement of **Vaqué and Vidreras (2018)** that common types of food fraud include the substitution of an ingredient with a similar, cheaper ingredient, the inclusion of undeclared ingredients, adulteration of foods to improve some of their characteristics; non-declaration or false declaration of processes and false declaration of the origin or geographic region of production of a food item.

There were reported several problems regarding the PDO label. EU quality policy aims at protecting the names of specific products to promote their unique characteristics, linked to their geographical origin as well as traditional know-how. By the **JRC Food Fraud Monthly Report (2019)** the inspectors that grant the Prosciutto di Parma and San Daniele PDO labels have resigned the irregularities that have recently been affecting the certification body responsible for the mentioned PDOs. In May 2019, inspectors revealed that 2.5 million hams did not comply with the requirements to bear the PDO labels.

Hypothesis 1 did not assume a link in the country's impact on food fraud. Based on the one-way ANOVA test, this hypothesis was confirmed (p = 0.0067). Hypothesis 2 assumed the influence of the country on which commodities were adulterated. Based on the one-way ANOVA test (, this hypothesis was confirmed (p = 0.000001). Hypothesis 3 did not assume the link among the countries and the years in which the cases were reported. Based on the result of the one-way ANOVA test, this hypothesis was confirmed (p = 0.110). Hypothesis 4 assumed that there was a link between foods that were adulterated and the years that occurred. Based on the result of the one-way ANOVA test, this hypothesis was confirmed (p = 0.0042). Hypothesis 5 assumed that there was a link between the type of counterfeiting and the years that occurred. Based on the result of the one-way ANOVA test, this hypothesis was confirmed (p = 0.009).

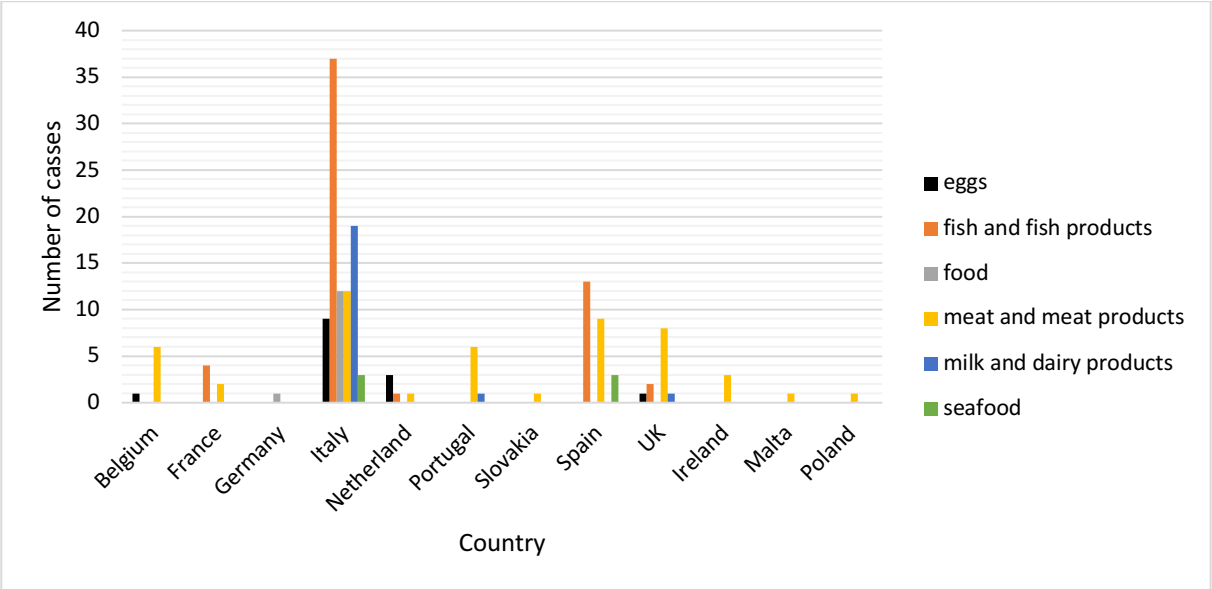

Figure 1 Country in Food Fraud Reports from 2017 to 2019 in Europe.

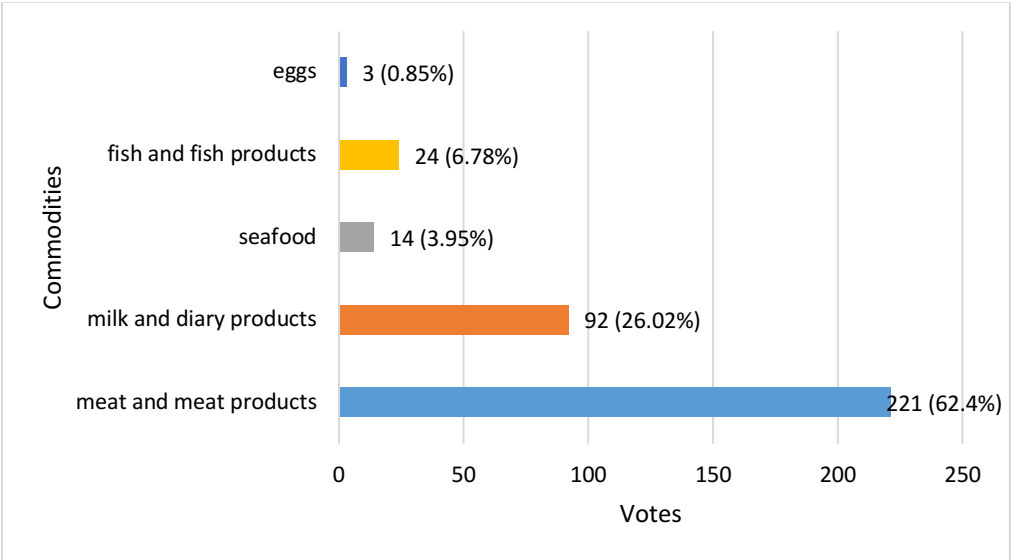

Figure 2 The answer to the question „which commodities are mostly adulterated?".

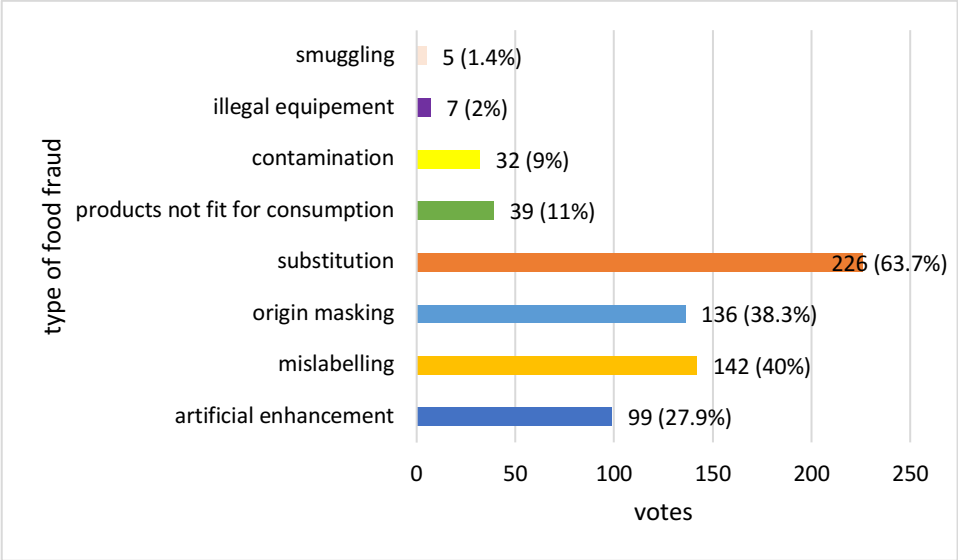

Figure 3 The answer to the question „which of the following causes of food fraud occur most often?".

Analyzes of secondary data from the questionnaire

Food scandals that happened in recent years have increased consumers' risk perceptions of foods and decreased their trust in food safety. A better understanding of consumer trust in food safety can improve the effectiveness of public policy and allows the development of the best practice in risk communication **(Kozelová et al., 2013a)**.

Among 354 respondents who participated in our questionnaire survey, 221 respondents (62.4%) replied to the first question concerning the commodity, that they believe to be the most adulterated is meat and meat products, which is partially in agreement with our results. Some respondents (26.02%) decided on milk and dairy products. Other commodities represented less than 10% (Figure 2).

The safety of milk has always been challenged due to the illegal use of preservatives and adulterants such as hydrogen peroxide, salicylic acid, benzoic acid, water, neutralizers, melamine, and so on **(Parminder and Gandhi, 2015)**.

At the question of which of the following causes of food fraud occur most often, respondents could select two options. 226 people (63.7%) decided for substitution, 142 people (40%) for mislabelling and 136 people (38.3%) for origin masking. Also, these results are partially in agreement with our results. Other types of adulteration received less than 100 votes (Figure 3). The question in which of these countries are food frauds reported mostly, they could also select two options. 310 people (87.6%) decided for Poland, 105 people (29.6%) voted for Slovakia and 43 people (12.1%) for Spain. Other countries received less than 10% (Figure 4). By the **RASFF-Annual report (2018)** there were 47 notifications on *Salmonella* in poultry products originating from Poland, most often (34 notifications) concerning *Salmonella* Enteritidis in fresh poultry. Two operators were identified as recurrent.

EU citizens have the right to be protected from fraudulent practices and to receive accurate information about the food they choose to purchase (**Vaqué and Vidreras, 2018).**

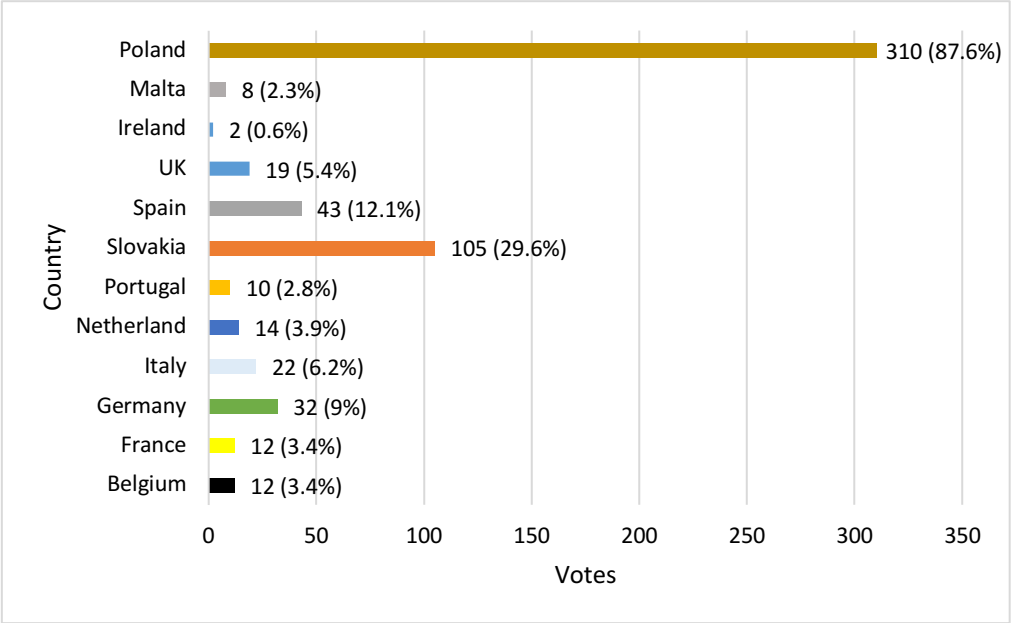

Figure 4 The answer to the question „in which of these countries are food frauds reported mostly?“

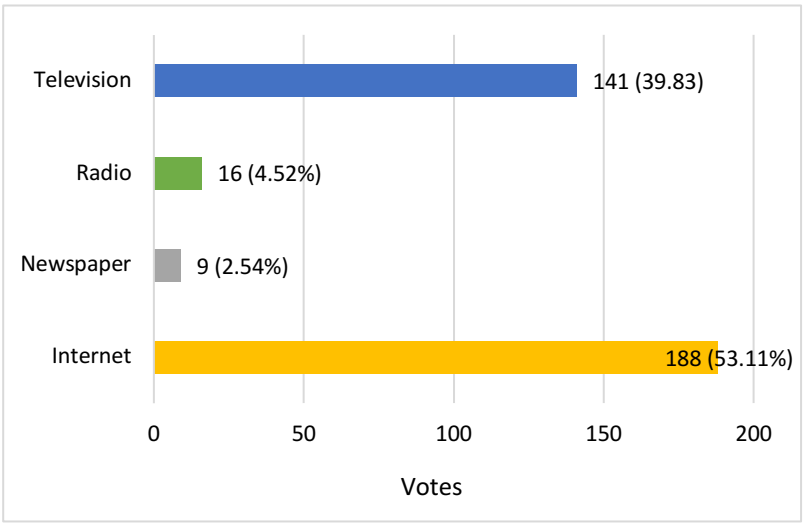

Figure 5 The answer to the question „from which media do you often receive information about food fraud“

So the last question was given about where your information is coming from 188 people (53.11%) select the Internet source and 141 (39.83%) the television source. Radio and newspaper as the source had the lowest number of votes (Figure 5).

CONCLUSION

The present work was focused on the current problems related to food fraud in the European Union countries. We have established hypotheses and confirmed their correctness. Of the total number of 163 cases during the period from 2017 to 2019 registered in KCFFQ, the most reported cases were in Italy and Spain. The most common commodities covered by these reports were fish and their products and meat and meat products. As the most common cause of food fraud was mislabelling. Based on confirmed hypotheses, we conclude that it is not statistically conclusive that the country has an influence on what type of fraud was performed but it has shown the link between the country and the food that has been adulterated. Also, there was no statistically confirmed correlation between countries and years when cases were reported, but a statistically significant correlation between years, commodities and the types of fraud that were reported. The results achieved in the evaluation of the responses from the individual questionnaires and the KCFFQ data indicate some level of information about food fraud topics. These results can be used as a basis for further investigation.

THE EFFECT OF ANTIOXIDANTS ON THE QUALITY OF SEMI-FINISHED MINCED RABBIT MEAT

Dodo Tavdidishvili, Tsira Khutsidze, Manana Pkhakadze, Aleko Kalandia, Maia Vanidze

ABSTRACT
Under the current adverse environmental conditions, enrichment of the human diet with essential nutrients, including antioxidants, which exhibit immunostimulatory and adaptogenic properties and protect the body against the negative effects of free radicals, is extremely relevant. Their use in food production, including that of semi-finished meat products, improves the quality of such products and extends their shelf life. It is of scientific and practical interest to enrich rabbit meat with the antioxidant-containing plant raw materials and to study their influence on the quality parameters of semi-finished products. In this work, modern, standard, commonly accepted methods of research were used to fulfill the stated objectives. Statistical processing of the results obtained and evaluation of the reliability of the data was carried out by statistical methods using IBM SPSS Statistics for Windows. This study demonstrates the expediency of using grape-seed powder, green tea extract, and amaranth/flax flour in semi-finished rabbit meat products. The optimum component composition and amount of multiple supplements to add to the semi-finished product were determined. The total phenolic and flavonoid content and antioxidant characteristics of the test samples were studied. The highest antioxidant potential was observed in samples with flax-containing multiple supplements. This paper demonstrates that microbiological indicators in all samples throughout the storage period, in line with hygienic requirements, were lower than those in semi-finished products containing multiple supplements as compared with a reference sample, while organoleptic indicators of quality were more stable. The content of toxic elements indicates the sanitary reliability of semi-finished products. Determination of the acid number and peroxide number values during storage revealed high resistance of semi-finished products containing multiple supplements to the accumulation of free fatty acids and peroxide compounds. The obtained data indicate the effectiveness of using developed semi-finished products as antioxidant products in the diet of the population.

Keywords: minced rabbit meat; plant raw materials; antioxidant properties; oxidation processes; quality indicators

INTRODUCTION
The maintenance of population health and quality of life is a major task of the world today. Scientific evidence has established that 10% of human health depends on the health system, 20% on hereditary factors, 20% on environmental factors, and 50% on human lifestyle and nutrition. Under the current adverse environmental conditions, enrichment of the human diet with essential nutrients, whose deficiency in the body leads to decreased immunity and metabolic disorders, as well as cardiovascular, oncological, and other diseases, is extremely relevant. In this regard, along with proteins, vitamins, and minerals, antioxidants, which have a wide range of biological effects, also deserve attention: they protect the body against the negative effects of free radicals and have immunostimulant, cardioprotective, anti-tumor and adaptogenic properties. **(Lapin et al., 2007; Gichev and Gichev, 2012; Packer, 2001; Plavinsky and Plavinskaia, 2013; Tarakhovsky et al., 2013)**. It is believed that despite their high effectiveness, some synthetic antioxidants have adverse effects on human health; however, antioxidants of natural origin, including polyphenolic compounds found in plant raw materials, are minimally toxic and do not cause adverse reactions **(Carocho and Ferreira, 2013; Kumar et al., 2013; de Oliveira et al., 2018; Shahidi and Ho, 2005; Shebis et al., 2013)**. The use of plant supplements that contain functionally different antioxidants is very important in the production of healthy foods, including semi-finished meat products. Preventing the accumulation of harmful oxidative products, they reduce losses resulting from oxidative spoilage and extend their shelf life **(Denisovich, 2006; Maqsood et al., 2013; Nasonova, 2008; Nikitina et al., 2011; Stratil et al., 2006; Tomović et al., 2017)**. In the food industry, antioxidant activities are the result of interactions between air and oxygen; they are also used to increase the microbiological stability of foods and improve their quality indicators **(Banerjee et al., 2017; Kuzmina et al., 2017; Mandro et al., 2009; Poliakov et al., 2017)**.

Among products containing natural antioxidants that can be used as an antioxidant supplement in semi-finished minced meat products, of particular importance are grape seed and green tea extract, which are characterized by a high polyphenol content **(Caleja et al., 2017; Higdon and Frei, 2003; Perumalla and Hettiarachchy, 2011; Shebis et al., 2013; Yashin et al., 2009)**. Together with natural antioxidants, we believe it is appropriate to use flax and amaranth as a functional supplement, as a source of plant protein enriching and additional biologically active ingredients **(Bernacchia et al., 2014; Kalač and Moudrý, 2000; Kidyaev et al., 2017; Oomah, 2001; Pastor and Acanski, 2018; Pękal and Pyrzynska, 2014; Perumalla et al., 2011)**. Therefore, it is of scientific and practical interest to enrich rabbit meat with the above-mentioned supplements and study their influence on the quality parameters of semi-finished products.

The work aims to develop technology to produce semi-finished rabbit meat products with antioxidant properties using a multiple plant supplement.

Scientific hypothesis

Scientific hypothesis

The addition of multiple supplements to semi-finished rabbit meat products will increase their resistance to the accumulation of oxidative products and improve quality indicators.

MATERIAL AND METHODOLOGY

The studies were carried out in the laboratories of the Department of Food of Akaki Tsereteli State University and the Department of chemical analysis and food safety of Shota Rustaveli State University. The study included natural semi-finished minced rabbit meat products made according to traditional recipes and model semi-finished and finished rabbit meat products containing plant supplements made according to recipes and technologies that we developed.

Test samples: 1 – Onion-containing semi-finished product; 2 – Fried onion-containing semi-finished product; 3 – Steamed onion-containing semi-finished product; 4 – Semi-finished product containing grape-seed and amaranth flour with multiple supplements; 5 – Fried semi-finished product containing grape-seed and amaranth flour with multiple supplements; 6 – A steamed semi-finished product containing grape-seed and amaranth flour with multiple supplements; 7– Semi-finished product containing grape-seed and flax flour with multiple supplements;

8 – Fried semi-finished product containing grape-seed and flax flour with aultiple supplements; 9 – A steamed semi-finished product containing grape-seed and flax flour with aultiple supplements.

Total phenolic compounds were defined using Folin-Ciocalteu spectral methods **(Stratil et al., 2006)**. The total flavonoid content (TFC) was determined by the aluminium chloride colorimetric method as previously described **(Pękal and Pyrzynska, 2014)**. Antioxidant activity was determined by using the DPPH (2,2-Diphenyl-1-pic-rylhydrazil) method **(Okawa et al., 2001)**.

During microbiological analysis, the quantities of mesophilic aerobic and facultative anaerobic microorganisms in rabbit meat were determined according to the state standard "Food products. Methods for determining the quantities of mesophilic aerobic and facultative anaerobic microorganisms" – State Standard **GOST 10444.15-94**. The number of intestinal bacilli was determined according to the state standard "Food products. Methods for the detection and determination of the number of bacteria of the *Escherichia coli* group (coliform bacteria)" – State Standard **GOST 30518-97/GOST P 50474-93**. *Salmonella* was determined according to state standard "Food products. Methods for the detection of bacteria of the genus Salmonella" – State Standard **GOST 30519-97**. The heavy metal content was determined on a SHIMADZU AA-6200 atomic adsorption spectrophotometer, the lead content by State Standard **GOST 26932-86**, the cadmium content by State Standard **GOST 26933-86**, the mercury content by State Standard **GOST 26927-86** and the arsenic content by State Standard **GOST 26930-86**.

The peroxide number value was determined according to State Standard **GOST 8285-91**. The method is based on the interaction of oxidative products of animal fats (peroxides and hydro-peroxides) with iodic potassium in a solution of acetic acid and isooctane or chloroform, with subsequent quantitative determination of iodine released by a solution of sodium thiosulfate using the titrimetric method.

The fatty acid value was determined according to the standard **GOST 13496.18-85**. The method is based on the neutralization of free fatty acids extracted from the product by a mixture of chloroform and ethyl alcohol with a 0.1 $mol.L^{-1}$ solution of potassium hydroxide.

Organoleptic indices were determined on a scale of 1 to 9 according to the following characteristics: appearance, colour, smell, taste, consistency, and juiciness.

Statistical analysis

To analyse the test parameters (total phenolic and total flavonoid content in the test samples, a correlation between total phenols and antioxidant activity) of natural semi-finished minced rabbit meat products, a statistical analysis was conducted of the obtained data, and the reliability of the obtained data was evaluated by statistical methods using the Windows IBM SPSS Statistics software program (version 20.0). To describe the continuous variables, we used statistical functions of the mean and standard deviation. Graphical interpretation of the results was carried out by using Microsoft Excel. The results of statistical analysis are presented in Tables 1 – 5 and Figures 1 – 4, and each value is an average of at least 10 determinations. Then, we computed the error of each measurement and calculated the squared errors to compute the absolute measurement error. We selected the value of reliability $p = 0.95$. Based on the number of measurements and the value of reliability, Student's coefficient equals $t = 3.77$ (Figure 2 and Figure 3) **(Romanov and Komarov, 2002)**.

RESULTS AND DISCUSSION

Pursuant to the stated goal, in the first stage of this work, we selected the main recipe components for the product. To prepare the reference samples, we added rabbit fat and spices to minced rabbit meat. The main ingredients in the reference sample recipes were minced rabbit meat, rabbit fat, onion, grape-seed powder, green tea extract, and amaranth/flax flour as multiple supplements. The multiple supplements were produced from grape-seed powder and hydrated amaranth/flax flour. Hydration was carried out in green tea extract - Hydromodulus 1:3 (1part of flour on 3 parts of extract). The multiple supplements were produced from grape-seed powder and hydrated amaranth/flax flour. Hydration was carried out in green tea extract - Hydromodulus 1:3 (1 part of flour on 3 parts of extract). The ratio of ingredients in multiple supplements was determined based on the optimum organoleptic parameters of semi-finished products under study.

The component and quantitative contents of multiple supplements are shown in Table 1. The amount of multiple supplements added to 100 g of semi-finished product was 30.2 g in the case of amaranth and 25.8 g in the case of flax flour.

In all samples except the one that did not contain a plant-based supplement, we determined the total phenolic content, flavonoid content, and antioxidant characteristics. To determine changes in these parameters as a result of heat treatment, meat was steamed. For this purpose, we took 9 test samples. The results obtained are illustrated in Figures 1 – 4. As can be seen from the diagrams, according to the total phenolic (Figure 1) and flavonoid (Figure 2) contents, samples with the flax supplements had the best characteristics. Since the contents of grape-seed and green tea extract in all test samples were almost identical, this difference can be explained by the chemical composition of flax, in particular, by the content of phenolic compounds and flavonoids.

Table 1 Components and quantitative composition of a multiple supplement.

No	Name of component	Content, %
1	Grape seed	0.7
2	Amaranth flour/flax flour	24.8
3	Green tea extract	74.5

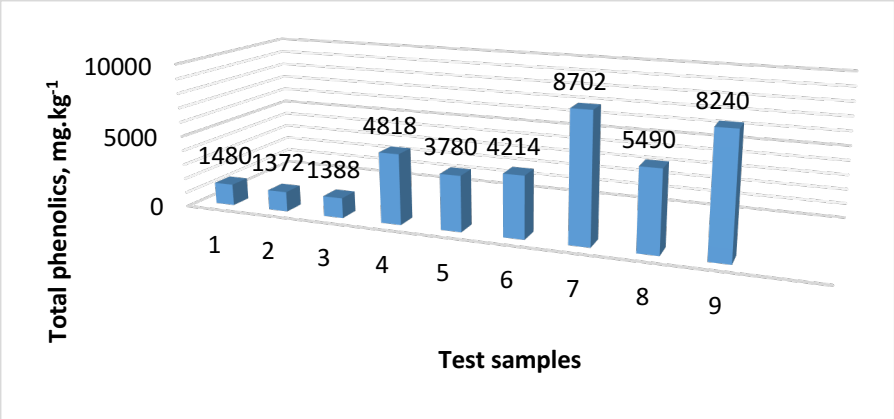

Figure 1 Total phenolic content in the test samples.

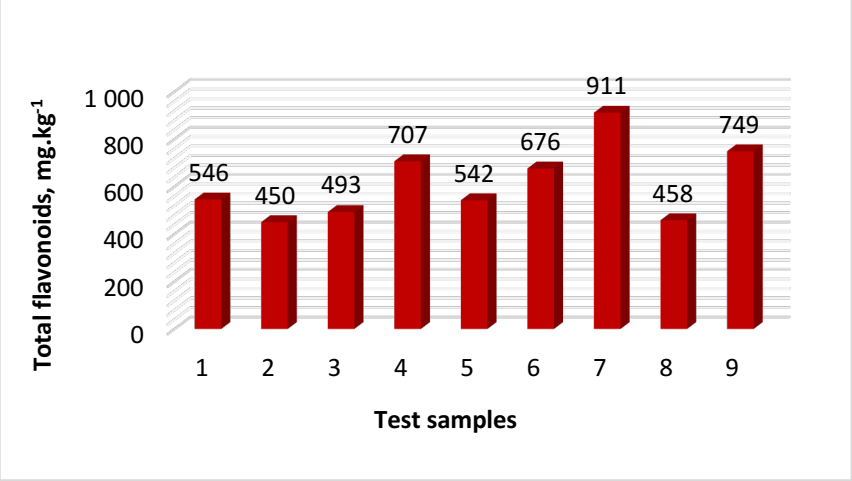

Figure 2 Total flavonoid content in the test samples.

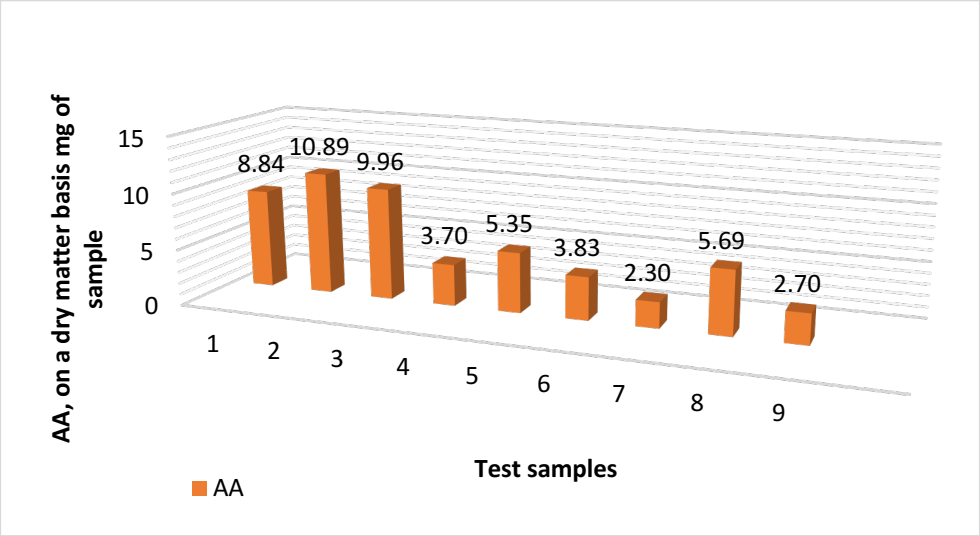

Figure 3 Antioxidant activity on a dry matter basis mg of sample.

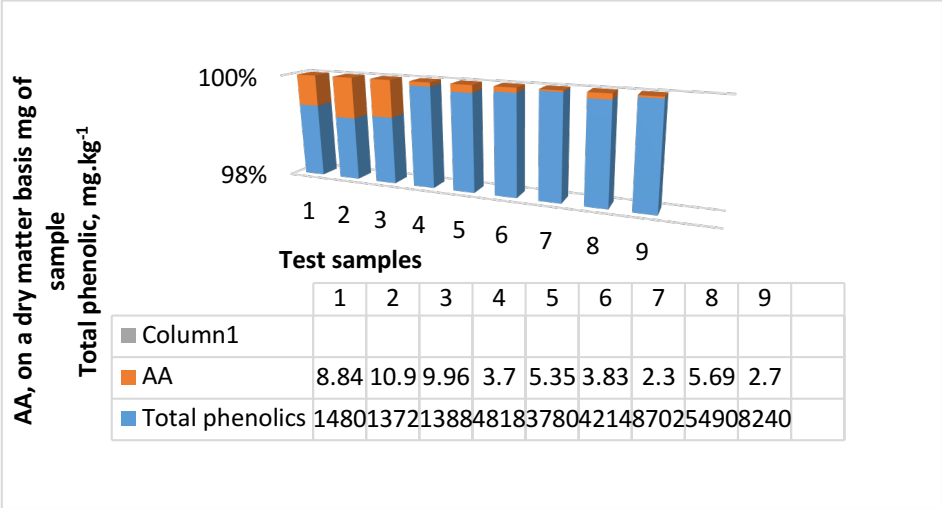

Figure 4 The correlation between total phenols and antioxidant aactivity.

The component and quantitative contents of multiple supplements are shown in Table 1. The amount of multiple supplements added to 100 g of semi-finished product was 30.2 g in the case of amaranth and 25.8 g in the case of flax flour. In all samples except the one that did not contain a plant-based supplement, we determined the total phenolic content, flavonoid content, and antioxidant characteristics. To determine changes in these parameters as a result of heat treatment, meat was steamed. For this purpose, we took 9 test samples. The results obtained are illustrated in Figures 1 – 4. As can be seen from the diagrams, according to the total phenolic (Figure 1) and flavonoid (Figure 2) contents, samples with the flax supplements had the best characteristics. Since the contents of grape-seed and green tea extract in all test samples were almost identical, this difference can be explained by the chemical composition of flax, in particular, by the content of phenolic compounds and flavonoids.

The total phenolic and flavonoid (Figure 2) contents were highest in semi-finished products (samples 1, 4 and 7), and after heat treatment, the value of phenolic compounds decreased by 5.3% in a steamed flax-containing sample (9) and by 36.9% in a fried flax-containing sample (8), and accordingly, the total flavonoid content decreased by 17.8% in the sample (9) and by 49.7% in the sample (8).

The phenolic compound content was 12.5% lower in the steamed amaranth-containing sample (6) and 21.5% lower in the fried sample (5). The total flavonoid content decreased by 4.4% and 23.3%, respectively. In the onion-containing samples, after their heat treatment, the phenolic compound content decreased by 7.3% in the fried sample (2) and by 6.2% in the steamed sample (3), while the flavonoid content decreased by 17.6% and 9.7%, respectively. The higher content of polyphenols in the steamed products was due to the use of the efficient mode of thermal treatment.

Figure 3 illustrates the antioxidant characteristics of a test sample. It shows that the highest antioxidant potential was observed in the sample containing the flax supplement. This would suggest that samples containing the flax supplement will be oxidized more slowly than other samples.

The diagram illustrating the correlation between total phenols and antioxidant activity (Figure 4) shows that the higher the total phenol phenolic content in samples, the higher their antioxidant activity (AA).

Accordingly, the semi-finished rabbit meat products exhibit antioxidant properties due to the presence of a multiple supplement additive in the recipe.

When storing semi-finished meat products, it is essential to avoid bacteriological contamination. Thus, at the next stage of this work, we studied changes in microbiological indicators of minced semi-finished products of the developed rabbit meat under low temperature (-18 °C) storage conditions: the mesophilic-aerobic and facultative anaerobic count, colon bacillus group (Coliforms) bacteria, pathogenic microorganisms, including salmonellas (Table 2).

The data obtained indicate that throughout the storage period, the mesophilic-aerobic and facultative anaerobic count, in all samples, being in compliance with the hygienic requirements of microbiological safety, was less in semi-finished products containing multiple supplements than in the reference samples. This allowed us to conclude that the multiple supplements had an inhibitory effect on the development of microorganisms.

No colon *Bacillus* group bacteria or pathogenic microorganisms, including salmonellas, were found in samples, which also indicates the safety of semi-finished products.

Under today's difficult environmental conditions, food safety issues are of high relevance. Therefore, we identified the content of the toxic substances in the meat of rabbit breeds under study (Table 3). An analysis of Table 3 shows that the contents of lead, cadmium, arsenic, and mercury in different rabbit breeds did not exceed acceptable standards, which indicates their safety, as well as their sanitary and hygienic reliability.

It is known that lipid oxidation processes occur in meat products during storage, resulting in the accumulation of superoxide compounds. Therefore, we studied the dynamics of changes in the peroxide number reflecting the intensity of oxidative processes during storage at a low temperature (-18 °C). In parallel, we determined the acid-number value, which indicates the formation of free fatty acids in the products as a result of the hydrolytic spoilage of fats. As a reference sample, we took natural minced rabbit meat semi-finished products. The results are shown in Tables 4 and 5.

The analysis of these tables showed that the storage of rabbit meat semi-finished products was accompanied by an increase in acid-number and peroxide values. However, these processes were more intense in a reference sample than in the samples containing onions and multiple supplements. In particular, after 48 days of storage, the acid- number value was 15.4% lower than in a sample containing the onion supplement, 60.1% lower in a sample containing multiple supplements with amaranth, and 64.3% lower in the sample with flax-containing multiple supplements. After 90 days of storage, the acid- number values of samples with aultiple supplements containing onion, amaranth and flax flours were 17.6%, 57.8% and 61.6% lower, respectively, and remained within permitted limits.

The difference between the acid-number values in the amaranth- and flax-containing samples, in our opinion, was due to the fact that flax flour contains more phenolic compounds than amaranth **(Bernacchia et al., 2014; Kalač and Moudrý, 2000; Kidyaev et al., 2017; Oomah, 2001; Pastor and Acanski, 2018; Pękal and Pyrzynska, 2014)**.

The dynamics of change in peroxide number values during the storage of semifinished products were approximately similar. Particularly, after 48 days of storage, the mean peroxide number values as compared with reference samples were 41.8%, 61.6%, and 64.2% lower in samples with the onion, amaranth and flax supplements, while after 90 days of storage, these values were 59.7%, 68.4% and 70.7% lower, respectively.

The higher stability of the test samples as compared with the reference samples to the accumulation of free fatty acids and peroxide compounds is explained by the presence of plant supplements with antioxidant activity in their composition that slows the rate of these processes.

The results obtained confirm similar data available in the literature. For example, the addition of grape-seed powder, green tea extract **(Perumalla et al., 2011; Reshetnik et al., 2014)**, dihydroquercetin **(Kuzmina et al., 2017; Nasonova, 2008)**, pignoli nut extract nut **(Litvinova, 2012)** and rosemary **(Sharigina, 2011)** to semi-finished meat products prevents the accumulation of oxidative products and protects semi-finished products against oxidative spoilage. According to **Sharigina (2011)**, this is caused by the impact of the supplement's active components (phenolic diterpenes, including carnosic acid, essential oils, bioflavanoids, catechins) on chain reactions.

We studied organoleptic indicators of the quality of semi-finished and finished products. After 60 days of storage of the semi-finished products, the reference sample had a more pronounced foreign flavour as compared with samples containing multiple supplements, which perhaps was due to faster accumulation of oxidative products in the reference sample. As to colour stability, after 60 days of storage, it was more stable in samples containing multiple supplements, which was due to the presence of ingredients with antioxidant properties.

The finished product had better consistency and juiciness than the reference sample, which is explained by the high water-retention and water-binding ability of amaranth and flax flour **(Carocho, Morales and Ferreira, 2018; Denisovich, 2006; Higdon and Frei, 2003; Tarakhovsky et al., 2013; Tavdidishvili et al., 2018; Vaitanis and Khodyreva, 2017)**.

Based on the above, samples containing multiple supplements, both semi-finished and finished products had better organoleptic indicators of quality during storage.

Thus, a multiple plant supplement that protects products against microbiological and oxidative spoilage and improves their quality imparts the antioxidant properties to the developed semi-finished products, demonstrating the effectiveness of their use in the production of healthy semi-finished meat products.

CONCLUSION

1. To impart antioxidant properties to minced semi-finished rabbit meat products, we have proven the effectiveness of using grape-seed powder, green tea extract, and amaranth/flax flour as multiple supplements in the recipe.
2. We have determined the optimum component composition of multiple supplements to added to semi-finished rabbit meat products: 0.7% grape-seed powder, 24.8% amaranth flour/flax flour, and 74.5% green tea extract. The amount of multiple supplements to be added to 100 g of semi-finished product is 30.2 in the case of amaranth flour and 25.8 g in the case of flax flour.
3. In the test samples, we studied the total phenolic and flavonoid content. It has been established that the highest antioxidant potential was observed in samples with flax-containing multiple supplements.
4. Microbiological indicators of semi-finished products with multiple supplements throughout storage at low temperature were in line with the hygienic safety requirements, and organoleptic indicators of quality were more stable as compared with a reference sample. The content of toxic elements indicates the sanitary reliability of semi-finished products.
5. The higher stability of semi-finished rabbit meat products with a control sample to the accumulation of free fatty acids and peroxide compounds has been established.

THE USE OF BIOFORTIFICATION FOR PRODUCTION OF SELENIUM ENRICHED GARDEN PEA

Silvia Jakabová, Jozef Čurlej, Martina Fikselová, Luboš Harangozo, Dagmar Kozelová, Ondrej Hegedűs, Alžbeta Hegedűsová

ABSTRACT

Biofortification of crops with selenium is one of the possible manners on how to increase selenium intake by humans. The effect of selenium fertilization in relation to selenium enrichment of pea and following the phytotoxicity symptoms in garden pea plants was studied. Pot experiments were established with a control variant without selenium addition and four variants where selenium was applied as sodium selenate into the soil in four different concentrations (1 – 6 mg Se.kg^{-1}) before seeding. Garden pea was grown in pots for 60 days and then plant material was dried and submitted to analysis. The total content of selenium was determined by the ZET-AAS method in the roots, above-ground parts of the plant (stems, leaves, extracted pods), and in seeds of a pea. Dean-Dixon´s test and paired t-test (α = 0.05) were used for statistical evaluation of the results. Transfer factors were calculated as a ratio between selenium content (mg.kg^{-1}) in individual plant material and soil. Transfer indexes were calculated as a ratio between selenium content (mg.kg^{-1}) in seeds and roots. The results showed that with the increasing addition of the Se to the soil, its contents in all parts of the plant proportionally increased. The content of the Se increased in the roots 43 to 173-fold, in the above-ground parts 79 to 372-fold, and in the seeds Se was accumulated 130 to 415 times more compared to control. Transfer factors and transport indexes were expressed. Transfer factors for pea varied from 11.05 to 19.25 in the case of Se transfer to the whole pea biomass. In the case of the Se transfer from soil to pea seeds, the highest transfer showed variant with addition 1 mg Se.kg^{-1} and the transfer factor gradually decreased with increasing addition of Se. Based on the amount of biomass produced, the experiments statistically confirmed the phytotoxicity of higher doses (4 and 6 mg Se.kg^{-1}) of selenium to plants. The highest transport index values are shown variants with the Se addition 1 and 2 mg Se.kg^{-1} (2.03 and 1.77, respectively). In these variants, Se was used the most efficiently. Our results showed that the best biofortification results were obtained in experimental variants with the lower selenium additions (1 and 2 mg Se.kg^{-1}).

Keywords: biofortification; selenium; garden pea

INTRODUCTION

Selenium (Se) is an essential micronutrient, which is involved in selenoaminoacids and selenoproteins. It has been proved to have multiple roles in the growth and functioning of living cells and has many crucial biological functions in animals and humans **(Birringer, Pilawa and Flohé, 2002; Tapiero, Townsend and Tew, 2003)**. As a cofactor of the enzyme glutathione peroxidase, and a catalyser of the reduction of peroxides, plays Se role in antioxidant defence. However Se is biologically active at low concentrations for normal growth and development, and at moderate concentrations for homeostatic function, at high concentrations, Se can cause toxicity **(Puccinelli, Malorgio and Pezzarossa, 2017)**. The proposed Recommended Dietary Allowance (RDA) of 55 µg Se day^{-1} for adults and a tolerable upper intake of 400 µg Se day^{-1} has been set by The Food and Nutrition Board of the Institute of Medicine (USA) **(Krinsky et al., 2000)**.

Central Europe has been identified as a region with suboptimal concentrations of selenium in agricultural soils that reflects in low selenium levels in the agricultural products coming from the area **(Sager, 2006)**.
