In the past, great efforts have been focused only on increasing crop yields, but enhancing the concentrations of mineral micronutrients including selenium has become an urgent task. Biofortification of trace elements can be achieved by their application within the agronomic process such as soil or foliar fertilization or crop breeding **(El-Ramady et al., 2014)**. Agronomic biofortification with Se could be a powerful tool to remedy Se deficiency as it may increase the Se concentration in the plant sources use in food production **(Poblaciones, Rodrigo and Santamaría et al., 2015)**. Use of common fertilizers with selenium (Se) for crop production is considered as an effective way to produce selenium-rich food and feed.

Legumes and cereals present the basis of the diet of billions of people. Legumes are able to accumulate

micronutrients that create the potential to be used in Se biofortification programs **(Thavarajah, Ruszkowski and Vandenberg, 2008; Thavarajah, Warkentin and Vandenberg, 2010)**. **Poblaciones, Rodrigo and Santamaria (2013)** confirmed that the pea has a strong ability to uptake and accumulate Se; therefore, it could be considered as a very strong candidate for inclusion in biofortification programs aiming to increase Se in the food chain. The value of green pea seeds and forages as an alternative protein source can be improved by using agronomic biofortification **(Garousi et al., 2017)**. Biological changes of garden pea (*Pisum sativum* L.) in dependence with the application of inorganic form of Se (and sodium selenate) at different concentrations have been studied. As a plant material was garden pea (*Pisum sativum* L.) that has been recognized as an important source of vitamins C, E, and a group of B vitamins including folic acid derivatives, so-called folates and mineral substances (Fe, K, P, Mn, Mg, Ca). Peas is also rich for soluble and insoluble fiber, vegetable protein and is a source of the macro elements **(Chrenková et al., 2003)**. It has highly valuable in proteins that are similar to those of animal origin. Also, the biological value of the pea protein is higher than that of the cereals. Both pea seeds and forages are rich in protein including lysine and other essential amino acids **(Garousi et al., 2017)**.

Our purpose was to investigate the most efficient selenium additions into the soil to achieve enhancement of Se levels in pea plants as well as identification of potential phytotoxic effects on the plants caused by different levels of inorganic selenium applied.

Scientific hypothesis

Increasing selenium additions in soil reflect in increasing selenium content in pea plants. Higher selenium additions have a potential phytotoxic effect on pea plants.

MATERIAL AND METHODOLOGY

Pot experiments with garden pea were carried out on soil biofortification by sodium selenate. As an experimental material was selected the garden pea (*Pisum sativum* L.) – the Oskar variety (Semo, The Czech Republic). This variety matures relatively early and is suitable for direct consumption and industrial processing, as well. In Slovakia, it is the variety produced intensively in agricultural conditions.

Pot experiments in the phytochamber were based on five variants and eight repetitions. Sodium selenate was applied to the soil substrate 5 days before the planting of pea seeds, in quantities 0, 1, 2, 4, and 6 mg $Se.kg^{-1}$ soil. On the fifth day, we planted 25 seeds of the pea in each container and placed them in the phytochamber with controlled temperature and light regimen. In the stage of technological maturity (60 days after the inception of the experiment) were the plants harvested and the plant material was separated into the total above-ground part, seeds and roots. A soil sample from each pot was taken for analysis and the separated plant material was weighed for each variant for the conversion of the Se content to the total biomass of peas.

The content of the Se has been determined in the roots, above-ground part of the plant (stems, leaves, extracted pods) and grain of peas. Dried soil and plant samples were wet decomposed in the mixture of nitric acid and hydrogen peroxide and after dilution measured according to the previously optimized method described by **Hegedűs et al. (2008)**. The determination of the total selenium was done by atomic absorption spectrometry with Zeeman background correction (ZET-AAS). The apparatus used for analysis was AA240Z Varian (Mulgrave Virginia, Australia), selenium hollow cathode lamp was used for the measurement, and the wavelength was set at 196 nm.

Statistical analysis

Dean-Dixon´s test and paired *t*-test ($p < 0.05$, n = 8) were used for statistical evaluation of the results by a Tanagra 2.0 software.

RESULTS AND DISCUSSION

Pot experiments in the phytochamber were realized to monitor the transfer of Se to the pea plant in model conditions. The results showed that with increasing addition of the Se to the soil, its contents in all parts of the plant proportionally increased (Table 1). Variants with an addition of 1 mg $Se.kg^{-1}$ and 2 mg $Se.kg^{-1}$, showed that the content of the Se was highest in grain, variants with 4 mg $Se.kg^{-1}$ and 6 mg Se.kg kg^{-1} had the highest content of the Se at the root. This fact can be probably linked to the slowdown of plant development due to the phytotoxicity of Se.

Further noted differences between the growth of the individual variants were in the total weight of the plant material where variants with 4 mg $Se.kg^{-1}$ and 6 mg $Se.kg^{-1}$ quantity of plant material was compared to the control 4.5 and 5.7 times lower. Also, the plants of the variants mentioned had at the time of harvesting the less developed seeds compared to the control and variants with the addition of 1 mg $Se.kg^{-1}$ and 2 mg $Se.kg^{-1}$. The content of the Se increased in all parts of the pea plant in variants I to IV, namely at the root of 43 to 173-fold, in the above-ground parts of 79 to 372-fold and in the grain Se was accumulated 130 to 415 times more compared to control. The analysis of the pea showed that selenium fertilization of soil with different selenium additions in the sodium selenate form resulted in a proportional increase of the total selenium content in all parts of the pea.

The statistical evaluation compared the means of the Se content within the different variants in the roots and in the grains. A statistically significant difference ($p < 0.05$) was not found only in the roots between variant I and II and between variants III and IV. For Variant IV, the roots showed symptoms of phytotoxicity and the roots were not able to uptake higher quantities of Se. The statistical evaluation of the Se content in a grain showed a significant difference ($p < 0.05$) between all the variants. The positive correlation between the transfer of Se content from the Se-fortified soil to the seeds of the garden pea reflects the graph of polynomic dependency in Figure 1.

We have found a tight positive correlation which is confirmed with a high coefficient of correlation (R = 0.9969) which was calculated from the coefficient of determination (R^2 = 0.9939) from the dependence of Se transfer from soil enriched with sodium selenate to garden pea seeds. With regard to doses applied, there was found

also a highly tight relationship between the Se content in other plant parts and the Se applied.

The positive effect of sodium selenate fertilization on enhancement of selenium content in peas confirmed also authors **Poblaciones, Rodrigo and Santamaria (2013), Poblaciones, Rodrigo and Santamaria (2015), Garousi et al. (2017), Hegedűsová et al. (2015), Smrkolj et al (2006)** and **Hegedűs, Hegedűsová and Šimková (2007)**.

Our experiments in phytochamber pointed at several times the higher accumulation of selenium in the conditions of regulated light regime compared to the experiments in greenhouse or field conditions. **Ros et al. (2016)** explored available results from selenium fertilization experiments in different conditions and across all observations, the strongest accumulation was achieved in the experiments in growth chambers, mainly in solutions. Probably this positive effect could be explained by even larger volatilization and transfer between the high Se-treatments to control and low Se-treatments during the growth.

Pot experiments with peas were realized with the same variants of the Se addition in outdoor conditions with normal light conditions, so the impact of UV-B should also be taken into account from the phytotoxicity point of view when comparing the results of experiments in the phytochamber and in the outer environment. UV-B radiation in normal light conditions for the accumulation of Se and the signs of phytotoxicity of the Se on the pea.

The Se phytotoxicity symptoms include the amount of biomass produced. The experiments carried out confirmed statistically the phytotoxicity of higher selenium doses (4 and 6 mg $Se.kg^{-1}$) to plants, based on the weight of the biomass produced is given in Table 2.

From the evaluation of the biomass weights, it can be assumed that the first signs of phytotoxicity begin to emerge after the application of 2 mg $Se.kg^{-1}$. The symptom was later maturation of the seeds compared to the control or variant I. The significant braking effect on the formation of biomass and seeds had Se additions 4 and 6 mg $Se.kg^{-1}$. The limit concentration with the phytotoxic effect on garden pea will probably be a selenium addition of 3 $mg.kg^{-1}$, which also confirmed the results of the work of **Vargová et al. (2009).**

In Figure 2, the phytotoxic effect of the Se addition in variants III and IV (4 and 6 mg $Se.kg^{-1}$) can be clearly observed. It was visible from the first days of plant germination and persisted throughout growing and ripening until the plants were harvested.

Table 1 Selenium content in pea and soil substrate - results of sodium selenate fertilization in the phytochamber.

Variant	**Plant part**	**Dry matter**	**Se content in dry matter**	**Total Se content in the whole phytomass**	**Se content in soil after experiment**

seed	5.93 ±2.07	4.95 ±2.02	3.45 ±1.30*	1.48 ±0.26*	0.17±0.06*

Note: *statistically significant difference (comparison with the control variant; $p < 0.05$, $t_{krit} = 2.365$). Experimental variants: K = 0; I = 1; II = 2; III = 4; IV = 6 mg $Se.kg^{-1}$ substrate.

The selenium supplement in these variants caused by braking growth, later development of flowers, and delayed seed formation.

The flowering in variant III occurred approximately 4 days and in variant IV by 7 days later compared to the control variant K. The results indicated that the phytotoxicity of the salt applied was not observed in the germination but later at the stage of growth, probably when the young plant starts to behave autotrophic and received dissolved ions of selenate from the soil solution. The Se concentration at which the phytotoxicity begins to occur is different for each species of cultural plant. Determination of the concentration limit of Se phytotoxicity is dependent on the soil enrichment technology. In recent years, increased attention has been paid to the protective role of Se in the plant against the stress caused by the higher intensity of UV radiation. **Hartikainen and Xue (1999), Germ, Kreft and Osvald (2005)** and **Smrkolj et al. (2005)** described that appropriate levels of Se in plants help to protect against oxidative stress caused by increasing UV-B radiation. The results confirm that in plants under normal light conditions, the appropriate addition of selenium helps to produce a larger crop.

The activity of the antioxidant enzymes superoxide dismutase, guaiacol peroxidase, and glutathione reductase in cucumber leaves was studied by **Jain, Kataria and Guruprasad (2004).** They found that the activity of antioxidant enzymes increased in cucumber leaves as a

III	4	57.20	14.30	12.19	0.98
IV	6	83.53	13.92	9.30	0.50

Note: TF_{SP} – transfer factor soil – plant, TF_{SG} – transfer factor soil – seeds, TI_{RG} – transport index root – seed.

response to the increasing intensity of UV-B radiation. Free radicals generated by UV-B radiation are likely to be associated with the induction of a defensive antioxidant system. The activity of UV-B induced enzymes is altered by the external application of antioxidants, which are also capable of scavenging free radicals and relieving plant stress due to UV-B radiation.

These facts lead to an explanation of the differences observed between the light regime during growth in the phytochamber (lower intensity of UV radiation) and normal outdoor light conditions. Increased cumulation of Se in peas in all variants compared to those grown under normal light conditions is evidence of this.

Transfer factor and transport index

The transfer factor (TF) is considered as an indicator of the element's entry into the plant. The concentration of chemical elements in soil and dry matter of plant samples are used for calculation **(Uchida, Tagami and Hirai, 2007; Blanco Rodríguez et al., 2006; Bitterli, Banuelos and Schulin, 2010)**. Transfer factors for peas varied from 11.05 to 19.25 in the case of Se transfer to the whole pea biomass (TF_{SP}), in the case of the Se transfer from soil to pea seeds (TF_{SG}), the highest transfer showed in variant I and gradually decreased with increasing addition of Se (Table 3). In general, transfer factors are higher than those reported in the literature. Literary data describe transfer factors under natural conditions without soil fortification, therefore selenium content in vegetables was naturally lower.

The transfer factor (TF) depends on the type of plant, part of the plant, and the soil characteristics as well as the chemical forms of the element in the soil **(Bitterli, Banuelos and Schulin, 2010)**. The leaves of plants have a higher transpiration rate, therefore they require more water and essential elements than other parts of the plant, and therefore trace elements are used to accumulate to a higher extent in the leaves. Therefore, there is a higher transfer factor in these parts of the plant compared to the others, as confirmed by several authors, **Uchida Tagami and Hirai (2007)** and **Blanco Rodriguéz et al. (2006)**.

Uchida Tagami and Hirai, (2007) reported TF in for 68 vegetable and cereal samples. At a mean Se content in the soil of 0.54 $mg.kg^{-1}$, cabbage had a TF of 0.011 – 0.036, soybean 0.016 and lettuce 0.017 – 0.0083.

A transport index (TI) is used to evaluate the ability of a plant to transport an element to a collectible portion of a plant. **Blanco Rodriguéz et al. (2006)** defines the transport index as the ratio of element concentration in above-ground resp. in the consumption part and its concentration in the root. The transport index was used to quantify the relationship of Se transportation from roots to grains. The Se concentration ratio in the grain to the concentration in the root in peas is expressed by the TI_{RG} values in Table 3. The highest TI_{RG} values are shown for variants I (2.03) and II (1.77). These variants used Se the most efficiently.

CONCLUSION

Our findings proved that Se biofortification has positive effects on the improvement of selenium status in garden pea that can provide Se enriched food source for the production of a proper functional product. The results suggest that peas are suitable vegetable species for agronomic biofortification and can introduce Se into the human and animal diet. Garden pea has a great ability to accumulate high amount of Se in the grain. Our investigations proved that a relatively small amount of Se fertilizer can highly enhance Se supply in the grain. A strong linear relationship between the total Se content in pea and the dose rates of the application were also proved, however from the phytotoxic point of view, concentrations over 2 mg Se kg^{-1} of soil resulted in a decrease of plant growth and delay of seed development. This fact presents valuable information for potential recommendations for agronomic practice. In conclusion, our results could be used as valuable information for suitability of peas for inclusion in Se biofortification programs; however, another additional research on the sustainability of biofortification with even low selenate addition into different soils should be considered in relation with a potential environmental impact on arable soils and surface waters, as well.

RESEARCH OF MILK FAT OXIDATION PROCESSES DURING STORAGE OF BUTTER PASTES

Olha Yatsenko, Nataliia Yushchenko, Uliana Kuzmyk, Vasyl Pasichnyi, Oksana Kochubei-Lytvynenko, Nataliia Frolova, Olga Korablova, Ivan Mykoliv, Volodymyr Voitsekhivskyi

ABSTRACT

Basic quality indicators studied: acidity, peroxide, anisidine value and integrated value of complete fat oxidation. Butter paste was selected as a reference, consisting of butter, skim milk powder and fat-soluble emulsifiers. Peroxide value during storage at the temperature of (4 ±2 °C) for the first 4 days did not exceed 5.0 1/2 O mmol.kg^{-1}, on the 15th day fat peroxide value of butter paste with milk-vegetable protein exceeded permissible limits that is indicative of milk fat contamination. At the temperature of (-3 ±1 °C) butter paste fat couldn't be qualified as fresh when storing during 15 days, peroxide value exceeds permissible limits on the 25th day of storage. Rising of the peroxide value above 5 1/2 O mmol.kg^{-1} was detected on the 25th day of storage, exceeding of threshold value was on the 45th day. It was established that rate of oxidation processes in butter pastes with vegetable protein is the highest among all studied samples in each particular control and observation point. It was determined that the rate of secondary lipid oxidation depends on the storage temperature and is observed when storing butter paste samples at a temperature of (-3 ±1 °C) on the 10th day, (-24 ±2 °C) – on the 30th day of storage. Acid value did not exceed recommended limits (2.5 °K) and was on average – 2.3 °K when storing butter paste during 10 days at a temperature of (4 ±2 °C); 2.1 °K during 20 days at the temperature of (-3 ±1 °C), 2.4 °K during 40 days at the temperature of (-24 ±2 °C). In view of obtained results of fat phase stability evaluation of studied butter pastes, the following storage maximum time is recommended: at the temperature of (4 ±2 °C) – 7 days, at the temperature of (-3 ±1 °C) – 15 days, at the temperature of (-26 ±2 °C) – 30 days.

Keywords: butter paste; milk protein; vegetable protein; milk; fat; oxidation

INTRODUCTION

Relatively high calorific value of butter often serves as limitation when adding to food ration of a modern human and compels scientists and producers of dairy products to develop technologies similar to butter with lower fat content. Fat exclusion from the ration for a long term is inadvisable and dangerous in as much as lipids have exceptional value in human physiology. Lipids are source of energy and fulfil a range of functions in the body: heat insulation, protection of internal injury, exercise anatomic and tectonic function as part of cell membrane, arranging order of metabolites flow in the body **(Kubicová, Predanocyová and Kádeková, 2019)**. Biological value of fats is determined first of all by availability of polyunsaturated fatty acids – linoleic, linolenoic and arachidonic acids. These fatty acids are not synthesized by human body, if they are insufficient in food products lipid exchange processes fail in the body. Linoleic and linolenoic acids are contained primarily in vegetable fats, arachidonic – in animal fats **(Zahorui, Mazur and Kalinina, 2019; Bozhko et al., 2017)**. Milk fat is unique as it contains all three aforesaid fatty acids at once. Besides, fat-soluble vitamins, in particular vitamin A and β-carotene are also assigned to milk lipids. Therefore, development of new butter paste types which are low-caloric substitute of butter is topical trend of researches.

Since butter pastes are defined by high moisture contents, skim milk powder, milk or vegetable proteins, protein polysaccharide complexes etc. are used for their structure stabilization **(Kochubei-Lytvynenko et al., 2018a; Ondrušíková et al., 2019; Kumbár et al., 2017)**. Free moisture is suitable environment for biochemical transformations, that is why during production and storage of butter pastes there is a danger of biochemical transformations of milk fat and other components, primarily proteins and carbohydrates limiting storage life of such products **(Golian et al., 2018; Frolova et al., 2019)**.

One of the main processes occurring during storage of butter pastes and causing product spoilage is milk fat oxidation. Fatty acid content of milk fat exercises significant influence on preservation of butter pastes

during storage **(Dyman and Zahoruy, 2008; Bubelová et al., 2017)**. First of all polyunsaturated fatty acids are prone to oxidation under influence of atmospheric oxygen, causing accumulation of peroxide and carbonyl compounds. Therefore, the course of oxidation changes in developed butter pastes were studied when controlling peroxide and anisidine values. Oxidation stability of fat as part of a product also depends on production conditions, heat and light impact, concentration and type of oxygen, presence of free fatty acids, mono- and diglycerides, metals of variable valency, peroxides, thermal oxidized compounds, pigments and antioxidants. These factors mutually influence on the oxidation process and it is practically impossible to determine their individual effect, however at initial oxidation stages chemical and organoleptic indicators of fat have little or no change.

Fat oxidation process is free radical chain reaction, comprising initiation, branching and termination stage and which takes place involving molecular oxygen **(Piven, 2007)**:

Chain initiation	$H \rightarrow R\cdot + H\cdot$
Chain branching	$R\cdot + 3O_2 \rightarrow ROO\cdot$
	$ROO\cdot + RH \rightarrow ROOH + R\cdot$
Chain termination	$ROO\cdot + R\cdot \rightarrow ROOR$
	$R\cdot + R\cdot \rightarrow RR$
	(R – lipid radical)

Depending on storage conditions and initial qualities of product the oxidation may take place under different mechanisms. Products of described reactions are first and foremost hydroperoxides, from which aldehydes, ketones, short-chain hydrocarbons, spirits and ethers are formed by autoxidation mechanism. Hydroperoxides formed in the reaction with oxygen can be determined by peroxide value, products of their further transformation – by anisidine value **(Tsisaryk, Musiy and Shereshkov, 2016)**.

Lipids oxidation is followed by deep breakdown of triacyl glycerides with formation of peroxide compounds, aldehydes, ketones etc. At this time foreign flavours and odours appear in the product. Oxidation may be nonenzymic and enzymic. Nonenzymic oxidation is followed by peroxides accumulation at the beginning, thereafter aldehydes, ketones, oxyacids and other compounds, which add foreign flavours and odours to dairy products. This process takes place as a result of fat interaction with molecular oxygen. At first free milk butter not protected by membrane is exposed to oxidation, out of fatty acids – unsaturated ones. Oxidation process is controlled by peroxide value **(Javůrková et al., 2016; Korablova, 2011)**.

This value is very sensitive and is a reference for beginning and rate of fat oxidation. Fresh fat is free from peroxides. At initial oxidation stages for some time chemical and organoleptic indicators of fat are almost unchanged. During the storage fat begins spoiling. It can be detected by increase in peroxide value and change of organoleptic properties of fat **(Decker, 2002; Li et al., 2018; Saláková et al., 2019)**. End products of milk fat splitting are free fatty acids **(Martin-Polvillo, Marquez-Rui and Dobarganes, 2004)**, accumulation of which result in bad taste and odour of the product and acidity level increase. In addition to, accumulation of organic acids may be a result of deep breakdown of proteins and carbohydrate components, in particular lactose.

Thus, the study of the milk fat oxidation processes of butter pastes during storage at different temperatures will allow specifying conditions and storage life of products and ensuring product safety for a consumer.

Scientific hypothesis

Fat splitting process in butter pastes, stabilized by protein polysaccharide complexes, has the same tendency, but slightly slower as compared to butter paste, which contains skim milk powder. Process deceleration can be explained by reduction of free moisture content through using more active structure-forming agents and by synergism of their interaction.

MATERIAL AND METHODOLOGY

Material

Authors developed formulations of butter pastes, stabilized by protein polysaccharide complex and justified technological modes of their production. **(Kochubei-Lytvynenko et al., 2018a; Kochubei-Lytvynenko et. al., 2018b)**. Figure 1 represents the photo of a butter paste stabilized with protein-polysaccharide complex.

Figure 1 Butter paste stabilized with protein-polysaccharide mixture.

In order to ensure stable properties of butter pastes and prevention of their spoilage during storage, changes in quality during storage by acidity, peroxide (PV) and anisidine (AV) values were studied. Product samples were stored in an unsealed package at three technological modes: at a temperature of (4 ±2 °C) during 15 days, (-3 ±1 °C) during 25 days and at a temperature of (-26 ±2 °C) during 45 days at relative air humidity of not less than 85% without sunlight. Acidity was determined directly in collected sample, oxidation indicators – at fat extraction by digestion method after each 5 days of storage (3 days at a temperature of (4 ±2 °C). Butter paste was selected as a reference, consisting of butter, skim milk powder and fat-soluble emulsifiers.

Methods

Determination of fat peroxide value was conducted under State Standard of Ukraine DSTU 4570:2006 **(DSTU 4570, 2006)**. The method is based on the reaction of interaction of fat oxidation products (peroxides and hydroperoxides) with potassium iodide in acetic acid and chloroform solution and the subsequent quantitative determination of released iodine with sodium thiosulfate solution by the titrimetric method. For determination of peroxide number

such chemical reagent were used: distilled water, glacial acetic acid, chemically-pure (C.P.), chloroform (trichloromethane), aqueous solution of potassium iodide C.P. mass content 50 – 55% freshly prepared, solution of starch mass content 0.5%, aqueous solution of ($Na_2S_2O_3$. $5H_2O$) molarity 0.01 mol.L^{-1}, final of sodium sulphite with mass of substance in vacuum-sealed ampule , which equals 0.1 gram-equivalent. Peroxide value is a ration of substance amount in a sample related to active oxygen, which under reference conditions oxidize potassium iodide, to the weight of studied sample. The value characterizes the amount of primary products of fats oxidation – peroxide compounds (hydroperoxides, peroxides, dialkyl peroxides), which are able to separate iodine from aqueous solution of potassium iodide. It is expressed in millimole of active oxygen per sample kilogram. Peroxide value is an indicator of fats freshness grade. The method principle is based on the interaction reaction of fat oxidation products with potassium iodide in acetic acid and chloroform solution and further quantitative determination of discharged iodine by sodium thiosulfate solution using titrimetric method.

Peroxide value (PV) 1/2 O mmol.kg^{-1} is calculated by formula:

$$PV = (V - V_0)*c*1000/ m \quad (1)$$

Where: V, V_0 – volume of sodium thiosulfate solution in main and control study respectively, cm^3; C – concentration of sodium thiosulfate solution, mol.dm^{-3}; m – mass of studied sample, g; 1000 – ratio, which includes conversion of measurement result in mmol.kg^{-1}.

Peroxide value is expressed in 1/2 O millimole per kilogram, which corresponds to the amount of oxygen, used in the given oxidation-reduction reaction, in milliequivalents per kilogram.

Determination of anisidine value was conducted under DSTU 6885-2002 **(DSTU 6885, 2002)**. The principle of the method is in dissolving the test sample of the fat product in isooctane, interacting with p-anisidine, and measuring the optical density of the solution at a wavelength of 350 nm. For determination of anisidine value such chemical reagent were used: sodium sulfate (Na_2SO_4) C.P.; 2,2,4-trimethylpentane (isooctane), which has optical density ≤0.01 in relation to water within the wavelength 300-380 nm; 4-methoxyaniline (p-anisidine); glacial acetic acid C.P., with content of water ≤0.1%; sodium sulphite (Na_2SO_3) C.P., anhydrous; activated carbon clarify powdered; anhydrous calcium chloride ($CaCl_2$) C.P.; laboratory items: spectrometer UV-1800 SHIMADZU, range of values 190 – 1100 nm, pathlength of cuvette 10 mm, suitable for measurement at the wavelength 350 nm. Anisidine value (AV) shows concentration of aldehydes (primarily, 2-alcanal) in animal fats. This is a dimensionless value, which is numerically equal to centuplicated optical density fat solution in isooctane upon processing by anisidine reagent, measured on spectrophotometer with a wavelength of 350 nm. The method principle consists in preparation of the studied sample solution in isooctane, reaction with acetic solution of p-anisidine and measurement of optical density at 350 nm.

Anisidine value is calculated by formula:

$$AV = 100 \cdot Q \cdot V [1.2 (A_1 - A_2) - A_0] / m, \quad (2)$$

Where: Q – adjusted concentration of studied solution in g per cm^3 (Q = 0.01 g.cm^{-3}); V – dissolved sample volume (V = 25 mL), A_0, A_1, A_2 – optical density of nonreactive analytical, color and control solution respectively; m – sample mass, g.

Integrated value of full fat oxidation (IV) is calculated by formula:

$$IV = 2\times PV+AV \quad (3)$$

Fat acidity is expressed in degrees c (°K), it is a volume (cm^3) of sodium or potassium hydroxide solution of molar concentration 0.1 mol.dm^{-3}, spent for neutralization of free acids in 10 g of product.

Statistical analysis

Obtained measurement results and graphical representation of experimental data were conducted using standard programs of statistical processing Microsoft Excel 2010. Precision of obtained results was ensured by three-, fivefold repetition of studies. The analysis of variance (ANOVA) of the obtained results was conducted; confidence range under t-criterion for parallel measurements with *p*-value less than 0.05 was determined. For building graphical dependencies and in the table the arithmetic results of parallel measurements with value of $p = 0.05$ are indicated.

RESULTS AND DISCUSSION

Since the peroxide value (PV) is regulated by state standards system for fat-containing products, there is a possibility to predict storage life of developed products under this value **(Coppin and Pike, 2001; Mehta et al., 2018)**. Generally accepted quality level of fat-containing products PV at the level up to 5.0 1/2 O mmol.kg^{-1}, when its value more than 10.0 1/2 O mmol.kg^{-1} the product loses its nutritional value **(Fatouh et al., 2005; Dyman and Zahoruy, 2008)**. Guaranteed storage life is established at the level of 50% of a term, during which the product does not lose its nutritional value, if expected storage life does not exceed 30 days and at the level of 70%, if expected storage life does not exceed 30 days **(Stele, 2006)**.

It was established that accumulation rate of peroxides during the storage of butter pastes directly depends on the storage temperature (Figure 2), caused by enzymic component of biochemical transformations of milk fat **(Jacobsen et al., 2008; Jones et al., 2005; Rodrigues and Gioielli, 2003)**. At temperature decrease the enzymes strength decreases and practically levels in condition of deep freezing (Figure 2a). It was determined that during storage at a temperature of (4 ±2 °C) (Figure 2a) within first 4 days, no major changes of peroxide value were observed, on further storage the accumulation rate of peroxides was rising ($p \leq 0.05$) significantly, on the 10^{th} day fat of butter pastes was defined by peroxide value higher than 5.0 1/2 O mmol.kg^{-1}, that was indicative of the beginning of spoilage processes, on the 15^{th} day of storage the peroxide value pf butter paste fat with milk and vegetable protein slightly exceeded permissible limits.

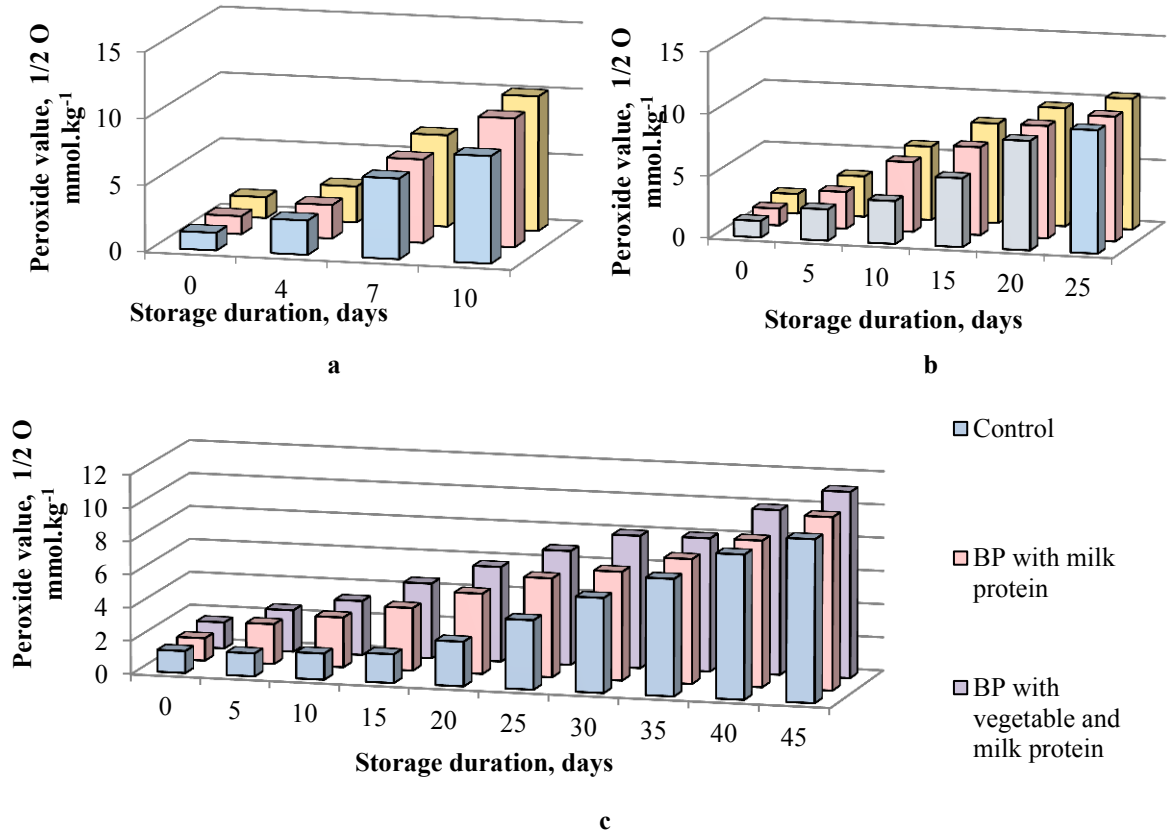

Figure 2 Dynamics of peroxide number of butter pastes at different temperature regimes: a – (4 ±2 °C); b – (-3 ±1 °C); c – (-24 ±2 °C); (n = 3 – 5, $p \leq 0.05$).

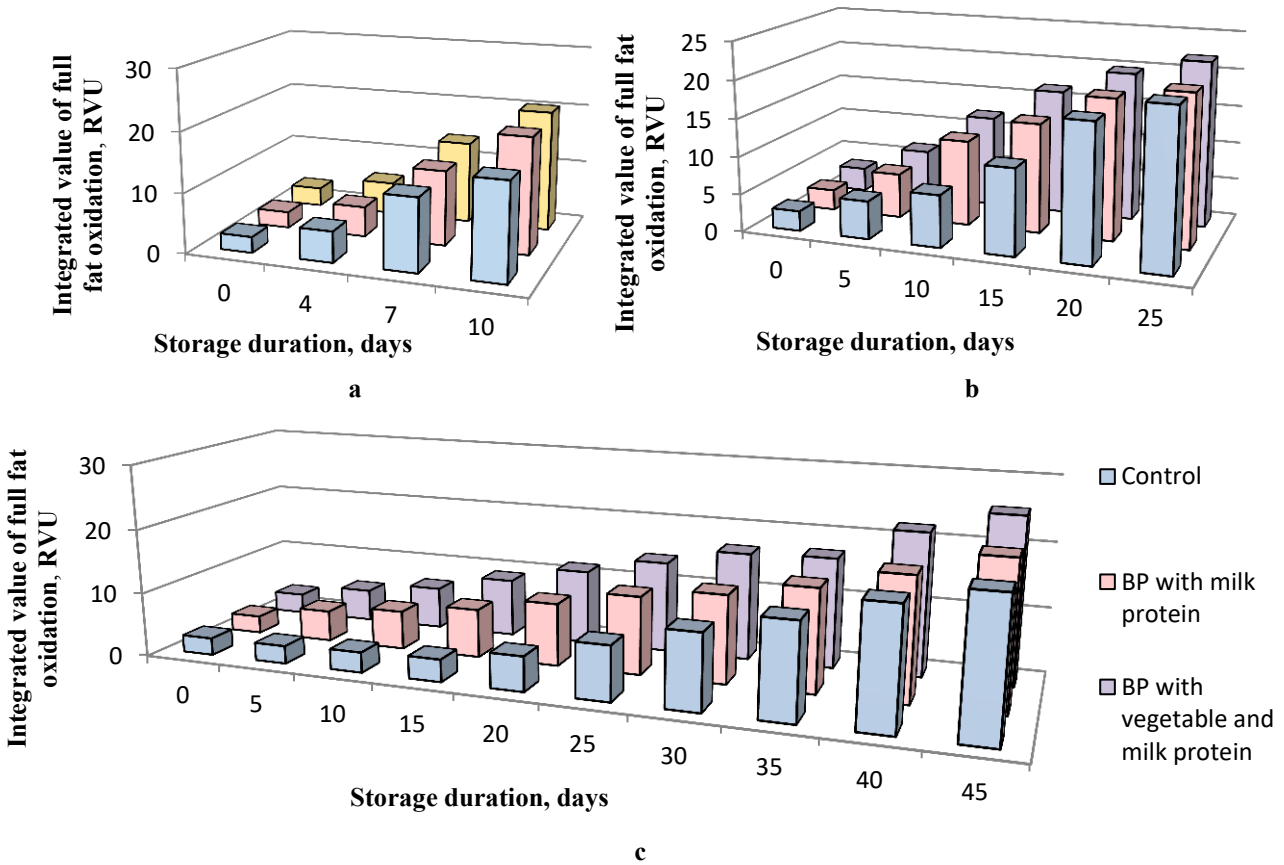

Figure 3 Dynamics of integral index of complete oxidation of butter pastes (relative value unit (RVU)) at different temperature regimes: a – (4 ±2 °C); b – (-3 ±1 °C); c – (-24 ±2 °C); (n = 3 – 5, $p \leq 0.05$).

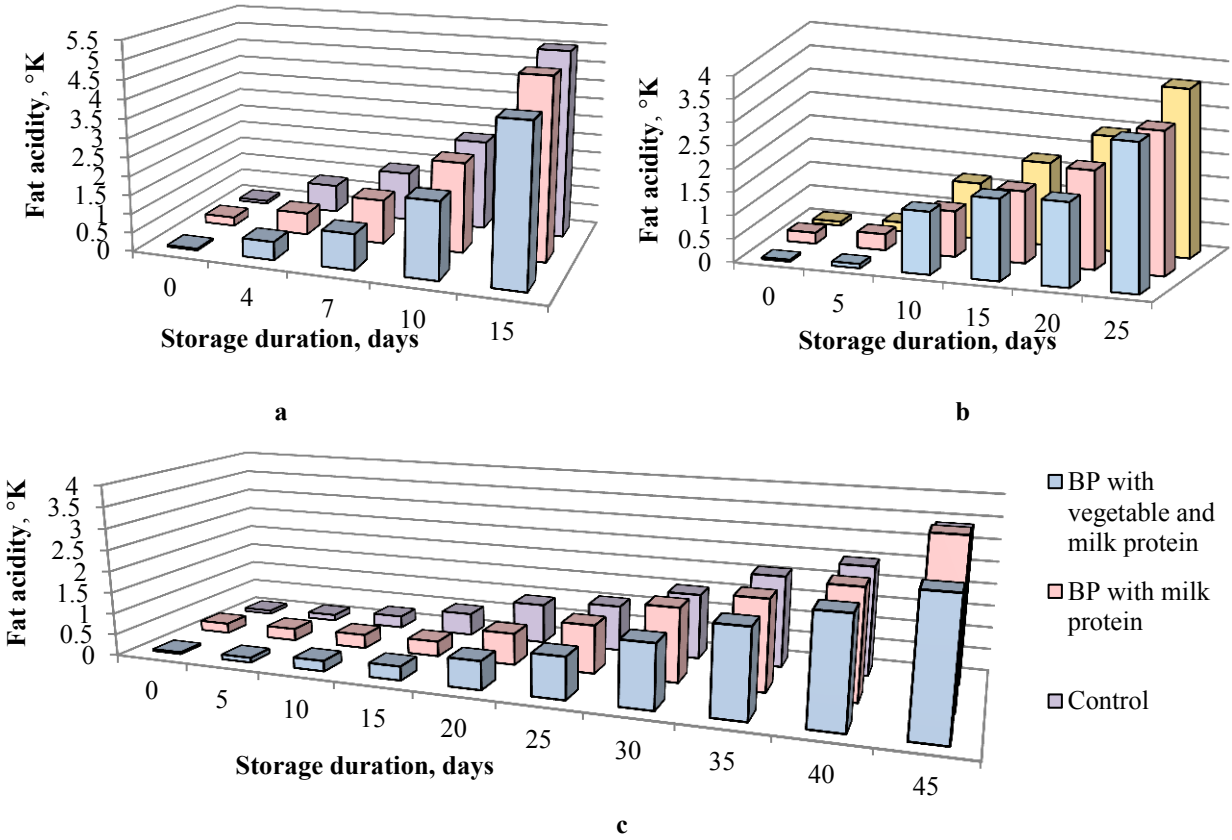

Figure 4 Acid dynamics of butter pastes at different temperature conditions: a – (4 ±2 °C); b – (-3 ±1 °C); c – (-24 ±2 °C); (n = 3 – 5, $p \leq 0.05$).

Based on obtained results we can conclude about the possibility of establishing guaranteed storage life – not more than 5 days. Accumulation rate of peroxides in butter pastes with vegetable protein is the highest among all studied samples in each particular control and observation point. The revealed trend can be explained by residual enzyme strength – lipooxidase, which is contained in vegetable isolate and catalyses reactions of lipid peroxide oxidation **(Lobanov and Shcherbin, 2003)**.

Similar trend was observed when studying peroxide value history at a temperature of (-3 ±1 °C) (Figure 2b). It was determined that butter paste fat could not be qualified as fresh when storing during 15 days at a said temperature, peroxide value exceeds permissible limits and is on average 10.4 1/2 O mmol.kg^{-1}. Thus, the guaranteed storage life of butter pastes at a said temperature should be maximum 15 days.

Rising dynamics of the peroxide value during storage of butter pastes at a temperature of (-24 ±2 °C) (Figure 2c) was far slower, peroxide value above 5 1/2 O mmol.kg^{-1} was detected on the 25th day of storage, exceeding of threshold value was observed on the 45th day of storage, allowing to establish guaranteed storage life of butter pastes for not more than 30 days at a temperature of (-24 ±2 °C).

The anisidine value is used to control processes of secondary oxidation by content of malondialdehyde. Substances with aldehyde functional groups are formed as a result of oxygen effect on peroxides, consequently they appear only at deep oxidation stages. When storing butter pastes at a temperature of (4 ±2 °C) secondary oxidation products were not detected. Under such storage conditions intense primary milk fat splitting takes place, resulting in product spoilage earlier that secondary oxidation products accumulate in it.

Obtained results show that AV at subzero temperatures does not exceed 1 c.u. value during the whole storage duration (Table 1). Aldehydes accumulation begins during the second half of storage in all studied temperature conditions.

Rising dynamics of full oxidation of butter pastes, stabilized by protein polysaccharide complexes based on milk and vegetable protein, was faster as compared to control. It is explained by the presence of fat-soluble emulsifiers in the formulation of butter paste as a reference product **(Lucas et al., 2010)** (Figure 3) that have a protective effect on milk fat glycerides. Fat splitting process in butter pastes with protein polysaccharide complexes takes place with almost the same intensity (due to the influence of milk protein concentrate, **(Abdullah et al., 2018)**).

Fat breakdown with formation of fatty acids can assist in acceleration of oxidation process because free acids oxidize first. Total amount of acidic substances in the product is indirect indicator of hydrolytic fat decomposition during the product storage and is characterized by acid value **(Musiy and Tsisaryk, 2014)**. Besides, acidity of butter pastes is stipulated by the

presence of organic acids, formed during the breakdown process of plasma lactose, by acidic products of proteins breakdown etc. **(Hladyshev, 2012; Malfia et al., 2008)**. Results depicted on Figure 4 show that acid value of developed butter pastes is credibly lower than acidity of reference sample. Accumulation of organic acids takes place slower in butter pastes with protein polysaccharide complex under all studied temperature conditions regardless of freezing depth **(Ruttarattanamongkol, Afizah and Rizvi, 2015)**.

Thus, acid value did not exceed recommended limits (2.5 °K) and was on average – 2.3 °K when storing butter paste during 10 days at a temperature of (4 ±2 °C); 2.1 °K during 20 days at a temperature of (-3 ±1 °C), 2.4 °K during 40 days at a temperature of (-24 ±2 °C). Slightly lower acid values of milk fat of reference sample can be similarly explained by protective effect on lipid of formulation components – fat-soluble emulsifier **(Bodnarchuk, 2016)**.

CONCLUSION

It was established that storage of butter pastes at above-zero temperatures causes intensive milk fat splitting forming primary splitting products – peroxides that results in product spoilage. Research results of milk fat oxidation processes of new butter paste types stabilized by protein polysaccharide complexes and reference sample during storage at below zero temperatures showed common trends. At first accumulation of primary and secondary oxidation products takes place slower, upon which jumping increase at the expense of organic acids accumulation was observed that causes intensification of oxidation processes. Based on the obtained evaluation results of fat phase stability of studied butter pastes, the following storage life is recommended: at a temperature of (4 ±2 °C) during maximum 7 days, at a temperature of (-3 ±1 °C) during maximum 15 days, at a temperature of (-24 ±2 °C) during maximum 30 days. Research results and found regularities will be used for complex evaluation of quality and stability of new butter paste types, stabilized by protein polysaccharide complexes for the purpose of justification of their guaranteed storage life.

THE INFLUENCE OF CAVITATION EFFECTS ON THE PURIFICATION PROCESSES OF BEET SUGAR PRODUCTION JUICES

Marija Zheplinska, Mikhailo Mushtruk, Tatiana Kos, Volodymyr Vasyliv, Yuliya Kryzhova, Roman Mukoid, Marina Bilko, Anatolii Kuts, Yuliia Kambulova, Sergiy Gunko

ABSTRACT
The existing technology for the purification of diffusion juice and its hardware design has not fundamentally changed over the past four decades. The lack of the necessary theoretical developments and experimental data hinders the development of existing and the development of new technological processes. Therefore, the main direction of improving the purification efficiency of juices of sugar beet production is the disclosure of its unused reserves and their implementation in practice. The scientific problem of choosing the rational direction for improving the technology of juice purification, which ensures the production of consumer granulated sugar in the face of changes in a wide range of quality of raw materials, is relevant and has important economic importance, especially in the context of the transition of beet sugar factories to a market economy. One way to solve it is to make fuller use of the adsorption capacity of calcium carbonate particles while increasing the filtration properties of saturation sediments. Therefore, the study investigates the effect of cavitation effects – vapor condensation and hydrodynamic processing of diffusion juice on the processes of purification of diffusion juice, juices of preliminary defecation, first and second saturations. The analysis of the influence of various effects of cavitation processing of juices from the point of view of improving the purification efficiency, the optimal place of the purification process in the technological scheme of production is established.

Keywords: diffuse juice; preliminary defecation; saturation; intensification; cavitation

INTRODUCTION
Classical methods of intensifying the processes of calc-carbon dioxide purification of diffusion juice of sugar beet production by changing the temperature, alkalinity, or duration of individual stages do not provide an increase in the purification efficiency. In particular, analyzing the conditions of the processes at the previous defecation is found **(Ozerov and Sapronov, 1985; Johnson, Zhou and Wangersky, 1986)** that the limiting factor at this stage is the rate of delivery of reagents to the reaction zone. In this regard, the authors of **(Lee et al., 2012)** propose a method of intensifying preliminary bowel movements using hydrodynamic (HD) cavitation, which significantly accelerates the mixing of reagents due to shock-wave action during the collapse of cavitation bubbles. But under these conditions, along with positive signs, there is also a slight deterioration in the sedimentation-filtration properties of juice of I saturation **(Almohammed, et al., 2015; Palamarchuk et al., 2019)**, which can most likely be explained by cavitation destruction (grinding) of sediment particles formed during the previous defecation.

There is also information about the application of the method of blowing steam into the juice stream to intensify the purification and sedimentation processes **(Lebovka, et al., 2007; Dalfré Filho, Assis and Genovez, 2015)**, which helps to reduce the content of calcium salts and the color of the juice of II saturation **(Kim et al., 2016)**.

But in the mentioned works (especially on the injection of water vapor), the physical essence of the effects and the mechanisms of their action on the physicochemical transformations of non-curved diffusion juice is not considered, but only the positive consequences taking place, in this case, are given. In addition, the literature does not contain data comparing the effects of hydrodynamic (HD) or vapor condensation (VC) cavitation processing of juices in terms of improving the purification efficiency and research to establish the optimal place in the technological scheme of purification and has become the subject of our research.

Scientific hypothesis
The scientific hypothesis lies in the rational direction of the intensification of the technology for the purification of beet sugar juices. It is assumed that an increase in the quality and yield of sugar is possible due to the collapse of steam bubbles during the vapor condensation and

hydrodynamic cavitation. The latter accelerate the main reactions at the stages of juice purification, leading to an increase in the overall purification effect.

MATERIAL AND METHODOLOGY

The objects of research are diffuse juice, juice of preliminary defecation, juice of the first and second saturation. Diffuse juice is processed in a hydrodynamic cavitation installation under optimal conditions. Samples of diffusion juice according to standard methods **(Ozerov and Sapronov, 1985)** in laboratory conditions are processed before the juice of preliminary defecation and the first and second saturation.

For preliminary defecation juice and juice of the first saturation, the sedimentation rate and juice sedimentation volume after settling are determined after 20 minutes; for the second saturation juice, the content of calcium salts in percent by weight of the juice and its purity are determined.

It is known that the shock-wave effect of a hydrodynamic cavitation field on the medium is processed, determined by the stage of cavitation **(Sheiko et al., 2019; Sukhenko et al., 2019)**. In this case, the effective regime of cavitation mixing and dispersion corresponds to the maximum of the shock-wave action of cavitation field bubbles on the medium, it is being processed **(Matyashchuk et al., 1988)**. Therefore, the cavitation stage λ is used by us as a determining parameter for characterizing the operation mode of a hydrodynamic cavitation device and ranged from 0.62 to 4.0. This choice is because at λ = 1.0 a flow regime arises, which is characterized by a bubble form of cavitation, which can be considered transitional from turbulent to cavitation. At λ = 4.0, which is characterized by a mixed form of cavitation, a super-cavitation regime begins to form.

To determine the sedimentation rate, a 2-liter cylinder was used, which was used to determine the height of the clarified suspension and the sedimentation rate after 5 minutes. To determine the purity of the juice it is necessary: to divide the sucrose content by the dry matter content. The dry matter content was determined using a URL-1 refractometer (supplier company PrimaRia, Kiev, Ukraine), and the sucrose content was determined using a SU-4 saccharometer (supplier company PrimaRia, Kiev, Ukraine).

Processing of the medium in the working area of the hydrodynamic cavitation installation occurs under the influence of cavitation bubbles, splashing. Therefore, the number and size of the formed cavitation bubbles are the determining factors of the technological efficiency of the cavitation treatment. In turn, the structure of the field of cavitation bubbles depends on the hydrodynamic parameters of the process, the main of which are the flow rate in the gap between the cavitator and the wall of the working section of the cavitation device and the stage of cavitation λ **(Luo et al., 2019)**. Therefore, the establishment of the hydrodynamic operating conditions of the installation was first carried out on barometric water with a temperature of 50 °C, which is similar for diffusion juice (diffusion column). The compression ratio of the flow in the working area of the laboratory setup is changed by establishing cavitators of different diameters with a Reynolds number of (23.6 – 25.4) $x10^4$. The cavitation stage was also determined on the water by visual measurement of the cavitation length in its characteristic radius.

Statistic analysis

Mathematical and statistical processing of experimental data was carried out in determining the criteria of Cochran's C test, Fisher and Student's *t*-test. The accuracy of the data was determined using the Cochrane criterion, and the adequacy of the mathematical model was checked using the Fisher and Student criteria. Statistical processing was performed in Microsoft Excel 2013 values were estimated using mean and standard deviations.

RESULTS AND DISCUSSION

In **Kozelová et al. (2011)** and **Zheplinska et al. (2019)** it is found that the efficiency of processing diffusion juice in a hydrodynamic cavitation device with increasing compression ratio increases and is largest at $d_{к\text{-}ра}/d_p$ = 0.8. Therefore, the effect of the cavitation stage on juice processing is determined at a given constant value of the compression ratio **(Jia-Qian, 2015)**. Figure 1 shows the technological parameters of the juice of preliminary defecation during the processing of diffusion juice in the HD cavitation device with a compression ratio of 0.8.

As can be seen from Figure 1 the best technological indicators of juice when cutting diffusion juice during the cavitation stage 2.3. This is indicated by the maximum deposition rate and the smallest amount of sediment juice pre-defecation. Therefore, the cavitation stage, equal to 2.3, is chosen for processing diffusion juice to determine the effect of cavitation effects on subsequent juice purification processes. In the work of the authors **(Somaratne et al., 2019; Shmyrin, Kanyugina and Kuznetsov, 2017)** the stage of cavitation 3.3 was chosen, which in our opinion will lead to a decrease in the yield of the main product.

Comparative characteristics of diffusion juice samples, the purifications of which are carried out according to the standard scheme and according to the scheme with preliminary processing of diffusion juice in a hydrodynamic cavitation device, are given in Table 1.

As can be seen from the experimental data, cavitation processing of diffusion juice intensifies the processes of coagulation of substances of a colloidal dispersion of diffusion juice at the previous defecation and adsorption of non-curvatures at the stages of the first and second saturation, as evidenced, in particular, by an increase in the purity of purified juice by 0.7%. The authors of **(Bhatia et al., 2016)** concluded that cavitation treatment of diffusion juice intensifies the processes and leads to an increase in the purity of purified juice by only 0.3%, and the authors of **(Verma et al., 2018)** purity of purified juices on the contrary decreases by 0.1%

To determine in the technological scheme, the most appropriate place for the hydrodynamic cavitation processing of sugar production juices, let's carry out studies in which juices: diffuse, preliminary defecation, and main defecation are cleared in the hydrodynamic cavitation installation. Samples of juices after a single treatment from the cavitation stage λ = 2.3 in laboratory conditions are brought to the juice of the first saturation and S_5 and V_{20} re determined in them. Figure 2 presents the values of these

values for each of the juices. As can be seen from the research results, the best indicators of the juice of the first saturation according to the scheme when the diffusion juice is processed in the hydrodynamic cavitation device.

In this case, the deposition rate during the processing of diffusion juice in a hydrodynamic cavitation device compared with the conventional method increases by 19.4%, and the sediment volume decreases by 14%. When processing juices of preliminary and main defecation, the technological properties of the juice of the first saturation significantly (confidence probability $p = 0.95$).

deteriorate in comparison with the usual purification method. Similar results were obtained in studies presented in the works of the following authors **(Katariya, Arya and Pandit, 2020; Krasulya et al., 2016).**

Processing in the installation of juices of preliminary and main bowel movements leads to a slight deterioration in the indicators of the juice of the first saturation – a decrease in the sedimentation rate of juice by 6 and 12.5%, respectively, and sediment volume by 7 and 20.7% compared with the usual method of juice purification. This indicates that during the processing of juices of preliminary and main defecation, the sediment particles formed at the stage of preliminary defecation are destroyed, followed by hydration of the substances of colloidal dispersion (SCD) particles that are adsorbed on it. Due to this, the deposition rate decreases, and the volume of juice sediment after settling increases. Similar data were obtained in work **(Guo et al., 2018)**, in which the juice of preliminary defecation was processed in a cavitation apparatus with a cavitator of a dynamic type before the main defecation, where the milk of lime is fed **(Dhar et al., 2015)**.

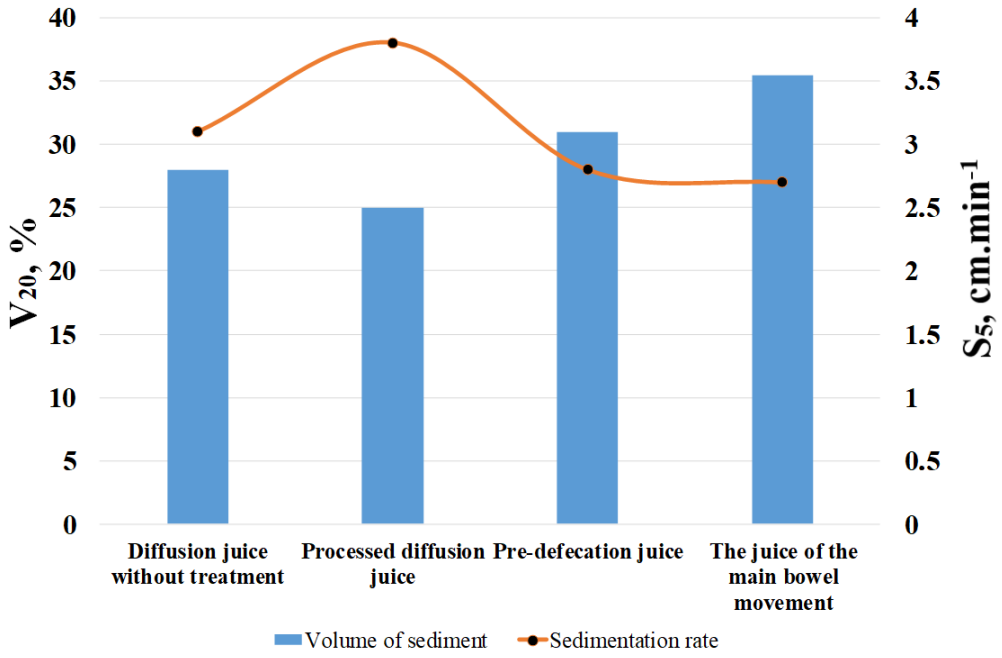

Figure 2 Technological indicators of the juice of the first saturation in the processing of juices of the main unit

The authors found improvements in the physicochemical parameters of the juices of the first and second saturation.

Such changes are explained by the fact that the activity of Ca^{2+} ions is increased, which are released from the clathrate structure of the hexo aqua complex, which interacts more fully with non-sugars juice. However, the sedimentation rate of the juice of the first saturation decreases by 10%, and the filtration coefficient increases.

From an analysis of laboratory studies, it can be assumed that the cavitation treatment of diffusion juice in a hydrodynamic cavitation device is the first step in the conversion of particles of substances of a colloidal dispersion of juice. After a certain period of time, they interact with each other, or with a chemical reagent, if any, which will contribute to the formation of a compact, low-hydrated coagulate precipitate during the previous defecation, which is resistant to peptization under conditions of basic defecation. As a result, the filtration properties of juice and carbonation will improve and the effect of the juice of I purification as a whole will increase.

To establish an analogy of the effect of the studied effects on the purification of diffusion juice in cavitation devices, parallel experiments are conducted in which the diffuse juice after treatment in hydrodynamic and vapor condensation cavitation devices is cleaned according to the following scheme: optimal previous defecation at a

temperature of 55 – 65 °C, which is fed 0.25 – 0.3% CaO at pH_{20} 10.8 – 11.2, heating to a temperature of 80 – 85 °C, the main defecation with the addition of 2.5% CaO, the first saturation to pH_{20} 10.8 – 11.2, sediment separation of the juice of first second saturation by decantation followed by filtration; second saturation; filtering the juice of the second saturation.

Comparative values of juices according to the standard scheme and with cavitation processing of diffusion juice are given in Table 2.

According to research results, when processing diffusion juice in cavitation devices, the performance of juices is improved compared to the usual purification method. So, the sedimentation rate of preliminary defecation juice after processing diffusion juice in a vapor condensation cavitation device increases by 15.6%, and in a hydrodynamic cavitation device by 21.8%, the volume of juice sediment decreases in both cases by 12.9%. A similar dependence is observed in the juice of the first saturation: the sedimentation rate of the juice sediment processed in the vapor condensation cavitation device increases accordingly by 21.8%, in the hydrodynamic cavitation device - by 25%, the volume of juice sediment decreases by 15.3 and 18, 6, respectively % The same dependence remains with the content of calcium salts in the juice of the second saturation. According to calcium salts are reduced by 28.2 and 46.2%.

The authors **(Buniowska et al., 2017; Alves et al., 2017)** conducted similar studies only without the use of cavial influence and other temperature characteristics, the volume of juice precipitate decreases by only 8.3 and 9.6%.

Purification is carried out after sampling under the action of gravitational forces in production conditions, ie the process of deposition (settling). The difference in the results is that the samples were taken at the existing sugar factory directly in the production conditions in the stream, so the possibility of their variation depends on the technological parameters, which may vary slightly.

CONCLUSION

From comparisons of the technological indicators of juices, it can be concluded that upon the collapse of steam bubbles in vapor condensation and hydrodynamic cavitation devices, structural transformations of non-curved diffusion juice occur. This means that during the collapse of bubbles in vapor condensation and hydrodynamic cavitation devices, similar effects occur that positively affect the efficiency of juice purification. However, the indicators of juices processed in a hydrodynamic cavitation device are somewhat better than in the vapor condensation one. This indicates, in our opinion, that the distribution of bubbles in the hydrodynamic cavitation device is more uniform than in the vapor condensation one due to the fact that the flow velocity in the hydrodynamic cavitation device is higher, and, as a consequence, the flow turbulence is higher. It is established that the cavitation treatment of diffusion juice before liming causes a significantly (p = 0.95) acceleration of the course of the main reactions to the previous and main bowel movements and an increase in the overall purification effect. But the mechanism of the influence of cavitation phenomena on the components of diffusion juice remains unknown and will be the subject of our further research since without this it is impossible to improve or optimize the processes of sugar beet production.

The proposed purification scheme allows compared to the typical scheme to reduce the content of lime milk for the second saturation by 0.018% CaO (almost 2 times), accelerate the process of separating the solid phase from the liquid (settling), as evidenced by the volume of juice and sedimentation rate. are better by 3.4 and 2.5%, respectively, and increase the purity of the juice by 0.7 units. And this will increase the yield of sugar.

A RANDOMISED CONTROLLED TRIAL OF INNOVATIVE SPECIALISED MEAT PRODUCT FOR PATIENTS WITH CARDIOVASCULAR AND METABOLIC DISORDERS

Irina Chernukha, Elena Kotenkova

ABSTRACT

Cardiovascular diseases remain one of the leading causes of death globally. A lot of dietary patterns for CVD prevention have been proposed, but special attention is paid to functional foods. Bioactive proteins and peptides from animal sources are also considered tools for the prevention of CVDs. Here, 40 overweight or obese adult men and women aged between 61 and 66 years, with a body-mass index between 28 and 61 $kg.m^{-2}$, were enrolled into a randomised controlled trial of new meat products for specialised nutrition. Participants in the control group (n = 20) consumed a standard hyponatric low-calorie diet for 28-30 days (10 days inpatient and 18-20 days outpatient), and in the experimental group – a low-calorie diet and 100g developed meat product (ratio of the porcine aorta to hearts 1:3) per day. Total cholesterol, triglyceride, cholesterol low-density lipoprotein, and cholesterol high-density lipoprotein levels were measured in the serum; from this, the atherogenic index was calculated. The positive effect of developed meat products on the serum lipid profile of patients during the trial was mild but noticeable. A significant reduction in cholesterol levels was noticed in the experimental group, by 18.2% and 14.0% after 7 – 10 and 28 – 30 days, respectively, while the cholesterol level in the control group returned to its original level after 28 – 30 days of dieting. The difference between the control and experimental groups was not significant, while data in the percentiles were. Therefore, it is more preferable to use a developed product as a component in diet therapy for hyperlipidaemic humans for over 28 – 30 days. Pronounced effects of the product could be linked to the unique proteome and peptidome of heart and aorta tissues based on organ-specific gene expression and the presence of tissue-specific substances.

Keywords: CVD; metabolic disorder; functional food; hyperlipidemia; cholesterol

INTRODUCTION

According to World Health Organisation data, cardiovascular diseases (CVDs) are the leading cause of death globally, taking an estimated 17.9 million lives each year. An unhealthy diet is one of the main risk factors for CVD, as well as high blood cholesterol and high blood sugar or glucose levels. Therefore, CVDs are often accompanied by metabolic syndrome and diabetes **(Han and Lean, 2016; Saklayen, 2018)**.

A lot of dietary patterns for the prevention of CVDs have been proposed, such as low-fat diets enriched with monounsaturated (MUFA) and polyunsaturated (PUFA) fats, low-carbohydrate diets enriched with fibres, the Dietary Approach to Stop Hypertension (DASH) diet providing more calcium, potassium, magnesium, and dietary fibre and less fat, saturated fatty acids (SFA), cholesterol, and sodium, and the Mediterranean diet characterised by a relatively high fat intake (40–50% of total daily calories), of which SFA comprises ≤8% and MUFA 15–25% of calories **(Eilat-Adar et al., 2013; Anand et al., 2015; Mozaffarian, 2016)**.

Composition modification (fatty acids modification, sodium chloride control), fermentation (formation of bioactive compounds) and the introduction of functional additives (plant components (oils, extracts, fibres), soy protein, natural and synthetic antioxidants, lactic acid bacteria, and fish oil are successfully used in functional food processing **(Mine and Shahidi, 2006; Cencic and Chingwaru, 2010; Alissa and Ferns, 2012; Hui, 2012; Griffiths et al., 2016; Lordan et al., 2018)**.

Peptides of animal origin released from milk and meat proteins during proteolysis, fermentation or food processing possess hypotensive, antioxidant, antimicrobial, antitumor, antithrombotic, lipid-lowering, and opioid *etc.* actions, and can be considered functional additives to food **(Arihara, 2006; Ahhmed and Muguruma, 2010; Ryan et al., 2011; Udenigwe and Howard, 2013; Lafarga and Hayes, 2014; Bhat, Kumar and Bhat, 2015; Liu et al.,**

2016; Sánchez and Vázquez, 2017). However, tissue-specific proteins and peptides contained natively in slaughter by-products have still not been well-studied.

In previous studies, we confirmed the lipid-lowering effect of functional meat products derived from the porcine heart and aorta on hyperlipidaemic rats **(Chernukha et al., 2018; Kotenkova and Chernukha, 2019)**. This paper reports the analytical results of a randomised controlled trial of meat products for specialised nutrition in patients with cardiovascular and metabolic disorders.

Scientific hypothesis

A wide range of tissue-specific proteins and peptides were identified in raw porcine heart and aorta, some of which were decomposed during meat product processing. The hypothesis that tissue-specific proteins could decompose into active peptides with similar biological action was proven in hyperlipidaemic rats that consumed the innovative product.

Nevertheless, the effectiveness of the product on rodents and humans can vary significantly; therefore, the hypolipidaemic action was studied during a randomised controlled trial on patients with cardiovascular and metabolic disorders.

MATERIAL AND METHODOLOGY

Meat products (MsP) for specialised nutrition were produced on ZAO "Yoshkar-Olinskiy Myasokombinat". Porcine hearts were chopped with a particle size of 2 – 3 mm and salted for 12 h. Porcine aortas were chopped with a particle size of 2 – 3 mm and homogenised in a cutter at 3000rpm for 2 – 3 min. Minced hearts with the juice were quantitatively transferred in the cutter and homogenised at 3000rpm for 6 – 8 min (ratio of the aorta to hearts 1:3). The obtained mince was packed in cans of lamister and sterilised at 115 °C and a pressure of 0.23 MPa for 40 min. Meat products contained 17.53 ±0.95% protein, 3.82 ±0.13% fat, 0.305 ±0.015% sodium chloride, and 2.35 ±0.25% starch.

Study design

The open, prospective, and randomised study was conducted based on the Department of Cardiovascular Pathology of the Federal Research Centre of Nutrition and Biotechnology from June 01, 2019, to October 15, 2019.

The study protocol was approved by the Ethics Committee of the Federal Research Centre of Nutrition and Biotechnology (Protocol No. 7 of 03.12.2018). In accordance with the GCP program, all participants signed written informed consent.

Randomization and study groups

Forty overweight or obese adult men and women aged between 61 and 66 years, with a body-mass index between 28 and 61 kg.m^{-2}, were enrolled.

Patients were randomised into two groups by flipping a coin. The participants were not blinded to their group assignment. Participants in the control group (n = 20) consumed a standard hyponatric low-calorie diet (LCD) for 28 – 30 days (10 days inpatient and 18 – 20 days outpatient), and in the experimental group received LCD and 100g MP per day.

Dietary intake

LCD is a diet with a significant restriction of fat and easily digestible carbohydrates, normal protein, and complex carbohydrates, with an increased amount of dietary fibre and a reduction of table salt (3 – 5 g/day). Dishes are boiled, stewed, baked, pureed, and not pureed, as well as steamed. The food temperature ranged from 15 °C to 60 – 65ºC, while the free liquid is 0.8 – 1.5 L. Nutrition is fractional, with addition 4-6 times a day.

Comparative characteristics of the chemical composition of LCD and modified diet with the inclusion of MP are presented in Table 1.

Biochemical analysis

Blood samples for biochemical studies were taken on 0, 7 – 10 and 28 – 30 days. Biochemical investigations were carried out on an automatic analyser BioChem FC-360 (HTI, USA) according to the instructions supplied with the measurement kits (HTI, USA). Total cholesterol (TCL), triglyceride (TG), cholesterol low-density lipoprotein (CL LDL), and cholesterol high-density lipoprotein (CL HDL) levels were measured in serum. Atherogenic index (AI) = (TCL - CL HDL)/CL HDL.

Statistical analysis

STATISTICA 10.0 software was used in this study for the statistical analyses. The results were calculated as "middle value ± standard deviation" ($M \pm SD$) and "percentile" ($P_{25\backslash 75}$). Significant differences were tested by nonparametric statistical Mann-Whitney U tests for independent variables and Freidman ANOVA for dependent variables. Differences with p-values less than 0.05 were considered as statistically significant.

RESULTS AND DISCUSSION

The null hypothesis about the influence of control and experimental diets on serum lipid profile inside the group were checked according to Freidman's ANOVA for all patients and patients with a BMI below 40 kg.m^{-2} ($n_{control}$ = 11, $n_{experimental}$ = 10) and above 40 kg.m^{-2} ($n_{control}$ = 9, $n_{experimental}$ = 10). The results are presented in Table 1. It was shown that LCD consumption (control) for 7 – 10 days led to total cholesterol reduction by 11.2%, mainly due to its reduction in the serum of patients with a

Table 1 Comparative characteristics of the chemical composition of LCD and modified diet with the inclusion of MP.

Diet	Chemical composition			
	Energy value, kcal/day	Proteins, g/day	Fat, g/day	Carbohydrates, g/day
LCD	1350.0 – 1550.0	70.0 – 80.0	60.0 – 70.0	130.0 – 150.0
LCD+MP	1437.0 – 1682.0	86.5 – 98.0	63.0 – 76.0	131.0 – 151.5

Note: p <0.05 mean that diet consumption influence on lipid parameter in serum.

BMI below 40 kg.m^{-2} by 17.7%.

The cholesterol level returned to its original level after 28–30 days of dieting. Revealed changes were not significantly reliable. LCD with MP consumption (experimental) led to a statistically significant total cholesterol reduction by 18.2% and 14.0% after 7 – 10 and 28 – 30 days, respectively, mainly due to its reduction in the serum of patients with a BMI above 40 kg.m^{-2} by 28.4% and 12.8%, respectively. Despite the lack of statistical significance, it was noted that the total cholesterol level reduction was higher in patients with a BMI below 40 kg.m^{-2} and equal to 15.0% compared with day 0.

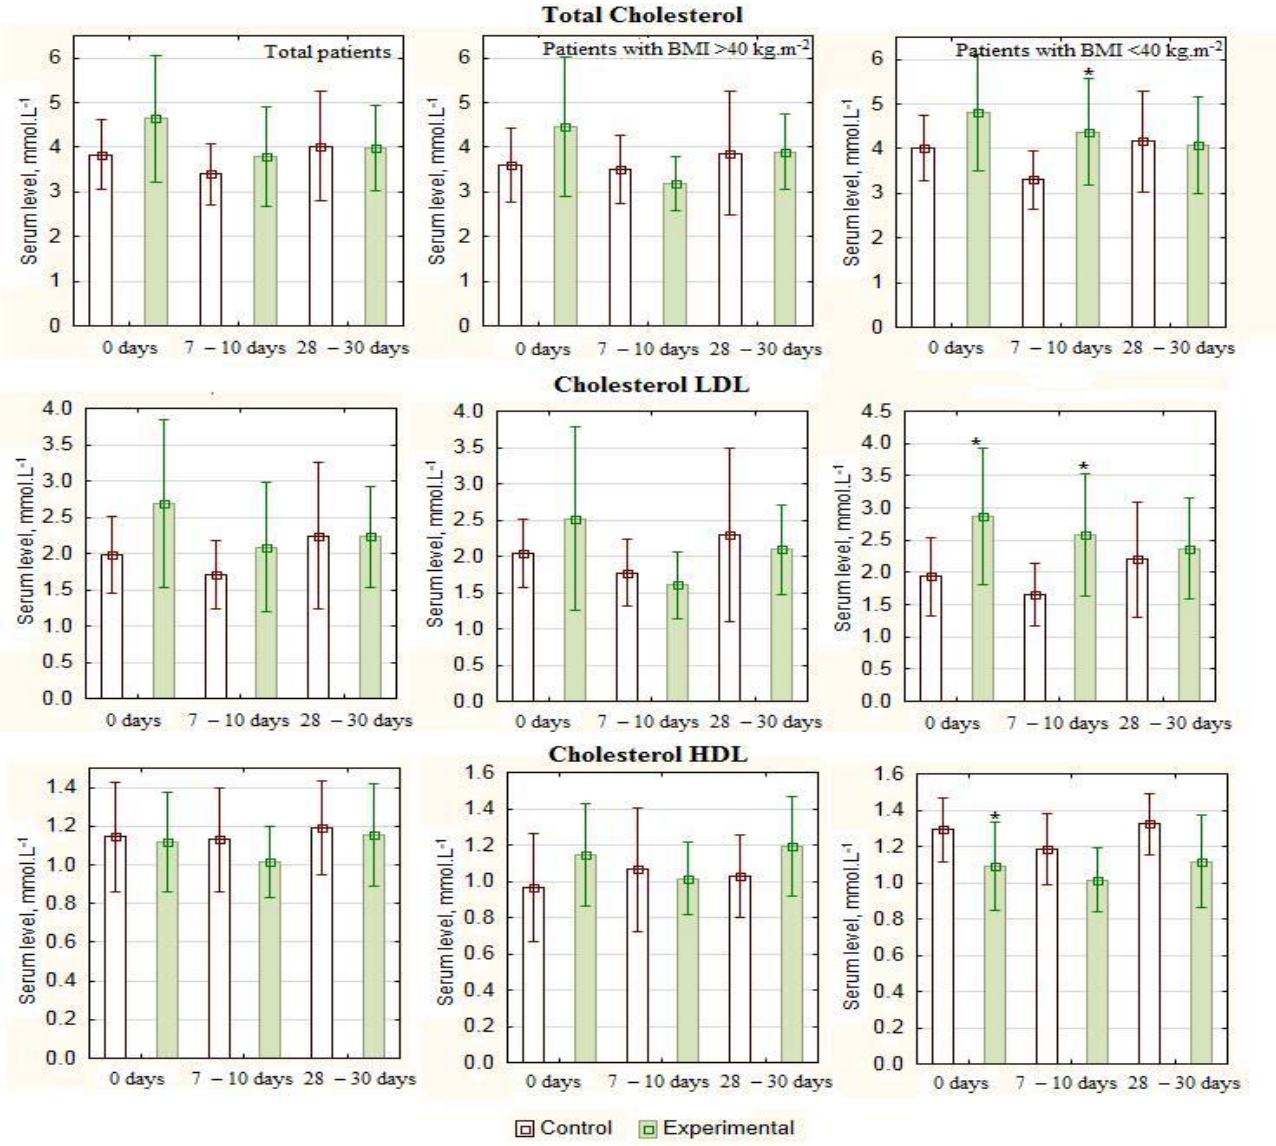

Figure 1 Cholesterol distribution in the serum of patients during the trial. Note: * - significant difference between the control and experimental groups (p <0.05)

In the control group, a statistically significant cholesterol LDL reduction by 13.8% was noticed after 7 – 10 days, mainly due to its reduction in the serum of patients with a BMI below 40 kg.m^{-2} by 14.1%. LDL cholesterol level decline was also marked in the serum of experimental patients and was equal to 22.4% after 7 – 10 days, mainly due to its reduction in the serum of patients with a higher BMI of 40 kg.m^{-2} by 36.4%. The cholesterol LDL level returned to its original level in both groups after 28 – 30 days of dieting. The same tendency was noticed concerning the cholesterol HDL level.

There were no significantly reliable changes to triglyceride levels and serum atherogenic index in both groups. However, after 7–10 days after the diets, a decrease in triglyceride levels in the control group amounted to only 3.9% and returned to its original level after 28 – 30 days, while the reduction in experimental patients was equal to 12.0% and continued to reduce until 28 – 30 days to 17.4%. The same tendency was noticed concerning serum atherogenic index (AI). Also, 7 – 10 days after the diets, the decrease in AI in the control group amounted to 16.4% and returned to its original level after 28 – 30 days, while the reduction was equal to 13.7% in experimental patients and continued to reduce until 28 – 30 days to 20.4%.

Cholesterol levels on days 0, 7 – 10 and 28 – 30 days were compared between the control and experimental groups according to the Mann-Whitney U test. There were no significantly reliable changes in cholesterol levels in the two groups for all patients and patients with a BMI higher 40 kg.m^{-2}. Cholesterol LDL on day 0 in the serum of experimental patients with a BMI lower than 40 kg.m^{-2} was higher than in the control group by 48.3% (p <0.05), while cholesterol HDL was lower by 15.7%; therefore, there was no difference between total cholesterol levels.

After 7 – 10 days, the cholesterol LDL in the serum of experimental patients with a BMI below 40 kg.m^{-2} was still higher than in the control group by 55.4% (p <0.05), but returned to the original level in both groups after 28 – 30 days of dieting.

With such heterogeneity of groups, it is advisable to consider changes in the lipid profile in dynamics and compare changes in parameters between groups. Dynamics were evaluated between 0 day and 7 – 8 days and 0 day and 28 – 30 days and are presented in Table 2 in percentiles ($P_{25\backslash75}$); statistical differences were calculated according to Mann-Whitney U tests.

There were no significantly reliable changes in Δ total cholesterol after 7 – 10 days of diet consumption, but after 28 – 30 days in the serum of experimental patients it was significantly lower than in the control, mainly due to LDL cholesterol reduction especially in patients with a BMI below 40 $kg.m^{-2}$. The same tendency was noticed concerning Δ triglycerides. There was still no significantly reliable changes in the Δ serum atherogenic index, despite its remarkable reduction in the experimental group by 13.7% and 20.4% at 7 – 10 and 28 – 30 days, respectively (Table 1). Nevertheless, a positive effect of MP on the activity (**Chernukha et al., 2016; Chernukha et al., 2018; Kotenkova and Chernukha, 2019**).

On the other hand, numerous authors also considered animal proteins as abundant sources of functional peptides, including those which demonstrated a lipid-lowering effect **(Bauchart et al., 2006; Ahhmed and Muguruma, 2010; Toldrá et al., 2012; Udenigwe and Howard, 2013; Lafarga and Hayes, 2014; Cicero, Fogacci and Colletti, 2017)**. **Nakade et al. (2009)** revealed that cattle heart protein hydrolysate could suppress cholesterol absorption in Caco-2 cells.

It is known that aorta tissue is enriched with collagen and elastin, while collagen-derived peptides have been better studied and are characterised by their lipid-lowering effect **(Koyama and Kusubata, 2013; Hongdong and Bo, 2017; Tometsuka et al., 2017; Tomosugi et al., 2017; Yazaki et al., 2017; Arrutia et al., 2017; Wahart et al., 2019)**. In this regard, aorta tissue is a good source of

Table 2 Dynamics of serum lipid profile changes in patients during the trial.

Note: * -significant differences between the control and experimental groups (p <0.05)

serum lipid profile of patients during the trial is noticeable.

In a previous study it was shown that meat products characterised by milder hypolipidaemic action compared with native raw material or isolated active fractions; a slight effect was observed after 28 days of consumption by hyperlipidemic rats, while a significant effect was only seen after 42 days of consumption **(Kotenkova and Chernukha, 2019)**.

The pronounced effect of meat product could be linked to the unique proteome and peptidome of the heart and aorta tissues based on organ-specific gene expression and the presence of tissue-specific substances **(Fagerberg et al., 2014; Breschi et al., 2016; Guschanski, Warnefors and Kaessmann, 2017; Sonawane et al., 2017; Barbeira et al., 2018)**. Previously, we also observed that sterilisation led to the decomposition of most parts of the target tissue-specific proteins and peptides into active peptides with apparently similar biological actions or retained residual glyproline peptides with hypolipidaemic action **(Lyapina et al., 2015; Shabalina Lyapina et al., 2015; Myasoedov et al., 2016)**. Presumably, active peptides could be generated both during meat product processing and digestion processes.

CONCLUSION

The positive effect of developed meat products on the serum lipid profile of patients during the trial was mild but noticeable. Presumably, it is more preferable to use this as a component in a diet therapy for hyperlipidaemic humans for 28 – 30 days. Earlier, the same effect was revealed on hyperlipidaemic rodents, which confirms the lipid decreasing ability effect of innovative products and can be recommended as part of a diet to fight CVD. The pronounced effect of the product could be linked to the unique proteome and peptidome of the heart and aorta tissues based on organ-specific gene expression and the presence of tissue-specific substances.

UTILISATION OF QUINOA FOR DEVELOPMENT OF FERMENTED BEVERAGES

Jolana Karovičová, Zlatica Kohajdová, Lucia Minarovičová, Michaela Lauková, Mária Greifová, Gabriel Greif, Jarmila Hojerová

ABSTRACT

Lactic acid fermentation of pseudocereals represents a useful tool for the preparation of value-added beverages with beneficial properties to consumers. The aim of this work was the development of a novel quinoa-based beverage fermented with commercially available probiotic culture including *Bifidobacterium sp., Lactobacillus acidophilus,* and *Streptococcus thermophilus*. The results concluded that fermentation of quinoa beverages significantly increased proteins and total phenolic content and antioxidation activity in the final products (by 36.84%, 26.67%, and 14.74%, respectively). In general, the overall acceptability of unfermented quinoa beverages was low (less than 46%), but the fermentation process slightly increased their acceptability (by 9.43%). A significant improvement of acceptability was observed, when the raspberry syrup was supplemented into the fermented beverages (by 90.98% compared to the no supplemented samples). Viability of fermenting microorganisms, pH, total acidity, and organic acid content were determined during the storage of beverages for 21 days at 5 °C. It was found that prepared quinoa beverages had a good probiotic potential (>6 CFU.mL^{-1} of lactic acid bacteria cocci). Furthermore, this study also showed that the quinoa represents a suitable raw material for formulation novel gluten and dairy-free fermented beverages with increased content of nutritionally important compounds.

Keywords: quinoa; fermentation; lactic acid bacteria; beverages; sensory acceptance

INTRODUCTION

Recently, there is a growing demand for new types of cereal products with a higher nutritional value, which can offer health benefits to consumers due to the content of biologically active substances **(Dallagnol et al., 2013)**. In this respect, considerable attention is focused on the use of pseudocereals, mainly quinoa (*Chenopodium quinoa*) **(Dallagnol et al., 2013; Bhargava, Shukla and Ohri, 2006)**. Quinoa is regarded one of the best vegetal protein sources (12 – 23%), as its protein levels are similar to those found in milk and higher than in true cereals such as wheat, rice and maize **(Gordillo–Bastidas et al., 2016; Kaur and Tanwar, 2016; Nisar et al., 2017; Zannini et al., 2018).** Moreover, quinoa contains a significant amount of starch (52 – 60%) with low amylose content (7 – 11%) **(Ahmed, Thomas and Arfat, 2019)** and the amount of dietary fibre in the quinoa is higher than in the other grains (9 – 16%) **(Gordillo–Bastidas et al., 2016)**. In addition, quinoa is a rich source of bioactive compounds like antioxidants, polyphenols, flavonoids, minerals (magnesium, zinc, iron, potassium, phosphorus) and vitamins (E, B group and C) **(Kaur and Tanwar, 2016; Tang and Tsao, 2017; Ahmed, Thomas and Arfat, 2019)**.

Due to the above mentioned nutritional benefits, the quinoa seeds have recently been incorporated into the functional food products **(Lorruso et al., 2018; Ujiroghene et al. 2019)**. Several authors investigated the potential of quinoa for the production of beverages with using various methods of treatment such as soaking, germinating, cooking, malting **(Pineli et al., 2015; Kaur and Tanwar, 2016; Urquizo et al., 2017; Zannini et al., 2018)**. On the other hand, only a few research works are focused to the production of probiotic quinoa-based fermented beverages **(Bianchi et al., 2014; Lorusso et al., 2018)**. Currently, the study of **Lorusso et al. (2018)** was oriented to assessment the suitability of quinoa for making yogurt-like beverages fermented by using probiotic lactic acid bacteria strains (*Lactobacillus rhamnosus* SP1) and **Bianchi et al. (2014)** developed a potentially synbiotic beverage fermented with *Lactobacillus casei* LC-1 based on aqueous extracts of soy and quinoa with added fructooligosaccharides. More recently **Ujiroghene et al. (2019)** reported that quinoa-based fermented beverages can be applied for diabetes mellitus treatment due to their ability to inhibit α-amylase activity and reduction or prevence hyperglycemic conditions associated with increased levels of sugar glucose in the blood.

Scientific hypothesis

In recent decades, there is an increasing interest of consumers related to the consumption of value-added beverages. In response to consumer demands, this study aimed to evaluate if quinoa could be used for the production of fermented probiotic beverages and could increase its biological value, protein, phenolic content, and antioxidant activity. The sensory acceptability of fermented beverages and their stability during storage was also determined.

MATERIAL AND METHODOLOGY

Raw materials

Quinoa seeds and raspberry syrup purchased from the local Slovak market were used in this study. Before using seeds for the preparation of fermented beverages, the seeds were desaponificated according to the method described by **Urquizo et al. (2017)**. Dried commercial probiotic culture of Lactoflora (Milcom a.s., Prague, Czech Republic) including *Bifidobacterium sp., Lactobacillus acidophilus,* and *Streptococcus thermophilus* was used for the preparation of fermented quinoa beverages.

Preparation of fermented quinoa beverages

Fermented beverages were prepared according to the modified procedure previously documented by **Urquizo et al. (2017)**. Desaponificated quinoa seeds were dried at 60 °C for 8 hours and milled to flour. In the next step, the quinoa flour was mixed with tap water at a concentration of 5% (w/v), afterward, the mixture was gelatinized at 95 °C for 10 min and cooled to 20 °C. The dried commercial probiotic culture was used for direct inoculation of beverage after dilution (initial total lactic acid bacteria count: 10_8 CFU.mL^{-1}). Samples were fermented at 37 °C for 6 hours. After fermentation, the beverages were stored in closed glass containers for 21 days at 5 °C.

Proximate analyses

Proximate analyses of beverages included determination of dry matter (AACC method 44-19.01), proteins by the method of Kjeldahl using a factor of 6.25 (AACC method 46-13.01), crude fat (AACC method 30-25.01) and ash (AACC method 08-01.01) **(AACC, 2000)**. Total dietary fibre (TDF) content was determined by enzymatic-gravimetric method 985.29 **(AOAC, 2003)**. Saponin content in seeds before and after desaponification was measured according to the method described by **Koziol (1991)**. pH of beverages was determined by using a pH-meter (Inolab WTW, Weilheim, Germany). Total acidity was measured by the visual titration method with a standard solution of NaOH (0.1 mol.L^{-1}) and using phenolphthalein as the indicator. Lactic, acetic, and citric acids were determined using the method of capillary isotachophoresis **(Kohajdová Karovičová and Greifová, 2006; Magala et al., 2015)**. Isotachophoretic measurements were realised using an isotachophoretic analyser and the ZKI01 columns connection technique (Villa Labeco, Spišská Nová Ves, Slovak Republic), equipped with a conductivity detector and two-line recorder TZ 4200 (Laboratory instrument, Prague, Czech Republic). The total phenolic content (TPC) was determined using the Folin-Ciocalteu assay **(Park et al., 2017)**. The analysis of TPC was realised by comparison to a calibration curve constructed by gallic acid. Amount of TPC was expressed as milligrams of gallic acid equivalents (GAE) per 100 g of quinoa sample. Antioxidant activity was monitored by DPPH (1,1-Diphenyl-2-picryl-hydrazyl) assay according to the method described by **Kaur and Tanwar (2016)**.

Microbiological analyses

Presumptive counts of lactic acid bacteria cocci and presumptive counts of lactic acid bacteria rods were determined after dilution and cultivation on M17 and MRS agar plates respectively according to STN ISO method 15214 **(STN ISO 15214, 2002)**.

Technological properties

The viscosity of beverages was measured using rotation viscosimeter (Haake VT 550, Haake Mess – Technic, Germany) according to the method reported by **Magala et al. (2015)**. Water holding capacity (WHC) of beverages was determined according to the method previously described by **Zannini et al. (2018)**.

Sensory evaluation

Sensory characteristics of beverages were evaluated by panel assessors (11 – member panel) using a 5 – points hedonic scale (1 – dislike extremely; 2 – dislike slightly; 3 – either like nor dislike; 4 – like slightly; 5 – like extremely) **(Graham, Agbenorhevi and Kpodo, 2017)**. The assessors evaluated overall appearance, taste, odour, colour, and consistency of fermented products. The overall acceptability of beverages was evaluated using 100 mm graphical unstructured line segments with specified end-points **(Kohajdová, Karovičová and Greifová, 2006)**.

In the next step, raspberry syrup sweetened with fructose (selection was performed concerning persons treated to diabetes as potential consumers) was used for increasing sensory acceptability of fermented beverages. After fermentation, the appropriate part of beverages were mixed with raspberry syrup (10%, v/v) and evaluated. The level of this ingredient was chosen on the basis of the previously performed preliminary trial.

Statistical analysis

All analyses were carried out using three independent determinations and expressed as the mean value ± standard deviation. Statistical analyses were performed using Microsoft Excel (Microsoft Corp., Redmond, WA, USA) with XLSTAT for MS Excel Addinsoft SARL, Paris, France). Differences among means were analyzed by Student's *t* - test. The significance level (p) was set at 0.05.

RESULTS AND DISCUSSION

The fermentation of cereals improves the nutritional properties and sensory characteristics of final products and has a positive impact on human health **(Rollán, Gerez and LeBlanc, 2019)**. Nowadays, many scientific studies are focused on the preparation of new types of cereal-based fermented beverages with probiotic and functional properties **(Rathore et al., 2012; Nionelli et al. 2014;**

Ghosh et al. 2015; Magala et al., 2015). Therefore, considering the nutritional and health benefits of quinoa, in this study, the fermented quinoa-based beverages with probiotic potential were developed.

Saponins are bitter compounds that are naturally present in quinoa seeds in the range from 0.1 to 5.0% **(Pytel et al., 2018)**. The content of saponins in the quinoa seeds used in this study was 0.30 ±0.02% (results are not shown). For remove of saponins, washing or water maceration is recommended **(Pineli et al., 2015)**. Washing with tap water was used for removing of saponins in this study. After desaponification, the amount of saponins in quinoa seeds was present in the non-detectable level. Previously **Pytel et al. (2018)** demonstrated a reduction number of lactic acid bacteria during fermentation of yogurts with 3 and 5% content of quinoa flour. Moreover, it was reported that saponins present in the quinoa seeds also cause a negative effect on protein solubility **(Pineli et al., 2015)**. For these reasons, the removal of saponins from the quinoa seeds representing an important step before the production of lactic acid fermented quinoa-based beverages. Proximate composition of quinoa-based beverages before and after 6 h fermentation is presented in Table 1.

During the fermentation process, the pH decreased and total acidity increased significantly in the beverages. This effect was previously described by **Magala et al. (2015)** in rice fermented beverages and **Urquizo et al. (2017)** in the quinoa fermented beverages prepared from various quinoa varieties. A rapid decrease of the pH at the start of fermentation is important to obtain the final product of high quality **(Kohajdová and Karovičová, 2008)**, as well as the rapid increase of total acidity minimizes the growth of undesirable and pathogenic bacteria **(Kohajdová Karovičová and Greifová, 2006)**.

During the lactic acid fermentation, different organic acids (mainly lactic acid) are produced due to the degradation of some components present in the raw material **(Kohajdová, Karovičová and Greifová, 2006; Magala, Kohajdová and Karovičová, 2013; Cho et al., 2015)**. Determination of organic acid profile represents an important tool for monitoring the metabolic activity of fermentation microorganisms **(Cho et al., 2015)**. In this study, the significant increasing of lactic and acetic acids concentration was observed in the fermented beverages in comparison to unfermented samples. Furthermore, slightly decreasing in citric acid content was recorded. This can be attributed to its usage as a substrate in secondary reactions during fermentation process **(Magala, Kohajdová and Karovičová, 2013)**.

Moreover, it was found that, the lactic acid fermentation no significantly influenced dry matter, ash and crude fat content in the quinoa-based beverages. On the other hand, however, after fermentation a significant increasing in protein content was observed in the beverages (increasing about 36.84%). **Tangyu et al. (2019)** reported that fermentation can increase protein content by the growth of the fermenting microorganisms and by improving protein solubility. According to **Simwaka et al. (2017)** the increase in protein content after fermentation has been attributed to the increase in nitrogen content released when microorganisms utilize carbohydrates for energy.

From the results also concluded that the fermentation not significantly influenced the content of TDF in the samples of beverages. Similar trend was also observed by **Marko et al. (2014)** in different fermented cereal matrices. On the other hand, **Jorgensen et al. (2010)** reported that the fermentation of cereals substrates can concluded in reduction of TDF content as a consequence the enzymatic degradation of fibre.

Table 1 Proximate composition, microbial counts and technological properties of quinoa-based beverages.

Fermentation (h)	0	6
Proximate composition		
pH	6.89 ±0.15	4.19 ±0.05*
Total acidity (mmol.L-1)	1.01 ±0.07	5.50 ±0.13*

Presumptive count of lactic acid bacteria cocci (log CFU.mL^{-1})	7.21 ±0.08	7.13 ±0.16	7.01 ±0.02*	6.12 ±0.08*
Presumptive count of lactic acid bacteria rods (log CFU.mL^{-1})	6.12 ±0.13	5.79 ±0.20*	5.57 ±0.14*	4.94 ±0.01*

Note: * denotes that means within a line differ significantly (p <0.05), ND – non detectable.

Since TDF represent an important functional compound with beneficial health effects, the incorporation of fibre rich raw materials obtained from plant processing by products into the non-dairy beverages can be a good strategy for increasing intake of TDF. In this respect, it seems to be a good alternative application of apple pomace as a fibre rich (more than 50% of TDF) by-product obtained from the juice processing industry that was usefully incorporated to cereal-based products in our previous study **(Kohajdová et al., 2014)**. Moreover, this by product can improve sensory acceptance of non-dairy fermented beverages as a flavouring ingredient due to pleasant fruity odour and taste **(Sudha, Baskaran and Leelavathi, 2007)**.

The phenolic compounds are important for human health and nutrition mainly due to their antioxidant activities **(Hole et al., 2012; Tang and Tsao, 2017)**. As shown in Table 1, the significant increasing of TPC was observed in the quinoa-based fermented beverages. A similar effect was also reported by **Hole et al. (2012)** and **Lorusso et al. (2018)** for the barley, oat, and quinoa substrates processed by lactic acid fermentation. Previously **Bustos et al. (2017)** and **Lorusso et al. (2018)** reported that, during the fermentation process the esterase activity of lactic acid bacteria and endogenous enzymes of cereal substrates can hydrolyse the complex phenolic compounds and their glycosylated forms into free phenolic acids.

Several studies documented that the quinoa seeds are an excellent source of antioxidants and that, the antioxidant

activity is in a good correlation with the content of TPC **(Kaur and Tanwar, 2016; Tang and Tsao, 2017)**. This fact was also confirmed in this study when the increased TPC content in the fermented beverages corresponded to a proportional increase of the antioxidant activity of fermented products.

After 6 h fermentation, the content of lactic acid bacteria cocci and rods reached values 7.21 log CFU.mL^{-1} and 6.12 log CFU.mL^{-1} respectively. The population of lactic acid bacteria in the fermented beverages was increased significantly by 1.08 (cocci) and 1.65 (rods) log orders. This indicates that quinoa is a suitable substrate for lactic acid fermentation.

Consistency represents an important parameter for the development of new functional fermented non-dairy beverages **(Magala et al., 2015)**. The viscosity of quinoa-based beverages significantly increased during the fermentation process. This agreed with **Bianchi et al. (2014)** and **Lorusso et al. (2018)** that also observed increased viscosity in the fermented beverages produced from aqueous extract of quinoa and yogurt-like quinoa beverages. **Ndife et al. (2019)** reported that the increase in the viscosity of cereal beverages after fermentation could be due to an increase in biomass density of the microorganisms.

No significant differences were found in the WHC of beverages before and after fermentation. This indicates that the WHC of beverages remaining stable during the fermentation process.

Sensory characteristics of quinoa-based beverages are shown in Table 2 and photodocumentation of quinoa-based beverages is presented in Figure 1.

Väkeväinen et al. (2020) newly documented that the saponins present in the quinoa seeds decrease the acceptance of quinoa-based products. Following this recommendation and due to the other fact presented in the above part of this article, the quinoa seeds were desaponificated before the use in beverages manufacture. The results concluded that the overall acceptance of nonfermented beverages was lower than 42%. Lactic acid fermentation significantly enhanced overall appearance, taste and odour, but no significantly influenced the overall acceptability of beverages. Fermented beverages were characterised with creamy light colour and sour odour and taste. Due to the low sensory acceptability of beverages, the raspberry syrup was applied as a supplement to improve their acceptability. This ingredient was sweetened with fructose, a sweetener with a low glycemic index that is usually consumed by persons treated to diabetes. The addition of this supplement significantly improved the overall acceptability of fermented beverages. A similar trend was observed by **Urquizo et al. (2017)** after the addition of bilberries and chocolate flavouring to lactic acid fermented quinoa beverages.

The shelf life of fermented beverages was also monitored for 21 days of storage at 5 °C (Table 3). During the fermentation, the pH of beverages slightly decreased. Moreover, the significant increasing of total acidity was recorded. A similar trend was previously described by **Bianchi et al. (2014)** after 28 days of storage of fermented quinoa and soy beverages at 5 °C. Furthermore, it was found that no significant differences were recorded in the content of lactic and acetic acids. The results also concluded that during storage, the citric acid was degraded as the consequence of the metabolic activity of fermenting microflora.

The presumptive count of lactic acid bacteria was also determined in this study. It was observed that lactic acid that presented bacteria cocci and rods showed a high rate of survival percentage during the storage of beverages (84.88 and 80.72% respectively). The viability of bacteria is an important characteristic of the use of probiotics in beverages, once they should survive during the shelf life, with minimal desirable value 6 log CFU.mL^{-1} **(Georgieva et al., 2009; Gallina et al., 2019)**. This value corresponds to ingestion an 8 log CFU per serving portion of 100 mL **(Pereira and Rodrigues, 2012)**. It was found that lactic acid bacteria cocci (*Streptococcus thermophilus*) were present in the beverages at the level above this requirement. On the other hand, the population of lactic acid bacteria rods (*Bifidobacterium* sp*., Lactobacillus acidophilus*) reached at the end of storage only counts 4.94 log CFU.mL^{-1}. **Kurman and Rasic (1991)** and **Samona and Robinson (1994)** previously suggested that the minimum level for probiotic microorganisms in fermented milk to produce therapeutic benefits should be a value above 5 log CFU.mL^{-1}. After 14 days of storage the population of lactic acid bacteria rods remained above this value. From the obtained results can be indicated that experimental beverages had a probiotic character.

CONCLUSION

The potential of quinoa as a raw material for the production of lactic acid fermented beverages was presented in this study. It was shown that the fermentation process significantly increased proteins and total phenolic content and antioxidation activity in the products. Sensory evaluation showed that the overall acceptability of quinoa-based fermented was lower than 46%. The addition of flavouring agent (raspberry syrup) significantly improved acceptability of beverages (79.58%). Regarding these finding, the application of flavourants could be a useful strategy for enhancing consumers' acceptance of these types of beverages. Moreover, further studies are needed to select suitable flavouring agents according to the preferences of potential consumers. The functionality of commercial probiotic culture was demonstrated by high viable bacterial counts in the fermented beverages (7.21 log CFU.mL^{-1} of lactic acid bacteria cocci and 6.12 log CFU.mL^{-1} of lactic acid bacteria rods) and during the storage (above 6 CFU.mL^{-1} of lactic acid bacteria cocci).

In conclusion, the quinoa is naturally gluten-free raw material and thus, quinoa-based fermented beverages represent a suitable alternative for people having celiac disease. Moreover, quinoa has a low glycemic index and in combination with appropriate ingredients, these beverages can be incorporated into the diabetic diet.

FRUIT RED COLORANTS IMPACT ON THE ANTIRADICAL ACTIVITY DETERMINED BY DPPH METHOD

Ondrej Hegedűs, Boglárka Borovicza, Katarína Szarka, Andrea Vargová, Dániel Reménység, Adriána Maťová, Barnabás Czibor, Alžbeta Hegedűsová

ABSTRACT

This work is focused on the determination of antiradical activity (ARA) by the method of free radical scavenging of 2,2-Diphenyl-1-picrylhydrazyl (DPPH). Since the DPPH solution is intense purple-coloured and absorbs at a wavelength of 517 nm, similar to the anthocyanin colorants of fruits, the modification of the method examined the effect of the colour of the sample extracts on the result of the ARA determination. Statistical evaluation of the results of the analyses using Youden's graphing method revealed that the two compared method adjustments gave consistent results over the observed range of antiradical activity. It also showed that there was no statistically significant difference between the mean ARA values obtained by the two treatments. Investigation of the effect of the evaluated fruit components revealed a strong correlation between the content of ascorbic acid and ARA in samples containing no anthocyanin colorants. For the fruit samples studied, ARA values showed a strong correlation with polyphenol content.

Keywords: DPPH method; antiradical activity; dependence; ascorbic acid; polyphenols

INTRODUCTION

The antioxidant capacity is often measured by a method based on decolorizing stable radicals of 2,2-Diphenyl-1-picrylhydrazyl (DPPH) with various antioxidants. This method is simple, efficient, and relatively cheap. DPPH is commercially available, stable, and poorly sensitive to degradation, which will significantly affect its use. The DPPH colour is intense purple and shows a strong absorption band in the 515-520 nm range. The original method of DPPH analysis was developed by **Marsen Blois (1958)**, which later underwent various modifications **(Brand-Willams, Cuvelier, and Berset, 1995; Chen, Bertin, and Froldi, 2013)** and are also widely used. The DPPH method is a mixed HAT (Hydrogen Atom Transfer) and SET (Single Electron Transfer) method, since, in the presence of an antioxidant molecule, DPPH can receive one electron or even one proton from the antioxidant molecule. This turns it into a more stable reduced form, which also changes its intense purple colour to faint yellow. The antiradical activity of the sample (ARA) can be quantified by spectrophotometric measurement of this conversion.

Measurement results are often expressed as "EC50 value", ("efficient concentration" or EC50 value), which represents the substrate concentration to achieve a 50% reduction in the original DPPH concentration. This parameter was introduced by **Brand-Willams et al. (1995)** and subsequently applied by a few adjustments to several groups of workers to present their results **(Kedare and Singh, 2011)**. This parameter depends on the initial DPPH concentration as well as the chosen reaction time chosen by the authors over a relatively wide time span. This makes the comparability of the results more difficult but gives a good idea of the ARA value of the samples analysed.

Although considered to be simple and effective, this method is characterized by various limitations that make measurement difficult. Many studies have pointed out that there is no linear dependence between antioxidant concentration and DPPH radical scavenging activity. Thus, the EC50 expression can be problematic in many cases **(Mishra, Ojha, and Chaudhury, 2012; Carmona-Jiménez et al., 2014; Sánchez-Moreno, Larrauri and Saura-Calixto, 1998)**.

Some authors recommend measuring the result of a blank sample **(Chang et al., 2001; Lachman et al., 2006; Jakobek et al., 2008; Vollmannová et al., 2013; Žiarovská et al., 2014)**, others recommend drawing the results to the absorbance value at time T_0 for each sample separately **(Dawidowicz, Wianowska, and Olszowy, 2012)**, whereby the possible interference of other colorants in the extract (e.g. carotenoids and anthocyanins) at the wavelength used of 517 nm would be eliminated **(Apak et al., 2007)**.

The antioxidant activity itself is influenced by the presence of many compounds present in natural materials.

First of all, it is a question of polyphenols and vitamin C **(Jakobek and Seruga 2012; Hegedűs et al., 2015)**. The influence of content substances on antioxidant activity was also investigated by **Ivanišová et al. (2010)** and showed a very high correlation between DPPH content and polyphenol content and vitamin C content.

Scientific hypothesis

Based on the fact that samples of fruit extracts with a high content of anthocyanins strongly absorb wavelength light as well as DPPH solution, this may lead to differences in results when analysing intensively coloured extracts. The main objective of the work was based on the assumption that by modifying the method it is possible to correct this effect.

As the ARA value is influenced by different compounds, we assumed a dependence between the determined ARA value and some components by analysing a wide range of fruits.

MATERIAL AND METHODOLOGY

Chemicals and Reagents

2,2-Diphenyl-1-picrylhydrazyl (DPPH) and L-ascorbic acid CertiPUR were purchased from Merck, Darmstadt, Germany, Methanol from Fisher Scientific UK, Loughborough, UK, Gallic acid from MP Biomedicals, LLC, France and Folin-Ciocalteu reagent from VWR International S.A.S., France. All other reagents were of analytical reagent grade. Deionized water was used to prepare all solutions.

Instrumentation

Spectrophotometer Jenway 6301, Bibby Scientific Ltd., UK was used for absorption measurement. WATERS HPLC system with Waters 2489 UV/VIS Detector was used for ascorbic acid determination.

Samples and Sample Preparation

For the testing method purpose, we analysed 19 fruits from several growers from the districts of Komárno and Nové Zámky (elevation 110 – 150 m a.s.l.) from southern Slovakia. The assortment of fruits was supplemented with samples of southern fruits: bananas, lemons, and oranges, which were purchased from the retail network. These were the following fruit species: apricot (*Prunus armeniaca* L.), raspberry (*Rubus idaeus* L.), sour cherry *(Prunus cerasus* L.), blackcurrant (*Ribes nigrum* L.), redcurrant (*Ribes rubrum* L.), black mulberry (*Morus nigra* L.), josta (*Ribes* × *nidigrolaria* Rud. Bauer et A. Bauer), greengage yellow and red (*Prunus domestica* L. *subsp. italica* (Borkh.) Gams ex Hegi), gooseberry green (*Ribes uva-crispa* L.), gooseberry pink (*Ribes uva-crispa* L.), white mulberry (*Morus alba* L.), blueberry (*Vaccinium myrtillus* L.), cherry plum Nigra (*Prunus cerasifera* Ehrh. *subsp. pissartii* (Carriere) C. K. Scneid. cv. *'Nigra'*), Sea buckthorn (*Hippophae rhamnoides* L.), common fig (*Ficus carica* L.), summer apple (*Malus domestica* Borkh.), white and red grapes (*Vitis vinifera* L.), banana (*Musa x paradisiaca* L.), orange (*Citrus sinensis* (L.) Pers.), lemon (*Citrus limon* (L.) Burm.).

For the determination of ARA and polyphenols, methanol extracts were obtained from average samples of individual fruit species by extraction of 10 g of the sample in 70% methanol, which was used for spectrophotometric measurement.

Methods of determination

ARA was determined by DPPH and expressed as % inhibition of DPPH radicals per g of sample **(Hegedűs et al., 2019a)**. Two modifications of the method were used:

- the absorbance results of the samples 30 min after the addition of DPPH were related to the initial absorbance of each sample separately,
- the absorbance results of the samples 30 min after the addition of DPPH were related to the absorbance of the blank.

The absorbance of the samples was measured at a wavelength of 517 nm.

The anti-radical activity was calculated as the percentage of DPPH discoloration per 1 g sample using the following formula:

$$\% \text{ ARA} = (1 - A_{t30} / A_{t0}) * 100 / n * V_2 / V_1) \quad (1)$$

Where: A_{t30} – absorbance of the sample after 30 min; n – weigh of the sample in g; V_1 – the pipetted volume of the sample (0.1 to 2.0 mL); V_2 – supplemented volume of the extract by methanol (according to the stated method always 2.0 mL); A_{t0} – the initial sample absorbance value.

Total phenolic contents were determined using the Folin-Ciocaltu method, using Gallic acid as standard **(Sánchez-Rangel et al., 2013)**. From the prepared sample extracts, 0.1 to 1.0 ml was pipetted and made up to 1.0 mL with deionized water. After standing for 5 min, 5.0 mL of Folin-Ciocalteu reagent, and 4.0 mL of 7.5% sodium carbonate solution were added. After 1 hour, the absorbance of the examined solutions is measured at 765 nm.

The determination of L-ascorbic acid was performed by the HPLC method, using sample extract in 2% oxalic acid medium **(Hegedűs et al., 2019b)**.

Statistical analysis

Statistical evaluation of the two averages was performed by paired t-test at the significance level $\alpha = 0.05$. The hypothesis was tested:

H_0: $\bar{x}_A = \bar{x}_B$ against the alternative

H_1: $\bar{x}_A \neq \bar{x}_B$, where $\bar{x}$ is the average value.

The evaluation of two modifications of the method in the obtained range of ARA values was made using Youden's graphing method in a linear regression model. The two methods compared can be considered identical if the slope of the regression line is equal to one and the offset of the regression line is zero (ideal case). Since in practice these values are always slightly different from ideal values, they were tested against the ideal values. If the results are consistent over the observed range, the dependence of y (method B) on x (method A) is linear:

$$y = \beta_1 . x + \beta_2 \quad (2)$$

with zero offset $\beta 2 = 0$ and the slope one $\beta 1 = 1$, ie. the line equation takes the form:

$$y = x \quad (3)$$

When evaluating the results, it was tested whether the estimates of β_1 and β_2 calculated by regression analysis were statistically significantly different (or not different) from the required values for the match of the results of both methods ($\beta_1 = 1$ and $\beta_2 = 0$). The hypothesis was tested:

H_0: $\beta 2 = 0$ and $\beta 1 = 1$, against the alternative
H_1: $\beta 2 \neq 0$ and $\beta 1 \neq 1$.

The estimated offset of the regression line β_2, calculated by the linear regression should be in the area:

$$b_2 - t_{1-\alpha/2}(n-2) \cdot \sqrt{s}_{b2} \leq \beta_2 \leq b_2 + t_{1-a/2}(n-2) \cdot \sqrt{s}_{b2} \quad (4)$$

If the calculated interval includes zero, then β_2 cannot be considered significantly different from zero.
Similarly for the slope:

$$b_1 - t_{1-\alpha/2}(n-2) \cdot \sqrt{s}_{b1} \leq \beta_1 \leq b_1 + t_{1-a/2}(n-2) \cdot \sqrt{s}_{b1} \quad (5)$$

Where: b_1 – an estimate of the slope of the regression line, b_2 – an estimate of the offset of the regression line, $t_{1-a/2}(n-2)$ – a quantile (critical value), s_{b2} – the standard deviation of the estimate of β_2, s_{b1} – the standard deviation of the estimate of β_1.

If the calculated interval also includes a unit, the β_1 region cannot be considered significantly different from one **(Meloun and Militký, 1994; Hegedűs, Čepelová, and Hegedűsová, 2015)**.

The linear regression and correlation analysis method were used to evaluate the dependence of ARA on the monitored fruit substances. The strength of the correlation relationship was evaluated by the correlation coefficient value. Correlation coefficient values of 0.7 to 0.9 were considered strong, so there is a strong interdependence between variables. Values 0.3 to 0.7 were considered for moderate and values 0.1 to 0.3 for weak correlation **(Dancey and Reidy, 2004).**

RESULTS AND DISCUSSION

The method evaluation

One of several methods of antioxidant activity determination is the DPPH method. The results of this method are often referred to as antiradical activity (ARA) since the reaction mechanism involves quenching stable DPPH radicals with the antioxidant of the substance to be tested. The first reactions of antioxidants with DPPH occur in approximately the first 30 seconds, but moderate reactions are usually complete within 2 min **(Sánchez-Moreno, Larrauri, and Saura-Calixto, 1998)**. Then the decolorization rate of the reaction mixture gradually decreases until the stabilization decrease. Ultimately, the time after which the absorbance value is read is the result of a compromise between the time required and the relative stabilization of the quenching of the free radicals DPPH and is often given for 30 min **(Gülcin, 2005)**.
The course of the quenching reaction of the DPPH colour free radicals in the reaction mixture of the extracts and the DPPH solution of several fruit species is shown in Figure 1. Some authors read the decrease in absorbance after a shorter period of antioxidant exposure to DPPH **(Vollmannová et al., 2013; Lachman et al., 2006; Jakobek et al., 2008)**.

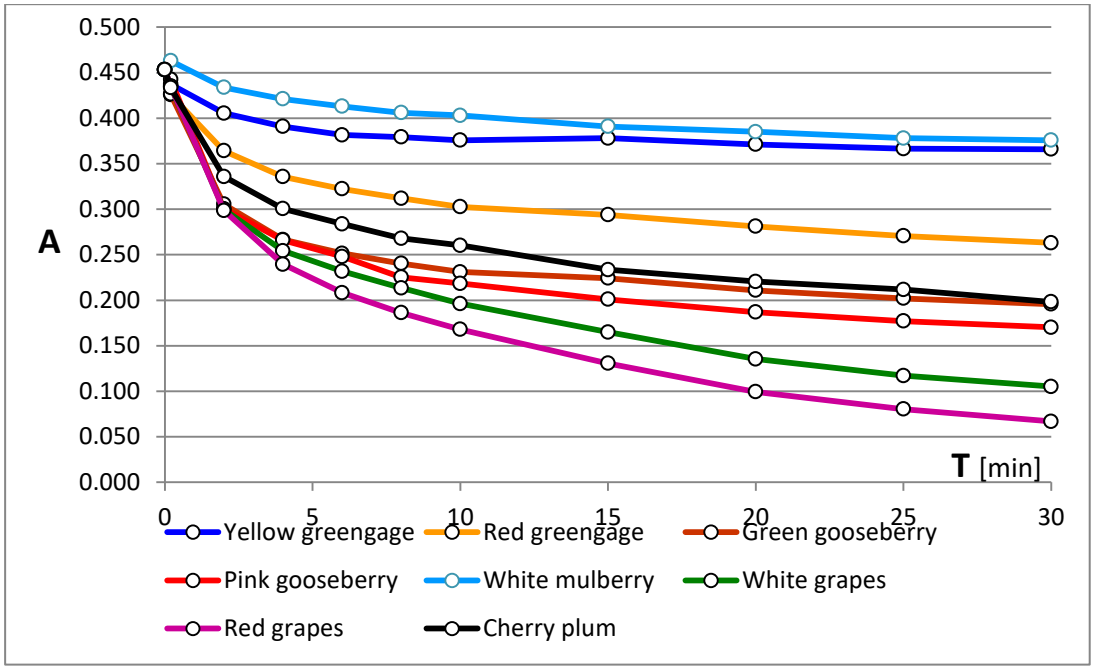

Figure 1 Examples of a decrease in the absorbance of the DPPH reaction mixture with fruit extracts.
Note: (**A** – absorbance; **T** – time).

From the decolouration of the reaction mixture according to the measurement results of Figure 1, it can be seen that in the case of several samples the colour is stabilized slowly. This may have a significant influence on the accuracy of the measurement. In the case of white and red grapes, even after 30 min the colour did not stabilize, although the changes in the decline are already apparently lower. The DPPH alcohol solution is purple and intensively absorbs output radiation at a wavelength of 517 nm (the measuring wavelength). When determining the antiradical activity of samples with a high content of anthocyanins, the question arises as to whether this fact will significantly affect the results of the determination, respectively how to adjust the method so that this problem does not occur. This is due to the intensive red to reddish-purple colour of anthocyanins, which give an intense coloration in alcohol extracts **(Apak et al., 2007)**. Several authors report the results of the assay as a measure of the reduction in DPPH staining intensity relative to a blank sample, which is a DPPH solution at the same dilution as the sample reaction mixture with DPPH **(Chang et al., 2001; Lachman et al., 2006; Vollmannová et al. 2013)**. Other authors calculate the results not relative to the blank sample, but on the initial absorbance of each DPPH reaction mixture with the sample separately **(Dawidowicz, Wianowska, and Olszowy, 2012)**, which requires more time and routine measurement, but can eliminate the problem with coloured samples. To determine the possible effect of staining the sample extract on the final result, the different fruits were analysed which gave a red-coloured alcohol extract with different shades of colour using the two methods of measurement. The results of the analyses are shown in Table 1.

After testing the hypothesis at the significance level $\alpha = 0.05$:

H_0: $\bar{x}_A = \bar{x}_B$ against the alternative

H_1: $\bar{x}_A \neq \bar{x}_B$ was found:

that after the analysis of red-coloured fruit extracts containing red-purple plant colorants (Table 1) we accept the zero hypothesis ($t_{cal.} < t_{crit.}$), thus there is no statistically significant difference between the mean ARA values obtained by two method modifications. In practice, this means that the analyses can be safely performed by correlating the results of the measured absorbance of the samples with the value of the blank, which in laboratory practice is a simpler variant. After examining the agreement of the averages, the evaluation by the Yoden graph method was also proceeded. The Yoden method statistically evaluates the equivalence of the results obtained by both adjustments over the full range of ARA values obtained. The result of the graphical analysis is shown in Figure 2.

Table 1 Antiradical activity value of samples containing red colorants measured by two method modifications.

Fruits	ARA [%/g]	
	A_{0sl}	A_0
Sour cherry 1	810	795
Sour cherry 2	750	759
Raspberry 1	547	590
Raspberry 2	440	425
Black currant	1130	1190
Red currant	544	553
Black mulberry 1	638	817
Black mulberry 2	785	817
Josta 1	646	593
Josta 2	559	677
Red greengage 1	114	76
Red greengage 2	102	88
Blueberry 1	509	465
Blueberry 2	463	423
Cherry plum 1	126	119
Cherry plum 2	116	103
Average	517	530
SD	283	309
	***t*-statistic**	
$t_{cal.}$	0.828	
$t_{crit.}$	2.131	
Degrees of freedom	27	

Note: A_0 – ARA calculated on the initial absorbance of each DPPH reaction mixture with the sample; A_{0sl} – ARA calculated on the blank absorbance value; ***SD*** – standard deviation; *t*-statistic: t_{cal} – calculated value; $t_{crit.}$ – critical value.

The graphical presentation of the results of the analyses with both modifications of the method shows that the results obtained by both modifications of the method give a regression line that is almost identical to the ideal course of the regression line. Thus, the graphic assessment does not point to the possibility of a proportional error.

The demonstration of the existence of a proportional error was based on estimates of the parameters $\beta 1$ and $\beta 2$. Linear regression dependence parameter estimates are:
Estimation of the slope of the regression line, b_1 is 1.015,
Regression line offset estimate, b_2 is -8.166,
Coefficient of determination, R^2 is 0.962,
The number of parallel analyses, n_A, and n_B, was 44.

By solving relations (4) and (5) we found out when the estimate of the guideline b_1 can be considered equal to 1 and the estimate of the displacement b_2 equal to 0. Since in practice we always work with a certain variance of the tested parameters, in our case the confident areas are important, in which the values of β_1 and β_2 lie with the chosen significance level $\alpha = 0.05$. The limits of the regression line parameters β_1 and β_2 are:
Lower limitation of the regression line, $\beta_{1\min.}$ is 0.950,
Upper limitation of the slope of the regression line, $\beta_{1\max.}$ is 1.079,
Lower limitation of the regression line offset, $\beta_{2\min.}$ is -34.813,
Upper r limitation of the regression line offset, $\beta_{2\max.}$ is 18.481.

The results obtained show that the calculated interval for the offset β_2 also includes zero, so the segment b_2 cannot be considered significantly different from zero. Similarly, the calculated interval for β_1 includes one, so the estimate of slope b_1 cannot be considered significantly different from one. For our case, this means that there is no statistically significant difference between the compared method modifications under the conditions described and the concentration range of the assay. In practice, this means that coloured fruit extracts do not affect the result of the analysis simply because of their colour. This can be explained by the fact that the anthocyanin colours that are reddish carriers are also important antioxidants. They can quench free DPPH radicals and thus stain themselves.

Effect of fruit components on ARA

It was assumed that the value of antiradical activity will be influenced by several fruit substances. Therefore, it was considered a complicated mechanism when monitoring. Since various phenolic compounds as well as ascorbic acid are present in fruits, the ultimate effect was likely the result of their interactions.

Effect of ascorbic acid on ARA

Ascorbic acid is present in various fruit species and its content is at different concentrations. It is capable of quenching free DPPH radicals. It is sometimes used as an equivalent to express the antiradical activity of a sample **(Du Toit, Volsteedt and Apostolides, 2001)**. The influence of ascorbic acid on the determined ARA value was investigated on the example of analysed fruits. The results of the analyses are shown in Figure 3 as the dependence of ARA on the determined amount of ascorbic acid in all samples analysed, ie. samples containing and without red plant colorants.

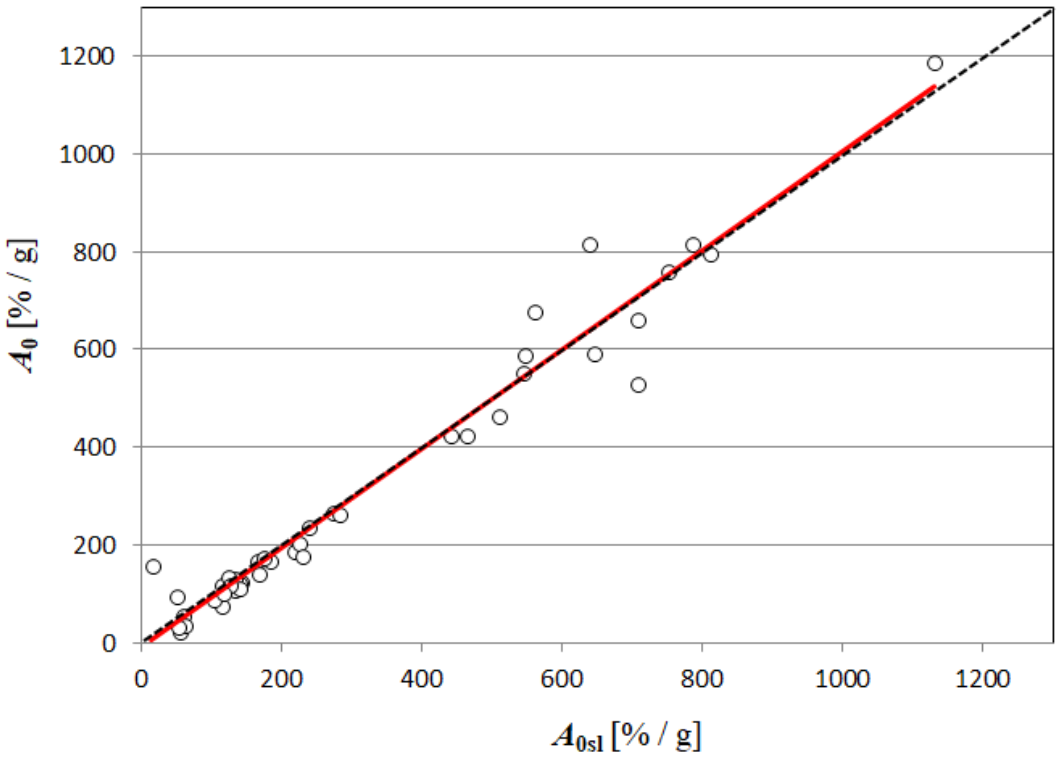

Figure 2 Graphical evaluation of the determined ARA values.
Noter. ARA values calculated on the blank absorbance value (A_{0s1}) and the compared ARA values calculated on the initial absorbance of each DPPH reaction mixture with the sample (A_0). ------- ideal regression line with zero offset and unit slope; ——— regression line calculated from the determined ARA values.

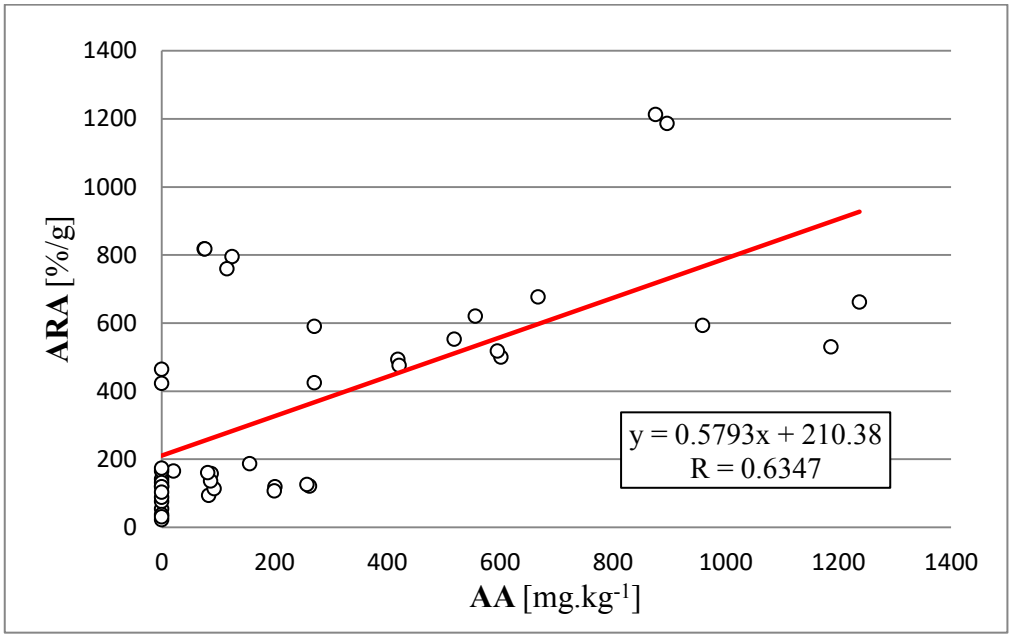

Figure 3 Dependence of the determined antiradical activity (ARA) value on the L-ascorbic acid (AA) content for all samples analysed.

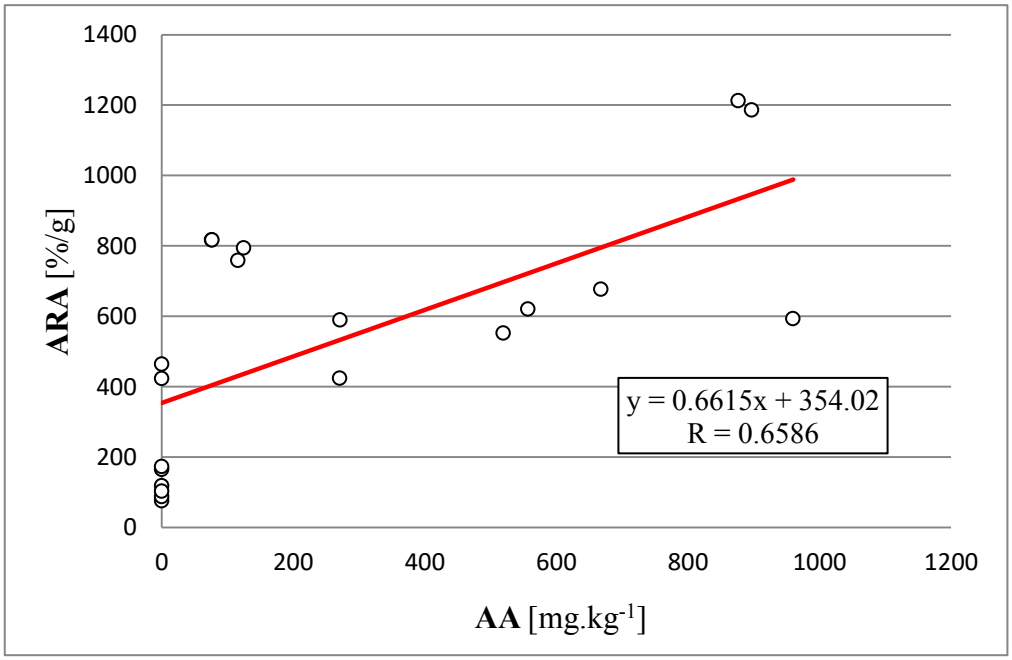

Figure 4 Dependence of the determined antiradical activity (ARA) value on L-ascorbic acid (AA) content for samples containing red plant colorants.

The correlation dependence between monitored values was searched from the analysed data. It was assumed that the higher the content of ascorbic acid, the more it would show its antioxidant properties, thus the higher the ARA value. Data analysis for all analysed samples shows that the calculated correlation coefficient is 0.6347, indicating a slight correlation between the ascorbic acid content and the corresponding ARA value.

Based on the fact that in addition to ascorbic acid, many other substances, among them red anthocyanin colorants affect the ARA value, the analysed samples were divided into two groups for further investigation of this dependence. In one group, samples with a red-coloured extract from the presence of anthocyanin colorants were included. In the second group were sampled with extract without red plant colorants. Figure 4 shows the dependence of the value determined by ARA on the content of L-ascorbic acid (AA) for red-coloured sample extracts.

The analysis data shows that the calculated correlation coefficient is 0.6586. As in the case of all samples, it shows a slight correlation between the ascorbic acid content and the corresponding ARA value.

The correlation dependence of ARA on the content of ascorbic acid for samples with extract without red colorants is shown in Figure 5.

Analysis of the data for samples with no colorant extract shows that the calculated correlation coefficient is 0.9038. This indicates a strong correlation between the ascorbic acid content and the corresponding ARA value. Based on the correlation dependencies observed, ascorbic acid is the predominant antioxidant component for samples containing no anthocyanin colorants. When investigating the antiradical activity of small kinds of fruits **Jakobek and Seruga (2012)** also found the significant antiradical potential of ascorbic acid, which was weaker than the potential of some polyphenols. **Hegedűs et al. (2010)** also found a correlation between antiradical activity and ascorbic acid in apricot, but the correlation relationship was weaker than for polyphenols.

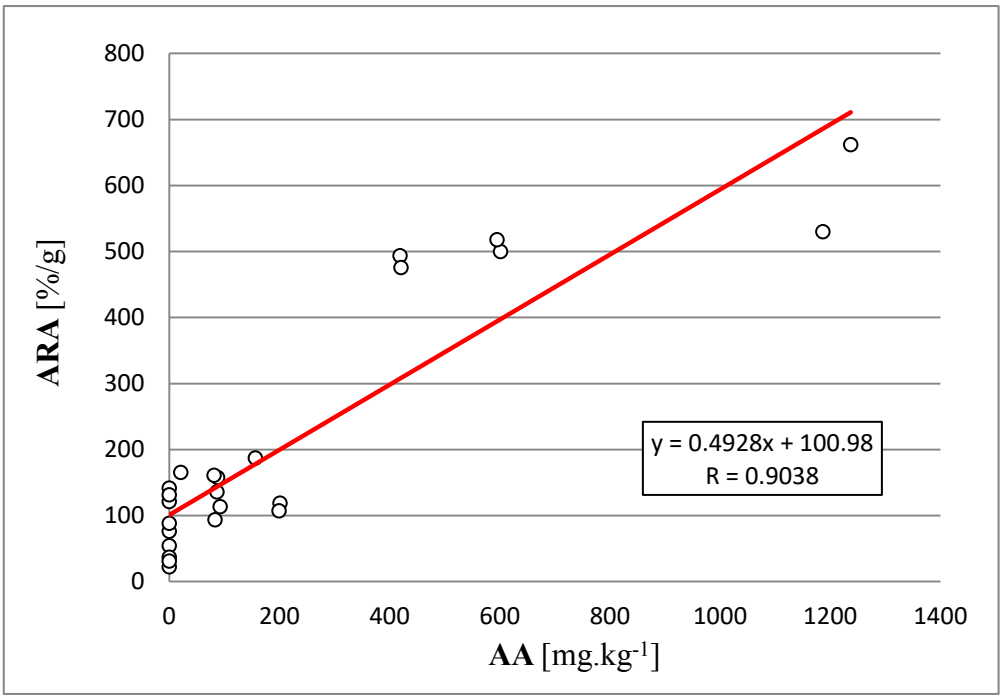

Figure 5 Dependence of the determined antiradical activity (ARA) value on the L-ascorbic acid (AA) content for extracts without red plant colorants.

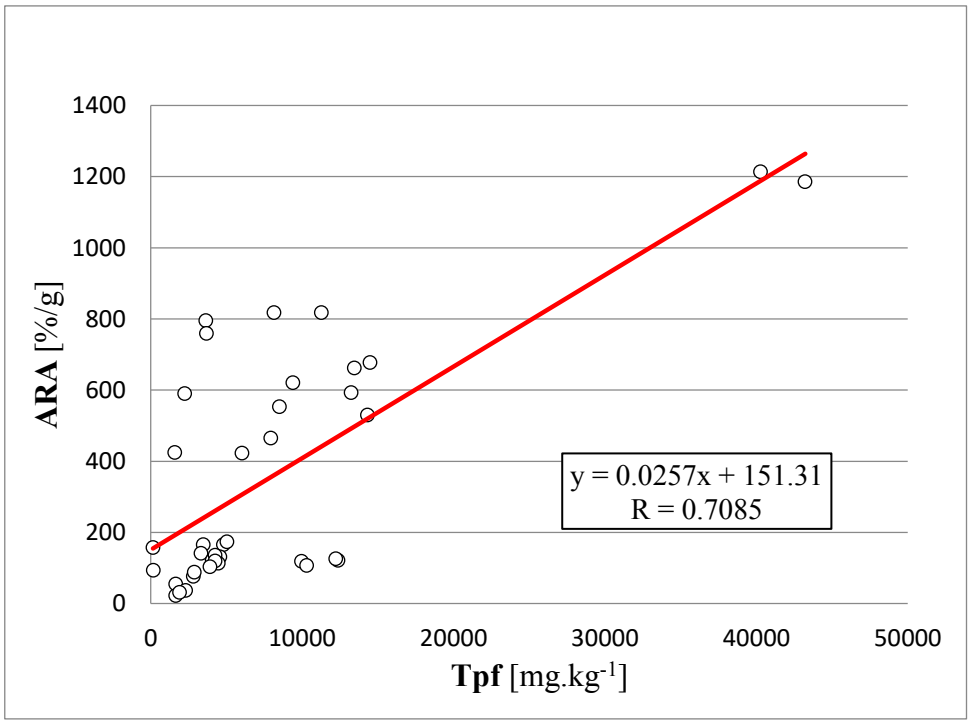

Figure 6 Dependence of the determined antiradical activity (ARA) on the total phenol content (Tph) for all samples analysed.

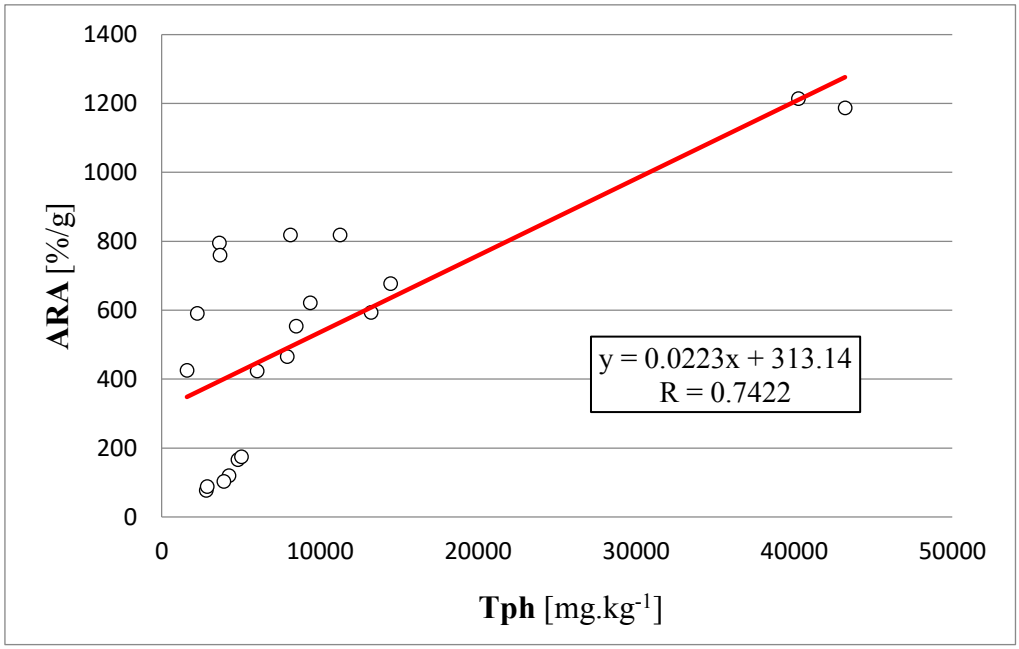

Figure 7 Dependence of determined antiradical activity (ARA) value on the total phenol content (Tph) for samples stained red.

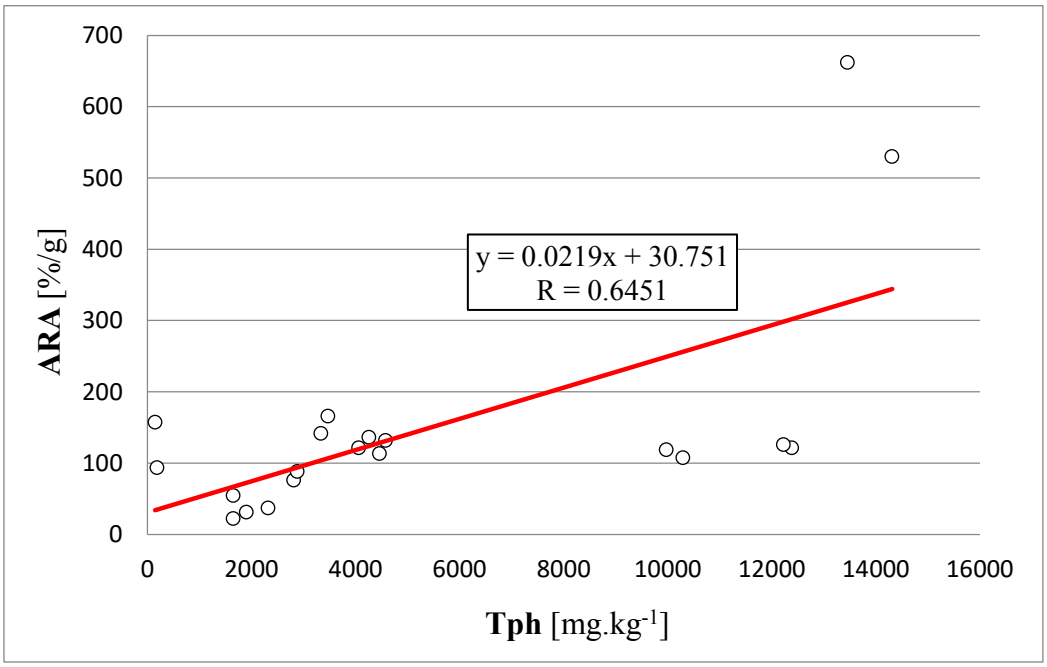

Figure 8 Dependence of determined antiradical activity (ARA) value on the total phenol content (Tph) for samples without the presence of red colorants.

Effect of total phenols on ARA

Another group of substances with antioxidant properties, we have studied due to their proven effect of ARA are phenolic compounds. These compounds are present in fruits as a large group of flavonoids, including a large number of flavonols, flavones, catechins, flavanones, anthocyanidins, and isoflavonoids. They are characterized by strong antioxidant effects, similarly, like ascorbic acid, they quench free DPPH radicals. The effect of total phenols on ARA based on our analysis is shown in Figure 6.

Based on the correlation analysis, the results show a strong correlation between the polyphenol content and the corresponding ARA value (correlation coefficient value is 0.7085). Given the wide variety of phenolic compounds, it is understandable that this results in a milder correlation dependency than that of ascorbic acid.

To obtain more detailed information on the effect of phenolic compounds that carry red colouring of the fruit (anthocyanin colorant group), samples containing these compounds were removed from the study and subjected to further analysis. The results are shown in Figure 7.

Based on the regression analysis of the results shown in Figure 7, it is evident that in the case of red-coloured fruits, the strength of the dependence of the ARA on the total phenol content does not differ significantly from that observed for all samples analysed together.

It was expected a significant difference in dependence by comparing the group of red-coloured fruits to the group of red colorants free fruits. Dependence results for fruit species without red plant colorants are shown in Figure 8.

Comparing the results of the correlation analysis for fruit species with and without red colorants, it is clear that the correlation coefficient value for red fruits is higher than for the group of fruits without red colorants (0.7422 vs. 0.6451). The anthocyanin colorants present have a greater influence on the ARA value and indicate a strong correlation dependence.

Similar results were obtained by **Jakobek and Seruga (2012)** when monitoring the effect of total phenols on ARA in small kinds of fruits. They found a strong correlation between the total phenol content and ARA, while the greatest effect on ARA values was found for anthocyanins.

A significant effect of phenols on the antioxidant activity is also described by **Gramza-Michałowska and Człapka-Matyasik (2011)**. They observed the highest levels of antioxidant activity in the aronia, which contained the most polyphenols and anthocyanins when considering the different fruit species. A high correlation between polyphenols and ARA has also been shown by other authors **(Jakobek et al., 2007; Hegedűs et al., 2010; Rinaldi et al., 2013)**.

CONCLUSION

Statistical evaluation of the results of the analyses by Youden's graph method revealed that the analysed extracts of red fruit species, although absorbing the light used at 517 nm as a DPPH free radical solution, did not affect the final ARA value determined. This means that coloured fruit extracts do not affect the result of the analysis by this method due to their colour. Investigation of the effect of the evaluated fruit compounds revealed a strong correlation between the content of ascorbic acid and ARA in samples containing no red plant colorants. For samples containing red colorants, the correlation was slight. The opposite trend was found in the case of fruit species with the presence of red colorants. It was proven a strong dependence of ARA on the total phenol content.

METHODS FOR DETERMINING THE BOTANICAL ORIGIN OF HONEY

Leonora Adamchuk, Vladyslav Sukhenko, Oleksandra Akulonok, Tetiana Bilotserkivets, Volodymyr Vyshniak, Dina Lisohurska, Olha Lisohurska, Natalia Slobodyanyuk, Olga Shanina, Ivan Galyasnyj

ABSTRACT

The demand for monofloral, original, and special (functional) kinds of honey, or those with geographical indication, is forecast. At the same time, there is a need to improve the methods for determining the botanical and geographical origin of honey. The purpose of the research was to select and apply a variety of techniques for identifying the botanical origin of honey for its correspondence to acacia species. Samples of honey from the Kyiv, Odesa, and Dnipro regions extracted in the spring and summer period were used in the research. Organoleptic, physicochemical, NMR spectrometry, and advanced melissopalynology methods were applied. The tests were carried out at the laboratories of the Department of Certification and Standardization of Agricultural Products, NULES, Ukraine; the Ukrainian Laboratory of Quality and Safety of Agricultural Products; and the Bruker BioSpin GmbH company (Germany). According to the research results, the requirements for acacia honey were met by the organoleptic method for samples B1 and B2; by the physicochemical method for A0 and A2; by NMR spectroscopy for not a single sample, all being assessed as polyfloral; and by pollen analysis for B1 and B2. The conducted studies confirm the need for a comprehensive approach to the identification of the botanical origin of honey for its conformity to acacia species. There is a need to review the physicochemical indicators for the compliance of honey with the acacia species obtained in Ukraine. After all, even the modern NMR spectrometry technique indicated that the specially fabricated sample that did not contain acacia pollen grains was acacia honey. Identification of the botanical origin of monofloral honey, in particular acacia, should be carried out in the following sequence: pollen analysis (by dominant pollen grains), safety (presence of antibiotics, pesticides), physicochemical parameters according to international requirements, organoleptic parameters.

Keywords: acacia honey; evaluation; method; NMR spectrometry

INTRODUCTION

According to **Global Industry Analysts Inc. USA (2016)**, the global honey market is projected to reach 2.4 million tonnes by 2022. **Carreck (2018)** believes that much of this growth is due to the demand for monofloral and special (functional) kinds of honey, or those that have a specific geographical region of origin. That is the relevance of our research, along with the improvement of the methods for determining the botanical and geographical origin of honey, methods of analysis and discrimination of individual varieties of product, its safety, and quality.

At the moment, the current regulatory and technical documentation in different countries of the world governing the safety and quality of honey is not harmonized. There are differences between European legislation and Codex Alimentarius standards. Also, different countries maintain up-to-date quality criteria that do not comply with the Codex or EU directives on honey. The necessity to establish national requirements for each country (harmonized with international ones) is mainly due to the lack of provisions regarding the physicochemical characteristics of monofloral honey and the declaration of its geographical origin **(Thrasyvoulou et al., 2018)**.

There are currently two documents in Ukraine governing the safety and quality of honey, **DSTU 4497:2005 (2007)** and **Nakaz MinAPK No. 330 (2019)**. Therefore, the search for methods that allow the main botanical varieties and geographical species of Ukrainian honey to be studied is a relevant area for analysis and subsequent research.

It has been established **(Ulloa et al., 2013; Lenhardt et al., 2015; Machado De-Melo et al., 2018; Maione, Barbosa and Barbosa, 2019)** that the organoleptic and physicochemical characteristics of honey vary depending on botanical and geographical origin, as well as climatic conditions, processing and storage. And other bee products as well **(Ivanišová et al., 2015)**.

It is relevant to use honey as a biomarker to collect environmental information, identify sources of environmental contamination and assess soil, water and air pollution **(Machado De-Melo et al., 2018)**. One of the first and most common methods of determining the botanical origin of honey is melissopalynology, that is, a microscopic analysis of the pollen contained in honey shows the nectar content of certain plants.

Maione, Barbosa and Barbosa (2019) consider that it is still used as one of the most accurate methods for qualitative or quantitative analysis of the content of pollen grains in honey. Along with this, there are several modern techniques. The botanical origin of honey is identified by PARAFAC (parallel factor) analysis of excitation emission matrix fluorescence spectra **(Lenhardt et al., 2015)**. Emissions of phenolic compounds and Maillard reaction products reveal the greatest difference among honey varieties of different botanical origin. Falsified honey samples with 100% sensitivity to variety compliance can be detected using the partial least squares discriminant analysis (PLSDA) classification model based on PARAFAC models. Among the honey samples tested, PLSDA identifies linden with a difference of 0.5%, acacia with 10%, and sunflower and polyfloral meadow honey with differences of about 20% compared to the results of pollen analysis. The disadvantage of the method is the large discrepancy between the results obtained even within the same honey variety, which indicates the need for its improvement.

Soares et al. (2015) proposed the use of DNA-based methods for the identification of botanical honey species. For this, five DNA extraction methods were used (NucleoSpin Plant Kit (methods A and B) and DNeasy Plant Mini Kit, as well as internal CTAB and Wizard-based methods). The results demonstrated that the Wizard method had the best performance in terms of DNA quality. The disadvantages of DNA-based methods are their cost and unsuitability to industrial conditions of use.

Today, the use of analytical methods is becoming widespread. Mainly, this concerns nuclear magnetic resonance (NMR) spectroscopy for the authentication of honey (botanical and geographical origin).

Siddiqui et al. (2017) consider NMR spectroscopy to be sufficiently powerful and accurate, and therefore suitable for creating prints for honey of different origin for their further comparison. In Romania, studies on stable isotopes, selected as representative discrimination parameters of different botanical or geographical origin of honey, have been conducted using isotope ratio mass spectrometry (IRMS) and site-specific natural isotope fractionation measured by nuclear magnetic resonance (SNIF-NMR) methods. The authors **(Dinca et al., 2015)** confirmed the high efficiency of the method but emphasized the need to create an informative base for prints of honey of different botanical origin.

Gok et al. (2015) established the predictive ability of Fourier transform infrared (FTIR) spectroscopy and chemometrics to determine the botanical composition of honey. **Cozzolino, Corbella and Smyth (2011)** proposed spectroscopic methods in the infrared (IR) wavelength range of the electromagnetic spectrum to evaluate and control the composition of honey. The use of IR spectroscopic technologies has its place in the determination of the botanical origin of honey by comparing the spectra of the mid-infrared (MIR) spectrum.

Etzold and Lichtenberg-Kraag (2008) used the most common types of honey for calibration, and classification models were obtained by calibration of principal components analysis (PCA) and properly graded FTIR concerning the physicochemical and sensory properties of the selected samples.

To improve honey discrimination, **Corvucci et al. (2015)** proposed the use of FT-micromanaging spectrography and multivariate analysis. At the same time, successful results using the PCA model have also been achieved by other authors. This method is currently being refined and enhanced.

Modern sensory methods include the use of an electronic nose (e-nose) in multivariate analysis and selection of sensors to detect the botanical origin and determine honey quality. **Huang et al. (2015)** first implemented three sensor selection algorithms, namely, uninformation variable elimination (UVE), successive projections algorithm (SPA) and competitive adaptive reweighted sampling (CARS), which were applied to analyse the e-nose fingerprints of honey. Three different sampling modes were tested for the classification of monofloral honey: static headspace sampling (SHS), solid-phase microextraction (SPME) and inside needle dynamic extraction (INDEX). The last two showed better ability to remove volatile components. In subsequent experiments, preference was given to the SPME sampling mode, which proved to be more accurate.

Ampuero, Bogdanov and Bosset (2004) found a positive correlation between e-nose and pollen analysis of honey. Discriminant function analysis (DFA) was also conducted using an e-nose based on a mass spectrometer when the DFA diagram indicated a significant separation of honey odours from other odour sources **(Hong et al., 2011)**. Thus, the e-nose method can be used to identify honey but needs further refinement.

Ulloa et al. (2013) investigated a method for determining the botanical origin of honey using sensory synthesis of impedance electronic language (e-language) and optical spectroscopy (UV-Vis-NIR), namely, PCA and cluster analysis (CA).

In 2016, the mathematical method for identifying honey was first described. **Gan et al. (2016)** considered the use of PLSDA, a support vector model (SVM), and an interval partial least squares model (iPLS). The results showed that the spectra and sensors classified the botanical origin of honey quickly and accurately, and the overall accuracy for the calibration and forecasting set was 100% for e-nose and electronic tongue (ET) analysis using the SVM model and near-infrared (NIR) and MIR analysis using the iPLS model. At the same time, overall accuracy for calibration and forecasting sets was above 96% in PLSDA NIR, MIR and ET models. The results showed that ET is more suitable for detecting botanical falsification of honey. However, there is a need to create calibration and forecasting sets for each sample of honey produced in the world. This makes it impossible to use this method in practice.

Son et al. (2019) investigated whether the zymography of nectar chitinases is a potential marker for determining or validating the botanical origin of honey. However,

zymography is the first examination of the activity of nectar enzyme in honey. This method is also being refined.

Chekryga, Niczievskaya and Borodaj (2019) have proposed a method for determining the botanical origin of honey, which is to use a natural drop of a honey sample without pre-treatment. According to the authors, the advantage of the proposed method over others is that when using it there is no deformation of pollen grains, which are in a natural state, including their spatial location. However, the proposed method casts doubt on the quantitative evaluation of pollen grains and the reliability of the analysis results due to the uneven arrangement of grains of different weights in the thickness of honey.

Sensory data obtained from ET and e-nose histograms of honey colour show a high discriminatory ability to determine the origin of honey. Therefore, many authors **(Machado De-Melo et al., 2018; Pascual-Maté et al., 2018)** believe that PCA, discriminant analysis (DA) and CA are the best methods for performing the experimental and predictive method for determining the origin of honey. PCA and DA continue to be favoured due to their ease of application and interpretation, while machine learning algorithms are more complex for modelling and the use of classifiers. Nevertheless, the use of both machine learning algorithms and PCA-DA models have achieved excellent results for discrimination of the origin of honey. Finally, a common trend is the use of hybrid methods that combine multivariate analysis of data and methods **(Peng Kek et al., 2017; Machado De-Melo et al., 2018; Pascual-Maté et al., 2018)**.

Ballabio et al. (2018) performed a comparative evaluation of methods for determining the botanical origin of honey. Thus, IR, NIR, Raman spectroscopy, PTR-ToF-MS and e-nose methods were applied to samples of common botanical varieties of honey. The best results were obtained with the synthesis of the NIR method and Raman spectroscopy, as well as PTR-ToF-MS. The accuracy of the final model was 99% on the test specimens and 100% on the calibration.

In Ukraine, due to a lack of the necessary equipment, only various pollen analysis techniques are used to identify the origin of honey. Therefore, the purpose of our work was to select and apply a variety of techniques to identify the botanical origin of honey for its correspondence to acacia variety.

Scientific hypothesis

According to many scientists, modern methods of researching honey can replace the classical methods of determining its botanical origin, such as pollen analysis and organoleptic evaluation. In studies, we expect to refute the view that NMR spectroscopy allows determination of the falsification of acacia honey without the use of melissopalynological research, provided that the geographical origin of the honey is not known.

As a result, one of the samples was falsified in a sophisticated manner and NMR spectroscopy did not reveal this. Also, two specimens were identified as acacia monofloral honey by pollen and organoleptic analyses. Instead, NMR spectroscopy showed that one of these samples did not meet the requirements for acacia honey by physicochemical parameters.

MATERIAL AND METHODOLOGY

Biological material

The research used honey samples obtained from the Kyiv, Odesa and Dnipro regions obtained in the spring and summer that could be realized on the market as acacia. Honey from bees was collected in March – May 2018. The samples were stored in glass containers at +15 to +20 °C away from sunlight until the start of the research in August 2018.

Honey samples

Sample A0 was obtained from nectar mixed with sugar syrup by bees (stored in the fall), which they processed into honey, put in cells and sealed; the sample was obtained from bees in the form of honey in March 2018 (Kyiv region). A1 – honey centrifuged from bee honeycombs in May 2018 (Kyiv region); A2 – in June 2018 (Kyiv region); B1 – in May 2018 (Odesa region); B2 – May 2018 (Dnipro region). Acacia bloom in Ukraine is due in May.

Organoleptic analysis

The analysis was conducted at the laboratories of the Department of Certification and Standardization of Agricultural Products, National University of Life and Environmental Sciences (NULES) of Ukraine, with the use of the methodology and requirements specified according to **DSTU 4497:2005 (2007)**.

Physicochemical analysis

The analysis was conducted at the Ukrainian Laboratory of Quality and Safety of Agricultural Products.

Chemicals

All chemicals were of analytical grade and were purchased from LLC "NVP"ALFARUS" (UA).

Mass fraction of water

The mass fraction of water was determined on an LR-01 laboratory refractometer (Maselli Misure s.p.a., Italy) using a standardized technique according to **DSTU 4497:2005 (2007)**.

Hydroxymethylfurfural, diastasis and proline

Hydroxymethylfurfural, diastasis and proline were investigated with a KFC-3 photocalorimeter (Russia) using standardized methods according to **DSTU 4497:2005 (2007)**. All the techniques have been pre-elaborated and described in detail for acacia honey of different geographical origin **(Adamchuk, Suchenko and Akulonok, 2019)**.

NMR spectrometry

The analysis was carried out at the laboratories of Bruker BioSpin GmbH **(Bruker, 2020)** (Germany) using Avance Neo and Benchtop NMR Fourier 80 devices (Germany) and a technique which allows the acquisition of a fingerprint to confirm the authenticity of the product or reveal adulteration by addition of sweetener **(Schievano et al., 2020)**. All NMR samples were prepared by dissolving ~240 mg honey in phosphate buffer solution (KH_2PO_4 in

D_2O), adjusting the honey (mg)/buffer (mL) ratio to exactly 240 mg.mL^{-1}. The pD was carefully adjusted from 133 to 4.40.

Botanical origin

Botanical origin was determined according to the adapted harmonized methods of melissopalynology **(Von Der Ohe et al., 2004)** using a Sigeta Biogenic Led Trino Infinity microscope (China) with 400× and 2000× magnification based in the laboratories of the Department of Certification and Standardization of Agricultural Products, NULES of Ukraine with the use of **DSTU 4497:2005 (2007)**. Identification of plants was carried out according to the methodology and experience of the team of the international network AgroBio*Net* **(Brindza et al., 2018)**.

Statistical analysis

Basic statistical analysis was carried out using SAS programming packages (SAS System V9.2). Correlation coefficients were calculated by CORR analysis **(SAS, 2009)**.

RESULTS AND DISCUSSION

In organoleptic research on honey for compliance with acacia variety requirements, evaluations were made by colour, taste, aroma, consistency, crystallization and the presence of signs of fermentation and mechanical impurities. The results of the organoleptic research are shown in Table 1.

According to the results of the organoleptic evaluation, only samples B1 and B2 met the requirements for acacia honey. Sample A0 had the lowest compliance (14%).

Among the physicochemical indicators were those that indicate the naturalness and enzymatic activity of honey – diastase number, and proline and hydroxymethylfurfural content. Also, they have values that are different from other honey varieties. The results are shown in Table 2.

According to the conducted studies, in terms of the mass fraction of water, hydroxymethylfurfural and diastasis number, all tested honey samples met the requirements. The highest proline content was found in the falsified sample A0 – 483.7 ±0.36 mg.kg^{-1}, which is 76% and 54% higher than the other samples from Kyiv region, which did not correlate with acacia varieties by organoleptic indicators; and 71% higher than the honey samples that corresponded to acacia species in organoleptic indicators (B1 and B2).

In general, according to the physicochemical parameters investigated, samples A0 and A2 corresponded to the requirements of **DSTU 4497:2005 (2007)** for acacia honey. At the same time, according to the requirements of another current regulatory document, which is used today for the circulation of the product in the country and its export, all the research samples met the established criteria.

Thus, according to the results of honey studies, which were carried out by standardized methods, the data obtained differed by organoleptic and physicochemical parameters in accordance with the acacia variety. By the latter, two samples, one of which was a pre-prepared falsification (A0), fully met the requirements for acacia honey compliance. This speaks about the need to review complex methods of evaluating honey to identify it as an acacia variety.

Table 1 Organoleptic honey research.

No.	Indicator		Honey sample				
	Name	Characteristic	A0	A1	A2	B1	B2
1.	Color	Colorless, light yellow, transparent	–	–	–	+	+
2.	Crystallization	Absent	–	+	+	+	+
3.	Signs of fermentation	Prohibited	–	–	–	+	+
4.	Taste	Sweet, delicate, without any foreign flavors	–	–	–	+	+
5.	Aroma	Very weak, no odours	–	–	–	+	+
6.	Consistency (liquid)	A small amount of honey is left on the spatula, which quickly drains into small drops	–	+	–	+	+
7.	Mechanical impurities	Prohibited	+	+	+	+	+
Compliance with acacia honey variety, %			14	43	29	100	100

Note: (+) – meets the requirements for acacia honey; (–) – does not meet the requirements for acacia honey.

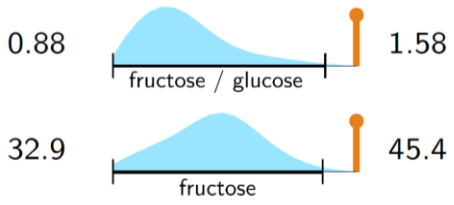

Figure 1 Discrepancy between the honey profile of sample B1 and the reference NMR database.

The next step was the evaluation of honey samples using a modern NMR spectroscopy technique that is widely used in internationally accredited laboratories. Its core consists of the complex analysis of physicochemical parameters, on the basis of which the profile of the honey is programmatically constructed and its botanical origin determined. NMR spectroscopy of honey made it possible to analyse 12 indicators for sugar, including the ratio of fructose to glucose (Table 3).

According to our data, the ratio of fructose to glucose (FG) ranged from 1.30 to 1.68. According to studies of the acacia honey profile by other scientists **(Marghitas et al., 2010)**, it is known that the FG index ranges from 1.43 to 1.57 (the content of acacia pollen grains in honey was in the range from 20.0% to 30.2%). According to other data **(Oddo et al., 2004)**, the highest average FG value for acacia honey from Europe is 1.61 (715 samples tested). At the same time, honey from Ukraine is accepted for export as acacia if FG is more than 1.5.

According to **Marghitas et al. (2010)** and **Schievano et al. (2020)**, sucrose and maltose content may also indicate botanical origin. Thus, for acacia honey, **Marghitas et al. (2010)** found that the sucrose content in acacia varieties ranged from 0.59 to 2.50 g.100g^{-1}, and the maltose content from 2.31 to 3.07 g.100g^{-1}. In addition, **Nakaz MinAPK No. 330** allows a sucrose content of not more than 10 g.100g^{-1}, and maltose is not specified. Thus, for sucrose, the honey we studied met the requirements for acacia variety compliance. The presence of sugars other than those listed in Table 3 was investigated, but their quantitative values were beyond the limit of determination. Among these were melezitose (limit of determination – 1 g.100g^{-1}), maltotriose (1 g.100g^{-1}), gentiobiose (0.3 g.100g^{-1}) and mannose (0.05 g.100g^{-1}).

The Honey-Profiling^{TM} profile was built from the set of indicators using software for NMR spectroscopy (Table 4).

Honey-Profiling^{TM} indicates a deviation from the norm for certain indicators. The profile of honey sample B1 contains red marks, which indicates the need for a more detailed analysis of individual indicators for this honey sample or re-analysis with NMR spectrometry (Figure 1).

If a negative result is obtained again, such samples are considered falsified. **Schievano et al. (2020)** recommend further CSSF-TOCSY experiments for refining the analysis to detect the sugar profile of honey and its falsification with sugar. According to their latest results, the level of fructose in the honey of European origin ranges from 36.7 to 49.4 g.100g^{-1}, which coincides with our results. NMR spectroscopy allows analysis of the acid composition of honey (Table 5).

Table 5 Acid NMR spectroscopy, mg.kg^{-1}.

		Basic criteria				
No.	**Organic acids:**	**A0**	**A1**	**A2**	**B1**	**B2**
1.	Citric acid	79	71	61	72	58
	Amino acids:	**A0**	**A1**	**A2**	**B1**	**B2**
2.	Alanine	11	7	8	<LOQ	8
3.	Proline	560	318	694	248	307
4.	Valine	11			<LOQ	
	Additional parameters of fermentation, processing and origin					
5.	Acetic acid	14	18	15	11	<LOQ
6.	Ethanol	21	6		<LOQ	
7.	Lactic acid	41	13	55	<LOQ	11
8.	Formic acid	25	27	50	10	21
9.	Pyruvic acid	15	<LOQ	21		<LOQ
10.	Succinic acid	17	7	21	5	7

Note: <LOQ – below the limit of quantification.

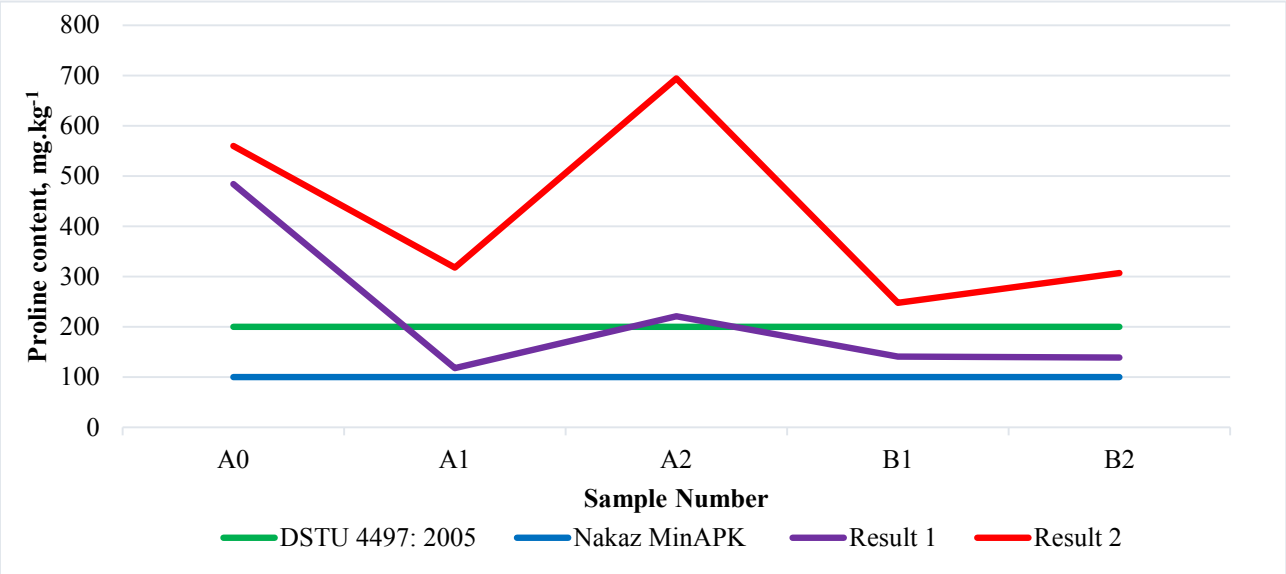

Figure 2 Proline in the investigated honey samples, mg.kg^{-1}: result 1 – by the method standardized according to **DSTU 4497:2005** "Natural honey. Specifications"; result 2 – by NMR spectrometry.

Among organic acids, citric acid was found in the range from 58 to 79 mg.kg^{-1}; malic (limit of detection – 100 mg.kg^{-1}) and quinic acids (300 mg.kg^{-1}) were beyond the limit of quantification qualification. High proline content was characteristic of all samples tested. The highest was found in sample A2 – 694 mg.kg^{-1}. In general, the results from proline studies differed from those obtained using standardized techniques. Some of the amino acids were beyond quantification, namely aspartic acid (detection limit – 150 mg.kg^{-1}), glutamine (200 mg.kg^{-1}), leucine (40 mg.kg^{-1}), tyrosine (50 mg.kg^{-1}) and phenylalanine (100 mg.kg^{-1}).

A comparison of the proline indicator results obtained according to the requirements of **DSTU 4497:2005 (2007)** and the criteria for the honey composition according to **Nakaz MinAPK No. 330 (2019)** is shown in Figure 2.

In addition, special substance markers are used to identify honey from individual geographical regions. For example, for manuka honey (New Zealand), it is methylglyoxal. The markers in the test specimens were beyond quantification, namely 3-phenyl lactic acid (quantification limit – 300 mg.kg^{-1}), dihydroxyacetone (20 mg.kg^{-1}), kynuric acid (60 mg.kg^{-1}), methylglyoxal (30 mg.kg^{-1}) and shikimic acid (80 mg.kg^{-1}).

Thus, NMR spectrometry makes it impossible to determine honey as regional (geographical definition of honey from Ukraine).

Also, additional indicators were used to control the parameters of fermentation, processing and origin (Table 5). Among these, acetic acid was detected in four test specimens, ranging from 11 to 14 mg.kg^{-1}; ethanol in two – from 6 to 21 mg.kg^{-1}; lactic acid in four – from 11 to 55 mg.kg^{-1}; formic acid in all samples in the range from 10 to 50 mg.kg^{-1}; pyruvic acid in two – from 15 to 20 mg.kg^{-1}; and succinic acid in all samples – from 5 to 21 mg.kg^{-1}. Other substances were beyond detection, namely 2,3-butanediol (detection limit – 20 mg.kg^{-1}), 5-hydroxymethylfurfural (5 mg.kg^{-1}), acetoin (20 mg.kg^{-1}) and fumaric acid (5 mg.kg^{-1}). All of them give an opportunity to evaluate the safety and quality of honey in terms of physicochemical composition, but do not give an understanding of its botanical origin.

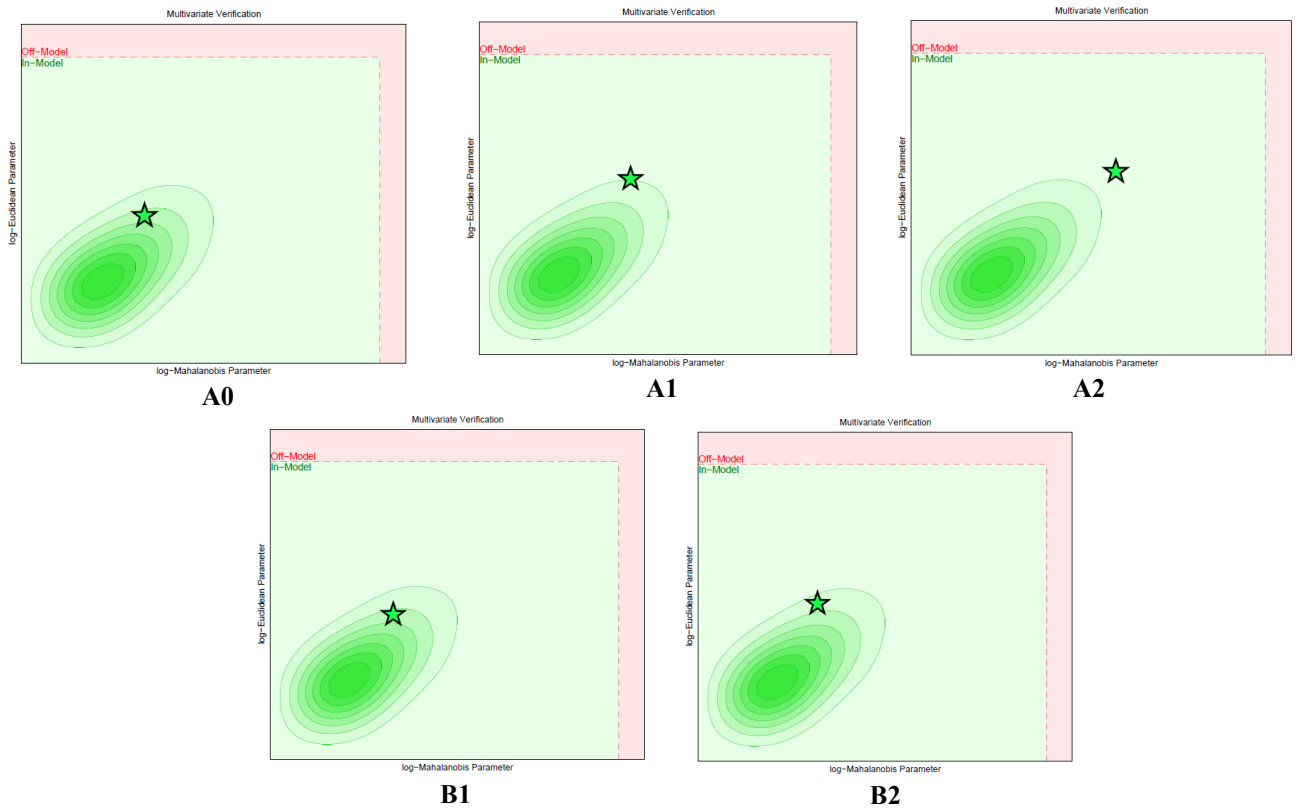

Figure 3 Multivariate verification models of investigated honey.

Upon completion of the test, software verification analysis was applied and graphical models of the studied honey samples were automatically constructed (Figure 3).

Displaying the results in the form of multivariate verification models gives us a visual understanding of how much a honey sample corresponds to the declared botanical origin by the complex of physicochemical parameters studied. Thus, samples A0 and B1 are closest to the centres of correspondence (intense green colour). For this, A0 is a falsification prepared in advance.

Schievano et al. (2020) claimed that no significant differences were found in the sugar profiles in a group of European (i.e. Italian and Eastern European) acacia honeys. This allowed them to assume the minor influence of different geographical origin on the sugar profile. However, in our opinion, the sugar profile should not change significantly if the honey is natural and not falsified with sugar.

At the same time, **Schievano et al. (2020)** found that the sugar profile of Chinese honey purchased on the Italian market did not match. They commented on the significant decrease in endogenous sugar, which they believe is the result of feeding bees with sugar syrups during the honey harvest period. This also confirms our previous conclusions regarding the confirmation of falsification.

However, in our sample A0, which was falsified using the method of feeding bees with sugar before winter, NMR spectrometry did not detect falsification.

Along with this, there are known methods **(del Campo et al., 2016; Spiteri et al., 2016)**, which allow the identification in honey of some species of plants, such as eucalyptus, heather, lavender, orange, thyme and rosemary. For this purpose, the authors used analysis of carboxylic acids (acetic, formic, lactic, malic and succinic acids), amino acids (alanine, phenylalanine, proline and tyrosine), carbohydrates (α- and β-glucose and fructose), ethanol and hydroxymethylfurfural.

Gerhardt et al. (2018) presented results where they were able to distinguish three varieties of honey, namely canola, acacia and honeydew honeys, with a predictive accuracy of 98.6% using additional HS-GC-IMS profiling.

Schievano et al. (2020) asserted that melissopalynological analysis and SCIRA also do not reveal any particular anomalies in Chinese acacia honey samples. This is probably due to new methods of falsification. According to our previous research **(Adamchuk, Suchenko and Akulonok, 2019)**, pollen analysis of honey using harmonized methods **(Von Der Ohe et al., 2004)**, which we adapted to the laboratory conditions of Ukraine, is reliable in the botanical identification of honey. Thus, in the 30 acacia honey samples tested, we found 20% to 30% *Robinia pseudoacacia* pollen grains. This indicates compliance with the current standards for acacia monofloral honey in Ukraine **(Nakaz MinAPK No. 330, 2019)**. In this case, the tested honey samples also met the requirements for diastasis and hydroxymethylfurfural.

For evaluation of the botanical origin of honey, the NMR spectrometry method proved to be ineffective for our samples. All honey was programmatically identified as polyfloral. Therefore, we applied the harmonized method of melissopalynology **(Von Der Ohe et al., 2004)**, which we adapted to the conditions of the laboratory at the Department of Certification and Standardization of Agricultural Products, NULES of Ukraine; and improved the way of counting and identifying pollen grains of different types of plants widespread in Ukraine.

The results of pollen analysis are shown in Table 6.

Table 6 Botanical origin of honey.

Sample	Pollen grains, %			
	Predominant ≥20%	**Secondary 10 – 20%**	**Minor ≤10%**	**Including ≤1%**
A0	-	Asteraceae *Barbarea vulgaris*	*Draba nemorosa* *Lamium album* *Trifolium repens* *Bistorta officinalis*	*Convolvulus arvensis* *Agrimonia eupatoria* Anemophilic species of plants
A1	-	*Robinia pseudoacacia* (17%) *Acer negundo* *Aesculus hippocastanum* *Ajuga reptans*	*Acer platanoides* *Acer tataricum* *Lamium album* *Salix* spp. *Tilia* spp. *Clinopodium vulgare* *Lycopus* spp.	Asteraceae Anemophilic species of plants
A2	-	*Robinia pseudoacacia* (16%) *Brassica napus* *Centaurea* spp.	*Ficaria verna* *Swida alba* *Ballota nigra* *Melilotus officinalis* *Tilia* spp. *Rosa canina* *Salix alba* *Catalpa bignonioides*	*Fragaria vesca* Fruit tree *Juglans* spp. Anemophilic species of plants
B1	*Robinia pseudoacacia* **(33%)**	Fabaceae *Acer* spp.	*Caragana arborescens* *Bunias orientalis* *Barbarea vulgaris* *Nasturtium officinale* *Brassica napus* *Salix* spp. *Lamium purpureum* *Primula* spp.	*Anemone* spp. Anemophilic species of plants
B2	*Robinia pseudoacacia* **(39%)**	*Gleditsia triacanthos* *Elaeagnus argentea*	*Salix* spp. *Vicia cracca* *Melilotus officinalis* *Quercus* spp. *Rhus hirta* *Lotus corniculatus* *Veratrum lobelianum* *Clinopodium vulgare* *Gagea* spp. *Allium ursinum* *Taraxacum officinale* *Cornus mas* *Geum rivale* *Ajuga reptans* *Scrophularia vernalis* *Tussilago farfara* *Amorpha fruticosa*	*Lamium purpureum* *Lamium maculatum* *Lamium galeobdolon* *Ribes* spp. Anemophilic species of plants

According to the results of the research, samples B1 and B2 correspond to the acacia variety by botanical origin. They contain 33% and 39% acacia (*Robinia pseudoacacia*) pollen grains, respectively. According to **Nakaz MinAPK No. 330 (2019)**, the only normative document regulating the criteria for monofloral honey varieties, for acacia honey, the *Robinia pseudoacacia* pollen grain content should be at least 20%.

Samples A1 and A2 also contained acacia grains, 17% and 16%, respectively. Along with this, sample A1 also contained a large amount of pollen from maple (*A. negundo*, *A. platanoides*, *A. tataricum*), horse-chestnut (*A. hippocastanum*) and bugleweed (*A. reptans*). Sample A2 contained a significant amount of pollen from rapeseed (*B. napus*) and several species of *Centaurea* spp., indicating the activation of flight activity of bees on field honey plants after the end of acacia flowering. The presence of willow (*Salix* spp.) pollen grains indicates a failure of adherence to acacia honey production technology, which is based on the use of additional cases of the 145-frame hive. Pollen from willow, which is an early pollen source, can only be present in the hive body.

The conducted studies confirm the need for a comprehensive approach to the identification of the

botanical origin of honey for its conformity to the acacia variety. There is a need to revise the physicochemical indicators regarding the conformity of honey obtained in Ukraine to the acacia variety. After all, even the modern NMR spectrometry technique indicated that sample A0, which did not contain acacia pollen grains and was specially fabricated, was acacia honey.

CONCLUSION

Identification of the botanical origin of monofloral kinds of honey, in particular acacia, should be carried out in the following sequence: pollen analysis (by dominant pollen grains), safety (presence of antibiotics, pesticides), physicochemical parameters according to international requirements, organoleptic parameters. The methods of determination and requirements for physicochemical indicators of honey require revision, improvement and harmonization.

In the future, the safety of acacia honey in terms of the content of contaminants that may be caused by anthropogenic environmental load requires analysis and research. Also, there is a necessity to find markers that will indicate the geographical origin of Ukrainian kinds of honey and thus protect them from falsification from other countries.

ANTIMICROBIAL POTENTIAL OF DIFFERENT MEDICINAL PLANTS AGAINST FOOD INDUSTRY PATHOGENS

Miroslava Kačániová, Jana Žiarovská, Simona Kunová, Katarína Rovná, Tatsiana Savistkaya, Dzmitry Hrinshpan, Veronika Valková, Lucia Galovičová, Petra Borotová, Eva Ivanišová

ABSTRACT

Work aimed to investigate the antimicrobial activity of medicinal plants against selected species of food industry pathogens *in vitro* conditions. The detection of antibacterial properties was examined by the disc diffusion method and the method of the minimum inhibitory concentrations (MIC). The cultivation of microorganisms after the 24 h was performed by disc diffusion method. Petri dishes have grown at 37 °C in which the Mueller - Hinton agar and application it to the sterile paper disc impregnated with the extract. The thickness of the resulting inhibition zone was measured with a ruler after completion of the culture. After the preparation of bacteria and extracts of certain concentrations of a subsequently added to wells microplates we use the method of the minimum inhibitory concentration (MIC) which was conducted out as the second measurement, and we took the readings absorbance spectrophotometer at 570 nm using the Glomax plate spectrophotometer. We found out, that *Equisetum arvense* demonstrated the largest zones of inhibition to the tested Gram-positive and Gram-negative bacteria. The greatest antimicrobial activity achieved *Equisetum arvense*, *Urtica dioica,* and *Taraxacum officinale* against *Salmonella enterica* subsp. *enterica* CCM 3807 and *Yersinia enterocolitica* CCM 5671. *Equisetum arvense* and *Taraxacum officinale* was the most effective against *Escherichia coli* CCM 2024 and the least effective were *Tussilago farfara* and *Mentha piperita w*ith using the method of minimum inhibitory concentrations.

Keywords: medicinal plants; antibacterial effect; Gram-positive and Gram-negative bacteria; disc diffusion method; MIC

INTRODUCTION

Salvia officinalis belongs to the largest genus of the family Lamiaceae containing approximately 900 different species worldwide. Some of them can be used as an ingredient in the kitchen, others have been used in the cosmetics industry, and their essential oils are also used as ingredients in various fragrances. Analysis of essential oils of different sage species has shown the most important components, which are made up of substances such as eucalyptol, borneol, thujone, or camphor. Eucalyptol or 1,8-cineol is a natural organic compound. These are cyclic ether and monoterpenoid. Positive properties of killing to leukemia cells have been found *in vitro* **(Baser et al., 1993; Baser et al., 1997; Ahmadi and Mirza, 1999)**.

The essential oil of sage extract as reported **Hammer et al. (1999) and Marino et al. (2001)** has inhibitory properties against the following bacteria: *Bacillus cereus, Bacillus megatherium, Bacillus subtilis, Aeromonas hydrophila, Aeromonas sobria, Klebsiella oxytoca, Candida albicans, Shigella, Salmonella,* and *Cryptococcus*. Small inhibition zones against *Escherichia coli* and *Staphylococcus aureus* have also been observed. The antimicrobial activity of sage *in vitro* was determined using a minimum inhibitory concentration (MIC) and achieved a higher activity against Gram-positive bacteria. The most sensitive of these were *S. epidermidis* (MIC = 12.5 $\mu g.mL^{-1}$), *B. cereus* and *B. subtilis* (MIC = 25 $\mu g.mL^{-1}$). In the case of Gram-negative bacteria, only significant activity was demonstrated against *E. coli, S. typhi* and *K. pneumoniae*, which showed the lowest MIC values (50 $\mu g.mL^{-1}$). It was moderately active against *P. vulgaris* and *S. enteritidis* (MIC = 100 $\mu g.mL^{-1}$) **(Tenore et al., 2011)**.

Melissa officinalis belongs to the family Lamiaceae. It is characterized by having 2 to 8 cm soft, slightly hairy leaves, with older, larger leaves having a heart shape **(Bown, 2001)**. Lemon balm as a medicinal plant has proven antimicrobial and antiviral effects. In addition to these effects, anti-fungal **(Darouche et al., 2006)**, immunomodulatory **(Fang et al., 2005)**, and antioxidant effects comparable to tocopherol have also been shown. In addition to soothing effects, lemon balm extract has anti-bloating effects, convulsions, antibacterial and antiviral effects, as well as anti-inflammatory, antioxidant and neuroprotective effects **(Dastmalchi et al., 2008; Pereira et al., 2009)**.

Mentha x piperita (*Lamiaceae*) is generally used for various therapeutic purposes. It comes from Europe and

the Middle East, is widespread in Brazilian culture, and can grow in all areas of the country thanks to its modesty. Essential oils show a strong bactericidal effect, in particular against *Escherichia coli*. When inhaled oil was used concomitantly with multiple drugs in patients with lung tuberculosis, the number of bacilli was demonstrably reduced **(Dejani et al., 2014)**. Mint contains a large amount of fragrant (0.1 – 1%) and essential oils. These are mainly monoterpenes, the main components of which are menthol (29 – 48%), menthone (20 – 31%), menthofuran (6.8%), and their derivatives (isomenthone, neomenthol, menthyl acetate, and pulegone). In menthol and peppermint oil, fungicidal and antiviral activity against *Candida albicans, Aspergillus albus*, dermatophytic microscopic fungi, and Herpes simplex virus has been demonstrated **(Spirling and Daniels, 2001)**.

Equisetum arvense (Equisetaceae) finds its use in internal use for flushing in bacterial and inflammatory diseases of the urinary tract, kidney sand, gout, and rheumatic diseases; as concomitant treatment in chronic lung diseases, osteoporosis, varicose veins, and immunosuppression. The gilt tea is used to relieve gastric mucosal irritations and heartburn. As the age in the human body increases, the silicon content decreases, so the use of this plant is particularly meaningful in geriatrics **(Bühringová, 2010)**. In determining the antimicrobial activity by the disk diffusion method, the essential oil from the gilt showed strong activity against all strains tested. With the highest inhibition zone, values were found against Gram-negative *S. enteritidis* (35 mm) and *K. pneumoniae* (37 mm). The antimicrobial activity of the essential oil of horsetail oil can be attributed to the presence of various substances, in particular phenol, monoterpenes, and thymol. Also, the combination of thymol and 1,8-cineol may result in an important synergistic fungicidal effect **(Vaťľák et al., 2014)**.

Taraxacum officinale belongs to the family Asteraceae. It has a beneficial effect on human health due to its antioxidant and antiallergic properties. The root extract can be used as a probiotic *in vitro* **(Yan et al., 2011)**. A very important part of the plant is the group of sesquiterpene lactones (have anti-inflammatory and anti-cancer effects), phenylpropanoids, polysaccharides and triterpenoids of saponins. The major components of sesquiterpene lactones can often be found in the form of glycosides. These compounds include taraxacine, taraxacerin, dihydrolactucin, ixerin **(Schütz et al., 2006a, b)**. Leaves and dandelion root have beneficial effects in digestion and are considered bitter digestive stimulants. Diuretic effects have also been shown. They probably share a high content of daisies. The root is significant due to mucoprotective, prebiotic, hypoglycemic, and immunostimulatory effects. The leaves in turn have diuretic and anti-inflammatory effects **(Trojanová et al., 2004)**.

Tussilago farfara has found its application in the treatment of cough, bronchitis, and asthmatic diseases. Phytochemical studies have shown that the flower contains several types of metabolites, including essential oils, sesquiterpenes, triterpenes, flavonoids, and phenylpropanoids **(Li et al., 2013)**. Studies have shown that coltsfoot has marked pharmacological and antagonistic effects and also has antioxidant and antimicrobial activity **(Gao et al., 2008)**. The antimicrobial activity of the coltsfoot *in vitro* was determined using the disk diffusion method. The highest antibacterial activity of *Tussilago farfara* was found on Gram-positive bacteria *Lactobacillus rhamnosus* (6.67 ±1.53 mm) and lower on yeast *Saccharomyces cerevisiae* (1.67 ±0.58 mm) **(Kačániová et al., 2013)**.

Urtica dioica (Urticaceae) has been known in Europe and has been used as a medicinal plant for over 2000 years. The leaf and the root are used for these purposes. Leaf extract has been found to be of use in the symptomatic treatment of arthritis, arthrosis, and rheumatic problems, as well as a diuretic for inflammatory diseases of the urinary tract and bladder and overall detoxification of the body. The whole part of the plant can be used for various purposes such as food, feed, medicines, cosmetics, biodynamic agriculture, and textile production **(Bodros and Baley, 2008)**. Clinical studies have shown that the juice obtained from this plant has a diuretic effect in patients suffering from congestive heart failure. It helps in digestion and promotes milk production of nursing mothers. It provides short-term pain relief and is therefore also used to treat rheumatism. It has also been used in the treatment of arthritis, urinary tract diseases, respiratory diseases, body cleansing, etc. It contains silicic acid, which has diuretic effects, chlorophyll with anti-inflammatory and disinfectant properties, anti-bleeding tannins, and glucokinins, which lower blood sugar **(Bisht et al., 2012)**.

Scientific hypothesis

The different antimicrobial effect exists among analysed medicinal plants for individual food industries pathogens. Antimicrobial activity to pathogenic bacterial strains of food industries is variable for individual medicinal plant species.

MATERIAL AND METHODOLOGY

Plant material

Extracts from 7 different medical plants, obtained from Nitra region, were used to demonstrate antimicrobial activity against selected pathogens. The plant parts such as stems, leaves, and flowers were left to dry in a well-aired dark place at room temperature. Ten grams of dried plants were crushed and extracted with 100 mL of ethanol. Extracts from the plants were leached for two weeks at room temperature and subsequently, ethanol was evaporated by vacuum evaporator (Stuart RE300DB, UK). The samples were stored in the freezer at -20 °C.

Tested strains of microorganisms

For determination of antimicrobial activity 5 bacterial species were purchased from Czech Collection of Microorganisms (CCM, Brno). Three of selected strains were Gram-negative (*Salmonella enterica* subsp. *enterica* CCM 3807, *Yersinia enterocolitica* CCM 5671, *Escherichia coli* CCM 2024) and two strains were Gram-positive (*Staphylococcus aureus* subsp. *aureus* CCM 2461, *Listeria monocytogenes* CCM 4699).

Table 1 Antimicrobial activity with disk diffusion method in mm (mean ±*SD*).

Medicinal plants	*Escherichia coli* CCM 2024	*Salmonella enterica* subsp. *enterica* CCM 3807	*Yersinia enterocolitica* CCM 5671	*Staphylococcus aureus* subsp. *aureus* CCM 2461	*Listeria monocytogenes* CCM 4699
Tussilago farfara	11.33 ±0.58	13.33 ±0.58	12.37 ±0.58	5.33 ±0.58	4.67 ±1.15
Equisetum arvense	14.67 ±0.58	14.33 ±0.58	15.33 ±0.58	6.33 ±0.58	6.67 ±0.58
Melissa officinalis	12.33 ±1.53	10.67 ±0.58	10.67 ±1.53	4.33 ±0.58	5.33 ±0.58
Urtica dioica	8.67 ±1.15	10.33 ±1.15	11.33 ±0.58	4.67 ±0.58	4.67 ±0.58
Taraxacum officinale	8.33 ±0.58	8.33 ±1.53	10.67 ±0.58	3.67 ±0.58	4.00 ±1.00
Salvia officinalis	7.33 ±0.58	9.33 ±1.53	9.33 ±0.58	3.33 ±0.58	4.67 ±0.58
Mentha piperita	7.67 ±0.58	9.33 ±0.58	8.67 ±0.58	4.33 ±0.58	3.33 ±0.58

Disk diffusion method

Five bacterial cultures grown overnight at 37 °C Muller Hinton broth (MBH) were diluted with distilled water to the turbidity 0.5 according to McFarland standard (measured on densilameter). Petri dishes with Mueller-Hinton agar were covered by 100 μL of cell culture with use of L-shaped cell spreader. Petri dishes were dried in a thermostat.

For each bacteria strain were prepared 9 discs with 6 mm diameter (7 discs with medicinal plants, 1 positive control and 1 negative control). Discs were soaked in plant extracts with use of sterile tweezers and afterwards were placed on Petri dishes with cell cultures. Disc with distilled water was used as negative control and disc with antibiotic (gentamycin for G^+ bacteria and tobramycine for G^- bacteria) was used as positive control.

Prepared samples were incubated for 24 hours at 37 °C. After incubation period, diameter of each inhibition zone was measured in 3 directions, and average size of inhibition zone was calculated.

Minimum inhibitory concentration

The microdilution method is carried out in 0.5 mL microtiter plates. There was A 96 well microtiter plate used in the assay. A stock solution of various concentrations of the medicinal plant is prepared for each well of the plate. There are 12 wells in row A – H into which we pipet 0.5 mL of Mueller – Hinton broth culture medium. The plant extract was pipetted in the next step from row A – H of the first column. Plant extracts were prepared according to the desired concentration and diluted with dimethylsulfoxide. The extracts were pipetted with the given microorganisms with a concentration of 0.5 McFarland. Using an automatic eight-channel pipette with a preset value of 100 μL, the suspension from the wells of the first column was transferred to the second column. We repeated the procedure until the concentration was reduced in this way. The whole plate concentration was measured with an absorbance spectrophotometer at 570 nm using the Glomax plate spectrophotometer. The cultivation proceeded from 16 to 18 hours. After its completion, we again measured concentration throughout the plate, and from the pre-and post-cultivation readings, we calculated the differences in absorbance. It can be stated that the minimum inhibitory concentration and its value had the lowest extract concentration at which inhibitory bacterial growth was detectable.

Statistical analysis

Mean and standard deviation with Excel were used for the disk diffusion method. Using obtained absorbance before and after the analysis, we were able to express the differences in absorbance between the measurements as a set of binary values. These values were assigned to exact concentrations. The following formula was created for this specific experiment: value 1 (inhibitory effect) was assigned to absorbance values lower than 0.05, while value 0 (no effect or stimulant effect) was assigned to absorbance values higher than 0.05. For this statistical evaluation probit analysis in Statgraphics software was used for minimal inhibitory concentration.

RESULTS AND DISCUSSION

Several studies have described different biological effects of *Equisetum arvense* L., *Tussilago farfara, Melissa officinalis, Urtica dioica, Salvia officinalis* and *Mentha piperita* extract or tea with natural extract, such as antioxidant, anti-inflammatory, antibacterial, antifungal, vasorelaxant, neuro and cardio protectors **(Dos Santos et al., 2005; Sandhu et al., 2010; Salehzadeh et al., 2014; Salih, 2014; Rabbani et al., 2015; Lee et al., 2019)**, and antiproliferative properties **(Yamamoto, Inoue and Hamako, 2004; Četojevic-Simin et al., 2010; Stanojevic et al., 2010)**. Disk diffusion method (Table 1) indicated that *E. coli, S. enterica,* and *Y. enterocolitica* were more sensitive to extracts from selected medicinal plants than *L. monocytogenes* and *S. aureus.*

The most significant antimicrobial effect was observed at *Equisetum arvense* that exhibited the largest inhibition zones against all bacteria. Considerable results were observed at *Y. enterocolitica, E. coli,* and *S. enterica* with sizes of inhibitory zones 15.33 ±0.58 mm, 14.67 ±0.58 mm and 14.33 ±0.58 mm respectively. Also, *L. monocytogenes* and *S. aureus* showed the highest sensitivity against *Equisetum arvense*.

Tussilago farfara and *Melissa officinalis* also showed significantly larger inhibition zones, while *Salvia officinalis* and *Mentha piperita* seemed to be the least effective. Overall this test indicated that Gram-negative bacteria are more susceptible to the antimicrobial activity of medicinal plant extracts.

According to the minimum inhibitory concentration test (Table 2), slight variations in antimicrobial sensitivity were observed against the disk diffusion method.

Table 2 Minimum inhibitory concentration of medicinal plants in μg.mL^{-1}.

Medicinal plants		*Escherichia coli* CCM 2024	*Salmonella enterica* subsp. *enterica* CCM 3807	*Yersinia enterocolitica* CCM 5671	*Staphylococcus aureus* subsp. *aureus* CCM 2461	*Listeria monocytogenes* CCM 4699
Tussilago farfara	**MIC50**	> 25.6	19.15	19.15	> 25.6	25.60
	MIC90	> 25.6	20.36	20.36	> 25.6	28.57
Equisetum arvense	**MIC50**	**9.59**	**9.59**	**9.59**	12.80	12.80
	MIC90	**10.20**	**10.20**	**10.20**	14.29	14.29
Melissa officinalis	**MIC50**	12.80	12.80	19.15	25.60	12.80
	MIC90	14.29	14.29	20.36	28.57	14.29
Urtica dioica	**MIC50**	12.80	**9.59**	**9.59**	12.80	12.80
	MIC90	14.29	**10.20**	**10.20**	14.29	14.29
Taraxacum officinale	**MIC50**	**9.59**	**9.59**	**9.59**	19.15	19.15
	MIC90	**10.20**	**10.20**	**10.20**	20.36	20.36
Salvia officinalis	**MIC50**	19.15	**9.59**	10.85	> 25.6	19.15
	MIC90	20.36	**10.20**	16.67	> 25.6	20.36
Mentha piperita	**MIC50**	18.03	**9.59**	25.60	25.60	> 25.6
	MIC90	29.07	**10.20**	28.57	28.57	> 25.6

However, the same trend with higher sensitivity against plant extract was observed in a group of Gram-negative bacteria *E. coli, S. enterica,* and *Y. enterocolitica*. Also, the most conspicuous growth inhibition was caused by *Equisetum arvense* extract with the lowest detected inhibitory concentration at MIC 50: 9.59 μg.mL^{-1} and MIC 90: 10.20 μg.mL^{-1} for Gram-negative bacteria and MIC50: 12.8 μg.mL^{-1} and MIC90: 14.29 μg.mL^{-1} for Gram-positive bacteria (*L. monocytogenes* and *S. aureus*). This observation corresponded with the previous test.

In addition, according to MIC test, also *Taraxacum officinale* and *Urtica dioica* extracts achieved comparable values of cell growth inhibition as *Equisetum arvense.* On the other side, *Mentha piperita* and *Tussilago farfara* seemed to be the least effective.

From the perspective of bacteria, the most sensitive to the antimicrobial activity of all tested medicinal plant extracts was *S. enterica* followed by another Gram-positive bacteria *E. coli* and *Y. enterocolitica* that were slightly more resistant especially to plant extracts with inferior antimicrobial effectivity.

A great interest in biologically active substances of plant origin increased in recent years. Many of these substances demonstrated an antimicrobial effect **(Essawi and Srour, 2000)**.

Kačániová et al. (2013) tested the antimicrobial activity of coltsfoot (*Tussilago farfara*) against selected species of microorganisms: *Escherichia coli* CCM 3988, *Enterococcus raffinosus* CCM 4216, *Staphylococcus epidermis* CCM 4418, *Lactobacillus rhamnosus* CCM 1828, *Pseudomonas aeruginosa* CCM 1960, *Serratia rubidaea* CCM 4684, and *Saccharomyces cerevisiae* CCM 8191. Ethanol extract of coltsfoot with two methods, disk diffusion method, and minimal inhibitory concentration method were used for testing. The extract was most effective against *Serratia rubidaea* CCM 4684 and *Saccharomyces cerevisiae* CCM 8191.

Janovská et al. (2003) demonstrated that extracts from *Tussilago farfara, Chelidonium majus,* and *Schisandra chinensis* had proven antimicrobial activity. Extract from each plant had significantly different activity against tested microorganisms, but various extracts showed greater antimicrobial activity against *Bacillus cereus* and *Staphylococcus aureus* than against *Escherichia coli, Pseudomonas aeruginosa* and *Candida albicans*.

Also, **Kokoska et al. (2002)** reported that *Tussilago farfara* extract had an antimicrobial effect on *Bacillus cereus* (15.63 mg.mL^{-1}) and *Staphylococcus aureus* (62.50 mg.mL^{-1}) by MIC susceptibility test. The antimicrobial effects of the coltsfoot extract against *Escherichia coli* were not determined, although sensitivity of *E. coli* was observed in other medicinal plants.

According to two statistical processing of disc diffusion method **Hleba et al. (2013)** indicated that the *Tussilago farfara* extract reached size of inhibition zones 16.7 ±3.65 mm for ampicillin and chloramphenicol resistant *Escherichia coli* isolated from conventional cow breeding and 8.3 ±1.41 mm for antibiotics when we consider that *Escherichia coli* has been isolated from organic mare breeding. In contrast, the methanolic extract of *Aesculus hippocastanum* (diameter of inhibition zones 9 ±1.88 mm) had the least antimicrobial effect.

Milovanović et al. (2007) investigated the antimicrobial effects of horsetail (*Equisetum arvense*) extract, with inhibition zones size 12.1 ±0.5 mm.

Modarresi-**Chahardehi et al. (2012)** compared various types of extract preparation of *Urtica dioica* related to antimicrobial activity. Ethyl acetate, hexane and chloroform extracts displayed higher antimicrobial activity than the other extracts. The highest growth inhibition of ethyl acetate extract was observed against *Bacillus cereus*, methicillin resistant *Staphylococcus aureus,* and *Vibrio parahaemolyticus*. Phenols from *Urtica dioica* are one of the major groups associated with the inhibition of microbial infections in cancer **(Dar et al., 2012)**. Also, *Urtica dioica* is a rich source of phytochemicals, such as phenolic compounds and minerals, that can be used as a potential source of useful drugs **(Ahmed et al., 2012)**.

Radulović et al. (2006) examined essential oil from *Equisetum arvense.* The study showed significant antimicrobial properties against all tested strains. Diameter of inhibition zone ranged from 23 to 37 mm with the

highest inhibition zone against Gram-negative bacteria *Salmonella enteritidis* (35 mm) and *Klebsiella pneumoniae* (37 mm). Significant reduction of bacterial growth was demonstrated in medically important pathogens, such as *Staphylococcus aureus* (28 mm). The antimicrobial activity was greater or similar to conventional antibiotics. In addition, activity against fungi *Candida albicans* and *Aspergillus niger* was observed. The study also suggested that Gram-negative bacteria *Klebsiella pneumoniae*, *Pseudomonas aeruginosa,* and *Salmonella enteritidis* were more susceptible to tested essential oils than Gram-positive *Staphylococcus aureus.* Exception was Gram-negative *Escherichia coli* which were the most resistant of all tested bacteria.

According to the MIC and MBC method used, the sage extract oil showed an interesting activity against Gram-positive pathogens. The most sensitive was *Staphylococcus epidermidis* (MIC = 12.5 $\mu g.mL^{-1}$), but the oil also showed very good activity against *Bacillus cereus* and *Bacillus subtilis* (MIC = 25 $\mu g.mL^{-1}$ for both). As regards Gram-negative bacteria, the sample showed significant efficacy only against *Escherichia coli*, *Salmonella typhi* and *Klebsiella pneumoniae*, which showed the lowest MIC values (50 $\mu g.mL^{-1}$), while being moderately active against *Proteus vulgaris* and *Salmonella enteritidis* (MIC = 100 $\mu g.mL^{-1}$) **(Tenore et al., 2011)**.

Results of **Mazandarani et al. (2013)** show that oil from *Achillea millefolium* extract may be an alternative to antibiotics in the control of some Gram-positive and Gram-negative pathogens. The antibacterial activity of some *Agrimonia eupatoria* extracts against pathogenic bacteria (*Staphylococcus aureus, Pseudomonas aeruginosa* and *Escherichia coli*) and their action on wound healing in rats has been confirmed. The presence of certain active substances in both aqueous and ethanol extracts has also been demonstrated, indicating that *Agrimonia eupatoria* may exhibit antimicrobial activity. The results of this study showed that the ethanol extract was more effective at inhibiting the bacteria tested than the aqueous extract. *Pseudomonas aeruginosa* was most resistant to the action of ethanol extract, while *Escherichia coli* with the highest zone of inhibition of 20 mm was the most susceptible. There was moderate activity against *Staphylococcus aureus* with 15 mm inhibition zone after application of ethanol extract (10 $mg.mL^{-1}$).

With regard to the antimicrobial activity of *Melissa officinalis* oil, **Romeo et al. (2008) and Hussain et al. (2011)** indicated its antibacterial activity against *Staphylococcus aureus, Bacillus cereus, Bacillus subtilis, Bacillus pumilus, Pseudomonas aeruginosa, Salmonella Poona, Escherichia coli* and *Listeria innocua*. Antimicrobial activity (expressed as $\mu g.mL^{-1}$) from four ethanolic extracts of *Achillea millefolium, Agrimonia eupatoria, Melissa officinalis* and *Tilia platyphyllos* against various strains of Gram-positive and Gram-negative bacteria. It was found that more susceptible to *Agrimonia eupatoria* extract with a MIC50 value of 0.80 $\mu g.mL^{-1}$ of *Bacillus cereus, Lactobacillus brevis* was less susceptible to *Agrimonia eupatoria* with a MIC50 value of 1.48 $\mu g.mL^{-1}$.

The bacteria *Lactobacillus hilgardii, Enterococcus faecalis,* and *Escherichia coli* were less sensitive to *Agrimonia eupatoria* extract and the values were higher MIC50 (MIC 2.56 – 17.06 $\mu g.mL^{-1}$). *Lactobacillus brevis* was more sensitive to *Melissa officinalis* with a MIC50 of 6.39 $\mu g.mL^{-1}$. In addition, the activity of *Achillea millefolium* against Gram-positive and Gram-negative bacteria was contrary to previous reports that antibacterial activity was limited to Gram-positive bacteria from medicinal herbs **(Ghaima, 2013)**.

CONCLUSION

Medicinal plants have been used for treating various diseases due to their beneficial effects and sources of bioactive secondary metabolites for long times. In recent years, research has been increasingly investigating their antimicrobial activity against various pathogens. The emphasis should be placed on further research and monitoring of their effects. The plants that we used in the research showed an antimicrobial effect against Gram-positive and Gram-negative bacteria.

ESTIMATION OF PHENOLIC COMPOUNDS CONTENT AND ANTIOXIDANT ACTIVITY OF LEAVES EXTRACTS OF SOME SELECTED NON-TRADITIONAL PLANTS

Olga Grygorieva, Olena Vergun, Svitlana Klymenko, Mykhailo Zhurba, Vladimíra Horčinová Sedláčková, Eva Ivanišova, Ján Brindza

ABSTRACT

The aim of the research is the determination of the total antioxidant activity and the content of phenolic compounds of the leaves of 12 species of non-traditional plants, namely, *Amelanchier alnifolia* (Nutt.) Nutt. ex M. Roem., *Aronia mitschurinii* A.K. Skvortsov & Maitul., *Castanea sativa* Mill., *Chaenomeles japonica* (Thunb.) Lindl., *Cornus mas* L., *Diospyros kaki* L., *Diospyros lotus* L., *Diospyros virginiana* L., *Lycium barbarum* L., *Lycium chinense* Mill., *Pseudocydonia sinensis* (Thouin) C.K. Schneid., *Ziziphus jujuba* Mill. Total phenolic content was evaluated using the Folin-Ciocalteu reagent assay. Antioxidant activity was measured using two different methods (DPPH – 2,2-diphenyl-1-picrylhydrazyl, MRAP – molybdenum reducing antioxidant power). Significant variability was observed in phenolic compounds content and total antioxidant activity. Total polyphenol content ranged from 38.02 (*Z. jujuba*) to 80.58 (*C. sativa*) mg GAE.g^{-1} DM, total flavonoid content from 22.47 (*P. sinensis*) to 54.61 (*L. barbarum*) mg QE.g^{-1} DM and phenolic acids content from 3.51 (*A. mitschurinii*) to 24.67 (*Ch. japonica*) mg CAE.g^{-1} DM. All tested samples exhibited DPPH• radical scavenging activities with values from 6.92 (*A. mitschurinii*) to 9.0 (*C. mas*) mg TEAC.g^{-1} DM. Antioxidant activity by molybdenum reducing antioxidant power method ranged from 109.43 (*A. mitschurinii*) to 322.95 (*C. mas*) mg TEAC.g^{-1} DM. Differences between the species of non-traditional plants were significant in all observed parameters. Obtained results of phytochemical composition demonstrated the possibility of leaves' use of non-traditional plants as sources of valuable bioactive compounds with health-promoting and disease-preventing properties.

Keywords: non-traditional plants; leaves; phenolic compounds; antioxidant activity

INTRODUCTION

Fruits constitute is a large group of functional food, whose consumption delivers several health benefits, but very limited studies about the leaves of plants especially lesser-known and non-traditional plants, among which fruit plants. Biological activity in plants present in leaves has attracted much attention to their beneficial health effects **(Yildirim, Oktay and Bülaloúlu, 2001; Olszewska, 2011; Amjad and Shafighi, 2012; Nam, Jang and Rhee, 2017; Yılmaz and Seyhan, 2017; Bhatt et al., 2018)**. Leaves of non-traditional plants are one of the promising sources of antioxidants **(Ipatova et al., 2003; Calliste et al., 2005; Sakanaka, Tachibana and Okada, 2005; Priya and Nethaji, 2015; Ferlemi and Lamari, 2016; Klymenko, Grygorieva and Brindza, 2017; Urbanaviciute et al., 2019)**. They can use in the tea production and may have potential health benefits as a therapeutic aid in many illnesses which could be attributed to their antifungal, anti-inflammatory, antimicrobial and antioxidant activities. For example, tea made up from leaves of the plant *Camellia sinensis* (L.) Kuntze, is the second most consumed beverage in the world **(Costa, Gouveia and Nobrega, 2002; Rietveld and Wiseman, 2003)**.

The leaves *Ziziphus jujuba* have been used for herbal tea as a folk medicine for hemorrhaging, diarrhea **(Mahajan and Chobda, 2009)** and also been used to improve sleep, nourish the heart and soothe the nerves **(Zhang et al., 2014)**. The effects of *Diospyros virginiana* leaf and bark were comparable to that of standard drug, Silymarin. The ethanolic extract *Diospyros virginiana* leaf and bark is not only an effective hepatoprotective agent but also possesses significant antioxidant activity **(Priya and Nethaji, 2015)**.

The leaves of *Diospyros kaki* are most widely used in countries in eastern Asia, including China, Korea, and Japan **(Ahn et al., 2017)**. They contain abundant bioactive chemicals, such as flavonoids, polyphenols, organic acids, and vitamins, which could contribute to their pharmacological characteristics, such as their potent radical-scavenging and antioxidant properties **(Kim et al., 2006; Lee et al., 2006)**. The leaves of *Diospyros kaki* show medicinal effects against hemostasis, diuresis, constipation, and hypertension, have beneficial effects on

eye diseases in humans **(Ryu et al., 2015; Xie et al., 2015; Ahn et al., 2017)**.

Aronia melanocarpa leaf extract effectively reduced lipid and protein peroxidation in brain homogenates obtained from rats subjected to immobilization-induced oxidative stress **(Cuvorova et al., 2005)**.

Scientific hypothesis

The results of this study will provide new knowledge and useful information about the content of phenolic compounds in some selected non-traditional plants leaves and the antioxidant activity of their extracts, which will give a wide range of possibilities to employing these plants as the sources of phenolic compounds.

MATERIAL AND METHODOLOGY

Selection of plants

Objects of this study were leaves of 12 species of non-traditional plants, namely, *Amelanchier alnifolia* (Nutt.) Nutt. ex M. Roem., *Aronia mitschurinii* A.K. Skvortsov & Maitul., *Castanea sativa* Mill., *Chaenomeles japonica* (Thunb.) Lindl., *Cornus mas* L., *Diospyros kaki* L., *Diospyros lotus* L., *Diospyros virginiana* L., *Lycium barbarum* L., *Lycium chinense* Mill., *Pseudocydonia sinensis* (Thouin) C.K. Schneid., *Ziziphus jujuba* Mill. (Figure 1). The raw materials were collected in the 2018 August on the experimental collection of the Institute of Biological Conservation and Biosafety, the Slovak University of Agricultural in Nitra.

The collected samples were packed in cotton bags and air-dried for several days. The air-dried samples were finely powdered using laboratory blender and kept in zip-locked bags until further analysis. Duplicate specimens were collected for the herbarium preparation.

Chemicals

All the chemicals used were of analytical grade and were purchased from Sigma-Aldrich (St. Louis, MO, USA) and CentralChem (Slovakia).

Preparation of sample extracts

The dry non-traditional plants leaves were used for the detection of total phenolic content and total flavonoid content. An amount of 0.25 g of each sample was extracted with 20 mL of 80% ethanol for 24 h. Then, the sample in 80% ethanol was centrifuged at 4605 RCF (Rotofix 32 A, Hettich, Germany) for 10 min and the supernatant was used for measurement with the DPPH and molybdenum reducing antioxidant power methods.

Total polyphenol, flavonoid, and phenolic acid content

The total polyphenol content (TPC) was measured by the method of **Singleton and Rossi (1965)** using the Folin-Ciocalteu reagent. A quantity of 0.1 mL of each sample was mixed with 0.1 mL of the Folin-Ciocalteu reagent, 1 mL of 20% (w/v) sodium carbonate and 8.8 mL of distilled water. After 30 min in darkness, the absorbance at 700 nm was measured with the spectrophotometer Jenway (6405 UV/Vis, England). Gallic acid (25 – 300 $mg.L^{-1}$; $R^2 = 0.998$) was used as the standard. The results were expressed in $mg.g^{-1}$ DM gallic acid equivalent.

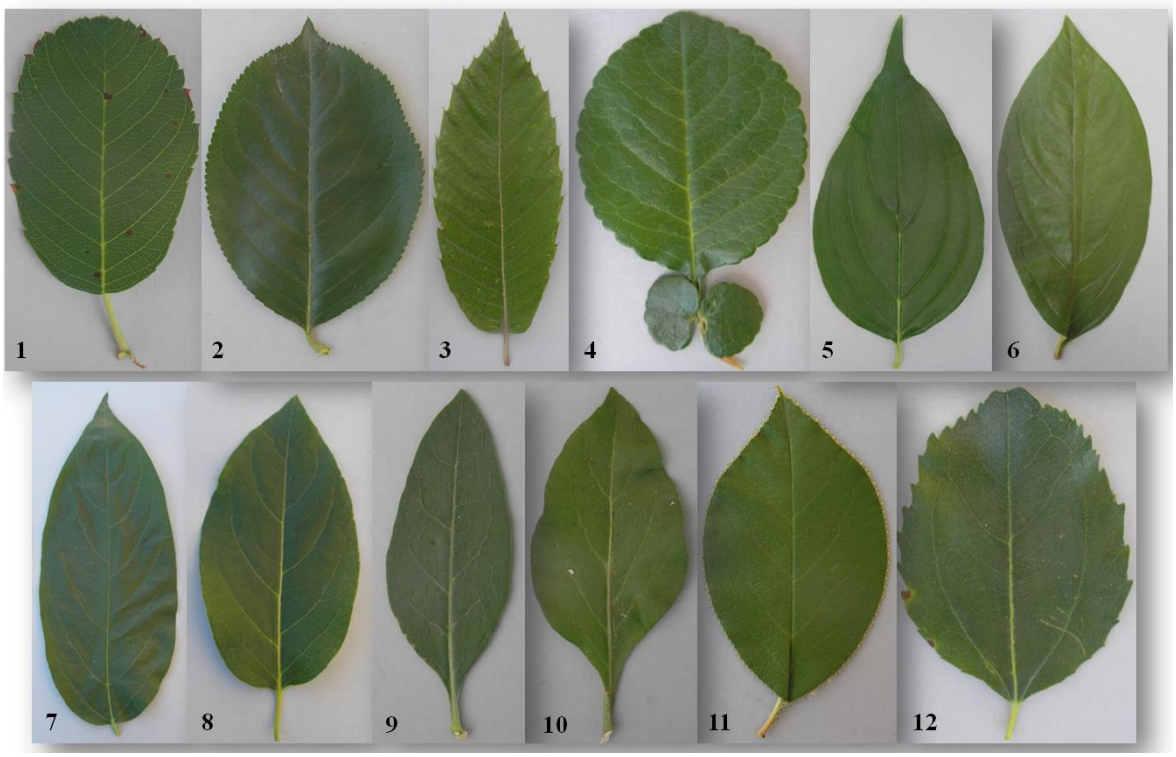

Figure 1 Leaves of non-traditional plants. Note: 1 – *Amelanchier alnifolia* (Nutt.) Nutt. ex M. Roem.; 2 – *Aronia mitschurinii* A.K. Skvortsov & Maitul.; 3 – *Castanea sativa* Mill.; 4 – *Chaenomeles japonica* (Thunb.) Lindl.; 5 – *Cornus mas* L.; 6 – *Diospyros kaki* L.; 7 – *Diospyros lotus* L.; 8 – *Diospyros virginiana* L.; 9 – *Lycium barbarum* L.; 10 – *Lycium chinense* Mill.; 11 – *Pseudocydonia sinensis* (Thouin) C.K. Schneid.; 12 – *Ziziphus jujuba* Mill.

The total flavonoid content (TFC) was determined by the modified method described by **Shafii et al. (2017)**. An aliquot of 0.5 mL of the sample was mixed with 0.1mL of 10% (w/v) ethanolic solution of aluminum chloride, 0.1 mL of 1 M potassium acetate and 4.3 mL of distilled water. After 30 min in darkness, the absorbance at 415 nm was measured using the spectrophotometer Jenway (6405 UV/Vis, England). Quercetin (1 – 400 mg/L; R2 = 0.9977) was used as the standard. The results were expressed in $mg.g^{-1}$ DM quercetin equivalent.

Total phenolic acid (TPA) content was determined using the method of **Farmakopea Polska (1999)**. A 0.5 mL of sample extract was mixed with 0.5 mL of 0.5 M hydrochloric acid, 0.5 mL Arnova reagent (10% $NaNO_2$+10% Na_2MoO_4), 0.5 mL of 1 M sodium hydroxide (w/v) and 0.5 mL of water. Absorbance at 490 nm was measured using the spectrophotometer Jenway (6405 UV/Vis, England). Caffeic acid (1 – 200 mg/L, $R^2 = 0.999$) was used as a standard and the results were expressed in $mg.g^{-1}$ DM caffeic acid equivalents.

Determination of antioxidant activity

Free radical scavenging activity

Free radical scavenging activity of samples was measured using the 2,2-diphenyl-1-picrylhydrazyl (DPPH) **(Sanches-Moreno et al., 1998)**. An amount of 0.4mL of the sample was mixed with 3.6mL of DPPH solution (0.025 g DPPH in 100 mL methanol). The absorbance of the reaction mixture was determined with the spectrophotometer Jenway (6405 UV/Vis, England) at 515 nm. Trolox (6-hydroxy-2,5,7,8-tetramethylchroman-2-carboxylic acid) (10 – 100 $mg.L^{-1}$; $R^2 = 0.989$) was used as the standard and the results were expressed in $mg.g^{-1}$ DM Trolox equivalents.

Molybdenum reducing antioxidant power

Molybdenum reducing (MRP) antioxidant power of samples was determined by the method of **Prieto et al. (1999)** with slight modifications. The mixture of the sample (1 mL), monopotassium phosphate (2.8 mL, 0.1 M), sulfuric acid (6 mL, 1 M), ammonium heptamolybdate (0.4 mL, 0.1 M) and distilled water (0.8 mL) was incubated at 90 °C for 120 min, then rapidly cooled. The absorbance at 700 nm was detected with the spectrophotometer Jenway (6405 UV/Vis, England). Trolox (10 – 1000 $mg.L^{-1}$; $R^2 = 0.998$) was used as the standard and the results were expressed in $mg.g^{-1}$ DMTrolox equivalent.

Statistical analysis

Basic statistical analyses were performed using PAST 2.17. Data were analyzed with ANOVA test and differences between means compared through the Tukey-Kramer test ($\alpha = 0.05$). The variability of all these parameters was evaluated using descriptive statistics. Correlation coefficients were calculated by CORR analysis.

RESULTS AND DISCUSSION

The main classes of natural antioxidant compounds such as flavonoids and phenolic acids often show a high correlation with antioxidant activity and have been identified in following non-traditional plants species: *Aronia melanocarpa* **(Tolić et al., 2015)**, *Cydonia oblonga* **(Bystrická et al., 2017)**, *Ziziphus jujuba* **(Ivanišová et al., 2017)**, *Diospyros virginiana* **(Grygorieva et al., 2018)**, *Sambucus nigra* **(Horčinová Sedláčková et al., 2018)**, *Asimina triloba* **(Brindza et al., 2019)**, *Cornus mas* **(Klymenko et al., 2019b)**, *Chaenomeles japonica* **(Klymenko et al., 2019a)** and other.

Total phenolic acid (TPA), flavonoids (TFC) and polyphenols (TPC) contents

Phenolic compounds have been proven to have a particularly strong antioxidant effect **(Scalbert et al., 2005; Pandey and Rizvi, 2009)**, which is closely related to the anti-inflammatory **(Pastore et al., 2009)**, strong antimicrobial **(Cushnie and Lamb, 2005)**, antiviral **(Chávez et al., 2006)**, and anticancer **(Kandaswami et al., 2005)** effect. Based on a large amount of scientific data proving the beneficial effect of phenolic compounds in humans, it is appropriate to perform estimation of these compounds content of leaves extracts of some selected non-traditional plants.

The amount of total phenolic acid content varied with the plant species (Figure 2). Total phenolic acids were ranged from 3.51 (*Aronia mitschurinii*) to 24.67 (*Chaenomeles japonica*) mg CAE.g^{-1} DM.

Comparing the works of literature, **Barreira et al. (2010)** reported a total phenol content of 228.37 – 522.98 $mg.g^{-1}$ of *Castanea sativa*. According to **Lavola, Karjalainen and Julkunen-Tiitto (2012)**, total phenolic acid content for *Amelanchier alnifolia* cultivars was from 22.78 to 26.75 $mg.g^{-1}$ DW. In this case, chlorogenic acids had maximal values (17.55 – 20.16 $mg.g^{-1}$). Also, this study showed that that among investigated organs of *A. alnifolia* cultivars leaves had the most content phenolic acids as well as other phenolic compounds. In our study leaves, extracts of this species showed less content of phenolic acids. The total phenolic contents of water extracts of *Cornus mas* was 341.09 $mg.g^{-1}$ **(Stankovic et al., 2014)**. Methanol extracts of *Ziziphus jujuba* had total phenolic content 68.10 $mg.g^{-1}$ **(Al-Saeedi et al., 2016)**. The total amount of phenolic compounds in the methanol extracts of *Chaenomeles japonica* leaves varied from 12.94 to 64.79 mg GAE.$100g^{-1}$ **(Urbanaviciute et al., 2019)**. The total phenolic contents have been investigated in other plant leaf extracts, including *Mangifera indica* L. (65 $mg.g^{-1}$), *Anacardium occidentale* L. (58.57 $mg.g^{-1}$), *Cymbopogon citratus* (DC.) Stapf (28.30 $mg.g^{-1}$), *Carica papaya* L. (21.80 $mg.g^{-1}$) **(Iyawe and Azih, 2011)**, *Euphorbia* spp. (19.10 – 20.30 $mg.g^{-1}$) **(Gapuz and Besagas, 2018)**, and *Azadirachta indica* A. Juss. (14.43 $mg.g^{-1}$) **(Iyawe and Azih, 2011)**.

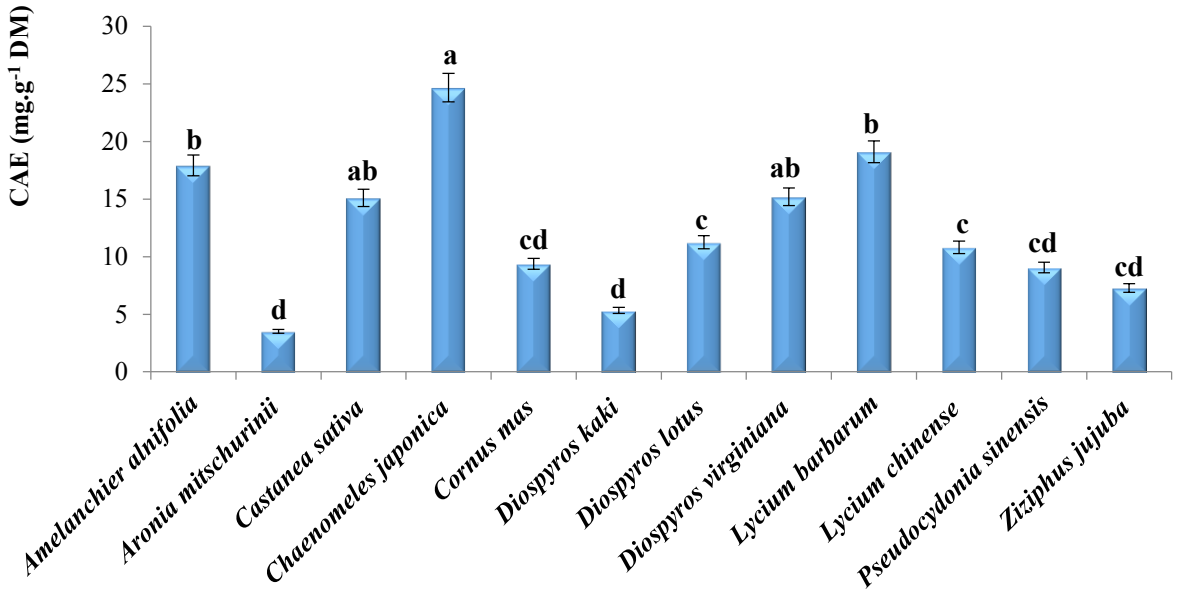

Figure 2 Total phenolic acid content in leaves of non-traditional plants.

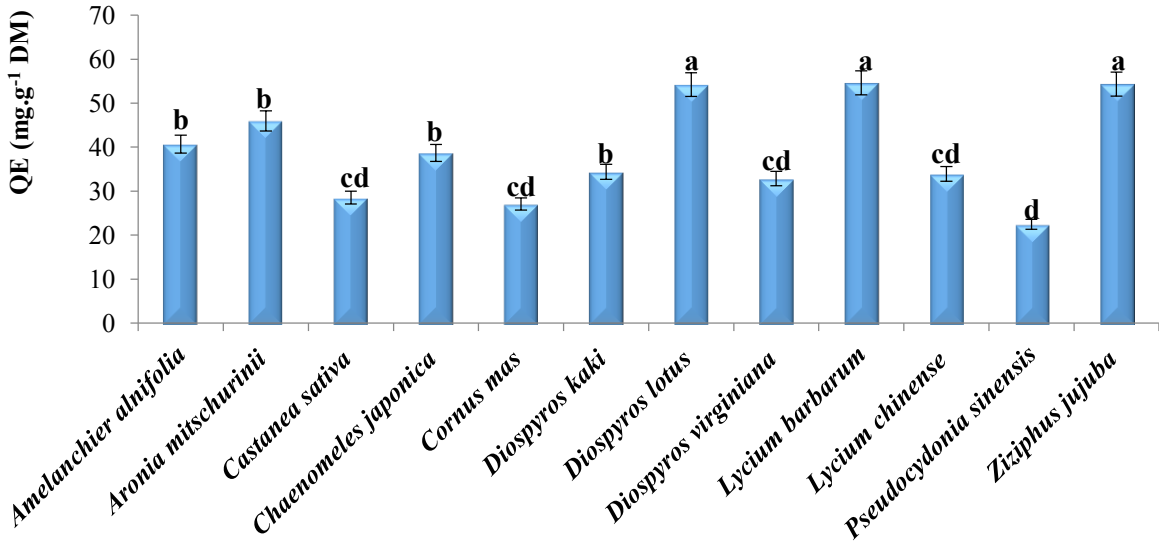

Figure 3 Total flavonoid content in leaves of non-traditional plants.
Note: different superscripts in each column indicate the significant differences in the mean at p <0.05); QE – quercetin equivalent.

The biological effects of many plant species depend on flavonoids; therefore, studies on the variation in their content are important and relevant **(Liaudanskas et al., 2014)**.

In the present work, *Lycium barbarum*, *Ziziphus jujuba* and *Diospyros lotus* leaf extract showed the highest amount of flavonoids (54, 61, 54.35 and 54.21 mg QE.g^{-1} DM, respectively) (Figure 3). The least value of flavonoids determined in extracts of *Pseudocydonia sinensis* (22.47 mg QE.g^{-1} DM).

According to **Barreira et al. (2010)**, total flavonoid contents *Castanea sativa* 73.31-90.39 mg.g^{-1}. Water extracts of *Cornus mas* leaves had total flavonoid contents 22.18 mg.g^{-1} **(Stankovic et al., 2014)**. *Aronia mitschurinii* leaves extracts in another study showed the content of flavonoids 103.6 – 163.7 mg CE.g^{-1} DW **(Thi and Hwang, 2014)**. Also, **Shahin et al. (2019)** found that the total content of flavonoids in dried leaves of *A. melanocarpa* was 96.16 mg.mL^{-1}. It should be noted that most studies about antioxidant parameters of *Aronia* species concerning of berries. The value of this parameter for *Ziziphus jujuba* methanol extracts was 90.28 mg.g^{-1} **(Al-Saeedi et al., 2016)** but ethanol extract of this species in our study was less. A study by **Aryal et al. (2019)** showed the flavonoid content in methanol leaves extracts eight selected wild vegetables from Nepal ranged from 37.86 to 66.1 mg QE.g^{-1}.

Natural plant antioxidants include main classes such as phenolic compounds, vitamins, carotenoids, etc. Phenolic compounds are a large group of antioxidants that can have structures from simple molecules to polyphenols (like flavonoids). Moreover, polyphenol compounds

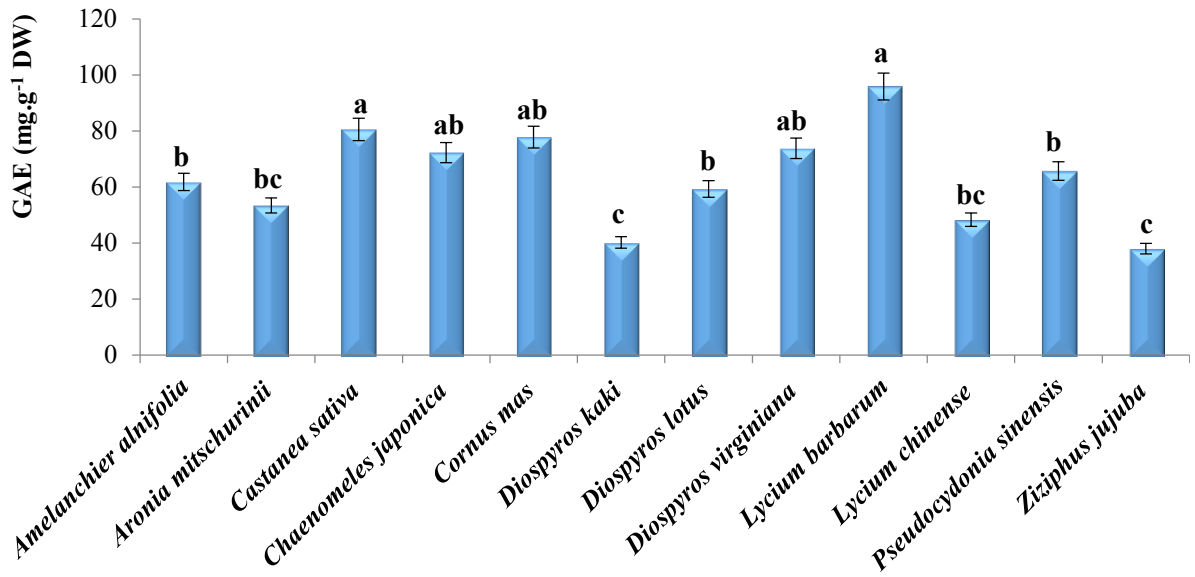

Figure 4 Total polyphenol content in leaves of non-traditional plants.
Note: different superscripts in each column indicate the significant differences in the mean at p <0.05; GAE – gallic acid equivalent.

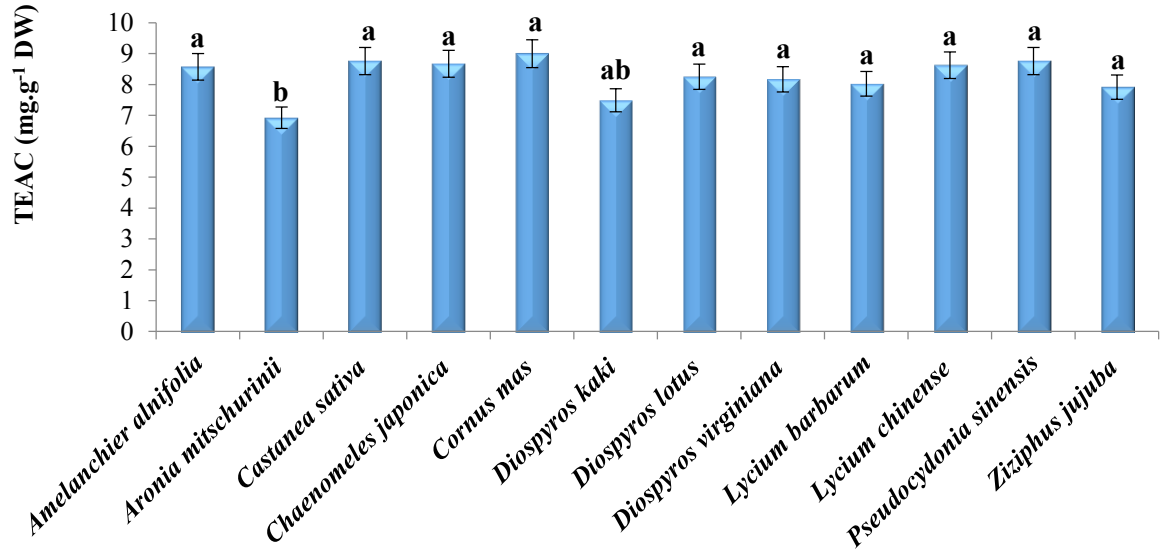

Figure 5 Antioxidant activity in leaves of non-traditional plants evaluated by the DPPH method.
Note: different superscripts in each column indicate the significant differences in the mean at p <0.05; TEAC – Trolox equivalent antioxidant capacity.

characterized by numerous activities that can be useful in human life such as antimicrobial, antifungal, anti-inflammatory, etc. **(Lourenço, Moldão-Martins and Alves, 2019)**.

The concentrations of total polyphenols content in non-traditional plant leaves are presented in Figure 4.

The highest total polyphenol content was obtained from *Lycium barbarum* and *Castanea sativa* (95.84 and 80.58 mg GAE.g^{-1} DW, respectively). In contrast, the lowest polyphenol content (40.24 and 38.02 mg GAE.g^{-1} DW, respectively) was obtained from *Diospyros kaki* and *Ziziphus jujuba* leaves.

Thi and Hwang (2014) found that *Aronia mitschurinii* total polyphenol content varied from 139.3 to 250.8 mg GAE.g^{-1} DW showed higher results than in the present study. The result of another study represented by **Shahin et al. (2019)** related to *Aronia melanocarpa* demonstrated that the total polyphenol content of dried leaves was 765.63 mg GAE.g^{-1}. As reported **Męczarska et al. (2017)**, leaves of *Amelanchier alnifolia* demonstrated the total content of polyphenols 185.23 mg GAE.g^{-1} DW that was 3 times less comparing with our result.

The antioxidative ability of leaves extracts

After studying the total phenolic compounds content it is important to examine and assess the antioxidant activity in the extracts of non-traditional plant species leaves. The results obtained during studies will be useful for the assessment and standardization of the quality of plant raw materials and will allow predicting an antioxidant effect of leaves non-traditional plants species.

The DPPH radical scavenging activities of non-traditional plant leaves at different stages of growth are shown in Figure 5. All tested samples exhibited DPPH•

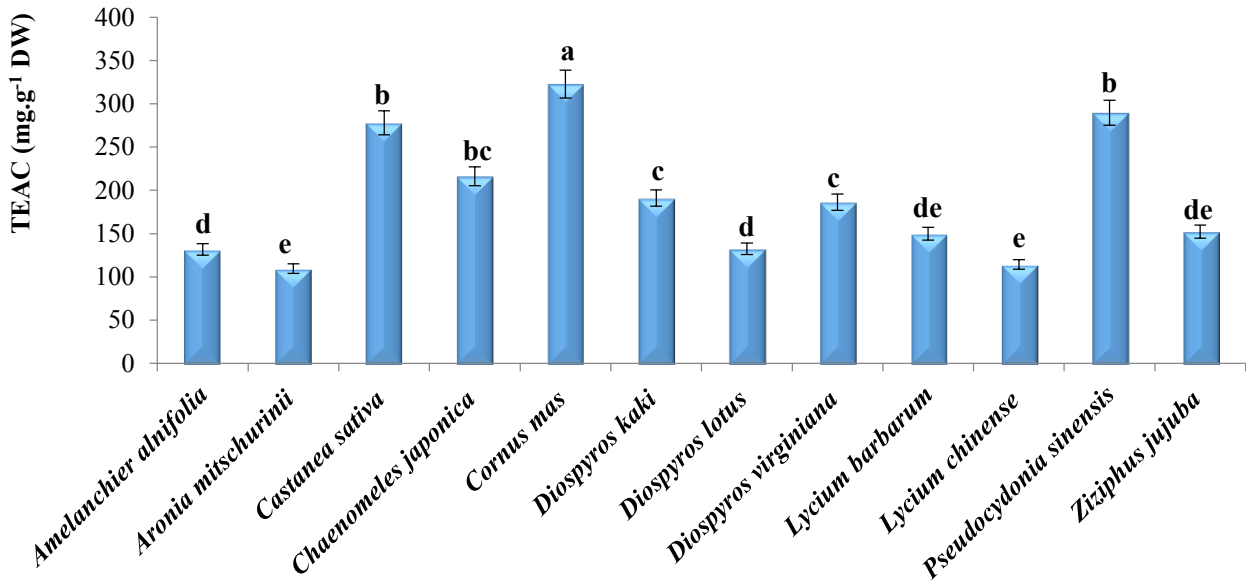

Figure 6 Antioxidant activity in leaves of non-traditional plants evaluated by the molybdenum reducing antioxidant power (different superscripts in each column indicate the significant differences in the mean at p <0.05); TEAC – Trolox equivalent antioxidant capacity.

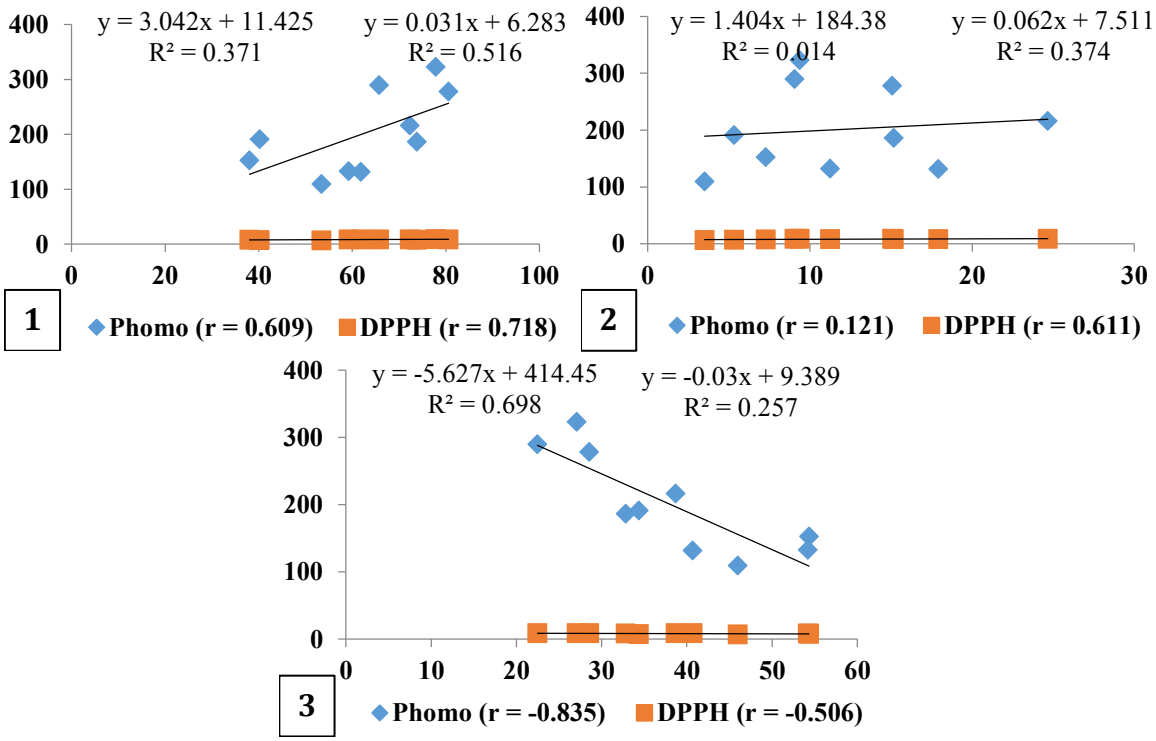

Figure 7 Correlation between antioxidant activity and TPC (1), TPA (2), and TFC (3) of non-traditional plants leaves extract.

radical scavenging activities with values from 6.92 (*Aronia mitschurinii*) to 9.0 (*Cornus mas*) mg TEAC.g^{-1} DW.

Serteser et al. (2009) reported that the methanolic extracts of the *Cornus mas* fruits showed EC50 (mg/ml) (DPPH reduction) values as 0.71.

The DPPH radical scavenging activity of the distilled water and 80% ethanol extracts of samples *Aronia mitschurinii* increased in a concentration-dependent manner (12.5~100 µg.mL^{-1}) **(Thi and Hwang, 2014)**. *Ziziphus spina-christi* (L.) Desf. ethanolic extracts exhibited good radical scavenging activity, with IC50 (the extract concentration providing 50% of inhibition) values of 54.3 µg.mL^{-1}, respectively (Khaleel et al., 2016). In the leaves of wild-growing plants of Nepal, the DPPH radical scavenging potency with a minimum IC50 value was recorded from 9.89 to 45.68 mg.mL^{-1} **(Aryal et al., 2019)**.

Antioxidant activity by molybdenum reducing antioxidant power method ranged from 109.43 (*Aronia mitschurinii*) to 322.95 (*Cornus mas*) mg TEAC.g^{-1} DM (Figure 6).

Comparison analyses of obtained data with results of other reviews often difficult to use in a similar study because of using different methods of determination of

antioxidant parameters, especially it is concerning standards that used and units.

The Pearson correlation coefficients between antioxidant activities and TPC, TPA, and TFC were depicted in Figure 7.

The result revealed the existence of a positive and negative correlation between tested antioxidant assays. TPC was significantly correlated with DPPH and phosphomolybdate assays (r = 0.609 – 0.718, p <0.05). The considerable correlation was noted in TPA and DPPH assay (r = 0.611).

CONCLUSION

In conclusion, the results of this study will provide new knowledge and useful information about the content of phenolic compounds in some selected non-traditional plants leaves and the antioxidant activity of their extracts, which will give a wide range of possibilities to employing these plants as the source of phenolic compounds. The highest total amounts of polyphenols and flavonoids were determined in the *Lycium barbarum* leaves (95.84 mg GAE.g^{-1} DW and 54.61 mg QE.g^{-1} DW, respectively). The preliminary experiments examining the antioxidant activity of leaf extracts of some selected non-traditional plants by the DPPH and phosphomolybdenum assays have shown that these extracts possess a strong antioxidant activity, which positively correlated with the total polyphenols content (r = 0.609-0.718, p <0.05). The ethanol extracts obtained from the apple leaves of the *Cornus mas* showed the highest TE values: 9.0 mg.g^{-1} DW by the DPPH method, 322.95 mg.g^{-1} DW by the molybdenum reducing antioxidant power. The findings of this study support the fact that leaves of some selected non-traditional plants are promising sources of potent antioxidants that can confirm the potential of investigated plants as a raw material in medical practice as well as the development and production of dietary supplements and cosmetic preparations rich in biologically active compounds.

GENETIC DIVERGENCE IN TUNISIAN CASTOR BEAN GENOTYPES BASED ON TRAP MARKERS

Martin Vivodík, Želmíra Balážová, Zdenka Gálová

ABSTRACT

In the present study, the representatives of the genus *Ricinus communis* collected from 12 different parts of Tunisia were differentiated by the DNA fingerprinting patterns using 30 TRAP primers. The efficacy of the TRAP technique in this study is further supported by the obtained PIC values of the primers used in the analysis. PCR amplification of DNA using 30 primers for TRAP analysis produced 490 DNA fragments that could be scored in all 56 genotypes of Tunisian castor. The number of amplified fragments varied from 3 (TRAP 04 x arb 1, TRAP 22 x arb 3 and TRAP 23 x arb 3) to 13 (TRAP 56 x arb 2), and the amplicon size ranged from 100 to 1600 bp. Of the 490 amplified bands, 377 were polymorphic, with an average of 5.71 polymorphic bands per primer. To determine the level of polymorphism in the analysed group of Tunisian castor genotypes polymorphic information content (PIC) was calculated. The lowest values of polymorphic information content were recorded for TRAP 10 x arb 1 (0.555) and the highest PIC values were detected for TRAP 44 x arb 2 (0.961) with an average of 0.770. A dendrogram was constructed from a genetic distance matrix based on profiles of the 30 TRAP primers using the unweighted pair-group method with the arithmetic average (UPGMA). According to analysis, the collection of 56 Tunisian castor genotypes were clustered into five main clusters. Moreover, functional TRAP markers would be efficiently useful in genetic studies for castor genetic improvement.

Keywords: castor; DNA; dendrogram; PCR; PIC

INTRODUCTION

Castor bean (syn. castorbean, castor, castor-oil-plant), *Ricinus communis* L. (2n = 20, X = 10), is a species of flowering plant in the spurge family, *Euphorbiaceae*. It is an oilseed crop cultivated mainly in India, Mozambique, Brazil, and China **(FAOSTAT, 2014)**. The seeds of castor bean have around 35 – 55% oil, and the commercial standard is 44%. The oil percentage of the seeds varies depending on the cultivation environment and the cultivar **(Costa and Ramos, 2004)**. The hydroxylated fatty acid ricinoleic is approximately 80 – 90% of the total fatty acids, which gives castor bean oil (ricin oil) unique chemical and physical properties. Ricin oil is a renewable resource and raw material with various industrial applications (e.g., to manufacture paints, lubricants, cosmetics, pharmaceutical drugs, dyes, anilines, disinfectants, germicides, low-temperature lubricating oils, glues and adhesives, fungicide and insecticide bases, printing inks and varnishes, nylon and plastic), and more recently its use as biodiesel has been explored **(Mutlu and Meier, 2010)**.

Now that some of these lineages have been developed, there is a need to study the genetic divergence among them. The genetic divergence among genotypes of any species can be evaluated with molecular markers, for example, target region amplification polymorphism (TRAP) markers. TRAP markers are functional markers that allow combining fixed and specific primers with arbitrary primers **(Hu and Vick, 2003)**. These markers have high levels of polymorphism, which makes them a promising option for the genotypification of germplasm and identification of genes related to desirable agronomic characteristics. Besides, TRAP markers optimize the genetic gains in genetic improvement programs and are a valuable tool used by these programs to study genetic divergence **(Agarwal et al., 2008)**.

Genetic diversity in castor bean was assessed by using both dominant and codominant molecular markers (random amplified polymorphic DNA, RAPD) **(Reddy, Nadigatla and Mulpuri, 2015; Vivodík et al., 2015)**, inter-simple sequence repeats (ISSR) **(Wang et al., 2013; Vasconcelos et al., 2016)**, start codon targeted (SCoT) **(Kallamadi et al., 2015; Reddy, Nadigatla and Mulpuri,**

2015), amplified fragment length polymorphism (AFLP) **(Allan et al., 2008; Quintero et al., 2013)**, simple sequence repeat (SSR) **(Gálová et al., 2015; Rukhsar et al., 2017)**, expressed sequence tag-simple sequence repeats (EST-SSR) **(Kanti et al., 2015; Wang et al., 2017)**, and random microsatellite amplified polymorphic DNA (RMAPD) **(Dong et al., 2012)**, and also advanced molecular markers, such as single nucleotide polymorphism (SNP) **(Foster et al., 2010)**, sequencerelated amplification polymorphism (SRAP) **(Lu et al., 2010; Mei-Lian et al., 2012)** and methylation-sensitive amplification polymorphism (MSAP) **(He et al., 2017)**. The polymerase chain reaction (PCR) has been used by many authors, such as **Vyhnánek et al. (2015)**; **Bošeľová and Žiarovská (2016)**; **Ražná et al. (2016)**; **Žiarovská et al. (2017)**; **Simões et al. (2017b)**; **Žiarovská et al. (2018)**; **Ansari et al. (2018)**; **Balážová et al. (2018)**; **El-Fiki and Adly (2019)**; **Žiarovská et al. (2019)**; **Cehula et al. (2019)**; **Vivodík et al. (2019)**.

Scientific hypothesis

TRAP markers are polymorphic enough to distinguish individual genotypes of Tunisian castor germplasm.

MATERIAL AND METHODOLOGY

Fifty-six castor (*Ricinus communis* L.) genotypes were used in the present study. Seeds of castor were obtained from the University of Carthage, National Institute of Research in Rural Engineering, Waters and Forests (INRGREF), Regional Station of Gabès, Tunisia. The ricin genotypes were obtained from 12 regions of Tunisia: S- Souassi (5 genotypes), BT- Bouthay (4 genotypes), GH- Ghomrassen (5 genotypes), BA- Sidi bou ali (5 genotypes), MT- Matmata (4 genotypes), AG- Mateur (5 genotypes), N- Nefza (4 genotypes), MD- Mednine (5 genotypes), M- Mornag (5 genotypes), G- Gabes (4 genotypes), K- Kebili (5 genotypes), KJ- Ksar jedid (5 genotypes). Genomic DNA of castor cultivars was extracted from leaves of 14-day old plantlets with GeneJET Plant Genomic DNA Purification Mini Kit according to the manufacturer's instructions. DNA concentrations were estimated by UV-Vis spectrophotometer Q5000, Quawell.

Amplification of TRAP fragments was performed according to **(Simões et al., 2017a)** using decamer arbitrary primers (Table 1 and Table 2). Amplifications were performed in a 15 μL reaction volume containing 1.5 μL of DNA, 7.5 μL of Master Mix (Genei, Bangalore, India), 1.5 μL of primer, and 4.5 μL H_2O. Amplification was performed in a programmed thermocycler (Biometra, Germany) with the following cycle: 94 °C for 2 min; 5 cycles at 94 °C for 45 s, 35 °C for 45 s and 72 °C for 1 min; followed by 30 cycles at 94 °C for 45 s, 40 °C for 45 s, 72 °C for 1 min; and a final extension of 72 °C for 7 min. Amplified products were electrophoresed in 1.5% agarose in 1× TBE buffer. The gels were stained with ethidium bromide and documented using gel documentation system.

Statistical analysis

A dendrogram based on hierarchical cluster analysis using the unweighted pair group method with arithmetic average (UPGMA) with the SPSS professional statistics version 17 software package was constructed. For the assessment of the polymorphism between genotypes ricin and usability RAPD markers in their differentiation, we used polymorphic information content (PIC) **(Weber, 1990)**.

RESULTS AND DISCUSSION

In the present study, the representatives of the genus *Ricinus communis* collected from 12 different parts of Tunisia were differentiated by the DNA fingerprinting patterns using 30 TRAP primers. The efficacy of the TRAP technique in this study is further supported by the obtained PIC values of the primers used in the analysis. PCR amplification of DNA using 30 primers (Table 1 and Table 2) for TRAP analysis produced 490 DNA fragments that could be scored in all 56 genotypes of Tunisian castor (Figure 2 and Table 3). The number of amplified fragments varied from 3 (TRAP 04 x arb 1, TRAP 22 x arb 3 and TRAP 23 x arb 3) to 13 (TRAP 56 x arb 2), and the amplicon size ranged from 100 to 1600 bp. Of the 490 amplified bands, 377 were polymorphic, with an average of 5.71 polymorphic bands per primer. Results indicated the presence of wide genetic variability among different genotypes of Tunisian castor. To determine the level of polymorphism in the analysed group of Tunisian castor genotypes polymorphic information content (PIC) was calculated. The lowest values of polymorphic information content were recorded for TRAP 10 x arb 1 (0.555) and the highest PIC values were detected for TRAP 44 x arb 2 (0.961) with an average of 0.770.

A dendrogram was constructed from a genetic distance matrix based on profiles of the 30 TRAP primers using the unweighted pair-group method with the arithmetic average (UPGMA). According to analysis, the collection of 56 Tunisian castor genotypes were clustered into five main clusters (Figure 1). Cluster 1 contained 2 unique genotypes of Tunisian castor (K-4 and BA-5) from different regions of Tunisia and cluster 2 was divided into two subclusters (2a and 2b). Subcluster 2a contained 7 genotypes of castor and subcluster 2b contained 4 genotypes of Tunisian castor. Cluster 3 contained 6 genotypes of Tunisian castor and cluster 4 was divided into 3 subclusters (4a, 4b, and 4c). Subcluster 4a contained 2 genotypes of Tunisian castor and subcluster 4b contained 6 genotypes of Tunisian castor and subcluster 4c contained 29 genotypes of Tunisian castor. (Figure 1).

TRAP markers were used by other authors **(Miklas et al., 2006; Hu et al., 2007; Yu et al., 2007; Alwala et al., 2008; Kwon et al., 2010; Yue et al., 2010; Andru et al., 2011; Barakat et al., 2013; Cheng et al., 2013; Crotti-Franco et al., 2014; Kumar et al., 2014; Carmo et al., 2015; Feng et al., 2015; Luo et al., 2015; Dias Kanthack Junior et al., 2020)**.

Zhang et al. (2013) assessment the genetic diversity and variation of *Pinellia ternata* collected from 43 populations in China using SRAP þ TRAP markers. A total of 13 SRAP primers in addition to 3 TRAP primer combinations yielded 292 bands in a total of which 286 were polymorphic (98.0%), with an average of 16 for each. The PIC value ranged from 0.88 to 0.95, with a mean polymorphic information content (PIC) of 0.92 over all the primers. **Luo et al. (2013)** developed and characterized sequence tags (ESTs)-simple sequence repeats (SSRs) and targeted region amplified polymorphism (TRAP) markers to examine genetic relationships in the persimmon genus *Diospyros gene* pool. In total, we characterized 14 EST-SSR primer pairs and 36 TRAP primer combinations, which were amplified across 20 germplasms of 4 species in the genus *Diospyros*. **Liu et al. (2016)** study the genetic structure and genetic diversity among and within the 21 populations using target region amplified polymorphism (TRAP) and simple sequence repeat (SSR) markers. Sixteen pairs of TRAP primers generated a total of 398 fragments, of which 396 (99.50%) were polymorphic; fourteen pairs of SSR primers generated a total of 60 fragments, of which 59 (98.33%) were polymorphic. **Al-Murish et al. (2013)** study efficiency of SRAP, TRAP, and SSR primers in detecting genetic variation among 17 *C. arabica* genotypes collected from the different valleys of Yafea City, Yemen, and estimate genetic similarity coefficients among these genotypes and classify them according to genetic relationships. The results of the present study demonstrated the presence of genetic variation among coffee genotypes within and between valleys.

In this study, **Liu et al. (2015)** estimated the genetic relationships within *P. aibuhitensis* using Target Region Amplified Polymorphisms (TRAP) and Amplified Fragment Length Polymorphisms (AFLP) that were derived from related populations on the coasts of China.

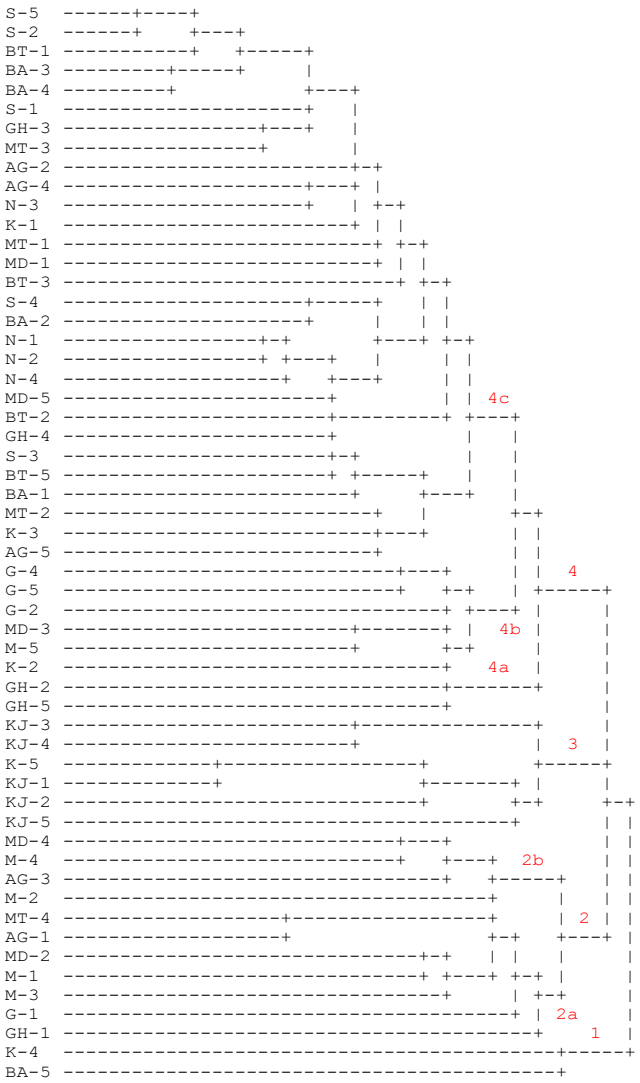

Figure 1 Dendrogram of 56 Tunisian castor genotypes prepared based on 30 TRAP markers.
Note: S – Souassi (5 genotypes), BT – Bouthay (4 genotypes), GH – Ghomrassen (5 genotypes), BA – Sidi bou ali (5 genotypes), MT – Matmata (4 genotypes), AG – Mateur (5 genotypes), N – Nefza (4 genotypes), MD – Mednine (5 genotypes), M – Mornag (5 genotypes), G – Gabes (4 genotypes), K – Kebili (5 genotypes), KJ – Ksar jedid (5 genotypes).

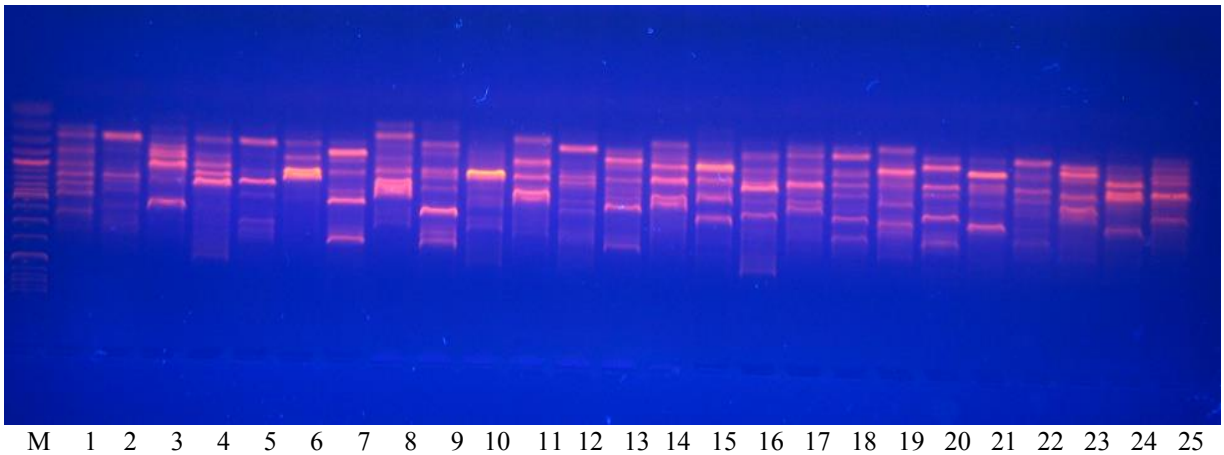

Figure 2 Electrophoretic profile, on 2% agarose gel, obtained from the amplification of the genomic DNA of 25 lineages of *Ricinus communis* L.
Note: (lanes 1-25) using TRAP 01 x arb 3 primer. Lane M: 100-bp molecular weight marker.

Among the TRAPs, 449 bands were observed in total, 439 of which (97.77%) were polymorphic between the *P. aibuhitensis* populations and were shared between at least four individuals. The Qinzhou (QZ) population had the highest PPB (78.62%), and the Dalian (DL) population had the lowest (60.13%). The objective of study **Farias da Silva et al. (2016)** was to analyze the genetic diversity of the clonal germplasm of the guarana plant using Target Region Amplification Polymorphism (TRAP) and Sequence-Related Amplification Polymorphism (SRAP) markers. Sixty clones of the guarana plant were analyzed; 18 were cultivars, eight were similar clones according to morpho-agronomic traits, and 34 were clones of a different origin. **Singh et al. (2017)** study the genetic variations among the twenty-five sugarcane genotypes employing functional molecular (TRAP) markers. Genetic diversity exists among sugarcane germplasm was exploited to identify promising genotypes bearing enviable agronomic traits (sucrose content and multiple disease resistance). Genetically diversified genotype could be exploited as proven parents in sugarcane hybridization programs to establish a promising cross. **Mirajkar et al. (2017)** study molecular marker profile using 57 markers, comprising of 27 TRAP and 30 SRAP markers in the gamma ray-induced sugarcane mutants. Collectively these markers produced 260 PCR amplicons among which 147 were polymorphic (56.54%). The TRAP marker-based analysis showed that the mutants AKTS-01 and AKTS-16 were more diverse (GS = 94 and 92%, respectively) than the rest of the mutants. In the study of **Fabriki-Ourang and Yousefi-Azarkhanian (2018)** target region amplification polymorphism (TRAP) and conserved region amplification polymorphism (CoRAP) markers were used for genetic diversity and relationship analysis of 25 Salvia ecotypes/species. Twelve TRAP and CoRAP primer combinations (four arbitrary primers and three fixed primers from *Salvia miltiorrhiza* expressed sequence tag sequences) amplified 180 loci, of which all were polymorphic. **Srivong et al. (2019)** study 17 sugarcane genotypes from Hawaii and Thailand using 12 target region amplification polymorphism (TRAP) markers and partial Sai nucleotide polymorphism. A total of 275 fragments were produced, of which 273 (99.27%) were polymorphic. The polymorphic information content (PIC) ranged from 0.912 – 0.959 with an average value of 0.938. Genetic similarity (GS) by Dice's similarity coefficient ranged from 0.19 – 0.81 with a mean of 0.44.

CONCLUSION

PCR amplification of DNA using 30 primers for TRAP analysis produced 490 DNA fragments that could be scored in all 56 genotypes of Tunisian castor. The number of amplified fragments varied from 3 (TRAP 04 x arb 1, TRAP 22 x arb 3 and TRAP 23 x arb 3) to 13 (TRAP 56 x arb 2), and the amplicon size ranged from 100 to 1600 bp. Of the 490 amplified bands, 377 were polymorphic, with an average of 5.71 polymorphic bands per primer. To determine the level of polymorphism in the analysed group of Tunisian castor genotypes polymorphic information content (PIC) was calculated. A dendrogram was constructed from a genetic distance matrix based on profiles of the 30 TRAP primers using the unweighted pair-group method with the arithmetic average (UPGMA). TRAP markers could be used to select elite parent genotypes, analysing genetic variation, utilization of genotype potential for trait improvement for adaptation to stress environment. It is therefore suggested that a focused breeding scheme should be adopted while analyzing genome diversity for parent selection to gain maximum value and practical impact on breeding program. TRAP markers exhibited remarkable discriminatory power for genetic diversity analysis.

EFFECT OF SUPPLEMENTATION WITH SOLID-STATE FERMENTED FEED IN THE DIET OF LAYING HENS ON EGG QUALITATIVE VARIABLES

Boris Semjon, Eva Dudriková, Iveta Jaďuttová, Martin Bartkovský, Tatiana Klempová, Dana Marcinčáková, Ondrej Slaný, Slavomír Marcinčák

ABSTRACT

The aim of this experiment was to evaluate the effect of the supplementation of laying hens diet with solid-state fermented feed on egg qualitative variables. The diet of laying hens was supplemented with 10% and 15% of solid-state feed fermented by the low filamentous fungal strain *Mortierella alpina* CCF 2861. For the trial, 30 Lohmann Brown classic layers, aged 17 weeks, were selected and individually weighed and divided into three groups (control and two experimental groups). The control group of laying hens was fed with basic feed mixture and the experimental groups received the same diet as a control group, but enriched with supplementation of solid-state fermented feed. The first experimental group was fed a diet supplemented with 10% of fermented feed and the second experimental group with 15% supplementation. The following egg qualitative variables were observed: the egg weight, Haugh units, quality grade, air cell depth, percentage of the shell, yolk and albumen, eggshell breaking force, pH of egg yolk and albumen, egg yolk colour, and antioxidant activity with the extent of lipid oxidation in egg yolk samples. The pH of yolk and albumen did not show differences between all examined eggs originating from the experimental groups of laying hens (p >0.05). The eggs from both experimental groups had a significantly higher eggshell hardness than eggs produced by the hens of the control group (p <0.05). Antioxidant activity of egg yolk of experimental samples increased with the supplementation of fermented feed in the diet of laying hens (p <0.05). The specific lightness of egg yolk colour increased significantly in the experimental group with 15% of supplementation (p <0.01). The obtained results showed that feeding laying hens with fermented feed positively affected the quality of produced eggs. This was the first study and further investigation before using the fermented feed in commercial laying hen farms is necessary.

Keywords: laying hen; egg; quality; solid-state fermented feed; colourimetry

INTRODUCTION

Eggs are an important source of polyunsaturated fatty acids (PUFA) in human nutrition. PUFA are biologically active substances that are beneficial for human health. The positive effect of PUFA on health is very well known. They are components of cell membranes and precursors of eicosanoids **(Gładkowski et al., 2011)**. They regulate architecture, dynamics, phase transition, and permeability of membranes as well as the behaviour of some membrane-bound proteins. In addition, PUFA, as essential compounds, are precursors of a multitude of diverse metabolites, such as prostaglandins, leukotrienes, and hydroxy fatty acids **(Ghadiri et al., 2016; Wang et al., 2017)**. Eggs are also interesting from the viewpoint that the content of individual significant n-3 and n-6 PUFAs in the lipid portions of an egg can be very easily changed by the composition of the fatty acids in the feed of laying hens. The weight and composition of a table egg are dependent on heredity, age, season, diet, and other factors **(Kusum et al. 2018)**. The main chemical components of hen egg are 12% lipids, 12% proteins, and the rest is water and small amounts of carbohydrates and minerals **(Sugino, Nitoda and Juneja, 1997)**. Most of the proteins are present in the egg white and the egg yolk, amounting to 50% and 44%, respectively; the eggshell contains the rest of the proteins **(Kusum et al. 2018)**. The protein fraction is distributed in both egg white (ovalbumin, ovotransferrin, ovomucoid, ovomucin, etc.) and yolk (high-density lipoproteins, low-density lipoproteins and livetins) **(Nimalaratne and Wu, 2015)**. The yolk accounts for slightly over one-third of the edible portion, but it yields three-fourths of the calories and provides all or most of the fat in whole eggs The yolk comprises 48% water, 16% protein, 32.6% fat, and some minerals and vitamins. The white consists of 88% water, 10% protein, and some minerals **(Ren, Wu and Renema, 2010)**. The yolk is a complex milieu containing 68% low-density lipoproteins (LDL), 16% high-density lipoproteins (HDLs), 10% livetins and other soluble proteins, and 4% phosvitins **(Réhault-Godbert, Guyot and Nys, 2019)**. The amount of lipid in the egg white is negligible (0.01%) compared with the amount present in the yolk. The shell makes up 11% of the weight of an egg, and approximately 98% of the shell consists of calcium. Carbohydrates are a minor

component of hen eggs. Their average content is about 0.5 g per egg, 40% of which is present in the yolk. **(Ren, Wu and Renema, 2010; Kusum et al. 2018)**.

Many egg proteins such as ovalbumin, ovotransferrin, phosvitin, egg lipids such as phospholipids, as well as certain micronutrients such as vitamin E, vitamin A, selenium, and carotenoids, are reported to have antioxidant properties, which prevents or removes oxidative damage to a target molecule by the regulation of antioxidant defence or inhibition of radicals production **(Nimalaratne and Wu, 2015)**.

Numerous studies have been published on the supplementation of hen's diets with ALA-rich seeds or oil; EPA/DHA-rich fish oil, fish oils combined with humic preparations **(Gładkowski et al., 2011),** microalgae (such as biomass of *Spirulina maxima*) **(Saeid and Chojnacka, 2015; Neijat, et al., 2016; Saeid et al., 2016)**.

Industrial processing of feeds destined for animal consumption and human nutrition results in high amounts of agroindustrial residues. Most of these residues have nutritional potential **(Graminha et al., 2008)**. These residues have been classified as agro-industrial by-products and recently they have been receiving greater attention **(Eun et al., 2006)**. In terms of cost efficiencies, the replacement of expensive conventional feedstuffs in animal diets with cheaper unconventional fermented feedstuffs may further encourage the use of the latter **(Sugiharto and Ranjitkar, 2019)**.

Solid-state fermentation (SSF) is the oldest known fermentation technique, which imitates the natural environment of the microorganism **(Marcinčák et al., 2018)**. SSF is characterized as a process in which microorganisms grow on a moist solid substrate in the absence of free water, simulating the fermentation reactions occurring in nature **(Pandey, 2003)**. Low filamentous fungi strains used in the SSF process simultaneously decrease the anti-nutrient compounds in the substrates and partially hydrolyse substrate biopolymers, the pre-fermented mass with a high content of PUFA, which may be used as an inexpensive food and feed supplement **(Čertík et al., 2008)**.

Several strains of oleaginous lower fibrous fungi, in particular Mortierella, Cunninghamella, Mucor, Thamnidium, Pythium and Thraustochytrium, are a good source of PUFAs **(Čertík et al., 2013)**. *Mortierella alpina* is a food-grade oleaginous fungus with the ability to release a high level of PUFAs, especially arachidonic acid (C 20:4-n-6) and eicosapentaenoic acid (C 20:5-n-3) **(Dai et al., 2016)**. The solid-state fermented feed, prepared by fermentation of distiller's dried grains with solubles and soybean meal by *Mortierella alpina* respectively, was successfully applied in poultry nutrition, resulting in an enhanced amount of PUFA in chicken breast meat **(Yang and Zhang, 2016)**. The product from the SSF process increased the PUFA content in chicken breasts and enhanced the proportions of n-6 and n-3. Hence, the requirement for new natural nutritional products could be potentially fulfilled by the method of the fermentation process **(Klempová et al. 2013)** and the subsequent use of the fermented products in the diet of laying hens. Pertaining to our studies, it should improve the egg quality and nutritional value of produced eggs, e.g. by the increase of PUFA content in egg yolk.

One of the most important factors is feeding of the laying hens, not only because of the effect on egg yolk colour but also because of the quality and safety of the final product. Many external and internal factors **(Tůmová and Ebeid, 2005; Dvořák et al., 2007)** affect the quality of eggs used in human nutrition. A multitude of scientific literature and data exist that discuss the replacement of corn, which represents the main ingredient of poultry diets, accounting for 60-70% of feed costs **(Laganá et al., 2011)**. For this purpose, soybean meal, sorghum, broken rice, millet, cassava meat, etc. have been proposed. However, a carotenoid source, or annatto (*Bixa Orellana* L.), and curcumin (main pigment in turmeric roots – *Turmeric longa* L.), must be added to ensure egg yolk pigmentation **(Assuena et al., 2008**. On the other hand, the dietary carrot can influence both the physical characteristics of the egg and yolk colour, the latter of which contains a higher amount of carotenes and a lower amount of xanthophylls and paprika **(Spasewski et al., 2018)**. It is known that egg yolk colour is affected mostly by the diet of the hen **(Colin et al., 2004)**, and the main source of pigment in conventional diets is yellow corn **(Lokaewmanee et al., 2010)**.

The main challenge of our research was evaluating the effect of supplementation of the diet of laying hens with solid-state fermented feed on egg qualitative variables. The diet of laying hens was supplemented with 10% and 15% of solid-state fermented feed by the filamentous fungi *Mortierella alpina* CCF 2861.

Scientific hypothesis

1. We assume that supplementation of solid-state fermented feed in the diet of laying hens affects the physical variables of the egg.
2. We assume that egg yolk colour of eggs will be affected by the application of solid-state fermented feed in the diet of laying hens belonging to the experimental groups.
3. We assume that solid-state fermented feed in the diet of laying hens influences antioxidant activity and extent of the lipid oxidation in egg yolk samples.
4. We assume that a higher impact will be made on qualitative variables of produced eggs with supplementation of 15% of solid-state fermented feed in the diet of laying hens, in comparison to 10% supplementation.

MATERIAL AND METHODOLOGY

The animal protocol for this research was approved by the Ethical Committee for Animal Care and Use of University of Veterinary Medicine and Pharmacy in Kosice (The Slovak Republic). The experiment was carried out in accordance with the 'European Directive on the Protection of Vertebrate Animals Used for Experimental and Other Scientific Purposes' **(European Parliament and Council, 2010)**.

Preparation of fermented feed

Fermented feed (FF) was prepared by fungal solid-state fermentation (SSF) according to the modified method of **Čertík et al. (2006)**. The low filamentous fungal strain *Mortierella alpina* CCF 2861 was used. *M. alpina* CCF

2861 was obtained from the Culture Collection of Fungi, Charles University, Prague, Czech Republic. For the preparation of the spore suspension, which was inoculated with the SSF substrate, *M. alpina* CCF 2861 was grown for 10 days on rice. After 10 days, the spores were washed with distilled water with 0.05% Tween 80 and filtered through a gauze to remove the solid substrate. The spore suspension thus prepared was diluted to a concentration of 2.10^5 spores.mL^{-1}. Wheat bran was used as a substrate.

Birds, Housing, Diets and Experimental Design

The experiment was carried out at the University of Veterinary Medicine and Pharmacy in Košice.

For the trial, 30 laying hens Lohmann Brown classic layers aged 17 weeks, were individually weighed and divided into three groups (10 hens per pen).

The control group of laying hens (C) was fed with a commercial feed mixture without the supplementation of FF (De Heus, Bučovice, Czech Republic). Components of commercial feed mixture were corn, wheat, calcium carbonate, sunflower pomace, soya meal, rapeseed meal, wheat bran, corn gluten feed, barley, dark distillery grape, vinasse, vegetable oil and sunflower fat, monocalciumphosphate and sodium chloride. The nutrition composition of basal and experimental feed mixtures is presented in Table 1.

The first experimental group of laying hens (FF10) was fed with commercial feed mixture supplemented with 10% of FF, and second experimental group with 15% supplementation (FF15). First two weeks of acclimatization for animals were assigned to the experimental groups. Fermented feed was supplemented to the laying hens after the beginning of egg performance, in the 21st week.

Determination of egg qualitative variables

To determine egg quality, 150 eggs, collected from week 25, were used for analyses.

Egg Analyzer™ (Orka Food Technology Ltd., Ramat HaSharon, Israel) was used to determine the egg weight, Haugh units (HU), quality grade and yolk colour. The device has measured egg weight (g), the height of the thick albumen (mm), and colour of the yolk. The first two measurements were used for calculation of HU, which indicates egg quality. The equation for working out the rating is shown below: $HU = 100 \log (h - 1.7w^{0.37} + 7.6)$, where: HU = egg quality in Haugh units; w = egg weight in grams; h = height of the thick albumen in mm **(Nagy et al., 2011)**.

The air cell depth of eggs was expressed in millimetres. The percentage of shell, yolk and albumen was calculated.

Eggshell breaking force was measured in accordance with the manufacturer's instructions by the Egg force reader (Orka Food Technology Ltd., Ramat HaSharon, Israel) - a compact system for automatic measuring of the eggshell breaking point. The unit of strength measurement involves gentle application of force on the eggshell until it cracks. The results were interpreted as kilogram-force (kgf).

The pH of egg yolk and albumin were measured by the WTW 7110 pH meter (WTW GmbH, Weilheim, Germany). Antioxidant activity of yolk was detected spectrophotometrically by the method of 2,2-diphenyl-1-picrylhydrazyl (DPPH) scavenging **(Brand-Williams et al., 1995)**. The extent of lipid oxidation in egg yolk samples was evaluated via measurement of thiobarbituric acid reactive substances (TBARS) according to the method **Reitznerová et al**. **(2017)**. Thiobarbituric acid reactive substances (TBARS) values were measured spectrophotometrically at 532 nm (Helios c; Thermo spectronic, Cambridge, UK). The results were quantified as MDA equivalents (mg.kg^{-1}).

Colour of egg yolk was determined by Minolta Chroma Meter CR-410 (Ø 50 mm, average daily light with a colour temperature of about 6500 K (D65) (Konica Minolta, Sensing, Inc. Japan), using a programme of a Colour Data Software CM-S100w SpectraMagic™ NX (Konica Minolta Sensing Inc., Osaka, Japan, 2014). The equipment was calibrated against a standard light white reference tile and the measurements were conducted under a 2° standard observer angle. The colour parameters L* − lightness was

Mn [mg.kg^{-1}]	195.44	173.44	176.67	166.08

Note: FF – fermented feed; C – control group of laying hens; FF10 – laying hens fed with diet supplemented with 10% of fermented feed; FF15 - laying hens fed with diet supplemented with 15% of fermented feed; *SD* – standard deviation.

measured on a scale of 0 to 100%; a* − redness; b* − yellowness. Colour measurements were determined according to the CIELab colour space system **(Commission Internationale de l'Eclairage, 1986)**.

The instrument was calibrated with a white reference plate (Konica Minolta, Sensing, Inc. Japan), with setting values (L* = 97.10, a* = -4.88, b* = 7.04) before the measurement.

CIE total colour difference (ΔE*), as the distance between the two points, was calculated according to the following formula: $\Delta E^* = [(\Delta L^*)^2 + (\Delta a^*)^2 + (\Delta b)^2]^{1/2}$. Chroma C* represents a value which measures the extent to which the particular colourity differs from grey. Chroma C* was calculated according to this formula: $C^* = (a^{*2} + b^{*2})^{1/2}$. Hue h_{ab} is expressed as the name of colour and this value was calculated according to the following formula: $h_{ab} = tg^{-1} (b^*/a^*)$.

Statistical analysis

Data analysis was carried out with GraphPad Prism 8.3.0.538 (GraphPad Software, San Diego, California, USA). The effect of the supplementation of laying hens diet with solid-state fermented feed with 10% and 15% on egg qualitative variables was set as the main factor. A one-way analysis of variance (ANOVA), followed by Tukey's post-test, was conducted and a confidence interval was set at 95%.

RESULTS AND DISCUSSION

Table 2 shows the results of the physical variables of eggs produced in the 25th week. The maximum egg weight was detected in the experimental group of laying hens (53.13 ±3.74 g) after 10% addition of fermented feed (FF10). Egg yolk weight increased in the experimental group FF15 to the value of 12.24 ±1.25 g per egg. Eggshell mean weight ranged from 6.91 ±0.58 g (FF15 group) to 7.48 ±1.92 g in the eggs originating from the control group (C) of laying hens. However, no statistically significant effect on physical variables of produced eggs was observed when the experimental diet was provided (p >0.05).

The effect of solid-state fermented feed on quality of the produced eggs was examined on the fifth week of egg performance (in 25th week). The results of the qualitative variables determinations are shown in Table 3. The eggs from F10 and FF15 experimental group had a significantly higher eggshell hardness, 5.80 ±0.96 kgf and 5.69 ±0.65 kgf, respectively, than eggs produced by the C laying hens group (2.78 ±1.16 kgf), which were fed only with basic feed mixture (p <0.05). The supplementation of 15% fermented feed in diet of the FF15 group showed an increase in HU values of egg performance. The experimental supplementation in the diet of laying hens had no significant effects on egg quality traits (Table 3) in terms of yolk and albumen index and in the size of air bubbles

(p >0.05). The pH of yolk and albumen did not show significant differences between both experimental groups of laying hens (p >0.05).

The eggshell hardness was statistically different among the experimental groups (p <0.05). Maximum eggshell hardness was determined in egg samples of FF10 group, which was 2.86 times higher than in the eggs of C group (Table 3). The supplementation of laying hens with an experimental diet showed a significant effect on eggshell hardness (p <0.05).

The results of DPPH radical scavenging activity (antioxidant activity) and malondialdehyde content in egg yolk samples of produced eggs are presented in Table 4. The antioxidant activity of the egg yolk was affected by the feeding of both 10% and 15% supplementation with fermented feed. The ability to scavenge free DPPH radicals was significantly higher in egg yolk of experimental groups (FF10 and FF15) in comparison to the values obtained for the eggs from the control group (p <0.05).

Malondialdehyde (MDA) values in samples of the eggs were lower for groups FF10 and FF15 than in the control group (C), although the differences between values for this parameter did not show significant differences (p >0.05).

Colourimetric parameters of egg yolks, obtained from eggs belonging to the experimental groups, were measured by Minolta Chroma Meter CR-410 (Ø 50 mm, average daily light with colour temperature of about 6500 K (D65), standard measurement angle 2°) and are listed in Table 5.

L* variable, which represents light shade intensity (0 – black, 100 – white), exhibited a significant difference (p <0.01). A decrease in the mean value of L* variable in the FF15 indicates darkening of the egg yolk. This suggests that the egg yolk from the eggs of laying hens fed with supplementation of 15% fermented feed contains higher concentrations of colour pigment. Variable a* reflects the changes in the area of red-colour wavelengths and can reach a maximum in sharp red colour (+120) or a minimum in green-blue colour (-80). Egg yolk obtained from all experimental groups of laying hens showed no significant changes in indicator a* (p >0.05).

According to the colour measurements, descriptive egg parameters were numerically affected only by the mean of L* variable and statistically differed (p <0.01). The highest L* value was obtained with higher egg yolk colour in FF15 of experimental eggs. The presented egg yolk colour was not significantly different in a*, b*, h*, C* and index of egg yolk values, respectively.

Table 2 Physical variables of produced eggs in the 25th week of egg performance (mean ±*SD*).

	C	FF10	FF15
Egg weight [g]	52.31 ±2.71	53.14 ±3.74	51.90 ±2.57
Yolk [g]	12.50 ±0.14	12.15 ±0.94	12.24 ±1.25
Albumin [g]	32.33 ±1.86	33.62 ±3.77	32.75 ±1.04
Eggshell [g]	7.48 ±1.92	7.37 ±0.91	6.91 ±0.58

Note: C – control group of laying hens; FF10 – laying hens fed with diet supplemented with 10% of fermented feed; FF15 – laying hens fed with diet supplemented with 15% of fermented feed; *SD* – standard deviation.

The specific lightness of egg colour, e.g. indicator L*, increased significantly in FF15 experimental group (p <0.01). Variable a* (red colour) in experimental eggs remained unaffected, egg yolk showed a trend towards orange colour (Table 5). Value of variable b* slightly increased after supplementation with 10% of fermented feed in hens diet and slightly decreased with 15%. However, the corresponding differences were not significant (p >0.05).

The indicators of colourity are shown in Table 5. Hue h* slightly increased (FF10) and decreased (FF15) with fermented feed. However, the change in h* variable was not significant (p >0.05). Also, chroma C* variable (the value by which particular colourity differs from grey) does not represent significant differences among groups (p >0.05).

Table egg colour can be controlled by a subjective method, with DSM YolkFan^{TM} or an objective method, the chromameter Minolta **(Hamelin and Hernandez, 2011)**. CIE total colour difference (ΔE*) was the only indicator that differs from the control. The difference was higher for the higher dose (2.61) of fermented feed in the diet of laying hens than for the lower dose (1.96) of fermented feed, 15% and 10%, respectively. The absolute value of the difference between FF10 and FF15 groups of experimental laying hens was low, 0.65. A ΔE* value higher than 1.00 expresses that the colour difference of two samples, which are measured, is detectable with human eye.

Egg producers, consumers and processors´ perspectives have different meanings for the definition of egg quality. Easy eggshell removal and separation of the yolk from the albumen, as well as functional properties of eggs, are very important for the processors of eggs **(Alleoni and Antunes, 2001).** For the egg producers, egg quality usually means the egg weight and quality of eggshell, whereas consumers are interested mostly in shelf life, the external appearance of eggs and sensorial qualities, such as eggshell and yolk colour **(Faitarone et al., 2016; Ketta and Tůmová, 2016)**.

Several studies have been published in recent years, in which filamentous fungi in SSF feed were successfully applied in poultry nutrition. However, most published scientific articles with an application of SSF feed in poultry production are related to broilers nutrition **(Bača et al., 2014; Marcinčák et al., 2018; Sugiharto and Ranjitkar, 2019)**. On the other hand, supplementation of laying hens diet with microbial probiotics, plant additives,

etc. were also studied. The influence of probiotic preparation based on lactobacillus, oregano essential oil, sumac (*Rhus coriaria*), propolis and pollen on egg quality parameters of Lohmann hybrid laying hens were studied by the authors **Arpášová et al. (2012)**, who observed that supplementation did not negatively affect monitored egg quality parameters. Influence of dietary inclusion of *Bacillus licheniformis* on laying performance, egg quality, antioxidant enzyme activities, and intestinal barrier function of laying hens was also studied **(Lei et al., 2013)**. The quality of the table eggs, their damage and spoiling in various age of the laying hens during the second phase of the laying cycle was studied by the authors **Angelovičová, Ševčíková and Angelovič (2015)**, who assumed that the values of egg shell weight were not directly related to egg weight and egg white weight.

Nevertheless, egg quality remains an interesting subject to investigate. Organoleptic properties and consumption of eggs are associated with the egg quality variables. **Kozelová et al. (2018)** examined the opinions of the Slovak consumers about the purchase and consumption of eggs and identified their preferences at egg purchase.

A wide variety of scientific literature investigates how the quality and composition of eggs can be altered concerning their use for human nutrition. These changes are often caused by the diet, using some specific ingredients in the feed of laying hens to reach a change in the profile of yolk lipids, mostly to improve the content of lipid fatty acid composition **(Koreleski et al., 2003; Faitarone et al., 2016)**. On the other hand, if the diet of laying hens contains sources of PUFA, e.g. via vegetable oil supplementation, the yolk of eggs can present high lipid oxidation, when compared with those derived from laying hens fed a diet without supplementation. **Faitarone et al. (2016)** stated in their work that the analysis of variance showed significant differences in yolk lipid oxidation values in eggs laid by white layers fed diets supplemented with different vegetable oils and their concentrations (e.g. linseed, canola, soybean oils and their different mixtures). In this experiment, it was detected, that after 10 days of storage at room temperature, the eggs laid by hens fed a diet with no oil supplementation or supplemented with 2.5% soybean oil showed a lower degree of yolk lipid oxidation in comparison to the eggs laid by hens fed diets supplemented with 5% linseed oil and with 2.5% canola oil +2.5% soybean oil. These results were not significantly different from the other treatments. **Giampietro et al. (2008)** stated that yolk lipid oxidation increased according to egg age, for instance: 0.1343 TBA values in fresh eggs *versus* 0.1698 in eggs stored for seven days, and 0.2138 in eggs stored for 14 days, respectively. According to **Koreleski et al. (2003)**, TBARS values in eggs stored for 15 days at a temperature from 4 to 8 °C were significantly higher for control group I (basal diet) and II than in the other groups. The basal diet in those groups was supplemented with 0.3% Lyso fish fat (groups II, III, IV and V), while reducing the proportion of blended fat by the same amount. So, the lowest yolk fat oxidation was detected in eggs of hens fed the diet supplemented with synthetic antioxidant or vitamin E, and then this was followed by the group supplemented with vitamin C.

Yolk colour was determined as the mean of five readings in the centre of the yolk of each egg by colourimeter Minolta CR-400. The colour of egg yolk is often related to the egg quality and it is an important biophysical parameter. Yolk colour depends on the chemical and physical properties of the light source (wavelength and intensity) and the actual ability of the observer to perceive colour. Determination of yolk colour in the CIELab system is therefore deemed to be much more beneficial, because information on both colour hue and lightness can be obtained, and such parameters give a good idea of colour changes **(Dvořák et al., 2007)**.

Many scientific works deal with investigating the effect of housing and feeding on the quality of eggs as well as on the yolk colour. **Dvořák et al. (2009)** refers that, during a 7-month period of monitoring, value b* for egg yolk colour increased significantly from the 3rd month under the deep litter system of rearing. **Kopřiva et al. (2014)** reported that the addition of dried beetroot at the amount of 1 and 2% per feeding dose caused a significant increase only in specific lightness (value L*). However, lighter egg yolks did not show significant changes in CIELab colour space for values a* and b*. This is in agreement with our study.

Therefore, different intensities of yellow are induced by feeding with different feed ingredients. For example, hens fed mash diets containing yellow maize and alfalfa meal laid eggs with dark yellow yolks, while diets based on cereals such as wheat, barley or rice need dietary maize to obtain deep colour **(Lokaewmanee et al., 2009)**. The effect of different levels of marigold and paprika on egg production and yolk colour was also observed by the authors **Spasewski et al. (2017)**. Among yolk sensorial attributes, its colour is considered as a quality indicator, and it, therefore, plays an important role in egg acceptance by the consumers. Higher yolk colour intensity increases egg acceptance by the consumers, who associated more intense yolk pigmentation with higher nutritional value **(Silva et al., 2000; Schreiner et al., 2004)**.

It was concluded that the inclusion of vegetable oils in commercial white layer diets does not significantly change egg yolk pigmentation, as colourimetrically evaluated. The yolks of the eggs laid by layers fed diets containing sources of PUFA presented high lipid oxidation, particularly when compared with those derived from layers fed a diet with no oil supplementation.

Lipid stability is also vital to evaluate, as the yolk fatty acids may suffer lipid oxidation during storage. Lipid stability, as another important egg quality parameter, affects food quality, particularly in aroma, taste and nutritional value, as well as in the production of toxic compounds **(Faitarone et al., 2016)**. Fatty acids, particularly unsaturated fatty acids, are the compounds most susceptible to oxidation **(Fennema, 2000)**. **Cherian et al. (2007)** reported that the inclusion of PUFA in layer diets may increase the susceptibility of eggs to lipid oxidation.

CONCLUSION

In this experiment, the effect of supplementing the diet of laying hens with solid-state fermented feed produced by the low filamentous fungal strain *Mortierella alpina* CCF 2861 on egg qualitative variables was observed. Based on the obtained results, we can conclude that supplementation of laying hens diet with SSF feed (10% and 15%)

positively influenced the quality of eggs in the 25th week of age of laying hens. Further studies are nonetheless necessary to investigate the effect of fermented feed on microbial, physical, and chemical properties of eggs, including the fatty acids profile of eggs. Multiple factorial analysis is a suitable method for further investigation.

THE EFFECTS OF NUTRITIONAL SUPPORT ON SELECTED LABORATORY PARAMETERS IN PATIENTS WITH COLORECTAL CANCER UNDERGOING SURGICAL RESECTION OF THE COLON

Mária Servátková, Peter Chlebo, Zuzana Chlebová

ABSTRACT

The benefit of the nutritional support provided to patients with colorectal cancer who have undergone the planned resection of the colon in relation to the laboratory markers of nutrition was examined. And it is currently being discussed, that pre-operative optimization of nutritional status reduces the incidence of post-operative complications in cancer patients and regulates selected laboratory parameters. This was a retrospective study where the treatment group (n = 52) received the enteral nutritional support 21 days before the scheduled surgery and the other group was formed of patients without preoperative enteral nutrition (n = 52). Laboratory parameters (CRP, leukocytes, albumin, total proteins) were monitored for at least one month before the planned surgery and just before the operation, and the effect of supplemental enteral nutrition on selected laboratory parameters between these two groups was compared. In a group of patients with enteral nutrition, serum albumin levels increased significantly, while CRP was significantly reduced during preoperative enteral nutrition (albumin S-ALB from 35.42 to 37.48, p = 0.0008, C reactive protein from 26.5 to 14.092, p = 0.0007). Nutritional support 21 days before surgery in oncological patients resulted in an improvement in laboratory parameters compared to the group of patients without nutritional enteric support. Malnutrition in patients who are candidates for major surgical intervention is a risk factor for postoperative morbidity and mortality. However, further studies are required to verify the effectiveness of this early nutritional intervention on medium and long-term clinical parameters in different types of cancer.

Keywords: nutridrink; enteral nutrition; malnutrition; colon; hypoalbuminemia

INTRODUCTION

Cancer of the colon and rectum is one of the most commonly diagnosed cancers in the world **(Torre et al., 2015)**. Although patients with early colorectal cancer could be successfully treated with surgical procedures, the large surgery itself may cause the dysfunction of homeostasis, defensive mechanisms, and inflammatory response, which may increase the rate of postoperative complications and extended hospital stay. Nutritional status is a key factor affecting clinical outcomes in patients **(Xu et al., 2018)**. Unintentional weight loss in cancer patients is an alarming constitutional change predicting the progress of the illness and shortened survival time **(Chow et al., 2020)**. It is important to provide nutritional support administered through enteral nutrition or parenteral nutrition **(Chow et al., 2020)**. Historically these approaches are accompanied by concerns with increased complications and costs. Therefore, enteral nutrition can be the preferred form due to its lower costs, less complications, and improved results **(Altintas et al., 2011)**.

Scientific hypothesis

We examine in our study, whether the administration of Nutridrink compact rises the level of albumin and lowers the level of C-reactive protein in patients with colon cancer before the planned surgery.

MATERIAL AND METHODOLOGY

Study design

The study was a retrospective one focused on individual cases that used the database of the surgical department of the Topoľčany city hospital in Slovakia. Data were collected from medical documentation of surgical department patients, including basic characteristics, laboratory, and perioperative data. This study was approved by the Ethics Commission of the Institute – World of Health, hospital Topoľčany. In Topoľčany hospital, it is recommended that patients with colorectal cancer should take enteric nutrition as part of preoperative optimisation of the nutritional condition before the planned colon resection.

Patient selection

The study ran from September 2015 to September 2019 and the criteria for patient spooling were as follows: age between 18 – 90 years, the diagnosis of colorectal cancer, the patient was subjected to a colorectal surgical procedure. All patients signed informed consent. The exclusive criteria were as follows: inadequate data on the patient for analysis, disapproval of the patient, non-compliance with the treatment regimen, patients who have undergone much greater surgical performance than originally planned, and patients who had already had a stoma and have previously undergone surgery for colorectal cancer, patients who have had a renal and hepatic failure, inability to consume food orally, psychiatric disorders, pregnancy, uncontrolled infection, and all patients who did not have the criteria for inclusion.

Grouping

In our database, 142 patients were identified, of which 38 patients were excluded because they did not meet the criteria for inclusion and had incomplete medical documentation and the remaining patients were divided into two groups. The treatment group was formed by 52 probants who accepted the proposal of the treating surgeon and received commercially available nutrition (Nutridrink Compact) at least 21 days before the planned surgical procedure as an addition to a normal rational diet. The patient's cooperation is an important factor in the treatment of enteral nutrition. Many patients poorly tolerate enteral nutrition and refuse to leave their normal diet. This resulted in a control group of patients who formed 52 probants who had rational nourishment as usual, and were verbally guided for nutrition.

Preoperative nutrition

Patients received Nutridrink Compact (Nutricia) as an addition to a normal rational diet, it is a high-energy nutritionally complete liquid designed for a dietetic procedure for malnutrition that is related to the disease. The content of Nutridrink is mentioned in Table 1.

Clinical evaluation

The following data were collected: body weight, height, a general state of health, age, gender, family status, degree of education, the onset of disease, number of symptoms, metastasis, co-morbidity.

Laboratory evaluation

The course of sampling is an important prerequisite for an objective assessment of the patient´s health. The sampling from the patient was realized once by a qualified nurse. Venous sampling was done in the morning after 8 – 12 hours long fasting. The patient was allowed to drink only a small amount of clear water. The blood sample was taken from the peripheral vein of the upper limb. The skin was disinfected with eighty percent ethanol. The blood was taken into the vacuum test tube, the test tube was filled to the mark and subsequently, the sample was mixed and labeled with the personal data of the patient. The material was transported into the laboratory of the company Medirex. The company Medirex is a holder of a certificate of conducting STN EN ISO 9001:2009 and simultaneously of the needed sampling certifications for individual examinations, namely hematological and biochemical. Subsequently, the result of the examination of the patient was recorded into the patient´s medical record.

Blood count, C-reactive protein, albumin, total proteins, and glycemia were recorded.

Assessment of the status of nutrition

Blood was collected minimally one month before the planned operation in both groups. In the treatment group, a high-energy nutritional supplement was added to the patient's rational diet for at least 21 days. Subsequently, blood was collected again just before surgery. The patient's weight was determined at least one month before surgery and the second time just before surgery in both patient groups.

Surgical procedures

The surgery was performed by one surgeon who specializes in the given disease of the colon by laparotomic and laparoscopic surgical techniques. The anastomosis was end-to-end or side-to-side depending on the location and the decision of the surgeon.

Statistical analysis

Statistical analysis was performed using Microsoft Excel 2010. Quantitative data are expressed as mean ± standard deviation and compared with the t-test. p-value $p < 0.05$ was considered statistically significant.

RESULTS AND DISCUSSION

A total of 142 patients were analysed, 38 were excluded because they did not meet the desired criteria for patient selection for our study, and subsequently 104 patients underwent evaluation.

The main characteristics are listed in Table 2. The female gender was 48.08% (n = 25) and male 51.92% (n = 27) in the treatment group. In the control group the female gender was 44.23% (n = 23) and male 55.77% (n = 29). The average age in the first group was 57.46 ±7.92 years and in the control group 57.92 ±8.27 years. Patients were most commonly married, 57.69% (n = 30) and 53.85% (n = 28) in the control group. The majority of patients in the treatment group completed secondary education, 73.07% (n = 38) and 80.76% (n = 42) in the control group.

The clinical characteristics of patients are mentioned in Table 3. The onset of the disease was noted just before surgery, where the first group of patients had symptoms at 57.69% (n = 30) 4 – 6 months ago, at 23.07% (n = 20) 7 – 12 months ago, at 9.61% (n = 5) 0 – 3 months ago, for 9.61% (n = 5) over 13 months ago. In the control group, 21.15% (n = 11) 0 – 3 months ago, 11.53% (n = 6) 4 – 6 months ago, 53.85% (n = 28) 7 – 12 months ago and 13.46% (n = 7) over 13 months ago. The most common stage of colorectal carcinoma reported prior to surgery was the stage II in the treatment group, 48.07% (n = 25), Stage I 19.23% (n = 10), Stage IV 19.23% (n = 10) and Stage III 13.46% (n = 7). In the control group the stage I 13.46% (n = 7), Stage II 19.23% (n = 10), Stage III 48.07% (n = 25) and stage IV 19.23% (n = 10).

Metastases occurred in the first group in 20 patients, representing 38.46% and in the control group in 7 patients (13.46%). 73.07% of patients had the mild systemic disease before surgery, 13.46% had a severe one and 13.46% were without systemic disease in the first group. In the control group, before surgery, 80.76% had mild systemic disease, representing 42 patients, three patients had severe systemic disease, representing 5.76%, and 7 patients had no systemic disease, representing 13.46%. The average height of the whole group of patients was 1.60 ±9.09 meters, weight 71.6 ±11.64 kilograms a month before surgery, and 71 ±12.61 kilograms just before surgery. The average weight in the first group of patients one month before surgery was 72 ±7.45 kilograms, just before surgery 73 ±12.85 kilograms and in the second group 71.9 ±10.87 kilograms a month before surgery and 71.5 ±9.64 kilograms just before surgery.

Laboratory variables

Laboratory variables are shown in Table 4. Changes in variables were reported, that means laboratory parameters of haemoglobin, leukocytes, albumin, total proteins, CRP, glycaemia in patients in initial state with enteral nutrition and just prior to surgical procedures, and then compared with the control group.

Table 3 Clinical characteristics of patient before surgery.

		Treatment group	Control group
Onset of illness in months	0 – 3	5 (9.61%)	11 (21.15%)
	4 – 6	30 (57.69%)	6 (11.53%)
	7 – 12	12 (23.07%)	28 (53.85)
	>13	5 (9.61%)	7 (13.46%)
stage	I.	10 (19.23%)	7 (13.46%)
	II.	25 (48.07%)	10 (19.23%)
	III.	7 (13.46%)	25 (48.07%)
	IV.	10 (19.23%)	10 (19.23%)
metastasis	no	32 (61.53%)	45 (86.53%)
	yes	20 (38.46%)	7 (13.46%)
comorbidity	mild systemic disease	38 (73.07%)	42 (80.76%)
	severe systemic disease	7 (13.46%)	3 (5.76%)
	without systemic disease	7 (13.46%)	7 (13.46%)

Table 4 Laboratory variables.

		Treatment group		
	Reference value	**Initial status**	**Status just before surgery**	***p*-value**
Haemoglobin Hb ($g.L^{-1}$)	Male (130 – 197) /Female (120 – 160)	114.2 ±18.04	116.90 ±16.26	0.0168
Leukocytes WBC ($10^9.L^{-1}$)	3.8.2010	8.72 ±3.6	7.74 ±3.168	0.0025
Albumin S-ALB ($g.L^{-1}$)	32 – 48	35.42 ±6.92	37.48 ±6.38	0.0008
Total proteins S-CB ($g.L^{-1}$)	57 – 82	56.02 ±6.43	61.1 ±8.7	0.0002
CRP-C reactive protein ($mg.L^{-1}$)	0 – 5	26.5 ±35.00	14.092 ±15.38	0.0007
Glycemia S-Glu ($mmol.L^{-1}$)	4.0 – 5.5	7.3 ±2.93	6.87 ±2.21	0.0153

Table 5 Postoperative complications.

	Treatment group	Control group	*p*-value
Septic complications	4%	25%	0.04
Total complications	21%	29%	0.51

In patients receiving enteral nutrition, the albumin and total proteins increased, which was statistically significant and there was a decrease in the number of leukocytes and CRP, statistically significant, and also glycemia was adjusted. In the treatment group, the haemoglobin changed from 114.2 to 116.90, $p = 0.0168$, leukocytes WBC from 8.72 to 7.74, $p = 0.0025$, albumin S-ALB from 35.42 to 37.48, $p = 0.0008$, total proteins S-CB from 56.02 to 61.1, $p = 0.0002$, CRP-C reactive protein from 26.5 to 14.092, $p = 0.0007$, glycemia S-Glu from 7.3 to 6.87, $p = 0.0153$. In the control group, the haemoglobin changed from 113.0 to 115.61, $p = 0.0097$, leukocytes WBC from 8.25 to 7.98, $p = 0.0973$, albumin S-ALB from 33.15 to 33.57, $p = 0.1073$, total proteins S-CB from 57.1 to 58.94, $p = 0.00108$, CRP-C reactive protein from 10.6 to 10.45, $p = 0.247$, glycaemia S-Glu from 6.31 to 5.85, $p = 0.027$. In the control group, there was a change in total protein, which was statistically significant.

Postoperative complications

Postoperative complications within 30 days are listed in Table 5. The number of septic complications was significantly lower in patients in the treatment group with enteral nutrition than in patients in the control group (4% compared to 25%, $p = 0.04$). There wasn´t a significant difference in the number of total complications between the two groups (21% compared to 29%, $p = 0.51$).

This study retrospectively examined the association of laboratory parameters, namely albumin, total proteins, leukocytes, CRP, glycemia, and preoperative enteral nutrition in patients who underwent a resection of the colon for malignancies. In our study, we reported adding Nutridrink to patients with the oncological disease for at least 21 days, which increased serum albumin, total proteins, and reduced CRP levels in patients undergoing planned colon resection. This preoperative preparation can be a useful strategy as a preoperative method to improve postoperative forecasts in patients. The systemic score of

inflammation and nutrition plays an important role in various cancers in certain situations. The reports have shown that inflammation promotes the invasion of tumors and metastases through the activation of IL-6 and T-lymfocytes **(Tokunaga et al., 2017)**. Our study showed that the addition of Nutridrink to treatment before surgery reduced CRP levels and increased serum albumin of total proteins in patients with colorectal cancer who had undergone a therapeutic resection of the colon. We believe that our result is remarkable because our two groups have been well aligned with respect to the basic demographic parameters, thus reducing confusing variables. The surgical variability was reduced because the surgical procedure was performed by one surgeon in both groups.

There are some limitations to this study. Firstly, our set of patients was small, second, nutrition disorders in cancer patients occur not only by cancer pathologies but also by preoperative chemotherapy or radiotherapy, thirdly, our study was retrospective and was performed on one institution. Nevertheless, it is a study, which in Slovakia is one of few comparing the effect of enteral preoperative nutrition in a patient with colorectal cancer undergoing surgical resection. Serum albumin levels are traditionally used as a biochemical indicator of individual nutritional status before surgery. It is considered to be the exact preoperative prognostic indicator for various surgical performances including cardiac, trauma, and general surgery **(Truong et al., 2016)**. While some believe that low albumin levels indicate malnutrition, others assume that hypoalbuminemia stems from a state of chronic disease, and this a resulting inflammation and is not caused by malnutrition, thereby preventing any beneficial effects of nutritional therapy **(Truong et al., 2016)**. With respect to serum albumin levels, this value gradually decreases between 0.08 and 0.17 $g.l^{-1}$ per year with age. In addition, elderly patients are usually complicated by comorbidities that increase inflammatory cytokines, and both loss of appetite and loss of muscle mass directly cause hypoalbuminemia **(Tominaga et al. 2019)**.

However, enteral and parenteral nutrition have been shown to improve the results in undernourished patients undergoing large elective surgical intervention **(Braga et al., 2002)**. The agreement is to stabilize the baseline nutritional status and administer the enteral or parenteral nutrition to the severely hypoalbuminate patients before surgery, even if it requires the delay of surgery. In 2012, **Oberhofer et al. (2012)** showed an increase in CRP in the early postoperative period after colorectal tract surgery correlated with a significant increase in complication rates (p <0.001), which was consistent with Welsch **(Welsch et al., 2007)**, who showed that CRP values greater than 140 $mg.l^{-1}$ on a postoperative day 3 or 4 predicted infectious complications and anastomotic leaks after colorectal surgery. In contrast, preoperative CRP levels did not correlate with the incidence of postoperative complications **(Truong et al., 2016)**. CRP is an acute-phase protein that is synthesized in the liver in response to proinflammatory cytokine signaling, primarily through interleukin-6 and alpha tumor necrosis factor. An important role of CRP is to bind phosphocholine to pathogens as well as to apoptotic or necrotic host cells, which in turn activate the complement system and obtain phagocytes.

Serum CRP increases rapidly in response to tissue damage or infection, but an increase in CRP (generally at low levels) is also seen in chronic inflammatory or neoplastic conditions, a process likely to be mediated by various signaling mechanisms **(Crockett et al., 2014)**. **Platt et al. (2012)** reported data on WBC, CRP, and albumin concentrations in 454 patients undergoing colorectal cancer surgery, of which 104 developed infectious complications. The results showed that CRP measurements after resection for colorectal carcinoma accurately predict infectious complications including anastomotic leakage.

The average time to onset of infectious complications, including anastomotic leakage, was 6 – 8 days after surgery. Colorectal surgery has traditionally been associated with significant morbidity and prolonged hospital stay. The overall complication rate was reported to be 26 – 35%. In particular, infectious complications are a major cause of morbidity and mortality after colorectal surgery **(Sonoda et al., 2015)**. Albumin is considered a negative protein in the acute phase because its concentration decreases during injury and sepsis. In patients with septic shock, the rate of albumin loss in tissue spaces increases by more than 300%. Hypoalbuminaemia is a risk factor for mortality and postoperative complications. Therefore, nutrition control is an important focus of perioperative management. The magnitude of the systemic inflammatory response during the perioperative period, as indicated by acute-phase proteins – in particular C-reactive protein (CRP) – can help identify the risk of postoperative infectious complications.

A correlation was reported between serum albumin and CRP with gastrointestinal cancer **(Feng, Zhao and Chen, 2014)**.

Anastomosis leakage after rectal surgery is one of the most serious and life-threatening complications and still poses a main clinical problem **(Welsch et al., 2007)**. Up to 50% of patients with anastomotic leakage are asymptomatic, which can be explained by extraperitoneal localization of leakage. Postoperative mortality on anastomotic complications is up to 22% and it is estimated, that it constitutes one-third of all deaths after colorectal surgery **(Nesbakken et al., 2005)**. New recommendations for operations and oncology were published in 2016 and 2017. Nutritional intervention before major surgery in patients with malnutrition should be made for at least 10 – 14 days, even at the cost of defering the operation (at least 7 – 14 days) and this is a strong recommendation. Enteral nutrition is the preferred way of feeding. Parenteral nutrition is recommended only if the patient cannot be fed through the digestive tract **(Weimann et al., 2017; Arends et al., 2017)**. However, enteral and parenteral nutrition has been shown to improve the results in undernourished patients undergoing large elective surgical intervention **(Braga et al., 2002)**. Undoubtedly the use of enteral nutrition reduces the number of perioperative complications and decreases the time spent in the hospital **(Heyland et al., 2001)**. It should be remembered that it is very important to continue the nutritional intervention even after the operation **(Klek et al., 2011)**. For example, Giger-Pabst **(Giger-Pabst et al., 2013)**, found that preoperative peroral supplementation

with an immune-enriched diet for 3 days did not improve postoperative outcome in patients with gastrointestinal cancer and meanwhile, no positive effects of immunonutritional support were found in patients on ICU. **(Atkinson, Sieffert and Bihari, 1998; Bower et al., 1995)**. The study, which included 1223 critically ill adults, also showed the deleterious effect of early immunonutritional administration **(Heyland et al., 2013)**. In the past, the originally popular parenteral nutrition was replaced by enteral feeding in the early 1990s. Many experts have supported changes in the nutritional approach, especially because there is a lack of evidence-based data. Few authors dared to express their doubts about the enteral technique, including difficulties in administering the required dose or the occurrence of complications **(Braga et al., 1999; Gianotti et al., 2000; Gianotti et al., 2002; Gianotti et al., 1997; Heslin et al., 1997; Klek et al., 2008)**. The management of malnutrition in patients with metastatic carcinoma belongs to the complex management of illness, so the tolerance and effectiveness of ever more aggressive treatment increases and the life quality of patients improve as well **(Gallois et al., 2019)**.

CONCLUSION

In conclusion, our study shows that albumin, total protein, CRP may be a useful marker in colorectal cancer patients suffering from malnutrition. In addition, further extensive studies are needed to evaluate the clinical utility of enteral preoperative nutrition and nutritional markers.

THERMAL STABILITY OF PREPARED CHICKEN FEET GELATINE GEL IN COMPARISON WITH COMMERCIAL GELATINES

Petr Mrázek, Robert Gál, Pavel Mokrejš, Ondřej Krejčí, Jana Orsavová

ABSTRACT

Gelatine is, due to its functional properties, currently widely used not only in the food industry (in the production of confectionery, dairy products, canned food) but also in pharmacy (soft and hard capsules) and cosmetics (creams, lotions) where it applies its ability to form thermoreversible gel stronger than most other gelling agents. What is more, it provides further excellent properties including emulsifying, foaming, stabilizing, film-forming, water and fat binding, texturizing, thickening, and adhesive attributes which makes it a very important hydrocolloid. Gelatine is obtained from the raw material of animal tissues containing collagen, usually mammalian skin or bones. For religious reasons in some countries, pork or bovine gelatine must be replaced by an alternative form, such as poultry or fish gelatine. The quality of gelatine is assessed mostly by the strength of gelatine gel which strongly depends on ambient temperature or humidity. Extraction conditions may also significantly affect the quality of gelatine. This study examined possible changes in the strength of gelatine gels prepared from laboratory-produced chicken feet gelatine and compared them with commercially available pork and beef gelatines at temperatures of 23, 29, and 35 °C at 60 and 80% humidity. While at 23 °C thermal stability of prepared chicken gelatine was monitored higher than in commercial gelatines, experiments at 29 and 35 °C provided equivalent results for chicken and commercial gelatines. Therefore, prepared chicken gelatine offers a significant potential to become an alternative to traditional gelatines. The information about gelatine gels thermal stability is of great importance for applications not only in the food; but also in the pharmaceutical industry.

Keywords: chicken feet; collagen; gelatine; gel strength; poultry by-products; thermal stability

INTRODUCTION

Gelatine is a multifunctional biopolymer acknowledged as a functional food due to its positive effects on human health **(Jellouli et al., 2011)**. The application of gelatine dates back to 4000 B.C. when Egyptians used glue based on gelatine to connect parts of furniture **(Koepff, 1985)**. At the end of the seventeenth century, commercial production of gelatine commenced. More than a hundred years later, the production process significantly enhanced and high molecular weight gelatine was produced. Thus, consequently, the high quality of gelatine gels was obtained **(Bogue, 1922; Smith, 1929)**. At present, annual gelatine production comprises approximately 583.400 tonnes per year worldwide **(Grand View Research, 2020)**.

Gelatine is acquired by thermal denaturation or partial hydrolysis of materials containing collagen which is **(Mohtar et al., 2010)** a fiber-forming protein important for maintaining the structure of animal tissues **(Li et al., 2009)**. It is the most widespread protein in mammals accounting for up to 30% of all proteins **(Perez-Tamayo, 1978)**. Scientific literature states that 29 different types of collagen have been currently identified **(Silvipriya et al., 2015)**. Collagen (type I) is an insoluble fibrous structural protein abundant (about 25%) in animal tissues, such as skins, bones, tendons, ligaments, and cornea **(Maroušek et al., 2015; Krishnamoorthi et al., 2017)**. Collagen possesses significant properties including high tensile strength, low antigenicity, and good biocompatibility **(Subhan et al., 2017)**. The collagen molecule is comprised of three polypeptide chains that form a helical structure. Chains conformation is changed during gelatine gelation and a three-dimensional network structure similar to the natural arrangement of collagen is created **(Bigi et al., 2004)**. Gelatine has a lower molecular weight than native collagen because it is composed of a mixture of polypeptide segments with a molecular weight in the range of 16 – 150 kDa **(Asghar and Henrickson, 1982)**.

Physical properties of gelatine, such as gel-forming ability, water holding capacity, fat binding capacity, or emulsifying and foaming properties, are of great significance in applications particularly in the food industry within many products, such as marshmallows, jellies or gummy bears. Thermal stability of gelatine at temperatures between 25 and 30 °C is also principal in

gelatine desserts or in applications of gelatine in combination with other hydrocolloids including agar-agar gels in fruit gummies where it is essential to maintain required clarity or textural properties **(Schrieber and Gareis, 2007)**. According to the analysis by **Grand View Research (2020)**, gelatine is applied most as a stabilizer (238.000 tonnes), thickener (186.000 tonnes) and gelling agent (147.000 tonnes) which emphasizes the fact that thermal stability of gelatine gels is one of the most significant required gelatine attributes. These functional properties primarily affect the texture and appearance of the final products **(Li et al., 2009)**. Gelatine´s ability to retain molecules of water is advantageously utilized also in cosmetic formulations **(Deyl et al., 2003)**. Considering these valuable characteristics, gelatine is also extensively used in biomedicine and pharmaceutical industry **(Bae et al., 2008)**. Gelatine has antimicrobial or antioxidant properties providing the ability to act as an anti-hypertensive agent via angiotensin inhibition (ACE) **(Gómez-Guillén et al., 2011**). Several studies have revealed that gelatine and especially gelatine hydrolysates exhibit regenerative effects on the human skeleton and spinal cord systems **(Schrieber and Gareis, 2007)**.

One of the most important quality indicators is gelatine gel strength (Bloom value). Reflecting its value, gelatine is classified into low gel strength gelatine (≤150 Bloom), medium gel strength gelatine (150 – 220 Bloom), and high gel strength gelatine (220 – 300 Bloom**) (Johnston-Bank, 1983)**. Gelatine gel strength may depend on several different factors, such as the age, species, and gender of the animal used as raw material, technological conditions of gelatine preparation, including pre-treatment method, extract temperature and time, and the ambient conditions - pH, temperature and humidity.

The thermal stability of different types of gelatines has been thoroughly examined. **Losso and Ogawa (2013)** determined the thermal stability of chicken keel bone collagen. **Pati et al. (2010)** isolated and characterized fish scale collagen of higher thermal stability. In both studies, thermal stability was established using denaturation temperature. **Michon et al. (1997)** investigated the influence of thermal history on the stability of gelatine gels using the DSC method. **Rodriguez-Rodriguez et al. (2019)** studied the development of thermal stability of gelatine/chitosan/PVA hydrogels. To determine the thermal stability of gelatines, the DSC method and rheological testing were applied. **Canpanean et al. (2013)** examined the enhanced thermal stability of gelatine coated gold nanorods in water solution. Thermal stability was established using UV-visible spectrophotometry and TEM microscopy. **Masutani et al. (2014)** monitored increased thermal stability of gelatine films by UV-induced cross-linking with glucose applying the DSC method, SEM microscopy, and UV-visible spectrophotometry. Cross-linking is one of the three methods to enhance the thermal stability of gelatines. **Rodriguez-Castellanos et al. (2014)** examined nanomechanical properties and thermal stability of recycled cellulose reinforced by a starch-gelatin polymer composite using SEM microscopy and TGA analysis. However, very little data deals with the thermal stability of gelatine gel strength which is a key parameter to evaluate gelatine quality in food, such as confections, aspics, dairy, and meat products. Therefore, this study focuses on the changes in gel strength of products containing gelatine gel during the storage at different temperatures.

THE AIMS OF THIS STUDY

The study aims to continue the research of biotechnological processing of poultry by-products into gelatine **(Mrázek et al., 2019)** and to prepare chicken feet gelatine (CFG), beef, and pork gelatine gels. Furthermore, to monitor an impact of temperature and humidity on CFG gels during the storage at different temperatures of 23, 29 and 35 °C as a simulation of standard storage conditions suitable for food products containing gelatine, and simultaneously, as a simulation of storage conditions in summers in the moderate climate zone and subtropical or tropical areas. It also provides tests at an increased relative humidity (60 and 80%) since gelatine gels are commonly stored in cooling facilities with humidity often up to 80%. It compares CFG with commercially available pork and beef gelatine.

Scientific hypothesis

The research has tested the hypothesis that the thermal stability of gelatine gels decreases with rising temperature and humidity.

MATERIAL AND METHODOLOGY

Appliances, tools, and chemicals

Stevens LFRA Texture Analyser for measuring gelatine gel strength (Leonard Farnell and Co Ltd., England), P 98 meat mincer (Brather, Spain), Memmert ULP 400 drying device (Memmert GmbH + Co. KG, Germany), LT 43 shaker (Nedform, Czech Republic), Kern 440 – 47 electronic scale, Kern 770 electronic analytical scale (Kern, Germany), A 10 labortechnik analytical mill (IKA-Werke, Germany), ULP 400 drying oven (Memmert GmbH+Co. KG, Germany), SLR heating board (Schott Gerate GmbH, Germany), Whatman No. 1 paper (Sigma Aldrich, UK), a metal filter sieve with the size of pores 1 and 2 mm (Labor-komplet, Czech Republic). Chemicals: NaCl, NaOH, petroleum ether, ethanol, and chloroform (Verkon, Czech Republic); all chemicals were of analytical grade. Proteolytic enzyme Polarzyme 6.0 T – serine endoprotease manufactured by fermentation of microorganisms that are not present in the final product (Novozymes, Denmark) with the declared enzyme activity of 6 KPU per g (kilo protease unit per g). Commercial mammalian gelatines: pork gelatines with the gel strength of 212 and 288 Bloom, beef gelatines with the gel strength of 266 and 273 Bloom.

Preparation and measurement of chicken feet gelatine (CFG) gels

Chicken feet were purchased in Raciola Uherský Brod, Czech Republic, and processed to chicken feet gelatine according to the method described by **Mokrejš et al. (2019)**. Two types of pork gelatines and two types of beef gelatines were purchased as well and used for the comparison.

Table 1 Initial Bloom values of chicken feet, beef and pork gelatine gels.

Type of gelatine	Beef266	Beef273	Pork212	Pork288	CFG240
Bloom value ±SD	266 ±3	273 ±2	212 ±2	288 ±4	240 ±3

Note: CFG denote chicken feet gelatine; Beef266 and Beef273 are beef gelatines with Bloom values of 266 and 273; Pork212 and pork288 are pork gelatines with Bloom values of 212 and 288.

Gelatine gels were prepared following **GMIA – Standard Testing Methods for Edible Gelatin (2019)** so that 7.5 g of gelatine was mixed with 105 mL distilled water and placed into a standardized bloom jar with a volume of 150 mL and dimensions as follows: overall height of 85 mm, inside diameter of 59 mm, outside diameter of 66 mm, neck inside diameter of 41 mm, and a shoulder height of 65 mm. The mixture was allowed to swell at room temperature for 1 – 3 h. Afterward, the bloom jar (Figure 1) was heated in a water bath at 65 °C to prepare a gelatine solution which was cooled at room temperature and maintained in a cooling box for 16 – 18 h to form gelatine gel. Gel strength (or Bloom value) was measured by Stevens LFRA Texture Analyser (Leonard Farnell and Co Ltd., England, Figure 1). Gelatine gel strength is defined as a force (weight in g) required to depress a measuring probe by specific penetration to a definite area of the gelatine surface to a particular distance.

Figure 1 Prepared chicken feet gelatine gels (left) Stevens LFRA Texture Analyser (right).

Determination of thermal stability of gelatine gels

Studies examining gelatine gels thermal stability mostly used methods of thermal analysis (DSC), rheological testing, or determination of activating energy. Considering a wide range of applications of gelatines in the food industry assessing the quality of gelatines based on their gels strength, this study has employed a method of measuring gel strength according to **GMIA - Standard Testing Methods for Edible Gelatin (2019)**. It has monitored a decline of gel strength in time which is in contrast with other studies that have not considered testing of gelatines on a long-term time scale. The thermal stability of gelatine gels was expressed as a percentage change (decline) of gelatine gel strength during the time period of 5 days. Gelatine gel strength was measured every hour within the first 8 hours of the experiment, and then after 16, 23, 87, 93, 111, and 120 hours. Experiments were performed at three different temperatures of 23, 29, and 35 °C with the relative humidity of 60 and 80%. In total, six series of experiments were performed in which 30 gelatine samples were analysed.

Statistic analysis

1-sample and 2-sample standard deviation tests on the significance level of $p = 0.05$ were applied to all results using Minitab 18 statistical software for Windows (Minitab, Ltd., USA). All analyses were performed in triplicate and arithmetic means and standard deviations were calculated.

RESULTS AND DISCUSSION

The gel strength of prepared chicken feet and commercial pork and beef gelatine gels

Table 1 displays initial Bloom values of commercial mammal and prepared chicken feet gelatines ranging in all samples between 220 and 300 which means all tested gelatines showed a significant gel strength **(Johnston-Bank, 1983)**. The highest gel strength was recorded in Pork288 and the lowest in Pork212. The gel strength of prepared chicken feet gelatine was 240 Bloom. Gel strength of commercial pork and beef gelatine gels ranging from 100 to 300 Bloom, whereas 200 – 250 Bloom is most preferred **(Holzer, 1996)**. Several studies discussing the preparation and testing of the strength of chicken feet gelatine gels were published. **Taufik et al. (2010)** examined the effect of age and extraction temperature on characteristics of chicken feet skin gelatine and reported Bloom values from 112 to 125 which is significantly lower than the values of chicken feet gelatine prepared in this study. **Rahman and Jamalulail (2012)** performed extractions of chicken feet gelatine, inspected its physicochemical characteristics and sensory quality, and recorded the value of 264 Bloom which is slightly higher than the value of chicken feet gelatine established in this study. **Widyasari and Rawdkuen (2014)** described gelatine obtained from chicken feet by acid and ultrasound-assisted extraction and reported Bloom values of 185 and 79 which is less than this study provided. **Chakka et al. (2016)** extracted chicken feet gelatine using food-grade acids and monitored the gel strength in the range from 119 to 204 Bloom which is less than it was recorded in this study. **Almeida and Lannes (2013)** extracted gelatine from chicken feet and characterized its physicochemical properties. They confirmed the gel strength of 295 Bloom which is more than it was measured in this study. **Sompie and Triasih (2018)** reported very low gel strength of chicken leg skin gelatine (78 Bloom). On the contrary, in the case of gelatine extracted from residues after mechanical processing of poultry meat, very high Bloom values were recorded: 309-318 Bloom **(Fonkwe and Singh, 1997)** and 374-380 Bloom **(Rafieian et al., 2013)** and **(Rafieian et al., 2015)**. High Bloom values have also been reported for poultry gelatine by other researchers: 294 Bloom **(Almeida, Calarge and**

Santana, 2013), 338 Bloom **(Du, et al., 2014)** and 355 Bloom **(Ee et al., 2019)** and **(Sarbon et al., 2013)**. Such differences in results may stem from different extraction conditions, particularly time and temperature, as well as from the applied pre-treatment method. The age and gender of the animal could also affect the quality of prepared gelatines.

Determination of thermal stability of prepared chicken feet and commercial pork and beef gelatine gels

The results of determination of the thermal stability of chicken feet, beef, and pork gelatine gels tested at the temperatures of 23, 29, and 35 °C and relative humidity of 60 and 80% are shown in Tables 2 – 7. Initial Bloom values of gelatines are expressed as 100%. Changes in gelatine gel strength (declines) are expressed as Bloom index in %.

Table 2 shows the results of the thermal stability of chicken feet, pork, and beef gelatines at a temperature of 23 °C and humidity of 60%. Gel strength gradually decreased as expected. After one hour of measurement, the slightest decline was recorded in CFG240 and the highest in Beef273. A drop of gel strength in other types of gelatines was approximately 25%; differences were not statistically significant (p >0.05). Similar trends were observed also in the following measurements with declines of gel strength between 30 and 65%. The smallest decrease of gel strength was recorded in chicken feet gelatine while the most significant drop was determined in Beef273 (3 – 5 h of measurement) followed by Pork212 (87 – 120 h of measurement). Within the last two measurements (after 111 and 120 h), no further changes in gel strength were established. The deepest decline in gel strength in the final measurement was monitored in Beef266 (more than 90%) while the smallest drop was identified in prepared gelatine CFG240 (approximately 75%); this gelatine showed this trend for the whole testing period. The reduction of gel strength in other types of gelatines was approximately 85% with statistically insignificant differences (p >0.05).

Table 3 summarizes the measurements of the thermal stability of chicken feet, pork and beef gelatines at the temperature of 23 °C and humidity of 80%. Prepared chicken feet gelatine CFG240 provided values with statistically insignificant differences (p >0.05) recorded at both levels of humidity – 60 and 80%.

However, within commercial gelatines in the first 6 hours of measurement, higher declines of gelatine gel strength with statistically significant differences (p <0.05) were recorded at the humidity of 80% than 60 %. In the following measurements, statistically significant (p <0.05) smaller declines of commercial gelatine gel strength were recorded at the humidity of 80% than 60%. After 1 h of measurement, the slightest drop of gelatine gel strength was identified in Pork288 and the most considerable in Beef273. In all the following measurement CFG240 showed the smallest decline. After two hours of testing, the fall of gelatine gel strength ranged from 33 to 64%. The deepest decline in 2, 3, and 4 h of measurement were recorded in Beef273 whereas in further measurements the most significant decrease was determined in Pork212. Nevertheless, within the measurement in 111 and 120 h, no further changes in gelatine gel strength were identified with the final declines of the strength of approximately 80%. Prepared chicken feet gelatine performed either comparable or even better thermal stability at a humidity of 60 and 80% if compared with commercial beef and pork gelatine.

The results of the thermal stability of chicken feet, pork, and beef gelatines at the temperature of 29 °C and humidity of 60% are displayed in Table 4. In contrast with the measurements at the temperature of 23 °C and humidity of 60%, a significantly deeper (p <0.05) decline of gel strength in all gelatines was monitored in 2-h measurement and further. After 1 h, the smallest decrease was monitored in Beef266 and both pork gelatines, while in CFG240 and Beef273 the deepest reduction of gel strength was recorded. In further measurements, the smallest drop was identified in Beef266 and Pork288 (63%), slightly deeper in Pork212 and CFG240 (65%), and the most significant decline in Beef273 (72%). After 3 and 4 h of measurement, the smallest decrease was recorded in Beef266, Pork288, and CFG240 and the deepest fall in Beef273 and Pork212. After 5, 6, 7, and 8 h, gelatine CFG240 showed the slightest decline of approximately 90% while other types of gelatines performed slightly higher, yet statistically insignificant (p >0.05) declines of gelatine gel strength. A similar trend was observed in further measurements and after 87 h of measurement, no gelatine showed a change in gel strength. The final decline of gel strength was almost 100%.

Table 5 shows the results of the thermal stability of chicken feet, pork, and beef gelatines at a temperature of 29 °C and humidity of 80%.

At this humidity, a slightly higher decline of gel strength was monitored in commercial gelatines than at the humidity of 60%; while in chicken feet gelatine no statistically significant differences (p >0.05) were recorded, similarly as at the temperature of 23 °C. After 1 h of measurement, the smallest decline was recorded in Beef266, slightly higher in pork gelatines and the deepest decrease in Beef273 a CFG240. In contrast, after 2 h of measurement, the smallest drop of approximately 70% was in CFG240, slightly deeper in Beef266 and Pork288, and the most significant reduction of approximately 80% in Beef273. After 3 h, the last drop was in CFG240, similarly to further measurements, while commercial gelatines performed slightly deeper reduction of gel strength. Further measurements showed a trend of a gradual decline of gel strength; importantly, commercial gelatines performed statistically significant (p <0.05) higher decrease of gel strength if compared with chicken feet gelatine. After 87 h, almost 100% declines in gel strength in all gelatines were monitored. It has been proved that chicken gelatine performs comparable or even better properties than commercial gelatines considering the thermal stability of gelatine gel strength.

Table 6 summarizes the results of the thermal stability of chicken feet, pork, and beef gelatines at the temperature of 35 °C and humidity of 60%. All gelatines performed a steep decline of gelatine gel strength at this temperature. After 1 h of measurement, the decrease ranged between 38 and 43% with the smallest drop in CFG240 and the highest in Beef266 and Pork212. A dramatic decline of gel strength from 83 to 90% was recorded in further measurements. The smallest reduction was determined in Beef266 and the highest in Beef273. After 3 h of measurement, the smallest decline of more than 90% was in CFG240 while all commercial gelatines showed at a drop of 97%. After 4 h, almost all gelatines performed a decrease of nearly 100% and no gelatine formed a gel after 5 h of measurement.

The results of the thermal stability of chicken feet, pork, and beef gelatines at the temperature of 35 °C and humidity of 80% are shown in Table 7. The figures do not differ much from the results at the same temperature at the humidity of 60%. After 1 h of measurement, the decline of gel strength varied from 36 to 42% which proves no statistically significant differences (p >0.05) between the experiments at the humidity of 80 and 60%. The smallest decrease of gel strength was established in CFG240 and Pork288 while the deepest drop was recorded in Beef266, equally as at the humidity of 60%. After 2 h of measurement, chicken feet gelatine showed the smallest decline (75%), and Pork212 together with other beef gelatines the biggest fall (85%). After 3 h, CFG240 performed a decline of gel strength of more than 91% and commercial gelatines of 97%. Nearly 100% decline of gel strength in all gelatines was recorded after 4 h of measurement. Equally, as in previous experiments, comparable declines of gelatine gel strength were recorded in both chicken feet and commercial gelatines at the temperature of 35 °C.

CONCLUSION

Chicken feet gelatine (CFG) was obtained from chicken feet, a slaughterhouse by-product, using a biotechnological method with a previous proteolytic enzyme pre-treatment and extracted at the temperature of 80 °C for 45 min. Samples of gels were prepared both from CFG and commercial pork and beef gelatine and their thermal stability were tested. For the experiments, the thermal stability of gelatine gels was defined as a percentage change of gel strength in time and it was recorded at temperatures of 23, 29, and 35 °C at the relative humidity of 60 and 80% for 5 days. These temperatures and humidities were proposed to reflect the climatic conditions common during the storage of products containing gelatine gel in the summer or tropical areas. The results have shown that the thermal stability of gelatine gels is lower at higher storage temperatures confirming the hypothesis. However, the assumption that higher humidity will cause a steeper decline in gel strength has not been proved.

The thermal stability of prepared chicken feet gelatine has not been significantly affected by humidity. On the other hand, the results of commercial gelatines at different humidities were not definite.

This fact favours the applications of chicken gelatine in the food industry; the thermal stability of chicken gelatine was higher or similar to the stability of commercial mammalian gelatines. Experiments at a temperature of 23 °C showed that the highest thermal stability was recorded in chicken gelatine at the humidity of both 60 and 80%. The decline of the strength of chicken feet gelatine gel was in earlier times of measurement approximately 1.5x lower and in later times of measurements even nearly as 2x lower than in commercial gelatines. At the temperature of 29 °C, comparable results in both commercial and chicken feet gelatines were established. The last tested temperature was 35 °C also providing a similar decline of the strength in chicken feet gelatine gels and commercial gelatines. This study has confirmed that laboratory prepared chicken feet gelatine provides similar thermal stability to gels of commercial pork and beef gelatine. Hence chicken feet gelatine may be employed as a potential alternative to traditional gelatines used in the food industry in the production of confections, aspics, or desserts. This data clarifying the behavior of gelatine gels thermal stability is beneficial also for further industrial sectors, such as for the preparation of hard gelatine capsules in the pharmaceutical industry.

DOES FOODSERVICE INDUSTRY CARE ABOUT CSR? A STUDY IN PORTUGAL AND UKRAINE

Oksana Sokil, Iveta Ubrežiová, Teresa Eugenio, Tânia Marques

ABSTRACT

The purpose of the article is to compare the CSR perception level of the food service industry in Portugal and Ukraine. The main goal of the study is to find the attitudes in Portugal and in Ukraine towards CSR. Additionally, two hypotheses were formulated to understand the possible relation between (1) the financial situation and (2) the duration of the company with the awareness level about the CSR concept. A quantitative approach, using questionnaires, was adopted to survey using a sample of 201 representatives of SMEs in the foodservice sector (101 Portuguese and 100 Ukrainian), in 2019. Descriptive statistics and Spearman test were used to analyze the data. The present work demonstrates a significant correlation between the financial situation of the company and the CSR awareness level of leadership. Furthermore, the research shows that activities related to the economic sphere and CSR workplace policy among food sector companies in Ukraine and Portugal are developed to a great extent. From this point of view, we can state, that the publication of the article is one of the results and supported by grant project KEGA 005SPU-4/2019 "Theory and Practice of the International Management and Entrepreneurship in Multicultural Environment". In this study, two different countries were chosen (Portugal and Ukraine), which are different in culture, history, and economic background. The paper focused on the food service industry and contributes to the ongoing debate about the SMEs and its involvement with CSR. It also helps schools to identify plans in CSR policy and topics for future research.

Keywords: Corporate Social Responsibility; Food service Industry; SMEs; Portugal; Ukraine

INTRODUCTION

The social orientation of the world economy requires the development of Corporate Social Responsibility (CSR) activities to ensure the free entry of domestic companies into world markets **(Van Marrewijk, 2003)** and to increase cooperation with foreign investors, maintaining a worthy competitive position in the international arena **(Secchi, 2007; Lee, 2008)**. The understanding of CSR importance pushes business to assume not only the behavior of law-abidingness but also to carry out voluntary participation in the implementation of corporate contribution to the development of the community, the territory, and establishing social partnership relations with the state **(Burja and Mihalache, 2010)**.

Although there has been an increase in CSR interest at a global scale trying to define CSR is not an easy task **(Nyarku and Ayekple, 2019; Aßländer, 2011)**. First of all, there are different economic traditions in Europe and the US, which results in different interpretations of corporations´ responsibilities. The American perspective of the concept is mainly oriented on ethical responsibility and corporate philanthropy (besides economic and legal obligations), while the European perspective sees such responsibilities as the task of government **(Kasych, 2014)**. As defined in **ISO 26000 (2010)**, social responsibility is the responsibility of an enterprise for the impact of its decisions and actions on society, the environment, through transparent and ethical behavior. Moreover, it is necessary to increase the number of studies related to CSR and SMEs **(Sweeney, 2007)**. Companies often lack a clear understanding and conscious recognition that CSR is not something exceptional, caused by special circumstances, but a norm that stems from the very essence of business, the philosophy of management **(2016; Kasych, 2014; Kravchenko, 2013)**. Furthermore, considering the new trend in the literature of describing the relationship between CSR and geography **(John et al., 2011; Loughran and Schultz, 2005; Sorenson and Baum, 2003)**, one can agree with the importance of showing the influence of company's geographical position on the process of CSR strategy formation. Thus, comparative researches on CSR development are needed not only within the neighboring countries but also within the countries which are located in different geographic areas **(Branco and Delgado, 2011)**.

Thus, this study aims to compare the CSR perception level in the foodservice sector in Portugal and Ukraine. Given the different geographic location and business environment, both countries, Ukraine and Portugal, are ideally suited for the study. It is also worth mentioning that the selected countries have a different cultural, historical, and economic background, which can affect the level of the CSR perception. However, the dynamic development of the food service market in Ukraine and Portugal is a common feature of the studied countries. For example, from the end of 2015 – beginning of 2016, the Portuguese public foodservice market has started to emerge from the crisis, driven by the growth of the tourism industry **(GIRA Foodservice, 2017)**. During the last years, the Ukrainian food service market is as well trying to recover after the political and economic crisis of 2014 – 2015. There is an increase in the competition between food establishments, the emergence of new formats, and the use of innovative approaches in the activities of food service enterprises of the country **(Hirnyak and Glagola, 2018)**. The food service market was chosen as the main field of our research based on the before-mentioned facts. Specifically, the main goals of the study are to find the attitudes in Portugal and Ukraine towards CSR: identifying what does motivate food service SMEs to implement the instruments of CSR; what are the main hindrances that food service SMEs face to implement the CSR principles into their business strategies; and what kind of CSR-related activities are commonly carried out by the food service companies in environmental, economic and social pillars of the triple bottom line approach. Additionally, two hypotheses were formulated to understand the possible relation between (1) the financial situation and (2) the duration of the company with the awareness level about the CSR concept.

The rest of the paper is structured as follows. The second section reviews the literature on the context of CSR, including sub-sections to describe the current CSR development in Portugal and Ukraine. The hypotheses are presented in the third section, followed by the methodological issues in terms of the research design and sample identification included in the fourth section. The results are presented in the fifth and are discussed in the sixth section, followed by the conclusion and limitations along with suggestions for further research avenues.

CSR and the specific cases of CSR in Portugal and Ukraine

Nowadays, the development of a CSR strategy for an enterprise is one of the crucial components for its success. The implementation of CSR principles into company activities leads to a higher level of interconnection with the society. Moreover, it is necessary to underline that CSR is one of the most important factors on the way to economic development for an enterprise, as well as for the country **(Ebner and Baumgartner, 2006)** and contributes to sustainable development **(Behringer and Szegedi, 2016; Kolk and Van Tulder, 2010; Aras and Crowther, 2008)**.

Even though the concept of CSR has emerged within the last century, there is no universal definition of CSR **(Duman, Giritli and McDermott, 2016; Ness, 1992)**. There are already several models in understanding the concept of CSR, like the models of **Carroll (1979)**, **Wartick and Cochran (1985)**, **Wood (1991)**, or **Clarkson (1995)**, the study of **Elkington (1999)** on the Triple Bottom Line (TBL), measures the three pillars of CSR, economic, environmental and social performance of the organization **(Elkington, 1999)**. The three Ps: (i) profit (i.e., financial), (ii) people (i.e., social), and (iii) the planet (i.e., the environment) are still perceived as synonymous of CSR **(Fauzi, Svensson and Rahman, 2010; Rubenstein, 2003)**.

CSR is being widely developed in the European Union, where companies make voluntary commitments to labor protection, waste management, business ethics while presenting similar requirements to their foreign units and partners **(Marushchak, 2012)**. Portugal, being a member of the European Union, is promoting the development of CSR initiatives, leading to responsible business behaviour, improving the situation on the labour market, the quality of products and services provided by companies, as well as sustaining the development of the country as a whole. CSR in Portugal is determined at a national level and is a policy component of the different ministries **(Shevchenko, 2014)**.

Recent studies using Portuguese samples and context showed that employees who are aware of their company's CSR investment activities tend to make an additional effort in their work and even agree with the fact that CSR practices can lead to more effective company performance **(Story and Neves, 2015)**, for Portuguese consumers environmental CSR practices are much more important than social activities and practices **Loureiro et al. (2012)**. Thus, Portuguese scholars are making a huge research effort into the CSR field. However, there are still great opportunities for expanding and promoting the development of broader and more detailed research in this field and to explore different geographic contexts **(Branco and Delgado, 2011)**.

The Ukrainian scientific literature has been increasing the number of publications related to the CSR sphere annually **(Kasych and Yakovenko, 2014; Kostyrko, 2014)**, despite, in Ukraine, social responsibility is at an early stage of development **(Kolyanko and Myronov, 2016)**. As a result, domestic enterprises often take foreign companies' experience and practice as an example when trying to implement a CSR strategy. The main obstacles to the development and promotion of social responsibility are lack of funds, high tax burden, lack of interest in social responsibility has been suggested in the study of **Burkovska and Lunkina (2016)**. The main trends, barriers, and prospects for CSR developing in Ukraine has been explored as well **(Zinchenko and Saprykina, 2017)**, recommending several steps for the future development in the CSR field, such as the development of a regulatory framework that would facilitate CSR activity, raising the awareness of the National Contact Center for Responsible Business Behavior, implementation of CSR courses into university programs, among others.

Scientific hypothesis

Social responsibility of business should be considered not only as a way of social stabilization but as an instrument for improving the financial situation of the company. However, the relationship between CSR and the company's financial situation can be positive, negative, or

neutral. Some studies have concluded a positive correlation between CSR and the company's financial performance **(Fauzi and Idris, 2009; Orlitzky and Benjamin, 2001; Simpson and Kohers, 2002; Yefimenko et al., 2014)**, others show a negative relationship **(Patten, 2002)** and some neutral relationship as well **(McWilliams and Siegel, 2001; Moore, 2001)**.

Thus, the following hypothesis is suggested:

Hypothesis 1: There is a significant correlation between the financial situation of the company and the awareness level about the CSR concept. The duration of the company's existence affects the level of CSR development among its' business units **(Okhrimenko and Ivanova, 2015)**. Researchers believe that companies that are operating for a long time have more experience in the business environment and therefore better understand how to properly implement and use the CSR method. Consequently, newly formed companies demonstrate the lack of CSR management experience and skills. Mostly it happens because business owners do not have a clear understanding of the CSR in the process of strategic development. Moreover, the lack of fast, obvious results from the implementation of the CSR strategy is the barrier of CSR activities development among newly formed companies **(Sardak and Shmyhovska, 2017)**. Thus, the following hypothesis is suggested:

Hypothesis 2: There is a significant correlation between the duration of the company's existence and the awareness level about the CSR concept.

MATERIAL AND METHODOLOGY

In the present study, it is compared to the development of CSR activities among Portugal a Ukraine food service companies. The objective to identify what does motivate food service SMEs to implement the instruments of CSR, what are the main hindrances that food service SMEs face to implement the CSR principles into their business strategies, and what kind of CSR related activities are commonly carried out by the food service companies in environmental, economic and social pillars of the triple bottom line approach. Additionally, who hypotheses were formulated to understand the possible relation between (1) the financial situation and (2) the duration of the company with the awareness level about the CSR concept, as presented in the previous section.

The research was conducted among the companies of the food sector of Portugal and Ukraine operating in three cities of each country (Portugal: Lisbon, Porto, Faro; Ukraine: Kyiv, Lviv, Odesa). The selection can be explained by the fact that according to Statistics Portugal – Web Portal **(INE, 2018)** and State Statistics Service of Ukraine **(UKRSTAT, 2018)**, the before-mentioned cities are the most visited ones. A questionnaire method was used to collect data in January – February 2019 (Ukraine) and March- April 2019 (Portugal). The questionnaire forms were fulfilled by representatives of executive positions. The communication with the respondents was conducted by sending out an online sample of the questionnaire via e-mail and, in some cases, through personal meetings with the respondents. The questionnaire was developed from a thorough literature review **(Zinchenko and Saprykina, 2017)**, which consisted of 15 questions grouped into 6 parts. The questionnaire includes closed and semi-closed questions:

- Part I: represents formal questions about company activities, such as financial status, the duration of the firm's existence, company size;
- Part II: includes questions that allow estimating level of leadership awareness of CSR notion. This part of the questionnaire allows us to find out factors which hinder CSR implementation and factors which, on the other hand, encourage companies to implement and develop activities in this area;
- Part III, IV and V: allow to evaluate the company's activities in three main CSR pillars: economic pillar; environmental pillar and social pillar;
- Part VI: includes questions regarding the company's plans for further CSR development activities.

The questionnaire adopted Likert scales, in which the respondent expressed the extent of his/her agreement or disagreement with a certain statement, ranging from 1 – "strongly disagree" to 5 – "strongly agree" or 1 – "not dealing with" to 5 – "dealing a lot". To analyze the data, Excel and XLSTAT version 2019.1.3 were used. In order to test the hypotheses, the Spearman correlation coefficient was used.

Statistical analysis

A total of 201 responses were collected: 101 (in Portugal) and 100 (in Ukraine), from representatives of executive positions in Portuguese and Ukrainian companies. Concerning the Portuguese sample companies, the majority was formed by the small-sized enterprises (80.2%) and medium-sized (19.8%). The company's existence duration was the following: 8.9% less than 1 year, 24.8% from 1 to 5 years, 51.5% from 5 to 10 years and 14.9% more than 10 years. The majority (88.1%) has a domestic or local owner and 11.9% of the respondents have a domestic owner with a foreign investor. 31% of respondents declared to have a very good financial situation, 32.7% – above average, 22.8 % – average and 12.9% – below average. In the case of 100 Ukrainian enterprises, most of them are small-sized (60%), and the medium-sized companies (40%). The company's existence duration was the following: 5% less than 1 year, 28% from 1 to 5 years, 47% from 5 to 10 years and 20% more than 10 years. 79% of respondents declared to have a domestic owner, 21% have a domestic owner with a foreign investor. The majority (40%) has a very good financial situation, 22% – above average, 20% – average, and 18% – below average.

RESULTS AND DISCUSSION

The first questions were aimed to explore the general attitude of the respondents toward CSR. 63.4% of Portuguese and 61% Ukrainian respondents declared that they are familiar with the term of CSR. Consequently, it can be stated that the CSR concept is well known for most of the enterprises in the investigated market.

The Likert scale helped us with further investigation of the food service companies. Table 1 explicitly shows the extent to which companies agree or disagree with the following statement: "The representatives of executive positions have a good knowledge of CSR concept and the

ways of CSR implementation into company's activities". Based on the results, only 16.8% of Portuguese and 19% of Ukrainian respondents strongly agree that the company's leadership has a good knowledge of the CSR concept. However, it is worth mentioning that 48.5% of Portuguese and 35% of Ukrainian respondents see themselves as a socially responsible enterprise.

Table 2 shows that regardless of the country, almost all respondents indicate moral-ethical reasons (97% of Portuguese and Ukrainian respondents), improvement of economic indicators (96% of Portuguese and Ukrainian respondents), maintaining/increasing of the company´s reputation (98% of Portuguese and 100% of Ukrainian respondents), increasing of the employee motivation (98% of Portuguese and 97% of Ukrainian respondents), increasing/maintaining the level of customers' loyalty (99% of Portuguese and 95% of Ukrainian respondents) as the main motivating factors for CSR implementation. It is also worth noting that third-party pressures do not motivate enterprises to implement CSR activities in their businesses.

A weak CSR legislation is one of the main barriers to implement/improve CSR activities among Ukrainian food service companies (78% of respondents). In turn, the majority of Portuguese respondents (75.2%) noted that for them the lack of time is one of the biggest obstacles for CSR implementation. The positive fact is that only a few firms have mentioned that CSR activities are not important for their company (5% of Ukrainian and 4% of Portuguese respondents) (Table 3).

Economic Pillar

Table 5 shows that most of the respondents (851% of Portuguese and 85% of Ukrainian companies) implement principles of fair trade while doing their business. Moreover, the majority tends to provide information to the stakeholders (consumers, suppliers) (64.4% of Portuguese and 73% of Ukrainian companies) and tends to carry out transparent activities (62.4% of Portuguese and 72% of Ukrainian companies). From the other side, considering the ethical principles of trade the sales business innovations related activities are not present among the foodservice companies' activities.

Social Pillar

Our study results show that most of the workplace policy activities listed in the questionnaire are being implemented to a high extent (Table 6). Regarding the overall view of the workplace policy (social pillar), respondents, regardless of the location, are trying to implement a considerable number of such activities: compliance with labour standards (Portuguese respondents – 95%, Ukrainian respondents – 95%); respect for human rights and freedoms (Portuguese respondents – 73.3%, Ukrainian respondents – 88%); safety and protection of health at the workplace (Portuguese respondents – 80%, Ukrainian respondents – 93%).

Another area of the social pillar (policy towards community) has a paradoxically low development level. Ukrainian companies cooperate with the public community only through non-financial contributions supporting the local community (38%). On the other hand, Portuguese companies support the community by helping in the organization of different events (33.7%) (Table 7).

Concluding Questions About CSR

The basic aim of this part is to examine the plans in CSR policy of the investigated companies.

The vast majority of the companies (79.2% of Portuguese and 91% of Ukrainian) is planning to increase CSR related activities in the next 3 years. It should be noted that none of the respondents expressed a desire to reduce the number of CSR related measures.

Testing the hypotheses

Analyzing the correlation between the financial situation of the company and the CSR concept awareness level among Portuguese and Ukrainian foodservice companies,

Table 6 The evaluation of the workplace policy (social pillar).

Table 8 Correlation matrix according to Spearman's correlation (H1).

Variables	Financial situation of the company in last three years	The level of CSR concept awareness
Portugal		
Financial situation of the company in last three years	1	0.788*
The level of CSR concept awareness	0.788*	1
Ukraine		
Financial situation of the company in last three years	1	0.855*
The level of CSR concept awareness	0.855*	1

Note: *<0.0001.

using the Spearman's correlation test, results are statistically significant correlated ($p = 0.001$, $p < 0.05$), for both Ukrainian and Portuguese samples. Regardless of the country, there is a significant positive relationship between the two variables (Table 8). Thus, it can be concluded that H1 is confirmed.

Results

In this study, we have compared the level of CSR perception in Portugal and Ukraine, aiming to explore the main factors influencing the CSR perception level among the foodservice companies in both countries. The results of the study show that despite the different economic, cultural conditions, and even different geographic position of Ukraine and Portugal, respondents from both countries demonstrate a similar CSR perception level and are implementing almost identical activities in relation to CSR, contrary to previous findings from the literature that assumed that the geographic position of the company influences CSR perception level **(Boeprasert, 2012; John et al., 2011; Loughran and Schultz, 2005; Sorenson and Baum, 2003)**.

The respondents' answers to "what are the main hindrances that foodservice SMEs face to implement the CSR principles into their business strategies?" help us to understand that Portuguese and Ukrainian respondents have different perceptions of the barriers on the way of implementing/improving CSR activities. Limited implementation time is the main barrier on the way of the CSR activities implementation among the majority of Portuguese respondents. On the other hand, Ukrainian respondents pointed out that weak CSR legislation and low awareness of CSR are the main barriers to CSR realization. These facts support previous literature that claimed that the lack of knowledge on CSR is the most significant barrier for CSR implementation/improving activities **(Kovach, 2013)**. Also, other authors are dealing with this problem from several sides like **Janošková and Csikósová (2019)** and **Halasi et al. (2019)**.

The respondents' answers "what does motivate foodservice SMEs to implement the instruments of CSR?", give a possibility to figure out which factors motivate/do not motivate companies to implement CSR policy. Almost all respondents indicated that moral-ethical reasons,

economic indicators improvement, better relationships with the community, maintaining/increasing of the company´s reputation, increasing employees' motivation, increasing/maintaining customers' loyalty level are the most common factors that motivate companies to implement CSR activities. It is also worth saying that third-party pressures do not motivate enterprises to implement CSR activities in their business. These results support previous literature findings that claimed that the possibility of economic indicators improvement is a strong motivator for companies in CSR implementation activities **(Simpson and Kohers, 2002; Yefimenko et al., 2014)**.

The respondents' answers to "what kind of CSR-related activities are commonly carried out by the food service companies?", show that minimization of the impact on the environment and waste sorting is the most common activity from the listed in the questionnaire. As for the economic pillar of CSR, the respondents show the high implementation level of almost all measures in this direction. This situation can be explained by the fact that such kind of activities help the companies to increase the profit, to improve financial and economic indicators, which is the main task for any enterprise. The study shows that companies have a well-developed policy at the workplace. Most respondents have a fair salary system, demonstrate compliance with labor standards, human rights, and freedom protection. Based on this we can sum up that companies understand that a successful business can be built only with the help of skilled workers who need to have a proper working condition. On the other hand, the social pillar (policy towards community) has a paradoxically low development level. In general, Portuguese and Ukrainian foodservice companies are usually engaged in the implementation of similar activities in all three CSR directions. This study also confirmed that enterprises choose activities that are low-priced or easy to implement **(Kolyanko and Myronov, 2016)**. Only measures that are regulated by law are implemented on a high level (such as fair trade, compliance with labor standards, etc.).

The present study claims that there is a significant correlation between the financial situation of the company and the awareness level of executive positions representatives about the CSR concept. Indeed, companies with a better financial situation demonstrate a higher level of awareness of the CSR concept and the ways of its implementation in the company's activities, corroborating our hypothesis 1. This conclusion supports previous literature findings that claimed a positive relationship between awareness of the importance of the CSR activities and the financial situation of the company **(Fauzi and Idris, 2009; Orlitzky and Benjamin, 2001; Simpson and Kohers, 2002; Yefimenko et al., 2014)**. On the other hand, results disprove the fact that the duration of the company's existence influences the company's leadership awareness of CSR concept **(Okhrimenko and Ivanova, 2015; Sardak and Shmyhovska, 2017)**, not corroborating our Hypothesis 2.

CONCLUSION

This study shows evidence that CSR practices in the environmental and social pillars are poorly developed compared to the other activities of the companies of our sample. Here the attention could be paid more to the privileges or so-called bonuses for companies that are trying to save energy, reduce the materials used, implement energy-intensive processes. Furthermore, the creation of the database on the local level that will clearly show regional requirements for social investments, promote social responsibility and help community development would be a great effective solution on the way of CSR implementation.

The empirical research findings of this study confirm a significant part of the literature review and help us to make important assumptions. The present work demonstrates a significant correlation between the financial situation of the company and the CSR awareness level of leadership. Furthermore, the research shows that activities related to the economic sphere and CSR workplace policy among food sector companies in Ukraine and Portugal are developed to a high extent.

Some limitations can be pointed out. Firstly, the sample is focused on one single industry, the food sector. Future studies could explore CSR perception and awareness in other business sectors with distinct features. Secondly, this study was conducted in Ukraine and Portugal only. Future research could focus on the CSR perception level of companies from countries located in different geographical areas, as outside of Europe. Thirdly, the questionnaire sample has a limited list of measures related to each of the CSR pillars. We suggest that future studies try to explore other CSR activities related to the environmental, economic and, social areas.

ASSESSMENT OF POSSIBILITIES OF STRAWBERRY JAM REFORMULATION

Ladislava Rýdlová, Tereza Škorpilová, Gabriela Juhászová, Aleš Rajchl

ABSTRACT

The prevalence of excessive weight gain, obesity, and associated diseases are permanently increasing. Therefore, the interest in food products with a composition suitable for people with the aforementioned health problems is also on the rise. The changes in food composition, nowadays often called reformulation, are mainly focused on reducing the amount of salt, sugar, or fat. Strawberry spreads with different sugar (10 – 40%) and strawberry (20 – 50%) content were prepared and the influence of strawberry jam composition on gel stiffness, colour, and sensory parameters was studied. This study aimed to determine the sensorial and technological limits (sugar and strawberry content) of strawberry jam reformulation. Carrageenan was chosen as a suitable gelling agent for the preparation of these reformulated strawberry products. strawberry spreads. The applicable concentration of carrageenan for the ideal stiffness of strawberry spreads was 2%. The results of the maximum compression force show a statistically significant increase of gel stiffness with increasing addition of strawberry puree, the effect of sugar content was also statistically significant (p = 0.05). This study showed that strawberry spreads with low strawberry and/or sugar content are sensorially acceptable.

Keywords: fruit spreads; carrageenan; texture characteristics; colour

INTRODUCTION

At the end of 2011, the world population had reached 7 billion and it is supposed the increase of one billion people to 2025. Around one billion people in the 21st century are starving and another billion people are suffering from micronutrient deficiency. On the other hand, over a billion people worldwide are deemed overweight or obese, with increased risk of associated diseases. Even with sufficient intake or excessive energy, consumed food can remain a poor source of essential nutrients. Opportunities to improve the nutritional profile and sustainability of the diet are found throughout the food chain, farm production, retail, and households. These include crop diversification, food enrichment, improvements in the efficiency of transport, waste minimisation, and last but not least food reformulation **(Buttriss, 2013)**.

The food industry has two main approaches to product reformulation: gradual reduction of nutrient content without introducing further changes in product formulation or partial/total replacement with other nutrients such as hydrocolloids, fat substitutes, and sweeteners **(Ares et al., 2018)**. However, some studies have found that products without added salt or sugars leave a negative sensory impression **(Phelps et al., 2006; DuBois and Prakash, 2012)**. Added sugars are defined as sugars that are added to foods during processing, preparation, or "on the table". They contribute to the energy value of the diet but have a little nutritional benefit and their high intake is associated with increased dietary energy, dental caries, and other adverse health effects such as excessive weight gain and reduced bone density. The current WHO recommendation is that the intake of added sugars should be less than 10% of the total energy intake **(WHO, 2015; Yeung et al., 2017)**. Replacing sugars in reformulated foods could represent a strategy to reduce sugar intake in the population without a significant change in the normal diet. However, reducing the sugar content of food is not easy because it results in changes to taste, texture, functionality and shelf life **(van Raaij, Hendriksen and Verhagen, 2009; Cruz et al., 2010)**. The hygroscopic nature of sugar plays an important role in reducing water activity in foods and helps maintain and prolong the shelf life of foods. Sugar prevents for example microbial spoilage of jams after opening. It is therefore always necessary to understand the function of sucrose in a particular food product before it is replaced **(Goldfein and Slavin, 2015)**.

Fruit, vegetables, and related products are often perceived by the consumer as "healthy" and consumable in any quantity. However, fruit and in particular for fruit products should be consumed with caution. Fruit products (compotes, fruit spreads, candied fruit, and other) often contain high sugar content. The effort to reformulate is then significant for the aforementioned reasons **(Rýdlová et al., 2019)**. The term "fruit spreads" is generally used in the food processing industry for marmalades, jams, jellies, and similar products. Fruit spreads have traditionally high

sugar content (60 – 65%), and there is the possibility for their reformulation. The formation of the desired jelly consistency of a fruit spread with reduced sugar content can be achieved by the use of low-esterified pectins or alternatively gelling agents based on gums or extracellular products of microorganisms **(Kadlec, Melzoch and Voldřich, 2012)**.

Scientific hypothesis

It is possible to reduce sugar content (up to 10%) and/or strawberry content (up to 20%) of the strawberry jam without it will result in less acceptable products.

There are technological and sensory acceptance limits for the sugar and/or strawberry content in strawberry spreads.

MATERIAL AND METHODOLOGY

Carrageenan C (CEAMGEL 9205; CEAMSA, Spain), citric acid (Hubka-Petrášek a vnuci s.r.o., Czech Republic), sucrose (DIAMANT; 1. Cukerní společnost Praha, s.r.o., Czech Republic), strawberry puree (100%) (Fruta Podivín, a.s., Hamé s.r.o., Czech Republic), distilled water, potassium hydrogen phthalate (SIGMA-ALDRICH, USA).

Sample preparation

Carrageenan gels (n = 2). 36 samples of carrageenan gels (C1 – C36, Table 1) with different sugar (10%, 20%, 30% and 40%), citric acid (0%, 0.25% and 0.5%) and carrageenan (1%, 1.5% and 2%) content were prepared. The calculated amount of sugar and carrageenan was added to boiling water in a multifunctional blender (Thermomix TM31, VORWERK, France), and the batch was agitated at 80 °C for 15 minutes. After 13 minutes of agitation, the calculated amount of citric acid was added (as a 50% water solution). The preparation of samples was carried out in the closed cooking blender. The total mass of one batch was 500 g. From each batch, 10 identical samples were prepared in 25 mL beakers. The cooked samples were stored in a refrigerator at 10 °C for 16 hours.

Strawberry spreads (n = 3). 16 samples of strawberry spreads (J1 – J16, Table 2, Figure 1) with different content of strawberry puree (20%, 30%, 40%, and 50%) and sugar (10%, 20%, 30%, and 40%) were prepared. Samples were prepared in the same way as carrageenan gels except that the strawberry puree was used instead of boiling water and heat-treated in a mixer at 90 °C for 10 min. The final mass of each batch was 500 g.

Methods

Gel stiffness (n = 10). Gel stiffness was analysed according to the method of **Sinthusamran, Benjakul and Kishimura (2014)** with a slight modification. The tests were performed with an Instron Model 5544 (Instron Ltd., USA). For the measurement, a 1-cm wide cylindrical plunger with a straight tip was used. The plunger's movement velocity was 80 $mm.min^{-1}$. The maximum force required to retract the plunger to a depth of 4 mm into the gel was recorded.

Titration acidity (n = 3**)** was measured by titration with 0.1 M NaOH (pH 8.1) and calculated as citric acid content (DL-22 Food & Beverage Analyzer, Mettler Toledo Co., Switzerland). Titration acidity was determined by **(AOAC, 2002)**.

Colour (n = 6). Colour determination was performed in the CIEL*a*b* (L^* lightness, a^* redness, b^* yellowness) colour space on a Minolta CM-5 spectrophotometer (Konica Minolta, Osaka, Japan). The parameters L^*, a^*, and b^* of strawberry spreads (J1 – J16) were determined **(Igual, Contreras, and Martínez-Navarrete, 2014)**. Samples were always dispensed into a cylindrical glass cell up to a height of 3 cm. The cell was placed on a measuring window with 30 mm diameters. Measurements were carried out in both the specular component included (SCI) mode and the specular component excluded (SCE) mode. The values measured in SCE mode were used for further processing in this study.

Soluble solid content (n = 3) of strawberry puree and strawberry spreads were measured using a digital refractometer (KRÜSS DR301-95, Germany).

Sensory analysis. The test room was equipped according to the requirements of the international standard **(UNI ISO 8589, 2007)**. The strawberry spread samples were evaluated by untrained sensory panellists (n = 30). The strawberry spread samples were evaluated for texture, sweet taste, sour taste, fruity taste, and overall acceptability. Sensory attributes were recorded using a nine-point hedonic scale (1 = dislike extremely; 5 = neither like nor dislike, 9 = like extremely).

Statistical analysis

Outliers, identified according to a Dean-Dixon test, were excluded at the significance level of $p = 0.05$. Results are presented as mean ± standard deviation. Data obtained from texture analysis, colour measurement, and sensory analysis were analysed using the Student t-test. Statistical analyses were carried out using the Statistica 12.0 software (Statsoft Inc., Tulsa, OK, USA). All the measurements of titration acidity and soluble solids were performed in triplicate. The measurement of colour was performed in six replicates, and the measurement of gel stiffness was performed ten times for each sample.

RESULTS AND DISCUSSION

According to the literature review **(Tang et al., 2019; Ellis et al., 2019; Ortiz-Tafoya et al., 2018)**, carrageenan was chosen as a gelling agent for reformulated strawberry jam. The model samples of carrageenan gel were prepared (Table 1), and gel stiffness was measured. The results of the carrageenan gel stiffness are shown in Figure 2, Figure 3, and Figure 4. The results show that carrageenan, sugar, and citric acid content influence the gelling ability and gel stiffness of carrageenan gels. The gel stiffness increased significantly with increasing amounts of carrageenan. Likewise, the addition of sugar slightly increased the gel stiffness, as confirmed by the results of studies by **Lopez-Sanchez et al. (2018)**, **Maurer, Junghans, and Vilgis (2012)**, **Deszczynski, Kasapis and Mitchell (2003)** and **Watase et al. (1990)**. However, the addition of citric acid significantly reduces the gel stiffness of carrageenan gels ($p = 0.05$).

Table 1 Recipes of carrageenan gels for evaluation of sugar and citric acid content on the gelling ability of carrageenan.

Content of citric acid = 0%		**Content of carrageenan C [%]**		
		1	1.5	2

Note: [a] Significant difference by Student's t-test (p = 0.05), [b] Significant difference by Student's t-test (p = 0.01), [c] Significant difference by Student's t-test (p = 0.001).

The results show that it is not necessary to add citric acid to strawberry spreads because of the natural occurrence of organic acids in a strawberry puree to improve the texture parameters **(Kallio et al., 2000; Sturm, Koron and Stampar, 2003)**. However, the addition of citric acid is necessary for the sensory parameter of the final product (balance of sweet and sour taste). Therefore, the same final concentration of 0.5% of citric acid was chosen for the preparation of all strawberry spreads.

One of the parameters of the overall sensory perception of this type of product for the consumer is gel stiffness **(Pérez-Herrera et al., 2020)**. The results of the strawberry spreads gel stiffness (Figure 5) show, that both, sugar and strawberry puree content contribute to this ability to form a gel (p = 0.05). The maximum force required to compress

the gel was higher than that of carrageenan gels with the same sugar and citric acid addition (p = 0.05). Samples containing 40 – 50% of strawberry puree and 30 – 40% of sugar achieved the highest gel stiffness. Only samples without strawberry puree and low sugar content (10 – 20%) showed low gel stiffness.

Colour is one of the most important parameters of strawberries and strawberry products for their final perception and attractiveness to consumers **(Bursać Kovačević et al., 2015)**. Parameter (L^*) of prepared strawberry spreads J1 – J16 is shown in Figure 6. The results show that the addition of sugar significantly reduces product lightness (p = 0.001). This fact is probably due to the amount of sugar, which contributes to the Maillard reaction **(Li et al., 2020; Liao et al., 2020; Shen, Chen and Li, 2018; Basu, Shivhare and Singh, 2013)**. The addition of strawberry puree also had a significant effect on parameter L^* of strawberry spreads (p = 0.05), but less than that of sugar.

The parameter a^* (redness, Figure 7) was not affected by the amount of sugar added (p = 0.05). Significantly lower was the redness (a^*) of the strawberry spreads with a strawberry puree content of 20%. On the other hand, the addition of strawberry puree affected the colour parameter a^* (p = 0.05).

Colour parameter b^* (yellowness, Figure 8) was lower for samples with a strawberry puree content of 20% (p = 0.05). Like the parameter L^*, parameter b^* decreased with the addition of sugar. This difference is statistically significant (p = 0.05).

The results of the sensory analysis of strawberry spreads (J1 – J16) are shown in Table 3. It is visible, that the evaluation of all samples was very subjective. The results of sensory evaluation of texture and sweet taste show that panellists identify differences between samples. In contrast to this fact, the differences in acid taste and overall acceptability (p = 0.05) were not perceived between samples. The overall acceptability values ranged across the whole hedonic scale for all samples. No statistically significant differences between the overall acceptability value of tested samples were observed (p = 0.05).

CONCLUSION

The reduction of sugar content in strawberry spreads was carried out with a focus on people with special nutritional requirements, specifically suffering from obesity and type 2 diabetes. Carrageenan is a suitable gelling agent for the preparation of reformulated strawberry spreads. The applicable concentration of carrageenan C in strawberry spreads for the ideal stiffness of strawberry spreads was 2%. The results of the maximum compression force show a statistically significant increase of gel stiffness (p = 0.05) with the increasing addition of strawberry puree. As the sugar content in the model increases, the maximum compression force values increase. This effect is also statistically significant (p = 0.05) but not as much as the effect of strawberry puree. It was possible to reduce the sugar content in strawberry spreads up to 10% with acceptable sensory perception. The production of this type of fruit spreads with standard characteristics is a complex task influenced by many factors, including the type of used gelling agent and characteristics of input raw material. These reformulated strawberry spreads may be an alternative to jams, which are not recommended because of their high sugar content, for people suffering from these diseases.

EFFECTS OF THE LACTATION PERIOD, BREED AND FEED ON AMINO ACIDS PROFILE OF MARE'S MILK

Miroslav Fišera, Stanislav Kráčmar, Květoslava Šustová, Pavel Tvrzník, Helena Velichová, Lenka Fišerová, Vlastimil Kubáň

ABSTRACT

The effects of the lactation period, breed, and feed on amino acids profile of mare's milk were investigated. The feed contained two major essential amino acids (EAAs) leucine (7.31 – 10.3 g.kg^{-1}) and arginine (6.37 – 9.59 g.kg^{-1}); it also included minor EAAs methionine (2.11 – 3.05 g.kg^{-1}) and histidine (2.48 – 3.60 g.kg^{-1}). Glu+Gln, Asp+Asn, and proline, major nonessential amino acids (NEAAs), constituted approximately 60% of total NEAAs (TNEAAs). The ratio of total EAAs to NEAAs ranged from 1:1.2 to 1:1.4. Amino acids (AA) content throughout all milk samples varied due to mare's different conditions and lactation days. Except for the 1P milk sample, total AA content in the 2 – 8Ps specimens caused by differences in breed oscillated from the 2nd to 28th day of lactation within the following limits: 21.9 – 54.6 g.kg^{-1}, 33.6 – 70.7 g.kg^{-1}, 38.1 – 71.2 g.kg^{-1}, 29.46 – 74.2 g.kg^{-1}, 52.2 – 87.1 g.kg^{-1}, 37.9 – 70.3 g.kg^{-1} and 26.4 – 64.5 g.kg^{-1}, respectively. In relation to TEAAs in milk, the highest EAAs levels were reached in arginine, leucine and lysine ranging between 2.41 – 4.35 g.kg^{-1}, 3.36 – 5.59 g.kg^{-1} and 2.72 – 4.80 g.kg^{-1}, respectively, while the lowest AAs amounts were indicated in histidine and methionine, 0.91 – 1.58 g.kg^{-1} and 1.23 – 2.04 g.kg^{-1} respectively. Total NEAAs content was slightly higher than that of EAAs; the TNEAAs to TEAAs ratio was 1:0.9 proximately. Glu+Gln, Asp+Asn and proline were determined as major NEAAs of milk ranging between, 6.77 – 11.0 g.kg^{-1}, 3.21 – 5.60 g.kg^{-1} and 1.25 – 2.18 g.kg^{-1}, respectively; levels of NEAAs such as cysteine and glycine oscillated between 0.89 – 1.52 g.kg^{-1} and 0.64 – 1.15 g.kg^{-1}, respectively. The average TAAs contents caused by breed differences were 62.8 g.kg^{-1}, 42.8 g.kg^{-1}, 44.7 g.kg^{-1} and 44.8 g.kg^{-1}, respectively, on the 2nd, 5th, 10th, and 28th lactation days.

Keywords: mare's milk; amino acids; minerals; lactation; feed; breed

INTRODUCTION

Milk is a fluid secreted by the female of all species of mammals. There are about 4500 species producing milk to cover the complete nutritional requirements of the neonate of the species, as well as to provide some immunological protection and to satisfy other physiological requirements. The milk of all species is similar but there are significant species-specific differences. Interspecies differences in the quantitative composition of milk probably reflect differences in the metabolic processes of the lactating mother and the nutritive requirements (amino acids, minerals, fatty acid, vitamins, etc.) of the sucking young. In addition to supplying all the nutritional requirements of the neonate, many of the micro-constituents of milk, such as oligosaccharides, immunoglobulins, metal-binding proteins, and enzymes serve protective roles. Because the nutritional and physiological requirements of each species are rather unique, the composition of milk shows substantial inter-species differences **(Fox, 2009; Fox and Mcsweeney, 1998; Wong et al., 1999)**.

Milk of only about 180 species of mammals has been analyzed up to now; the data for only about 50 species are considered reliable **(Fox and Mcsweeney, 1998; Park, 2009)**. Besides being the most important nutritional resource for foals during the first months of life, the mare´s milk is also one of the most important basic foodstuffs for human populations in Kazakhstan, Kirghizia, Tadzhikistan, Uzbekistan and Mongolia. Lactic-alcoholic beverages called Koumiss, Airag and Kumis are traditionally produced through fermentation **(Di Cagno et al., 2004; Montanari et al., 1996; Malacarne et al., 2002; Orskov, 1995; Pikul and Wójtowski, 2008)**. To a lesser extent, horses have been used as dairy herds in Eastern and Central Europe (Belarus, Ukraine, Hungary, and Bulgaria) **(Caroprese et al., 2007; Doreau and Martin-Rosset, 2002; Fox, 2009)**. Regarding Western Europe, where the most important product of equine breeding is represented by the foal, studies on mare's milk have concentrated mainly on the growth and health of the newborn horse, however, in two decades, the mare's milk has been subjected to through research and, as the result, consumed for human health and as a fundamental food **(Park, 2009)**. Besides the composition of mare's milk fat, the properties of its protein fractions and composition of

amino acids suggest that this product is more similar to human milk than to cow's milk. For the above reason, and because of the low cross-reactivity between cow's and mare's milk proteins, a clinical study has suggested that mare's milk could be used as a valid replacement for cow's milk in children with severe IgE-mediated cow's milk protein allergy **(Businco et al., 2000)**. More recently, the consumption of milk and other dairy foods, by virtue of their mineral, bioactive lipids, and protein components, has been shown to help reduce the risk of chronic disease disorders including osteoporosis, hypertension, excess body weight and body fat, dental caries, and some types of cancer **(Csapó et al., 1995; Curadi et al., 2001; Miclo et al., 2007)**.

The nutritional role of mare's milk as a component of the diet has traditionally been evaluated based on its overall contribution of essential and non-essential nutrients forming a high-quality diet for the support of optimal growth and development of the foal. The colostral period of mares is much shorter than that of cows and the colostrum shows significant differences from common milk only on the first day after foaling **(Barello et al., 2008; Huth, DiRienzo and Miller, 2006)**. The nutritional dependence of the foal on mare's milk composition seems to be most marked immediately after birth. In the case of dairy animals, it is well known that nutrients digested by the dairy cows have a significant effect on the maternal milk composition **(Huth, DiRienzo and Miller, 2006)**. For the proper nutritional management of horses (during the lactating period and of foals during the sucking period), it is essential to clarify the relationship between the intake of nutrients and the milk composition in mares. The daily nutrient requirements of lactating mares are very high, and they can be compared with those of racing horses in heavy training. Important nutrients are secreted by the mare to supply her foal with energy, proteins, fats, carbohydrates, vitamins, and minerals for optimal development and growth. To substitute these nutrient losses and at the same time to support maintenance requirements, lactating mares must consume adequate amounts of quality feeds **(Pagan and Hintz, 1986)**. It is known that the intake of minerals and amino acids is particularly important for the growth of foals. The protein requirement of the horse is influenced by the capacity of the protein to satisfy the amino acid needs of the animal. In the horse diet, there are currently four main essential amino acids: lysine, methionine, threonine, and tryptophan. These amino acids are the most important nutrients because limiting their levels will affect the growth and development of the horse.

In the last decade, quite detailed research on equine milk and colostrum composition and, especially studies on proteins, lipids, and minerals have been carried out for the above-mentioned reasons. Many authors have reported data on the profile of essential nutrients such as minerals, amino acids, and vitamins in mare's milk; however, no complex research including all the above factors has been implemented **(Fišera et al., 2018)**. Moreover, there are a few studies of the relationship between changes in mare's milk main components and the above affecting factors such as lactation stage and others.

Scientific hypothesis

Therefore, this study is focused on changes in contents of essential nutrients detected in mare's milk depending on lactation stages, feeding system, and on some breeds. The research aimed to analyze the content of significant nutritional components in mare's milk and lactating mare´s feed as well as to characterize the effects of several factors that affect milk properties such as lactation periods, breed, and mare's diet. More specifically, the aims of the study were i) to analyze changes in the major amino acid composition of mare's milk caused by differences in broodmares and by periods in the first month after parturition, ii) to analyze the major amino acid content and dry matter levels in the lactating broodmares´ feed during the lactation days after parturition and iii) to study the relations between the amino acid composition of milk and feed. The final goal was to get detailed information on the relationship between amino acids detected in mare's milk and their feed. Effects of the lactation period, breed, and feed on amino acids profile of mare's milk were investigated and successively evaluated.

MATERIAL AND METHODOLOGY

Selection of broodmares and broodmares' milk samples

To collect mare's milk and colostrum samples, eight different mature, well-developed, and normal broodmares were selected. All the selected mares were from seven to sixteen years of age (10 ±3 parities), with the live weight between 500 and 600 kg. They were kept indoor and outdoor individually and fed with 1.3 kg wheat bran, 2.1 kg hominly, 5.0 kg oats every day. Water was available from troughs at all times. All mares were vaccinated against influenza and herpes virus per 6 months.

The milk samples (approximately 40 – 50 mL) from selected broodmares were taken into plastic containers on 2, 5, 10, 28, and 56 days postpartum; 31 individual samples were collected in total (Table 1). Before milking, foals were separated from their mothers for approximately 2 hours to prevent suckling. The first milking of mares was carried out with hands as deep as possible. Some mares had not previously been subjected to any milking procedures. The second milking was done accordingly. Collected milk samples were taken directly to the laboratory and then immediately stored and frozen at -20 °C and -25 °C. The samples of feed mixture for the lactating mares (in the amount of approximately 500 g) were collected into polyethylene bags on the days of milk sample collecting altogether 29 samples were collected (Table 1). Then all the samples were taken to the laboratory and stored at room temperature.

All the collected milk samples were being frozen in a freezer at -80 °C for 4 hours, and then they were being lyophilized at 120 Pa and -50 °C for 2 days using vacuum lyophilization (Labicom, Czech Republic). All the lyophilized samples were stored in a fridge at -4 °C before their analysis. All the feed samples were being mixed or ground using a mixer for 3 min and then put into plastic containers. All the grounded samples were stored at room temperature prbeforeheir analysis.

Reagents and solutions: All reagents used were of analytical reagent grade (Sigma-Aldrich, St. Lois, Mo, USA). Concentrated hydrochloric acid 37% (v/v) HCl, 6 mol.L^{-1} HCl, argon gas, 0.1 mol.L^{-1} HCl, loading buffer of pH 2.2, 30% (v/v) H_2O_2, 85% (v/v) HCOOH.

Equipment: The contents of amino acids in all samples were determined by using an AAA 400 Amino Acid Analyzer (INGOS, Prague, Czech Republic), a liquid chromatograph designed for the analysis of amino acids on an ion-exchanger column with post-column derivatization by means of ninhydrin and for the determination of biogenic amines. A thermoblock (Labicom, Olomouc, Czech Republic), a rotary evaporator (Heidolph Instruments GmbH + Co. KG, Kelheim, Germany) and an oil bath (Memmert GmbH + Co. KG, Schwabach, Germany) were used for acid and alkaline oxidizing hydrolyses of all milk and feed samples.

Procedures

Analysis of dry matter

Dry matter (DM) was determined according to the AOAC standard procedure **(AOAC, 1990)**. Contents of dry matter were calculated according to the following equation DM (%) = $m_2.100/m_1$, where DM (%) is the percentage of a total dry matter, m_1 is sample weight before DM determination and m_2 is sample weight after drying.

Analysis of amino acid contents

The contents of amino acids in all samples were determined by using an AAA 400 amino acid analyzer (INGOS, Prague, Czech Republic). An amino acid analyzer is a special compact liquid chromatograph designed for the analysis of amino acids on an ion-exchanger column with post-column derivatization by means of ninhydrin and for the determination of biogenic amines.

The acidic hydrolyses of all milk and feed samples were performed with few modifications under hydrolysis time and temperature conditions according to **Buňka et al. (2009)** and **Buňka, Hrabě and Kráčmar (2004)**. Briefly, the lyophilized milk (50 – 60 mg) and dried feed samples (80 – 90 mg) were accurately weighed in screw-capped test tubes for acidic hydrolysis (capacity of 20 mL) with Teflon caps. 15 mL HCl (6 mol.L^{-1}) solutions were added to every tube with a sample. Afterward, the tubes were being purged by blowing with argon gas for approximately 20 seconds, and then the vacuum-sealed tubes were being heated in a thermoblock at 117 ±1 °C for 23 hours. The temperature of the thermoblock was independently controlled by using a thermometer immersed in a test tube filled with silicone oil (the test tube was placed in the thermoblock). After hydrolysis, hydrolyzed samples were filtered using a paper filter and washed with 0.1M HCl. Then the filtrates were firstly dried using a rotary evaporator at 50 °C and 90 rpm and evaporated secondly and thirdly after a double washing with distilled water (approximately 25 mL) until we obtained a dried mass. The dried mass was dissolved in loading buffer with pH 2.2 and made up to the mark in a 25 mL volumetric flask. Then 1.5 mL of this solution was put into a plastic container and filtered through a 0.45 μm filter and subsequently placed in a fridge until loaded to the amino acid analyzer. All analyses were performed in triplicate for every sample.

In order to determine sulphur-containing amino acids, all samples were hydrolyzed separately with HCl (6 mol.L^{-1}) after oxidizing the samples with performic acid according to methods elaborated by **Buňka, Hrabě and Kráčmar (2004)** and **Amarakoon (2009)** with few modifications. Performic acid was prepared in the ratio of 1:9 from 30% H_2O_2 and 85% HCOOH. After incubation at room temperature for 2 hours, the performic acid was being kept in a fridge at 4 ±1 °C for approximately 30 seconds. The lyophilized milk (50 – 80 mg) and dried feed samples 1000 – 8000 mg) were accurately weighed and put into a 250 mL Erlenmeyer flask. 15 mL of performic acid was added to each sample and then it was being cooled at 4 ±1 °C at least for 16 hours for sample oxidizing. After oxidation, 1 – 2 mL of concentrated HCl was added to the oxidized samples and incubated in the hood for approximately 30 min until chlorine gas was removed. Then 150 mL of 6 mol.L^{-1} HCl was added to the oxidized samples and heated in an oil bath at 117 ±1 °C for 23 hours. After hydrolysis, the samples were filtered with a paper filter, dissolved in 0.1 mol.L^{-1} HCl and made up to the 250 mL mark in a volumetric flask. 25 mL of the diluted sample was transferred with a 25 mL pipette into a flask and then the hydrochloric acid was evaporated in the rotary evaporator after washing it twice with distilled water until a dried mass was obtained. Then the dried mass was dissolved in loading buffer with pH-2.2 and made up to the mark in a 25 mL volumetric flask. Then 1.5 mL of this solution was put into a plastic container after filtering through a 0.45 μm filter and then placed in a fridge before loading it to the amino acid analyzer. All analyses were performed in triplicate for every sample.

Determination of amino acids

A standard mixture of 17 analyzed amino acids (aspartic acid + asparagine, threonine, serine, glutamic acid + glutamine, proline, glycine, alanine, valine, isoleucine, leucine, phenylalanine, tyrosine, histidine, lysine, arginine, methionine, and cystine) was obtained from INGOS (Prague, Czech Republic). The content of amino acids was determined by an AAA 400 device according to the manufacturer´s program. Then the column was being regenerated with 0.2 mol.L^{-1} NaOH for 10 min and stabilized for further 17 min with buffer A. The temperature of the column was set to 60 °C for a specific time slot (0 – 60 min and 90 – 102 min) and to 74 °C in the mean time (60 – 90 min). The following flow rates were employed: 0.3 mL.min^{-1} for buffers and 0.2 mL.min^{-1} for ninhydrin reagent. Each hydrolysate was analyzed in duplicate.

Statistical analysis

All the contents of total amino acids in all the analyzed samples were expressed as mean ±SD and calculated based on retention time obtained in chromatograms **(Buňka, Hrabě and Kráčmar, 2004; Ingos Ltd., 2006)**. The data were evaluated by summary statistics and the variance was calculated using an ANOVA procedure performed using Statistica® 12.0 software (StatSoft, USA). All data obtained by the AAA 400 were expressed as the mean levels in fresh milk using the following equation

TA = $A_0.\varepsilon_0$ = (L-C)/(D-C), where TA is amino acid content in fresh milk, A_0 is amino acid content of lyophilized milk, ε_0 is correlation coefficient, L is fresh milk weight, D is lyophilized milk weight and C is container weight.

RESULTS AND DISCUSSION

Dry matter in the feed

The dry matter (DM) content in all feed samples for the lactating mares is shown in Table 2. The percentage of DM content varied slightly in individual feed samples due to preparation conditions of feed mixture and because of the ratio of forages in the feed mixture. The average DM content oscillated between 88.6% and 90.6%. According to some researchers **(Looper et al., 2001),** the DM content in selected high-quality feed types for the lactating mares such as grains, hay, and chaff ranged from 87 to 91 % (w/w). The above results comply with NRC **(Pagan and Hintz, 1986)**. DM content in all the feeds, therefore, is in accordance with the standard level of DM in feed and forage for the lactating mare.

Amino acid composition of feed and milk

The amino acid content in the feed

In the experiment, the essential amino acids and non-essential amino acid profiles of each investigated feed for the lactating mare were determined. All the data are expressed as mean ±SD in g.kg^{-1} (p <0.005) and they also depict considerable variations in the amino acid content in feeds. The protein nutritive value is given by its amino acid profile. The protein contents in horse feeds such as in grains, hay, chaff, pasture, or in others range from 10 to 25% of total weight depending on the type of feeds **(Pagan and Hintz, 1986)**. Out of 20 amino acids, a human being or an animal can synthesize only nine. The remaining amino acids should be provided in their food. Arginine is regarded as a semi-essential amino acid **(Boisen, Hvelplund and Weisbjerg, 2000)**.

As shown in tables, AA contents in feeds for the lactating mares differed, which could have been caused by some of the above mentioned factors. Generally, NEAA glutamic acid (Glu+Gln) content (18 – 21 g.kg^{-1}) reached the highest values while the EAA methionine and histidine levels
(2.5 – 3.6 g.kg^{-1}) dropped the lowest among all feeds. EAA arginine and leucine, NEAA aspartic acid (Asp+Asn) and proline content in all feeds were higher than levels of other AAs, 7 – 9 g.kg^{-1}, 8 – 10 g.kg^{-1}, 7 – 9 g.kg^{-1} and 8 – 9 g.kg^{-1} respectively. In the animal diet, there are currently recognized four main essential amino acids: lysine, methionine, threonine, and tryptophan, which are the most important nutrients; limiting their levels will affect the growth and development of the horse **(Saastamoinen and Koskinen, 1993)**. Particularly in the horse, the daily lysine requirement for the lactating mare ranges between 13.8 – 16.9 g per 100 kg of body weight **(National Research Council. 2007)**. The contents of these above AAs in feeds were, except for tryptophan, which was not analyzed, relatively lower than the amounts of the others. Lysine levels ranged between 3.0 – 4.5 g.kg^{-1}, methionine amounts oscillated between 2.5 – 3.6 g.kg^{-1} and threonine content ranged between 3.4 – 4.0 g.kg^{-1}.

Regarding other AA such as EAA isoleucine, valine and phenylalanine, NEAA cysteine, glycine, serine and tyrosine, their levels did not differ much ranging between 3.4 g.kg^{-1}, 4.8 – 6.2 g.kg^{-1}, 4.7 – 6.0 g.kg^{-1}, 3.4 – 3.8 g.kg^{-1}, 5 – 6 g.kg^{-1}, 4.5 – 5.2 g.kg^{-1} and 3.4 – 7.0 g.kg^{-1}, respectively. According to some reports, tyrosine and cysteine are regarded as semi-essential amino acids, since they can be synthesized exclusively from methionine and phenylalanine, respectively **(Boisen, Hvelplund and Weisbjerg, 2000)**. Total NEAA amounts (approximately 50 – 66 g.kg^{-1}) in all feeds on all days were slightly higher than total EAA levels (approximately 40 – 51 g.kg^{-1}). The highest total EAA content reached a maximum (51.7 g.kg^{-1} in 5F) on the 2nd day while the lowest value was found in 1F on the 2nd day (40.5 g.kg^{-1}). In the case of NEAA, the highest amount increased to 66.8 g.kg^{-1} in 7F on the 2nd day and the lowest level was 50.4 g.kg^{-1} in 2F on the 5th day. The above amounts were comparable to levels found in some types of feeds such as oats, barley, sorghum and wheat **(Awadalkareem, Mustafa and El Tinay, 2008; Pagan and Hintz, 1986)**. The protein requirement of the horse is influenced by how well the protein provides for the amino acid needs of the animal; some EAAs are limiting essential amino acids in grass-based feeding programs. It has been reported that daily protein intake of the lactating mare averages at 1493 g.day^{-1} **(Pagan and Hintz, 1986)**. Levels of TAAs in examined feeds ranged between 92 – 116 g.kg^{-1}; their amount was higher than that in some species of oats and there was an agreement with their amount contained in good quality feed for animals **(Biel, Bobko and Maciorowski, 2009)**.

Average amino acid composition of feed

The average content of all AAs examined in 1F – 8F on different lactation days is summarized in Table 3. The average content of each amino acid was calculated in relation to amounts of the AA revealed in all feed on the 2nd, 5th 10th and 28th, days respectively. As shown in this table, all AA contents, except for EAA leucine and methionine and for NEAA proline, on the 28th day and in feeds on the 5th and 28th days slightly decreased. It was observed that the AA contents in feeds reached the highest levels on the 2nd day while the lowest amounts were detected in feeds on the 5th day. Nevertheless, EAA phenylalanine content on the 10th day was higher than the amount of the others. The contents of arginine and leucine, the major EAAs in feed, grew highest ranging between 7.70 – 8.42 g.kg^{-1} and 8.66 – 9.35 g.kg^{-1}, respectively.

Other EAA contents were two and three times lower when compared to major EAA amounts. Moreover, Glu+Gln, proline, alanine and Asp+Asn dominated among the NEAA in feeds ranging between 18.5 – 19.9 g.kg^{-1}, 7.31 – 8.30 g.kg^{-1}, 6.22 – 6.52 g.kg^{-1} and 7.90 – 8.36 g.kg^{-1}, respectively. Contents of the other AA did not differ mutually; methionine and histidine levels in feed scored lowest. Therefore, the total EAA content in all feeds was 1.2 times lower than NEAA content; the average ratio of EAA to NEAA was 1:1.2 (44.1 – 47.0 g.kg^{-1}: 56.4 – 61.2 g.kg^{-1}). It was proved that all feeds for the lactating broodmares were rich in EAA.

Table 1 Milk and feed sample characteristics.

Milk	Days postpartum					Feed	Days postpartum				
	2nd	5th	10th	28th	56th		2nd	5th	10th	28th	56th

TNEAA	**61.24**	**5.54**	**56.35**	**5.12**	**58.45**	**5.03**	**57.36**	**4.79**
TAA	**108.26**	**9.88**	**100.48**	**9.63**	**104.16**	**9.65**	**101.57**	**8.63**

Note: TEAA – total essential amino acid content, TNEAA – total non-essential amino acid content, TAA – total amino acid content.

The ratio of AA in some feeds for animals such as in oats grain was reported as 1:2.8 (27 g. (16 g N)$^{-1}$: 75 g.(16 g N)$^{-1}$) **(Biel, Bobko and Maciorowski, 2009)**. TAA levels in feeds ranged from 100.48 g.kg^{-1} to 108.26 g.kg^{-1} depending on feeding days. Overall, these AA concentrations in all feeds were considerably higher than those in daily feed intake of lactating mares **(Pagan and Hintz, 1986)**.

The amino acid content in milk

The variations in the amino acid contents in milk samples from the eight lactating mares on several days after parturition are shown in Table 4, as a representative example. As shown in this table, the AA contents in 1P on all days were three times lower than those in other mares while there were significant differences in AA contents in all milk. It was, perhaps, due to sample processing and the mare's physiological conditions. It was observed that the highest AA contents were reached in all milk on the 2nd day of lactation; afterwards, all AA contents dropped considerably on the 5th day. It corresponded to the end of the colostral period.

In many papers, the lactation period is the most significant factor influencing the composition of all mammalian milk, in particular of horse milk; protein content in colostral period is five times higher than that in milk period, due to providing the foal with all nutrients and immune substances during the first few days **(Kráčmar et al., 2005)**. The colostral period of mares was found to be significantly shorter than that of cows; quality of colostrum showed significant differences from that of normal milk only on the first 2 days after foaling **(Salamon et al., 2009)**. The AA contents in 2P, 3P, 4P, and 8P on the 10th day of lactation was increased significantly and then decreased gradually. In regard to 1P, 5P, 6P and 7P, the AA content was continuously decreasing till the 10th day of lactation, although on the 28th day it increased slightly again. These changes agreed with reports on mare's milk composition during the lactation period.

Some authors reported that after parturition, the AA content in mare's milk was decreasing continuously **(Csapó et al., 2009)**. Leucine, lysine, arginine and valine contents in all mares' milk samples were higher than those of other EAAs, ranging within 4.4 – 6.7 g.kg^{-1}, 3.7 – 6.5 g.kg^{-1}, 4.2 – 5.8 g.kg^{-1} and 2.7 – 4.9 g.kg^{-1}, respectively; the leucine content was the highest one while histidine content (1.2 – 2.2 g.kg^{-1}) was the lowest one in all milk samples. In the case of NEAA, Glu+Gln, Proline and Asp+Asn, their contents in milk ranged between 8.8 – 15.8 g.kg^{-1} and 4.7 – 7.6 g.kg^{-1} respectively; they reached the highest levels while glycine and alanine contents oscillating between 0.9 – 1.5 g.kg^{-1} and 1.3 – 1.9 g.kg^{-1}, dropped lowest in all milk samples. The above AA contents profile agreed with that foundby **Matsui, Inoue and Asai (2003)**.

Some authors reported that when the AA composition was expressed as AA g.100g^{-1} protein, the changes were noticeably less apparent; it was due to high amount of free AA in milk during the colostral period; after the colostral period, total free AA concentration decreased to half value from 0.6 g.kg^{-1} to 0.3 g.kg^{-1}. The contents of free AAs in colostrum, except for threonine, serine, and glutamic acid levels, were about twice as high as those in normal milk **(Csapó-Kiss et al., 1995)**. Overall, AA contents in 6P on lactation days were higher than those in the others; oscillations in 3P, 4P, 5P, 7P, and 8P AA during lactation days were comparable to each other and no significant difference was observed. Although the AA amounts in all milk on different lactation days differed from each other, they are suggested to depend on feed and breed differences.

Average amino acid composition of milk

Further, Table 5 shows the average total AA content in milk related to differences between eight broodmares, which were fed with above mentioned good quality feeds during lactation, relative to 2nd, 5th 10th and 28th days of lactation. It means that the content of each amino acid decreased, without any exception, considering the change of colostrum to milk (2nd to 28th day), although, on the 10th day, a slight increase of all AA contents in milk was observed in milk.

Generally, after the 2nd and 5th day of lactation, there was a slight difference in AA content which agrees with the data reported by some authors who suggested no changes in the amino acid composition of mare's milk proteins between the 8th and 45th day of lactation **(Csapó-Kiss et al., 1995; Davis et al., 1994)**. In the diet of the horse and the newborn foal, lysine, methionine, threonine, and tryptophan are considered the most important substances to affect its growth and development **(Saastamoinen and Koskinen, 1993)**. Lysine was detected to be one of the major EAAs in milk while methionine and threonine content were the lowest ones. The content of major EAAs arginine, leucine, lysine, isoleucine and valine on the 2nd day of lactation follow: 4.35 g.kg^{-1}, 5.59 g.kg^{-1}, 4.80 g.kg^{-1}, 3.01 g.kg^{-1} and 3.49 g.kg^{-1}, respectively. On the 28th day of lactation, their levels decreased to 2.41 g.kg^{-1}, 3.36 g.kg^{-1}, 2.72 g.kg^{-1}, 1.79 g.kg^{-1} and 2.10 g.kg^{-1}, respectively.

Regarding the oscillation of NEAA amounts, the pattern similar to that of EAAs was observed; the major NEAA Glu+Gln levels decreased from 11.0 g.kg^{-1} to 6.7 g.kg^{-1} and Asp+Asn content dropped from 5.6 g.kg^{-1} to 3.21 g.kg$^{-1,}$ etc. The decrease of AA content in milk between the 2nd and the 28th day ranged between 30 % and 40 %; it was comparable to a decrease of AA content studied by **Csapó et al. (2009)**. Total EAA content reached 30.3 g.kg^{-1}, 20.5 g.kg^{-1}, 21.2 g.kg^{-1} and 17.7 g.kg^{-1} on the 2nd, 5th, 10^{th,} and 28th days respectively, showing values lower than total levels of NEAA.

Therefore, the average ratio of total EAA to total NEAA content on lactation days was calculated as 1:1.1, which is in disagreement with the 1:2.2 value found by **Csapó et al. (2009)**; moreover, the ratio in colostrum was reported as 1:2 **(Lehtola and Saastamoinen, 2010)**, which was influenced by breeds and their feed. On the other hand, total EAA content was significantly higher, and the total NEAA was lower than the values mentioned in the literature. Total AA contents during lactation days reached 62.8 g.kg^{-1}, 42.8 g.kg^{-1}, 44.7 g.kg^{-1} and 37.1 g.kg^{-1} respectively; they decreased throughout lactation days analogically to those of EAAs and NEAAs.

Note: TEAA – Total essential amino acid; TNEAA – Total non-essential amino acid; TAA – Total amino acid.

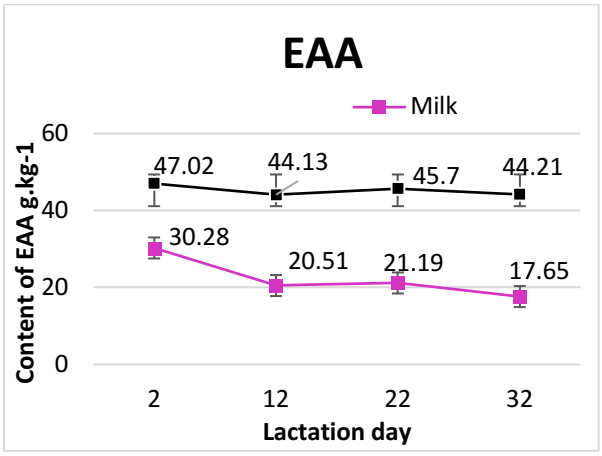

Figure 1 Relation between average total content of essential amino acids in milk and feed.

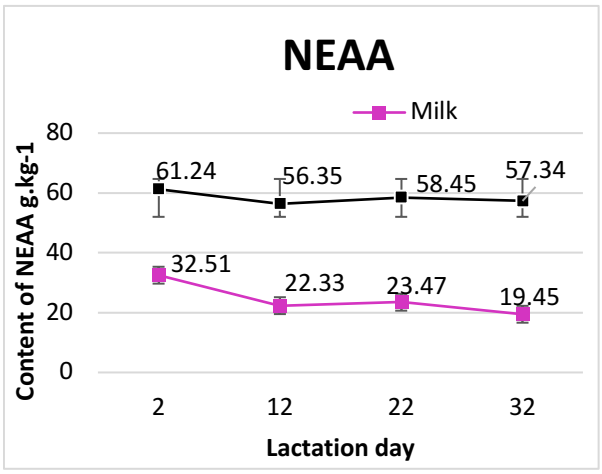

Figure 2 Relation between average total content of non-essential amino acids content in milk and feed.

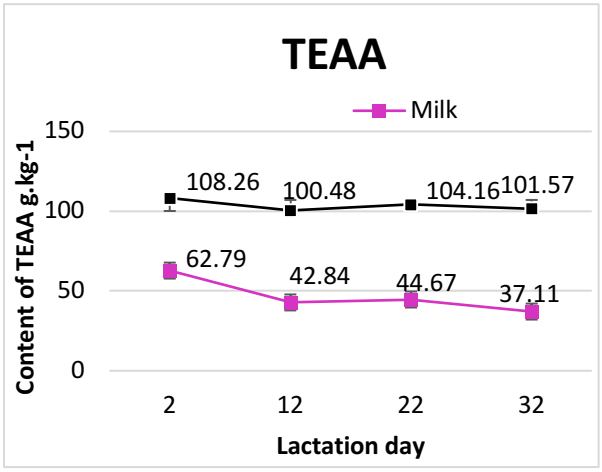

Figure 3 Relation between average total amino acid content in milk and feed.

Some authors reported total AA concentration in mare's colostrum to reach its peak in the first 24 hours after parturition; it ranged from 160 to 170 $g.kg^{-1}$ dropping then to 40 – 42 $g.kg^{-1}$ on the 2 – 5th days, while it decreased to its minimum value of 20 – 25 $g.kg^{-1}$ on 8 – 45th days of lactation **(Csapó-Kiss et al., 1995)**. Equine, milk on the 1st and 2nd day postpartum is considered as initial milk which shows both colostrum and milk properties; therefore, the TAA contents on the 2nd and 5th lactation days did not vary significantly. Nevertheless, TAA levels on the 10th and 28th days were considerably higher than the contents reported above. It has been found by several authors that there were no significant differences in the amino acid composition between the breeds but that total AA content depends on the feeding system and breeds **(Pagan and Hintz, 1986; van den Berg, 2009)**.

The relation between amino acid levels in milk and feed

Supplementary feed and nutrition are considered one of the most important factors that play a crucial role in enhancing the production of milk and its composition. Based on the contents of AA in all feeds and milk, which are given in Table 3 and Table 5, the relations between average contents of each AA in the milk of eight broodmares and studied feeds for the lactating mares on the 2nd, 5th, 10th and 28th days of lactation are summarized in Figure 1, Figure 2 and Figure 3.

Significant relationships between all the compared data were observed; it was indicated that the deviations in levels of each amino acid in milk correlated mutually with those found in feeds on all days of lactation, with the exception of the 2nd day. All amino acid contents on the 2nd day of lactation were considerably higher than AA levels on other days; the above was due to the end of the colostral period **(Csapó et al., 2009)**. Particularly in EAA arginine, isoleucine, leucine, lysine, and phenylalanine, in NEAA Asp+Asn, Glu+Gln, proline and serine, the above tendency was pronounced significantly.

From the 5th to 28th lactation days, all amino acid contents in milk slightly decreased. It was reported that total AA content on the 8 – 45th days was twice lower than that on the 5th lactation day **(Csapó-Kiss et al., 1995)**. In contrast, this study demonstrated that on the 10th lactation day all the AA concentrations, except for EAA lysine, methionine, threonine and for NEAA glycine, increased slightly while all amino acid concentrations in feeds increased.

Methionine, lysine and phenylalanine are the most limiting crucial amino acids contained in animal feed; some feeds slightly improve their amount in milk **(Abu-Ghazaleh, Schingoethe and Hippen, 2001)**. With the exception of methionine, these AA contents were found to be adequate for the lactating mares in all the feeds. Regarding feeds during all lactation days, AA contents in feed were found to be in an adequate amount to cover daily intake of the lactating mare. As reported in the literature, by increasing the level of energy in feed and of the proportion of protein concentrate in the diet, mare's milk amount increased, but milk protein content decreased by 4 $g.L^{-1}$. Moreover, the protein supplementation in the diet showed inconsistent effects on milk protein content.

Additionally, as researchers used a supplement of protein concentrate in a hay-based diet, milk protein content

increased from 17 to 22 g.kg^{-1} **(Martuzzi and Doreau, 2006)**. Further, ratios of total EAA and NEAA content in milk to that in feed on the lactation days obeyed the following values 1:1.5, 1:2, 1:2 and 1:2.4, and 1:1.9, 1:2.5, 1:2.5 and 1:2.8, respectively. In the case of TAA content, the ratio was 1:1.7, 1:2.4, 1:2.4, and 1:2.7. On the other hand, these ratios on the 5th and 10th days of the milk period were consistent while that relating to the 28th day of lactation slightly increased. It has been reported that the ingestion of high-quality protein increases the AA concentration in mare's milk **(Glade and Luba, 1990)**. Thus, the AA concentrations in milk found in this study were significantly related to AA concentrations in the feeds.

CONCLUSION

All results of this research indicated significant relations and changes in major minerals and amino acid composition of different lactating mares' milk throughout the lactation period and in feeds used to feed the mares.

The average DM content of the feed ranged within 89.2 ±0.72 % w/w (p <0.05). Total amino acid contents in all feed generally ranged from 84.4 g.kg^{-1} to 117.0 g.kg^{-1} and the highest total EAA content was 51.7 g.kg^{-1} in 4F on the 10th day while the lowest EAA content dropped to 38.4 g.kg^{-1} in 2F on the 5th day; the major EAAs were represented by leucine and arginine, whose levels ranged within 7.3 – 10.3 g.kg^{-1} and 6.37 – 9.59 g.kg^{-1}, respectively. Methionine and histidine were found minor EAAs with levels oscillating between 2.11 – 3.05 g.kg^{-1} and 2.48 – 3.60 g.kg^{-1}, respectively. In the case of NEAA, their levels were lower compared to those of EAAs contents, which ranged between 66.8 g.kg^{-1} and 50.7 g.kg^{-1}. Glu+Gln, Asp+Asn, and proline were the major NEAAs which represented approximately 60% of TNEAA. The ratio of total EAA to NEAA ranged from 1:1.2 to 1:1.4. Generally, average total AA content in feeds for the lactating mares was found at 105.0 g.kg^{-1}.

According to results obtained, the AA content in all milk samples varied, which was caused by differences in mares and by variations throughout lactation days. The AA contents in 1P milk were three times lower (12.2 – 20.4 g.kg^{-1}) compared to other mares. With exception of 1P, total AA content in 2-8 Ps caused by breed differences ranged 21.9 – 54.6 g.kg^{-1}, 33.6 – 70.7 g.kg^{-1}, 38.1 – 71.2 g.kg^{-1}, 29.5 – 74.2 g.kg^{-1}, 52.2 – 87.1 g.kg^{-1}, 37.9 – 70.3 g.kg^{-1} and 26.4 – 64.5 g.kg^{-1}, respectively, from the 2nd to 28th day of lactation. The average decrease of total amino acid content reached 45.5% from the initial milk period to the 2nd day of the milking period. The average total AA contents caused by breed differences on the 2nd, 5th, 10th and 28th lactation days reached levels at 62.8 g.kg^{-1}, 42.8 g.kg^{-1}, 44.7 g.kg^{-1} and 44.8 g.kg^{-1}, respectively on the 2nd, 5th, 10th and 28th lactation days. During the lactation period, total AA composition did not change, but their amount significantly altered. Concerning TEAA in milk, the highest levels of EAAs were represented by arginine, leucine, and lysine, whose amounts ranged between 2.41 – 4.35 g.kg^{-1}, 3.36 – 5.59 g.kg^{-1} and 2.7 – 4.8 g.kg^{-1}, respectively while the lowest EAAs were exemplified by histidine and methionine, whose levels oscillated between 0.9 – 1.6 g.kg^{-1} and 1.2 – 2.0 g.kg^{-1}, respectively. The total NEAA content was slightly higher than that of EAA; the TNEAA to TEAA ratio was found at 1:0.9 proximately. The major NEAAs in milk were represented by Glu+Gln, Asp+Asn, and proline, ranging between 6.8 – 11.0 g.kg^{-1}, 3.2 – 5.6 g.kg$^{-1,}$ and 1.3 – 2.2 g.kg^{-1}, respectively. In contrast, levels of NEAA cysteine and glycine ranged within 0.9 – 1.5 g.kg^{-1} and 0.6 – 1.2 g.kg^{-1}, respectively.

Significant relationships between all the compared data were observed; it was indicated that the deviations in each amino acid level in milk were accordingly correlated with those found in feed on all days of lactation, except the 2nd one. Overall, the ratios of total EAA and NEAA content in milk to that in feed throughout the lactation period follow 1:1.5, 1:2, 1:2 and 1:2.4; and 1:1.9, 1:2.5, 1:2.5 and 1:2.8, respectively. In the case of TAA content, the ratio was 1:1.7, 1:2.4, 1:2.4, and 1:2.7.

Further studies on mare's digestion of proteins, levels of free amino acids, and minerals in feed and on changes in the nutrients in blood and milk of the lactating mare are suggested to clarify changes in milk composition depending on feeding systems.

PHYTOCHEMICAL PROFILE AND BIOLOGICAL ACTIVITY OF SELECTED KIND OF MEDICINAL HERBS

Eva Ivanišová, Dajana Vasková, Grzegorz Zagula, Dzmitry Grynshpan, Tatsiana Aleksandrovna Savitskaya, Miroslava Kačániová

ABSTRACT

Medicinal herbs are used due to their health benefits, a special aroma, taste and are considered as one of the richest sources of bioactive compounds. The present study aimed to determine antioxidant activity (DPPH and phosphomolybdenum method), a total polyphenol (using Folin-Ciocalteu reagent), flavonoid (aluminium chloride method), phenolic acid content (using Arnov reagent), antimicrobial activity (disc diffusion method) and chemical composition (ICP-OES instrument) of medicinal herbs (ginger, comfrey, valerian, chicory, horseradish, and ramsons) grown in Slovak republic. Antioxidant activity by DPPH method ranged from 0.61 (ramsons) to 3.62 (ginger) mg TEAC per g of dry matter (TEAC – Trolox equivalent antioxidant capacity); by phosphomolybdenum method from 66.67 (valerian) to 204.14 (ginger) mg TEAC per g of dry matter. Total polyphenol content ranged from 4.37 (comfrey) to 13.19 (ramsons) GAE per g of dry matter (GAE – gallic acid equivalent); total flavonoid content from 1.07 (chicory) to 47.55 (ramsons) QE per g of dry matter (QE – quercetin equivalent) and total phenolic acid content from 0.99 (horseradish) to 9.77 (ginger) CAE per g of dry matter (CAE – caffeic acid equivalent). In a sample of ginger was detected the highest antimicrobial activity against *Bacillus cereus* CCM 7934 (5 mm). Among the mineral compounds – in all observed samples were dominated ($mg.100g^{-1}$) of potassium, phosphor, magnesium, and calcium. The amount of cadmium, chrome, and lead in observed samples was detected only in a trace amount, so our results reveal that the medicinal herbs do not represent in this study a potential health risk regarding the content of toxic elements. The consumption and using of medicinal plants as a part of the food mode of consumers due to health benefits is recommended.

Keywords: mineral compounds; antioxidant activity; polyphenols; antimicrobial activity; plants

INTRODUCTION

The use of herbal medicines is increasing steadily throughout the world as an alternative treatment for treating several health problems including civilisation diseases like cardiovascular problems, diabetes, high blood pressure and even certain types of cancer **(Kaur, Kaur and Mahajan, 2013)**. Herbs have been recognized as potential drug candidates because they possess drug-like properties **(Shakya, 2016)**. In Slovakia use of medicinal herbs is much more popular mostly in folk medicine. Unlike tablets and pills, herbal products are not regulated for purity and potency, so detection of benefits and risk is necessary.

Ginger (*Zingiber officinale* Rosco) which belongs to family *Zingiberaceae* is a plant containing a wide range of bioactive compounds especially gingerols, which are described by their pungency. The most abundant pungent component of ginger is 6-gingerol and is claimed to contain antioxidant and antimicrobial activity. Ginger has been widely used to treat nausea and vomiting; healing of wounds, cuts and has antipruritic, anticancer and anti-inflammatory activity **(Danwilai et al., 2017; Mošovská, Nováková and Kaliňák, 2015)**.

The comfrey (*Symphytum officinalis* L.) belongs to family *Boraginaceae*, is a plant that is used for therapeutic purposes mainly in traditional medicine. It is used externally for bruises, joint pains and rheumatic and also for the treatment of diseases of the gastrointestinal tract **(Nossa González, Talero Pérez and Rozo Núñez, 2016)**. The main bioactive compound of comfrey is allantoin responsible for cell division initiation and of growth of the conjunctive tissue, bones, cartilages and acceleration of wound healing **(Neagu, Roman and Radu, 2010)**.

Valerian (*Valeriana officinalis* L.) which belongs to the family *Valerianaceae* has long been used in folk medicine for the treatment of insomnia all over the world, mainly in the United States and Europe. The dominant mechanisms for the pharmacological action of valerian have been described based on their agonistic effects via gamma-aminobutyric acid, adenosine, barbiturate, and benzodiazepine receptors. Indeed, the health properties of some components present in valerian are believed to be associated with their antioxidant activities **(Sudati et al., 2009)**.

Chicory (*Cichorium intybus* L.) which belongs to family *Asteraceae* is widely distributed in Asia and Europe. All parts of this plant expose medicinal properties due to the presence of several bioactive compounds such as inulin, lactones, coumarins, vitamins, natural colorants, sterols, polyphenols, saponins and tannins **(Abbas et al., 2015)**. Preparations from chicory exhibiting antioxidant, immunomodulating, anti-inflammatory activity due to the presence of cichoric acid as a specific active compound **(Ahamad et al., 2015)**.

Horseradish (*Armoracia rusticana* Gaertn) which belongs to the family *Brassicaceae* is used freshly grated in gastronomy as an important ingredient for meat and fish products or into sauces and salads. The main bioactive substances of horseradish are glucosinolates that provide the characteristic flavour, aroma and are also responsible for health-promoting effects such as anti-cancer properties, antioxidant and antimicrobial activity **(Calabrone et al., 2015)**.

Ramsons (*Allium ursinum* L.) which belongs to the family *Amaryllidaceae* has been used for centuries in alternative medicine. Mostly of studies based on its composition and biological activity are fairly recent and scarce. The main bioactive compounds of ramsons are sulfur-containing compounds that are responsible for distinct garlic-like scent and also for health benefits: digestive stimulant, antimicrobial agent, removing toxins from the body, and to prevent cardiovascular disorders **(Sobolewska, Podolak and Makowska-Was, 2015)**.

Scientific hypothesis

Medicinal herbs are a good source of bioactive compounds with antioxidant and antimicrobial activity. In some cases that can also be poisonous due to the heavy metals content. In our study we assumed a high biological activity and low level of hazard mineral compounds, providing the possibility of using these herbs in different kinds of industry.

MATERIAL AND METHODOLOGY

Biological material

The medicinal herbs were collected from nature and gardens in Slovakia (the Year 2018; locality Runina; 560 m.a.s.l.): *Zingiber officinale* Rosco – rhizome, *Symphytum officinalis* L. – root, *Valeriana officinalis* L. – root, *Cichorium intybus* L. – root, *Armoracia rusticana* Gaertn – root and *Allium ursinum* L. – leaves. Before the analysis samples were pulverized in the mortar.

Sample preparation

The sample – 0.2 g was extracted with 20 mL of 80% ethanol for 2 hours. After centrifugation at 4000 rpm (Rotofix 32 A, Hettich, Germany) for 10 min, the supernatant was used for measurement (antioxidant activity, polyphenols, flavonoids, phenolic acids). All analyses were realized in triplicate.

Chemicals

All chemicals were analytical grade and were purchased from Reachem (Slovakia) and Sigma Aldrich (USA).

Antioxidant activity

DPPH method – radical scavenging activity

Radical scavenging activity of samples was measured using 2,2-diphenyl-1-picrylhydrazyl (DPPH) **(Sánchéz-Moreno, Larrauri and Saura-Calixto, 1998)** with slight modification. The extracts (0.4 mL) were mixed with 3.6 mL of DPPH solution (0.025 g DPPH in 100 mL ethanol). The absorbance of the sample extract was determined using the spectrophotometer Jenway (6405 UV/Vis, England) at 515 nm. Trolox (6-hydroxy-2,5,7,8-tetramethylchroman-2-carboxylic acid) (10 – 1000 $mg.L^{-1}$; $R^2 = 0.998$) was used as the standard and the results were expressed in $mg.g^{-1}$ Trolox equivalents.

Phosphomolybdenum method – reducing power

Reducing the power of samples was determined by the method of **Prieto, Pineda and Aguilar (1999)** with slight modification. The mixture of the sample (1 mL), monopotassium phosphate (2.8 mL, 0.1 M), sulfuric acid (6 mL, 1 M), ammonium heptamolybdate (0.4 mL, 0.1 M) and distilled water (0.8 mL) was incubated at 90 °C for 120 min, then rapidly cooled and detected by monitoring absorbance at 700 nm using the spectrophotometer Jenway (6405 UV/Vis, England). Trolox (6-hydroxy-2,5,7,8-tetramethylchroman-2-carboxylic acid) (10 – 1000 $mg.L^{-1}$; $R^2 = 0.998$) was used as the standard and the results were expressed in $mg.g^{-1}$ Trolox equivalents.

Total polyphenol content

The total polyphenol content of samples was measured by the method of **Singleton and Rossi (1965)** using Folin-Ciocalteu reagent. An amount of 0.1 mL of each sample was mixed with 0.1 mL of the Folin-Ciocalteu reagent, 1 mL of 20% (w/v) sodium carbonate, and 8.8 mL of distilled water. After 30 min. in darkness the absorbance at 700 nm was measured using the spectrophotometer Jenway (6405 UV/Vis, England). Gallic acid (25 – 300 $mg.L^{-1}$; $R^2 = 0.998$) was used as the standard and the results were expressed in $mg.g^{-1}$ gallic acid equivalents.

Total flavonoid content

The total flavonoid content of samples was determined using the modified method of **Willett (2002)**. An amount of 0.5 mL of each sample was mixed with 0.1 mL of 10% (w/v) ethanolic solution of aluminium chloride, 0.1 mL of 1 M potassium acetate, and 4.3 mL of distilled water. After 30 min in darkness, the absorbance at 415 nm was measured using the spectrophotometer Jenway (6405 UV/Vis, England). Quercetin (0.5 – 20 $mg.L^{-1}$; $R^2 = 0.989$) was used as the standard and the results were expressed in $mg.g^{-1}$ quercetin equivalents.

The total phenolic acid content

The total phenolic acid content of samples was determined using the method of **Farmakopea Polska (1999)**. An amount of 0.5 mL of each sample was mixed with 0.5 mL of 0.5 M hydrochloric acid, 0.5 mL Arnov reagent (10% $NaNO_2$ +10% Na_2MoO_4), 0.5 mL of 1 M sodium hydroxide (w/v) and 0.5 mL of water. Absorbance at 490 nm was measured using the spectrophotometer Jenway (6405 UV/Vis, England). Caffeic acid (1 – 200 $mg.L^{-1}$; $R^2 = 0.999$) was used as a standard and the results were expressed in $mg.g^{-1}$ caffeic acid equivalent.

Microbial strains

Six strains of microorganisms were tested in this study. Gram-negative bacteria: *Escherichia coli* CCM 2024, *Citrobacter freundii* CCM 7187, *Yersinia enterocolitica* CCM 7204 and Gram-positive bacteria: *Bacillus cereus* CCM 7934, *Staphylococcus aureus* subsp. *aureus* CCM 2461, *Listeria monocytogenes* CCM 4699. All tested strains were collected from the Czech Collection of microorganisms. The bacterial suspensions were cultured in the nutrient broth (Imuna, Slovakia) at 37 °C.

Antimicrobial activity

The antimicrobial activity of each extract was determined by a disc diffusion method. Briefly, 100 μL of the test bacteria were grown in 10 mL of fresh media until they reached a count of approximately 10^5 cells per mL. Then 100 μL of the microbial suspension was spread onto Mueller Hinton agar plates. The extracts were tested using 6 mm sterilized filter paper discs. The diameters of the inhibition zones were measured in millimeters. All measurements were to the closest whole millimeter. Each antimicrobial assay was performed in at least triplicate. Filter discs impregnated with 10 μL of distilled water were used as a negative control.

Chemical (mineral compounds) composition

The amount of mineral elements was analysed by the ICP-OES method (ICP-OES spectrophotometer, Thermo iCAP Dual 6500, USA) – the samples (0.2 g) were subjected to mineralization under high pressure, in HNO_3 65%, super pure. The samples were weighed and placed in Teflon vessels which were then filled with 8 mL of nitric acid and sealed tightly. For each group of nine samples, during the microwave dissolution process, the rotor of the digestion system was additionally filled with a blank sample comprising 8 mL of nitric acid alone. The samples were digested for one hour, with the applied algorithm of temperature increase as specified for biological samples, without exceeding 200 °C. This was carried out using Ethos One microwave digestion system from Milestone. The vessels were opened after the mineralization process had been completed and the samples with acid had been brought to room temperature. The samples were cooled down to room temperature and supplemented with water to the volume of 50 mL. The obtained detection threshold for each element was not lower than 0.01 $mg.kg^{-1}$ (with the assumed detection capacity of the measuring apparatus at a level exceeding 1 ppb). The measurements were performed with ICP-OES spectrometer, Thermo iCAP Dual 6500 with horizontal plasma, and the capacity of detection along and across plasma flame (Radial and Axial). Before measuring each batch of samples the method was calibrated with the use of certified Merck models. The measurement result for each element was compensated to account for the measurement of elements in the blank sample. In each case, a 3-point calibration curve was used for each element, with optics correction applying the method of internal models, in the form of yttrium and ytterbium ions, at the concentrations of 2 $mg.L^{-1}$ and 5 $mg.L^{-1}$, respectively.

Statistical analysis

All experiments were carried out in triplicate and the results reported are expressed as means with standard deviations. The experimental data were subjected to the analysis of variance (Duncan's test), at the confidence level of 0.05, using the **SAS 2009** (USA) software.

RESULTS AND DISCUSSION

Antioxidant activity

Antioxidant activity (Table 1) of analysed samples tested by the DPPH method ranged from 0.61 to 3.62 mg $TEAC.g^{-1}$. The highest value was determined in the sample of ginger, following by a sample of chicory and valerian. Antioxidant activity tested by the phosphomolybdenum method (Table 1) had a similar tendency – the highest value was measured in a sample of ginger (204.14 mg $TEAC.g^{-1}$). Similar value determined in ginger by reducing power method **Akinola, Ahmad and Maziah (2014)** – 266.95 mg $TEAC.g^{-1}$ The strong activity by DPPH, ABTS, and FRAP method of ginger was observed in the study of **Mustafa et al. (2019)**. This authors also reported that activity is influenced by the technological process – the best activity in FRAP and ABTS method was found in ginger sun-dried, while in the DPPH method the strongest activity was found in fresh ginger. Antioxidant activity of valerian was observed in the study of **Pilerood and Prakash (2014)**. These authors tested ethanol, methanol, acetone, 80% methanol, and 80% ethanolic extracts of valerian. The best activity determined by using 80% of ethanol – this extraction solution was also used in our study. In a sample of ramsons (Table 1) by the DPPH method was evaluated the lowest activity, whereas by the phosphomolybdenum method the activity was very strong. This result can be explained by the mechanism of action – in the DPPH method antioxidants from the sample act as scavengers of radical, whereas in phosphomolybdenum method antioxidants from the sample act as reductant agent. In the study of **Putnoky, Caunii and Butnariu (2013)** are described that the S–oxyde (+/−) of S–2–propenyl cysteine and the S–oxide of S–alkenyl cysteine, located in the cytoplasm and the enzyme alliinase located in the vacuole is the main bioactive compounds which bind reactive free radicals and act as reductant agent.

Total polyphenol, flavonoid, and phenolic acid content

Total polyphenols (Table 1) in tested samples ranged from 4.37 to 13.19 mg $GAE.g^{-1}$. The highest value was found in the sample of ramsons following by ginger and valerian. **Lachowicz et al. (2017)** determined in ramsons values ranged from 6.5 (bulbs) to 42.5 (leaves) mg $GAE.100g^{-1}$ fresh matter which is lower values compared to our study. **Pejatović, Samardžić and Krivokapić (2017)** determined values ranged from 13.05 to 18.33 mg $GAE.g^{-1}$, which is comparable with our findings. **Qadir et al. (2017)** in ginger extract found total polyphenols in the amount of 98.37 mg $GAE.100g^{-1}$, which is a lower level to compare with our results. These authors also published that 80% of ethanol is discovered more effective for the recovery of antioxidants from herbal plants to compare with methanol and acetone.

Table 1 Antioxidant activity, total polyphenol, flavonoid and phenolic acid content in tested samples.

Sample	DPPH (mg TEAC.g^{-1})	PM (mg TEAC.g^{-1})	TPC (mg GAE.g^{-1})	TFC (mg QE.g^{-1})	TPAC (mg CAE.g^{-1})

Note: mean ±standard deviation; different letters in column denote mean values that statistically differ one from another.

Total flavonoids (Table 1) in tested samples ranged from 1.07 to 47.55 mg QE.g^{-1}. The best value was measured in a sample of ramsons following by a sample of ginger and comfrey. **Pejatović, Samardžić and Krivokapić (2017)** determined in ramsons leaves extract values ranged from 13.75 to 20.00 mg QE.g^{-1}. **Ghasemzadeh, Jaafar and Rahmat (2010)** in a sample of ginger extract determined total flavonoids in amount ranged from 3.66 to 4.21 mg QE.g^{-1}, which are lower values to compare with our results. These authors by HPLC method determined that in ginger rhizomes the most abundant flavonoid is quercetin. In valerian the most abundant flavonoids are 6-methylapigenin and hesperidin, which are responsible for the sedative and sleep-enhancing properties of valerian root **(Marder et al., 2003)**.

Total phenolic acid content (Table 1) ranged from 0.99 to 9.77 mg CAE.g^{-1}. The highest value was determined in a sample of ginger following by a sample of ramsons and comfrey. **Fahmi et al. (2019)** published that chlorogenic acid (63.85 ppm) and hesperidin (156.91 ppm) are among the major phenolic and flavonoid constituents in dry ginger. In comfrey **Sowa et al. (2017)** by HPLC-DAD method found rosmarinic, *p*-hydroxybenzoic, caffeic, chlorogenic, and *p*-coumaric acid.

Antimicrobial activity

In a sample of ginger (Table 2) was observed activity to inhibit *B. cereus* CCM 7934, *Y. enterocolitica* CCM 7204 and *L. monocytogenes* CCM 4699. In the study of **Nas, Ali and Ahmad (2018)** *E. coli* were found to be the highest susceptible organisms with an average zone of inhibition of 13.6 mm, followed by the *Shigella spp.* (13.3 mm), *Salmonella typhi* (12.7 mm), *Staphylococcus aureus* (12.5 mm), *Pseudomonas aeruginosa* (10.8 mm) while the least average zone of inhibition is shown by *Klebsiella pneumoniae* (9.2 mm).

In the sample of horseradish (Table 2) was detected low potential to inhibit growing of *B. cereus* CCM 7934 and *L. monocytogenes* CCM 4699. In comfrey extract (Table 2) was detected activity to inhibit *E.coli* CCM 2024, *C. freundii* CCM 7187, *Y. enterocolitica* CCM 7204 and *L. monocytogenes* CCM 4699. The antibacterial activity of the root extract of *Symphytum officinale* was tested by the disc diffusion method in the study of **Sumathi, Kumar and Bai (2011)** and it was found that methanol extract showed maximum inhibitory effect against the *Proteus vulgaris* and *Staphylococcus aureus*.

In ramsons sample (Table 2) was observed slight activity to inhibit *E. coli* CCM 2024, *C. freundii* CCM 7187, *Y. enterocolitica* CCM 7204, *S. aureus* subsp. *aureus* CCM 2461 and *L. monocytogenes* CCM 4699. **Krivokapic et al. (2018)** reported that the antimicrobial activity of the plant extract is influenced by the extraction solvent. A methanol extract of ramsons has been shown to exhibits antimicrobial activity against bacteria including *Staphylococcus aureus*, *Bacillus subtilis, Escherichia coli, Proteus mirabilis, Salmonella enteritidis*. On the other hand, water extract was efficient only against *Bacillus subtilis*. Chicory extract in our study showed slight activity to inhibit *E. coli* CCM 2024, *B. cereus* CCM 7934, *Y. enterocolitica* CCM 7204, *S. aureus* subsp. *aureus* CCM 2461 and *L. monocytogenes* CCM 4699. In the study, **Liu et al. (2013)** were observed several extracts of chicory which displayed activities against *Escherichia coli, Staphylococcus aureus, Bacillus thuringiensis, Bacillus subtilis*, and *Salmonella typhi*. These authors also found that the best method for the chicory extract yield with antimicrobial activity was a combination of 70% ethanol v/v, 24-h impregnation time, 3 sonication rounds, and 300-W ultrasonic input power. In valerian extract (Table 2) was observed potential to inhibit the growth of *C. freundii* CCM 7187, *Y. enterocolitica* CCM 7204, *B. cereus* CCM 7934, *S. aureus* subsp. *aureus* CCM 2461 and *L. monocytogenes* CCM 4699.

Chemical composition

The results of mineral compounds composition are presented in Table 3. In a sample of ginger was determined potassium as the dominant compound following by magnesium and phosphorus. Very interesting was the amount of zinc which was the highest in this sample compared to other tested samples. According to **Chasapis et al. (2012)** zinc is one of the most important trace elements in the human body, with three major biological roles: catalyst, structural, and regulatory ion. Zinc has an important effect on homeostasis, immune function, oxidative stress, apoptosis, aging, and significant disorders of great public health interest are associated with zinc.

In samples of horseradish were dominant potassium, sulphur, calcium and phosphorus. The amount of sulphur was higher to compare with ginger, valerian, chicory, and comfrey. A higher amount of sulphur can be explained as the fact that horseradish is rich for glucosinolates. Glucosinolates are N-hydroxy-sulfates with a highly variable side chain and a sulfur-linked *beta*-d-glucopyranose. These compounds are the precursor molecules of the biologically active isothiocyanates components **(Bertóti et al., 2019)**.

In a sample of comfrey dominant compounds was potassium, following by sodium, phosphorus, and calcium. This sample was determined the highest value of copper, which is an essential mineral for human health but at the same time can be toxic, depending upon the amounts of ingested. Copper is associated with bone health, immune function, and increased frequency of infections, cardiovascular risk, and alterations in cholesterol metabolism **(Araya, Manuel and Fernando, 2007)**.

In the sample of ramsons was determined potassium as dominant compounds following by the sulphur, calcium, and magnesium. The amount of sulphur was the highest to compare with the other analysed samples. It is not surprising whereas the dominant bioactive compounds of this plant are based of sulphur (allicin).

In the sample of chicory, the main mineral compounds were potassium, sodium, magnesium and sulphur. The same tendency was observed in the study of **Mona, Wafaa and Elgindy (2009)** in which also authors determined higher content of iron in chicory root, which is comparable with our findings.

In the sample of valerian was determined potassium as dominant mineral compounds following by calcium and magnesium. In this sample was found the highest value of aluminium, this amount can be evaluated as a safe because according to Food Safety Authority **(Stahl et al., 2017)** the tolerable weekly intake of aluminium is 1 mg.kg^{-1} body weight for all groups of people.

Valerian root is used mainly in folk medicine to prepare a decoction to treat psychical problems and usually is not consumed as a vegetable. Generally, the amount of heavy metals in observed samples was detected only in a trace amount, so our results reveal that the medicinal herbs do not represent in this study a potential health risk regarding the content of toxic elements.

CONCLUSION

Medicinal herbs are a very important part of the industry, especially pharmacy and medicine. Nowadays these plants start to be very popular also in gastronomy and food technology. They are a good source of specific bioactive compounds, but their quality can be endangered due the to higher level of heavy metals. In our study, the highest antioxidant activity was determined in ginger (3.62 and 204.14 mg TEAC.g^{-1}). In the sample of ramsons was detected the highest value of phenolics (13.19 mg GAE.g^{-1}; 47.55 mg QE.g^{-1}). The wide spectrum of mineral compounds was generally found in all observed samples, while the amount of heavy metals was detected only in a trace amount.

EFFECT OF GERMINATED WHEAT (*TRITICUM AESTIVUM*) ON CHEMICAL, AMINO ACID AND ORGANOLEPTIC PROPERTIES OF MEAT PATE

Bahytkul Assenova, Eleonora Okuskhanova, Maksim Rebezov, Oksana Zinina, Nadezhda Baryshnikova, Evgeniya Vaiscrobova, Elena Kasatkina, Mohammad Ali Shariati, Muhammad Usman Khan, Godswill Ntsomboh Ntsefong

ABSTRACT

Germinated cereal crops are widely used in the technology of meat products, as they contain a significant amount of vitamins, minerals and protein. This study presents the formulation and processing technology of meat pate with the addition of wheat (*Triticum aestivum*) germ. Three treatments of 10, 15 and 20% of germinated wheat (GW) were prepared. Wheat sprouts were crushed and mixed for 6 minutes in a meat mixer together with broth, oat flour, and spices to obtain a smooth mass. This was mixed with minced meat and grinded on a cutter to obtain a more uniform finished paste that was dosed into lamister or tin containers, sterilized and stored for 2 years. This was followed by the determination of its proximate composition, water-binding capacity, and sensory analysis. Results show that the meat pate with 10% of GW in comparison with the control, contains more protein, is more nutritious with a lower fat content of 6.8%, and a lower carbohydrate content of 11.3%. The results of the organoleptic evaluation showed that the highest average score was for the meat pate with a recipe that contains 10% of germinated wheat, and the lowest was for the meat pate containing 20% of germinated wheat. Meat pate containing 10% of germinated wheat has a higher water-holding capacity and the optimal pH value. This study suggests that wheat can be used in appropriate formulation to improve the organoleptic quality of meat pate.

Keywords: meat pate; wheat; germination; water-holding capacity

INTRODUCTION

The modern approach of nutrition science applies high requirements to food products quality, taking into account not only its energy value but also the presence of components necessary for human health (a complex of biologically active substances, dietary fiber, pectin, organic acids, minerals, etc.) possessing immunostimulating, radioprotective, prophylactic and healing properties **(Kakimov et al., 2017; Kolbábek et al., 2019)**. Due to the deficiency of meat, meat industry experts are developing new methods of production by replacing meat with protein-containing raw materials and protein supplements that are close in quality to meat protein **(Kenenbay et al., 2017; Momchilova et al., 2019)**. Recently, there has been a steady trend in the development and production of combined meat products, where along with meat, the plant raw materials sampled from the local region are used to regulate the protein, lipid, amino acid, fatty acid, carbohydrate, mineral and vitamin composition of the food product **(Arihara, 2006; Kassenov et al., 2019)**. The production of combined meat products based on plant materials is one of the promising areas for the creation of food products for the medical and preventive purposes of the modern food industry (**Nishanova et al., 2020**). Pate is a meat product made of thermally processed ingredients with spreading consistency. The classic pate recipe includes liver, offal, meat, animal fats (lard, poultry fat, and butter), pepper, spices, and salt **(Okuskhanova et al., 2016; Smolnikova et al., 2019)**. The goal of this study was to evaluate the nutritive value of meat pate enriched with germinated wheat as a contribution towards the improvement of the organoleptic quality of this delicacy.

Scientific hypothesis

The scientific hypothesis of this work is the creation of low-waste, resource-saving technologies of new kinds of pate products, using low-grade meat raw materials and wheat sprouts, allowing to increase biological value (chemical, amino acid composition), physico-chemical and organoleptic characteristics of meat pate in a directed way.

MATERIALS AND METHODS

Materials: The technological process of production consists of the following operations

The meat trimmings from the head of cattle were washed and cut into small pieces. Then the pieces of meat trimmings were cooked for 1 – 1.5 hours. After cooking it was weighed and crushed in a meat grinder with a diameter of the plate holes (2 – 3) mm. Onions were peeled, washed, chopped

into cubes, sautéed in butter for 10 – 15 minutes, weighed, then minced in a meat grinder (plate with holes of diameter 2 – 3 mm). Wheat sprouts were crushed and the crushed components were mixed in a meat mixer. Broth, oat flour, spices were added and mixed into a smooth mass. The mixing time was 6 minutes. The minced meat was grinded on
a cutter to obtain a more uniform structure. The finished paste was dosed into a lamister container weighing 200 grams or a tin container weighing 360 grams. Lamister is a combined material that consists of foil and polypropylene film, interconnected by an adhesive layer. The pate was sterilized using the sterilization formula (20 – 40 – 20)/120, 150 – 200 kPa at a temperature of 120 ºC for 20 minutes. The pate was stored at a temperature of 18 – 20 °C with a relative humidity of 80% for 2 years. The technological scheme is presented in Figure 1.

Determination of proximate composition

The determination of the chemical composition of meat was based on the evaluation of the following constituents: moisture, fat, ash, and protein. The methods were performed as described by **Amirkhanov et al. (2017)**. To determine water content, a 2 – 3 g aliquot of each sample of meat was weighed to the nearest 0.001 g using a Mettler Toledo electronic balance (Greifensee, Switzerland) and placed into a metallic cup (IngoLab, Moscow. Russia). It was then dried for 1 h in a drying oven (SNOL 67/350; Umega, Utena, Latvia) at 150 °C. The moisture content was calculated using Equation 1, according to the **GOST 9793-74 (2010)** and **GOST R 51479-99 (2010)** standards.

$$x_1 = (m_1 - m_2) \cdot 100/(m_1 - m) \quad (1)$$

Where: x_1 is the moisture content (%), m_1 is the weight of the sample with a cup before drying (g), m_2 is the weight of the sample with the cup after drying (g), m is the weight of the cup alone (g).

After determining the moisture, each dried sample was moved to a glass cup. Then, 15 mL of ethyl ether (100% chemically pure; Skat, Almaty, Kazakhstan) was poured into the glass cup, and the contents were mixed for 3 – 4 min. During the extraction process, the organic fraction containing the fat residues was poured out and replaced with fresh ethyl ether. After 4 – 5 repetitions, the residual ethyl ether was evaporated at room temperature. The metallic cup containing the fat-depleted sample was dried at 105 °C for 10 min. The fat content was calculated according to the **GOST 23042-86 (2010)** standard using Equation 2.

$$x_2 = (m_1 - m_2) \cdot 100/m_0 \quad (2)$$

Where: x_2 is the fat content (%), m_1 is the weight of the cup and dry sample before extraction (g), m_2 is the weight of the cup, and sample after extraction (g), m_0 is the weight of the cup alone (g).

To obtain the ash content, the sample from which the fat was extracted was placed into a weighed and preheated (to 150 °C) crucible (50 cm^3; Mankor, Kyiv, Ukraine). Then, 1 mL of magnesium acetate (98% purity; Labofarma, Almaty, Kazakhstan) was added to the crucible and burned on an electric hot plate. After that, it was placed into a muffle furnace set at 500 – 600 °C (SNOL 7.2/1100; Umega) for 30 min. The ash content was calculated using Equation 3.

$$x_3 = (m_1 - m_2) \cdot 100/m_0 \quad (3)$$

Where: x_3 is the ash content (%), m_1 is the weight of the ash (in g), m_2 is the weight of the magnesium oxide obtained after mineralization of the magnesium acetate (g), and m_0 is the weight of the sample alone (g).

Protein content was assayed according to the **GOST 25011-81 (2010)** standard and calculated using Equation 4.

$$x = 100 - (x_1 + x_2 + x_3) \quad (4)$$

Where: x is the protein content (%), x_1 is the moisture content (%), x_2 is the fat content (%), and x_3 is the ash content (%).

Water-binding Capacity

The method used to determine the water-binding capacity (WBC) of the samples was based on exudation of moisture to a filter paper by the application of pressure. The moisture absorbed by the filter paper is evaluated based on the spot area on the filter paper. Specifically, for each sample, 0.3 g of minced meat was placed on a 15 – 20 mm diameter disk plate on a Mettler Toledo electronic balance, (Mettler Toledo, Switzerland). The meat was then transferred onto an ash-free filter (Munktell Filter AB, Sweden) and placed on a glass or plexiglass plate. The sample was covered with the same filter before a 1 kg load was carefully placed on top of the meat. The weight was left for 10 min. Once removed, the top filter was pulled off and bound water was calculated, as described below (see Equation 1 and 2). The filter was scanned using an Xpress M2070 scanner (SAMSUNG, Japan) after the contour of the wet spot was traced on the filter. The area was calculated using the Compas-3D V-10 software **(Kabulov et al., 2014; Okuskhanova et al. 2017)**

$$X_1 = (A\text{-}8.4B) \cdot 100/m_0, \quad (1)$$
$$X_2 = (A\text{-}8.4B) \cdot 100/A; \quad (2)$$

Where: X_1 is bound water content (expressed as % of meat), X_2 is bound water content (expressed as % to total water), B is a wet spot area (cm^2), m_0 is sample weight (mg), A is the total content of moisture in the sample (mg).

Sensory analysis

Sensory evaluation was done by a panel of twelve (12) skilled persons (aged 23 – 58). In case of defects in flavor and aroma (inadequate pronounced flavor, weedy flavor, and slightly acid flavor), consistency and structure, color, and packaging, the score mark were reduced for each defect according to the special sensory evaluation scale. The evaluation scale ranged from 1 to 5 points, where 1 – Unliked extremely; 5 – Liked extremely.

Table 1 Chemical composition of pate with germinated wheat grain.

Index	Pate with 10% of GW	Pate with 15% of GW	Pate with 20% of GW	Control beef pate "Kubley"
Protein (%)	14.36 ±0.30^{a}	12.60 ±0.28^{c}	13.20 ±0.31^{bc}	14.00 ±0.21^{ab}

Statistical Analysis

Statistical analysis was performed using Statistica 12.0 (STATISTICA, 2014; StatSoft Inc., Tulsa, OK, USA). The differences between samples were evaluated using the ANOVA method. The differences were considered to be statistically significant at $p \leq 0.05$.

RESULTS AND DISCUSSION

Previous studies revealed that meat trimmings from heads of cattle have lower vitamin and microelement contents compared to beef **(Berdutina, 2000; Bondarenko and Elizarova, 2014; Makangali et al., 2018; Verma et al., 2008)**. At the same time, it has a sufficient level of protein content with a higher total content of essential amino acids in comparison with beef – the content of essential amino acids in beef is 37.07 g.100g^{-1} of protein, and in the head of cattle – 38.66 g.100g^{-1} of protein. The chemical composition of meat pates is shown in table 1 in comparison with the control. The obtained results (Table 1) show that meat pate with 10% of GW in comparison with the control, contains more protein and is more nutritious with a lower fat content of 6.8% and a lower carbohydrate content of 11.3%. **Gorlov et al. (2019)** also used germinated lentils (15%) and carrot (15%) in meat pate formulation. In terms of chemical composition, the pate in their study contained more protein 17.44% and lower fat (4.52%) compared with our study. However, the carbohydrates and calorie values were the same. **Lyakh et al. (2016)** proposed an optimal formulation of pate, with a ratio of components: 50% of mutton and 50% of horsemeat with the replacement of meat by dill and addition of 2 g "Policorbovit-95". The sample with replacement of 10% of meat with dill had the best organoleptic indicators. The content of protein (17.8 %) and fat (12.56 %) considerably differs from our results.

Chizhikova et al. (2017) studied the chemical composition of minced meat with the addition of 26% germinated wheat and found that the protein content was 15.8%, fat 12.5%, and ash 1.16%. At the same time, the authors noted that the addition of such amounts of germinated wheat did not worsen the organoleptic properties of minced meat. **Martemyanova and Yasakov (2014)** used wheat bran, sea cabbage, inulin, ginger CO_2 extracts in liver pate formulation. The wheat bran was added from 10 to 20% instead of pork fat. The authors observed an increase in protein content and a decrease in fat as the quantity of plant components increased. As a result, a

prophylactic product with probiotic properties was obtained which could contribute to thyroid disease prevention.

Alexeeva et al. (2017) studied the possibility of applying vegetable food additives from wheat germ cake, alfalfa, and albumin seeds to pates from the liver. Their evaluation of the pate quality revealed that the addition of 15% vegetable food additive to the pate recipe had a positive effect on the water-binding, moisture-holding, and emulsifying ability as well as organoleptic characteristics. In terms of chemical composition, the protein content varied from 14.61 to 16.95 $g.100g^{-1}$, fat from 13.52 to 14.34 $g.100g^{-1}$ depending on the type of pate. The authors emphasize that the addition of vegetable food additives to the food dispersions does not require special technological methods and additional equipment.

Lukyanchenko and Makarova (2009) used germinated grains or lentil sprouts up to 15% to the mass of raw materials in the recipe of chicken liver-based meat pate. Adding to the pate high-protein legumes, such as lentils, allows us to obtain a product of high nutritional value. Water-binding capacity (WBC) characterizes the ability of a meat product to absorb and retain water **(Goh et al., 2012; Zhang et al., 2010)** and it significantly affects the rheological characteristics, organoleptic and sensory properties **(Rogov et al., 2009; Bakieva et al., 2019)**. The research results showed that meat pate with 10% of germinated wheat has the highest water-binding capacity (73%). This is probably because this sample contains 7% oat flour, which increases its strength and ability to retain moisture. Other samples contain less oat flour.

The degree and strength of water binding in minced meat also depends on the medium conditions (pH, temperature, salt composition) **(Damez and Clerjon, 2008; Rao et al., 1989)**. A similar trend in pH and WBC was observed in the work of **Veretnova and Safronova (2015)**, where combined minced meat with the addition of germinated wheat grain in the amount of 10% was investigated. The authors noted that the pH value of model minced meat coincides with the pH value of the control sample with the addition of up to 10% paste to the mass of minced meat instead of bread. The highest pH value was observed when 10% of germinated wheat grain was added. When more germinated wheat pasta (20 %) was added, the WBC value decreases by 1.5 %.

In the present study, the results of the organoleptic evaluation (Table 3) showed that the highest average score was obtained from the meat pate with a recipe that contains 10% of germinated wheat, and the lowest from the meat pate containing 20% of germinated wheat.

The biological value of proteins is determined by the optimal range of vital amino acids **(Alekseeva and Kolchina, 2019)**. The research results show that the meat pate with a content of 10% germinated wheat has a predominant content of essential and non-essential amino acids, as this sample contains a higher content of animal protein of meat trimmings. The amino acid composition showed a higher content of essential (7.742) and non-essential (10.612) amino acids in the pate sample with the addition of 10% GW. As the proportion of GW increases, these values decrease slightly. However, this amino acid composition is significantly higher in quantity than the amino acid in the pate control sample.

CONCLUSION

This study was focused on the assessment of the nutritional and biological value of meat pate enriched with germinated wheat. It revealed that in terms of chemical composition, meat pate with a content of 10% germinated wheat showed a high protein content of 14.36%. By analysing the amino acid composition, the pate enriched with 10% germinated wheat had an increased content of essential and non-essential amino acids compared to pates prepared with the addition of 15% and 20% of germinated wheat. The meat pate enriched with 10% germinated wheat provided the best amount of essential amino acids, had a denser consistency and maintained high consumer properties. This suggests that the nutritive value of meat pate enriched with germinated wheat is higher, demonstrating that wheat can be used in appropriate formulation to improve the organoleptic quality of meat pate.

ASSESSMENT OF FLAVONOIDS AND PHENOLIC COMPOUND ACCUMULATION IN INVASIVE *SOLIDAGO CANADENSIS* L. IN SLOVAKIA

Olga Shelepova, Yulia Vinogradova, Olena Vergun, Olga Grygorieva, Ján Brindza

ABSTRACT

Solidago canadensis L. was introduced to Europe as an ornamental plant from North America in 1645 and began to spread during the XIX-XX centuries. Nowadays the species is considered the most aggressive invasive species. On the other hand, *S. canadensis* is considered to be a medicinal plant. The raw material known as Herba Solidaginis includes herbs of *S. canadensis*, *S. gigantea*, and *S. virgaurea*. These species are known for their diuretic, anti-inflammatory, antimicrobial, antioxidant, antispasmodic properties. The purpose of our study was to analyze the chemical compounds and some biological properties of *S. canadensis*, growing in Slovakia, to evaluate its therapeutic potential. The total phenolic content (TPC) of the extracts from aerial parts of *S. canadensis* was determined by the Folin-Ciocalteu method. The evaluation of total flavonoid content (TFC) was performed by using a spectrophotometric method. The flavonoids content was expressed as rutin equivalents (mg REs) per g DW vegetal product. The phytochemical profile of *S. canadensis* extracts was assessed by liquid chromatography-tandem mass spectrometry (LC-MS/MS). The radical scavenging activity of samples was measured using the 2,2-diphenyl-1-picrylhydrazyl (DPPH) method. Reducing power of extracts was determined by the phosphomolybdenum method. Total phenolic contents (TPC) and total flavonoid contents (TFC) of the extracts varied from 204.19 to 293.43 mg GAE.g^{-1} DW, and 64.99 – 175.25 g QE.g^{-1} DW, respectively; the best results were obtained for ethanol extract. Some phenolic compounds were identified by HPLC with significant amounts of rutin (211.20 µg.mL^{-1}), quercetin (122.08 µg.mL^{-1}), quercitrin (102.50 µg.mL^{-1}) and chlorogenic acid (147.00 µg.mL^{-1}). The DPPH values in the inflorescences were higher than in the leaves: the antioxidant activity of leaf extracts was in the range from 5.34 to 17.16 mg TE.g^{-1}, for inflorescences, this parameter ranged from 6.09 to 19.87 mg TE.g^{-1}. The high total phenolic compounds and flavonoids can be used as a valuable source of phytochemicals in herbal remedies. Our study of *S. canadensis*, growing in Slovakia, shows the promising potential that can be evaluated as an effective antioxidant and antimicrobial agent in herbal medicines.

Keywords: *Solidago canadensis*; flavonoid; phenolic compound; antiradical activity

INTRODUCTION

Solidago canadensis L. was introduced to Europe as ornamentals from North America in 1645 and began to spread during the XIX-XX centuries **(Lambdon et al., 2008; Vinogradova, Mayorov and Choroon, 2010)**. The specie is considered as the most aggressive invaders, which is defined by the European and Mediterranean Plant Protection Organization as invasive species having a high potential for spread and posing an important threat to the environment and biodiversity in the region **(Invasive Species Compendium, 2015)**. Abandoned and poorly managed agricultural areas contribute to the rapid spread and high density of goldenrod populations, and it was also recorded as one of the most common weeds in suburbs.

Invasive goldenrod is negatively evaluated because it reduces the abundance of native plants. On the other hand, goldenrod is considered to be medicinal plant. The raw material known as Herba Solidaginis includes herbs of *S. canadensis*, *S. gigantea,* and *S. virgaurea* **(Wichtl, 2013)**. Goldenrod has been traditionally used to treat inflammations of the urinary tract. Preparations from goldenrods have a well-defined diuretic, spasmolytic and hypotensive effect together with anti-inflammatory, bacteriostatic, and analgesic properties **(Apáti et al., 2003; Pawlaczyk et al., 2009; Deng et al., 2015)**. In addition to the above indications, preliminary studies of *Solidago* species have demonstrated that these plants contain a high-molecular-weight polysaccharide-protein complex that has strong cytotoxic activity against prostate cancer cells and an antitussive effect **(Ravichandiran and Deepa, 2012; Šutovská et al., 2013)**. There are also antitumor activities in the saponins fraction of *Solidago* species and antimicrobial, sedative, cytotoxic, and hypotensive effects in the essential oils of *Solidago* species **(Kołodziej, Kowalski and Kędzia, 2011; Vinogradova and Kuklina, 2018; Shelepova et al., 2018)**. The toxicity and contraindications for goldenrods preparations have not been reported, and the available information is based

mainly on studies conducted on the native European goldenrod (*S. virgaurea* L.).

The flavonoids and phenolic acids are one of the most numerous and widespread groups of natural constituents in the plant kingdom. They exhibit biological activities, including antiallergenic, antiviral, anti-inflammatory, and vasodilating actions. Most research in recent years has been devoted to the antioxidant activity of flavonoids and phenolic acids, which is due to their ability to reduce the free radical formation and to scavenge free radicals. As a rule flavonoids and phenolic acids have low toxicity which, combined with high antioxidant capacity, makes these compounds extremely useful as pharmacological agents **(Pietta, 2000; Andersen and Markham, 2006)**. The effect of goldenrod preparations in urinary therapy is highly related to the biological action of flavonoids; they inhibit the enzyme neutral endopeptidase, which is responsible for the interaction of the atrial natriuretic peptide with the glomerulus, and, thus, they regulate the formation of urine via the excretion of sodium ions **(Melzig, 2004)**. However, despite the importance of flavonoids, investigations of these compounds in *Solidago* species are scarce. Studies on *S. canadensis* in China **(Wang et al., 2011; Deng et al., 2015)**, Lithuania **(Radusiene et al., 2015)** and Hungary **(Apati et al., 2002; Apáti et al., 2003; Apáti et al., 2006)**, *S. vigaurea* and *S. graminifolia* (L.) Elliot in Poland **(Roslon et al., 2014; Thiem et al., 2001)** and Romania **(Toiu et al., 2019)**, *S. caucasica* Kem.-Nath. and *S. dahurica* Kitag. in Russia **(Goryachkina, Buinov and Fedoseeva, 2012)** have been conducted.

Scientific hypothesis

Worldwide, works are being carried out the estimation of the content and accumulation of phenolic compounds during the growth of Solidago. The scientific hypothesis of the present study was to identify and quantify the concentrations of the principal phenolic compounds in widespread invasive *S. canadensis* in Slovakia to determine the importance of Solidago raw material as potential sources of phenolic compounds in foods and health-promoting ingredients for humans.

MATERIAL AND METHODOLOGY

Plant material

The population nearby Nitra city, Slovakia, has been observed. The population of *Solidago canadensis* (Figure 1) is very dense and occupies a large area. Thus, there is no shortage of this plant as a biological resource. Material has been dried in the shade, at a temperature of 20 – 30 °C. Because of our earlier studies proved the minimal concentration of functional ingredients in stems **(Shelepova et al., 2019)**, only leaves and inflorescences have been taken for analysis.

Figure 1 *Solidago canadensis* L.

Preparation of extracts

Air-dried plant material was mechanically ground with a laboratory mill to obtain a homogenous powder. All the samples of *S. canadensis* of approximately 0.1 g (weighed with 0.0001 g precision) were extracted in 10 mL of methanol (ME), ethanol (EE), acetone (AE) and aqueous (WE) extracts by ultra-sonication at 25 °C for 50 min. The prepared extracts were passed through a 0.22 μm filter and stored at 4 °C until analysis.

Quantitative analyses

The total phenolic content (TPC) of the extracts from *S. canadensis* aerial parts were determined by the Folin-Ciocalteu method **(Singleton, Orthofer and Lamuela-Raventós, 1999)**. The content in total phenolics was expressed as mg gallic acid equivalents (GAE).g^{-1} dry weight (DW) vegetal product. The experiments were performed in triplicate.

The evaluation of total flavonoid content (TFC) of the extracts from *S. canadensis* aerial parts was performed by using a spectrophotometric method **(Shafii et al., 2017)**. The flavonoids content was expressed as quercetin equivalents (mg QE).g^{-1} DW vegetal product.

HPLC conditions and analysis

The phytochemical profile of *S. canadensis* extracts was assessed by liquid chromatography-tandem mass spectrometry (LC-MS/MS). The equipment was an Agilent 1100 HPLC Series system (Agilent, Santa Clara, CA, USA) equipped with an autosampler, binary gradient pump, degasser, column thermostat (set at 48 °C), and UV detector. The mass spectrometer was an Agilent Ion Trap 1100 SL (LC/MSD Ion Trap VL, Agilent, Santa Clara, CA, USA) equipped with electrospray ionization (ESI) or atmospheric pressure chemical ionization (APCI). The flow rate was 1 mL/min and the injection volume was 5 μL. The separation of compounds was performed on a reverse-phase analytical column (Zorbax SB-C18 100 × 3.0 mm i.d., 3.5 μm particle).

UV and MS modes were used for the detection of the compounds. A standard solution of polyphenols was used for collecting all spectra and integrating them into a library. The minimal concentration which produced a reproductive peak characterized by a signal-to-noise ratio greater than three was considered for calculation of the detection limits.

The retention times for the compounds were determined using reference standards and were based on the mass spectrum for each compound. Spiking samples with a solution containing each polyphenol (10 μg mL^{-1}) was used for accuracy check.

For identification of compounds, their retention times and the recorded ESI-MS spectra were compared with those of standards, which were obtained under identical working conditions. The method of the external standard was employed for the quantification of polyphenols in each extract and the calibration curves for a five-point plot were linear in the range 0.5 – 50.0 μg.mL^{-1} (R^2 >0.999).

Antioxidant activity

Radical scavenging activity of samples was measured using 2,2-diphenyl-1-picrylhydrazyl (DPPH) according to **Sánchéz-Moreno, Larrauri, and Saura-Calixto (1998)** with slight modification. The ethanol extract (1 mL) was mixed with 4 mL of DPPH solution (0.025 g of radical in 100 mL of ethanol). The absorbance of the sample extract was determined using the spectrophotometer Jenway (6405 UV/Vis, England) at 515 nm. Trolox (6-hydroxy-2,5,7,8-tetramethylchroman-2-carboxylic acid) 10 –100 mg.L^{-1} (R^2 = 0.983) was used as a standard and the results were expressed in mg.g^{-1} Trolox equivalents (TE).

Reducing power of extracts

Reducing the power of extracts was determined by the phosphomolybdenum method of **Prieto, Pineda, and Aguilar (1999)** with slight modifications. The mixture of 1 mL of sample, 2.8 mL of monopotassium phosphate (0.1 M), 6 mL of sulfuric acid (1 M), 0.4 mL of ammonium heptamolybdate (0.1 M) and 0.8 mL of distilled water was incubated at 90 °C for 120 min, then rapidly cooled and detected by monitoring absorbance at 700 nm using the spectrophotometer Jenway (6405 UV/Vis, England). Trolox 10 – 1000 mg.L^{-1} (R^2 = 0.998) was used as the standard and the results were expressed in mg.g^{-1} TE.

Chemicals

Acetonitrile was of HPLC grade and supplied by Sigma-Aldrich (Steinheim, Germany). Methanol, ethanol, and acetone were of analytical grade and were purchased from CentralChem (Slovakia).

Water was filtered through the Millipore HPLC grade water preparation cartridge (Millipore, Bedford, USA). The reference substances, chlorogenic acid (purity ≥95.33%), rutin trihydrate (purity 97.11%), and isoquercetin (purity ≥94.16%), were purchased from HWI ANALYTIK GmbH (Germany); quercitrin (purity ≥98.0%) was obtained from Sigma-Aldrich (Steinheim, Germany).

Statistical analysis

The statistically treated data are given as the arithmetical mean values and their standard errors. Data were submitted ANOVA and differences between means compared through the Tukey-Kramer test (p <0.05).

RESULTS AND DISCUSSION

Several *in vitro* and *in vivo* studies revealed that the presence of polyphenolic compounds in plant extracts could be related to important biological properties, such as antioxidant, immunomodulatory, antimicrobial, anticancer, prebiotic-like, vasodilating activities **(Brglez Mojzer et al., 2016)**.

Since flavonoids and phenolic acids are among the most important phytochemical constituents of some *Solidago* species, we evaluated their content in *S. canadensis* extracts. The results of the quantitative determination of total phenolics and flavonoids from different extracts (mg extract per g plant material) are presented in Figure 2.

Total phenolic contents (TPC) and total flavonoid contents (TFC) of the extracts were determined; the TPC

and TFC of the aerial part extracts varied from 204.19 to 293.43 mg GAE.g^{-1} DW, and 64.99 – 175.25 g QE.g^{-1} DW, respectively. The highest values were observed in the aerial parts of *S. canadensis* ethanol extract, with total phenolics (293.42 mg GAE.g^{-1} extract) and flavonoids (175.25 mg QE.g^{-1} extract). In the aerial parts, the amount of TPC under investigation can be arranged in descending order: EE > ME ≈ AE ≈ WE (p <0.05). The EE (175.25 QE.g^{-1}) extracts showed the highest TFC, for ME (141.05 QE.g^{-1}) and AE (144.48 QE.g^{-1}) were found to be similar, the lowest level was in the aqueous extracts (WE) (64.99 QE.g^{-1}).

Obtained results were in good agreement with the ones presented by **Deng et al. (2015)**, who determined the total polyphenols and flavonoid contents in ethanol extracts from leaves of *S. canadensis*. Similarly, the highest contents of bioactive compounds were found in ethanol extracts from *S. graminifolia* (TPC – 192.69 mg.g^{-1}, TFC – 151.25 mg.g^{-1}) **(Toiu et al., 2019)**, *S. microglossa* (TPC – 226.0 mg.g^{-1}, TFC – 115.2 mg.g^{-1}) **(Sabir et. al., 2012)** and *S. virgaurea*, *S. canadensis*, *S. gigantea* (TFC – 118.0; 156.0 and 156.0 mg.g^{-1}, respectively) **(Kołodziej Kowalski and Kędzia, 2011)**. Recent research carried out by **Woźniak et al. (2018)** on *Solidago* sp. showed that the methanol extracts from aerial parts from *S. canadensis* contain 82.1 mg flavonoids per g extract and 130.5 mg polyphenols per g extract, which is lower than the content determined in *S. canadensis* in our study. Studies pointed out that certain factors, such as the extraction method, the type of solvents and solubility of active compounds, the temperature, the extraction time, and the ratio of solvent-to-sample are essential parameters that greatly influence the yield and quality of obtained extracts from plant materials.

Also, it should be noted that the flavonoid content meets the quality criteria of European Pharmacopoeia mentioned at *Solidaginis herba* (minimum 2.5% flavonoids).

Taking into account that the highest amounts of total flavonoids and total phenolics were observed in *S. canadensis* extracts, the HPLC analysis for identification and quantification of polyphenolic compounds was carried out and the obtained results are presented in Table 1.

Three groups of phenolic compounds have been identified in the aerial parts of *S. canadensis* – phenol carboxylic acids, such as chlorogenic acid, caftaric acid and t-ferulic acid (and other acids according to the mass spectrum), and flavonoids, such as flavonol glycosides (rutin, hesperidin, quercitrin), flavonol aglycones (quercetin, kaempferol), and catechin (Table 1). These compounds had chromatographic and spectral characteristics similar to those previously identified in *S. canadensis* L. **(Apáti et al., 2003; Apáti et al., 2006; Woźniak et al., 2018)**.

Rutin (200.45 – 211.20 mg.g^{-1}), quercetin (121.74 – 122.41 mg.g^{-1}), quercitrin (102.50 – 125.70 mg.g^{-1}) and chlorogenic acid (134.95 – 147.00 mg.g^{-1}) were the major active compounds in *S. canadensis* aerial parts ME, EE and AE extracts. The WE extract was rich in polar compounds, especially chlorogenic acid (834.5 mg.g^{-1}) and vanillic acid (154.08 mg.g^{-1}), which was the major phenolic acid present, and represented 1186.87 mg.g^{-1} of the extract.

The majority of flavonoids in the WE extract were identified as monoglycosides (127.67 mg.g^{-1}) of kaempferol and quercetin (Table 1). Also, other compounds were detected that corresponded to rutin (44.77 mg.g^{-1}), quercitrin (35.84 mg.g^{-1}) and hesperidin (11.55 mg.g^{-1}).

Rutin (quercetin-3-rhamnosyl glucoside) and quercetin were the main flavonoids identified in *S. canadensis* aerial parts extracts. These compounds are the important contributors to the antioxidant, anti-inflammatory, vasodilator, antiatherosclerotic, antihypercholesterolemic, anti-obesity, and angioprotective potential of plant extracts **(Yang, Guo and Yuan, 2008; D'Andrea, 2015)**. Chlorogenic acid (5-O-caffeoylquinic acid) is a plant secondary metabolite widely distributed in coffee, tea, many fruits, vegetables, and herbs. Recent studies on this phenolic compound have demonstrated multiple biological properties, such as antioxidant, anti-inflammatory, antibacterial, antiviral, cardioprotective, hepatoprotective, neuroprotective, antihypertensive, anti-obesity, antidiabetic, antiapoptotic. Additionally, many *in vivo* studies and clinical trials have been done concerning the health benefits of chlorogenic acid as a nutraceutical agent for the prevention and treatment of metabolic syndrome and associated diseases **(Naveed et al., 2018)**.

Due to their multiple biological activities, the phenolic compounds from some *Solidago* species have been formerly examined. *S. gigantea* methanol extracts contain the chlorogenic acid (0.1 mg.g^{-1} DW plant material) and the quercitrin (4.5 mg.g^{-1} DW plant material) **(Woźniak et al., 2018)**, ethanol extracts of *S graminifolia* contain the chlorogenic acid (997.88 mg.100g^{-1} extract), quercitrin (431.59 mg.100g^{-1}) and hyperoside (253.19 mg.100g^{-1}) **(Toiu et. al., 2019)**. Ethanolic extract of leaves of *S. microglossa* contains the quercetrin (51.9 mg.g^{-1}), gallic acid (24.1 mg.g^{-1}), rutin (3.82 mg.g^{-1}), and quercetin (2.57 mg.g^{-1}) **(Sabir et al., 2012)**. The hydroalcoholic extract of *S. canadensis* found rutin (8.93% w/w) as the main compound, as well as caffeic acid derivatives **(Apáti et al., 2006)**.

Because the most significant differences of *S. canadensis* in different extracts were determined by rutin, quercetin, quercitrin, and chlorogenic acids establishing the metabolic profile of polyphenols that may contribute to ensuring plants material of high quality and safety for more efficient phytopharmaceuticals.

Considering that plant extracts are complex mixtures of numerous natural compounds with synergic or additive effects, the investigation on new sources of chlorogenic acid could reveal possible applications in medicine and pharmacy.

Plants are a potential source of natural antioxidants, which act as reducing agents, hydrogen donators, oxidants, and free radical scavengers. The antioxidant activity evaluation was carried out by DPPH and RP radical scavenging activity assays. These frequently used methods are rapid and valuable for the evaluation and quantification of the free radical scavenging activity of natural compounds from plant extracts. As shown in Table 2, there were wide variations in the DPPH and RP of the leaves and inflorescences *S. canadensis*, ranging from 5.34 to 19.87 mg TE.g^{-1}, and from 66.78 to 258.22 mg TE.g^{-1}, respectively.

Acetone extract	17.16 ±0.53^{a}	19.87 ±0.42^{a}	214.70 ±3.01^{a}	228.22 ±2.54^{a}
Aqueous extract	5.34 ±0.28^{c}	6.09 ±0.21^{d}	66.78 ±1.51^{d}	97.15 ±1.75^{c}

Note: Values are expressed as the mean ±SD (n = 3). Means in columns followed by different letters are different at p <0.05.

The DPPH radical is a stable lipophilic free radical and is a measure of non-enzymatic antioxidant activity of plant extracts **(Deng et al., 2015)**. The higher the DPPH values, the higher the antioxidant activity. The DPPH values in the inflorescences were higher than in the leaves under all kinds of extraction. We found that the antioxidant activity of investigated extracts of leaves *S. canadensis* was in the range from 5.34 to 17.16 mg TE.g^{-1} (Table 2). For inflorescence extracts of *S. canadensis,* this parameter ranged from 6.09 to 19.87 mg TE.g^{-1}. The AE extracts of inflorescences and leaves had the highest DPPH radical scavenging activity, followed by the ME extracts; the poorest antioxidant activity was found in the WE extracts. The scavenging effect on the DPPH radical in the leaves and inflorescence extracts decreased in the order: AE >ME >EE >WE.

The RP assay is based on the redox reaction of the reduction of Mo (VI) to Mo (V) ion in the presence of a reducer and is expressed as absorbance value at 700 nm, in which a greater absorbance corresponded to a higher reducing activity. All kind's extracts of inflorescences of *S. canadensis* exhibited more significant antioxidant activity compared with the leaves extracts (p <0.05). The AE inflorescence extracts had the highest reducing power, followed by the ME extracts; the WE extracts exhibited the smallest RP. The RP ascended in the order: EE <WE <ME ≈ AE for the inflorescences extracts and WE <EE <ME <AE for the leaf extracts.

The results of our research indicate that the antioxidant potential may be due to the presence of phenolic acids and flavonoids, which were found in significant amounts in *S. canadensis* all kinds of extracts. Each phenolic compound reacts differently and its antioxidant effect is closely related to the structure, for example, rutin and quercetin contain vicinyl dihydroxyl groups. The presence of vicinyl dihydroxyl groups was shown to affect the ability of phenols to inhibit iron and copper-catalyzed production of initiating radical species **(Yang, Guo and Yuan, 2008)**. Thus, it is likely that metal chelation and/or free radical scavenging properties contribute to the inhibition of glucose autoxidation by rutin and quercetin metabolites containing vicinyl dihydroxyl groups. While chlorogenic acid inhibits lipid oxidation in oil-in-water emulsion through a complex effect, metal-chelating in the hydrophilic phase and free radical scavenging in the hydrophobic phase **(Santana-Gálvez, Cisneros-Zevallos and Jacobo-Velázquez, 2017)**.

CONCLUSION

S. canadensis in Slovakia was a poorly studied species of the genus *Solidago*, which includes medicinal plants known for their diuretic, anti-inflammatory, antimicrobial, antioxidant, antispasmodic properties. Saponins, flavonoids, salicylic acid derivatives, tannins, etc. contained in the plant material are active substances of medicinal products. We have studied the content of phenolic compounds in various extracts and the best results were obtained for ethanol extract. Some phenolic compounds were identified by HPLC in methanol, ethanol, acetone, and aqueous extracts of the aerial parts of *S. canadensis* with significant amounts of rutin, quercetin, quercitrin, and chlorogenic acid. The high total phenolic compounds and flavonoids content can be used as a valuable source of phytochemicals in herbal remedies. Our study of *Solidago canadensis*, growing in Slovakia, shows the promising potential that can be evaluated as an effective antioxidant and antimicrobial agent in effective herbal medicines.

ADAPTATION OF TWO-DIMENSIONAL ELECTROPHORESIS FOR MUSCLE TISSUE ANALYSIS

Anastasiya Akhremko, Ekaterina Vasilevskaya, Liliya Fedulova

ABSTRACT
It is important to understand the molecular mechanisms that take place in muscle tissues and to predict meat quality characteristics. One of the most popular methods is two-dimensional electrophoresis, which allows us to visualize, share and identify different molecules, including meat proteins. However, the standard conditions of this method are not universal for all types of raw material, so the authors suggest a new variation of two-dimensional electrophoresis for muscle tissue analysis. Samples were tested by the classical version of isoelectric focusing (cathode buffer in the top and anode buffer in the bottom chamber of the electrophoresis cell) and its variation (anode buffer in the top and cathode buffer in the bottom chamber of the electrophoresis cell). Next, extruded gels were incubated in two different buffer systems: the first was equilibration buffer I (6 M urea, 20% w/v glycerol, 2% w/v SDS and 1% w/v Ditiothreitol in 375 mM Tris-HCl buffer, pH 8.8) followed by equilibration buffer II (6 M urea, 20% w/v glycerol, 2% w/v SDS and 4% w/v iodoacetamide in 375 mM Tris-HCl buffer pH 8.8 and the second, buffer A, consisting of 5 M urea, 2% w/v SDS, 5% v/v mercaptoethanol, 62.5 mM Tris-HCl buffer, pH 6.8 and 0.01% w/v bromophenol blue. Electrophoretic studies of muscle tissue revealed the best protein separation after changing the direction of the current (authors' variation), while no differences were detected after changing incubation buffers.

Keywords: two-dimensional electrophoresis; muscle protein; isoelectric focusing; meat

INTRODUCTION
Meat and meat products will always play an important role in the human diet as a source of high-grade protein. There is a wide variety of meat processing products, the range of which is regularly updated. Depending on the processing technology, meat proteins undergo extensive modifications that affect their quality, shelf life, nutritional properties, and health effects. At the same time, tenderness and juiciness are the criteria most judged by consumers **(Cao et al., 2020; Hollung et al., 2007)**.

These criteria are influenced by the following factors: genetics, environment, animal welfare, and further processing. The molecular mechanisms underlying such processes are still of interest. However, genetic information remains static throughout the life of the body, while the protein composition is dynamic and changes depending on factors affecting protein synthesis or degradation **(Peng and Gygi, 2001)**. Thus, proteomics analysis makes it possible to better understand the molecular mechanisms that occur in tissues and to predict the most important characteristics, particularly in the case of meat **(Bendixen, 2005; Bendixen et al., 2005; Zamaratskaia and Li, 2017)**.

Proteomic methods over the past decade have found increasing application in various fields of science and agriculture. To date, proteomic tools have improved significantly, and mass spectrometric methods are being developed very rapidly. Most proteomic methods are based on the separation of proteins in at least two directions, using chromatographic or electrophoretic methods, with further identification using mass spectrometry methods **(Soares et al., 2012; Suman et al., 2014)**. In this paper, attention is focused on the method of two-dimensional gel electrophoresis (2-DE), because it is still an excellent way to visualize protein components and widely used in meat science, with an emphasis on sample preparation and aspects of isoelectric focusing (IEF).

Traditionally, 2-DE is carried out by fractionation of proteins according to two different physicochemical parameters. In the first direction, proteins are separated by charge according to their isoelectric point with IEF, and then in the second direction by their molecular weight with polyacrylamide gel electrophoresis (PAAG). Some variations of conducting 2-DE are discussed below to identify the most optimal variant for analysis of the meat proteome.

Scientific hypothesis

The classical variation of two-dimensional electrophoresis does not fully reveal muscle tissue proteins. It is necessary to select optimal conditions for the analysis. Changing the IEF parameters and additional incubation in lysis buffers will increase the resolution of the 2-DE method for muscle proteins.

MATERIAL AND METHODOLOGY

Materials

Chemical reagent: Urea, Thiourea, Ditiothreitol, Sodium hydroxide (NaOH), Glycerol, Sodium dodecyl sulfate (SDS), Tris, Acrylamide, Ammonium persulfate (APS), 2-Propanol, Acetic acid (PanReac, Spain); Bis-acrylamide, Tetramethylethylenediamine (TEMED), Mercaptoethanol, Bromophenol blue, Glycine, Coomassie Brilliant Blue G-250, Triton X-100 (Helicon Russia); Ampholyte (Serva, Germany) and Phosphoric (V) acid (H_3PO_4) (Component-reaktiv, Russia).

The object of the study was the Vietnamese Pot-bellied from healthy females of 60 – 65 days old pig *L. dorsi* muscle. Samples were taken within 20 minutes after slaughter and placed in dry ice. Frozen muscle tissues (50 mg) were homogenized in 1 mL 7 M Urea, 2 M Thiourea, 1% Ditiothreitol, 0.4% Triton X-100, 2% pH 3-10 Ampholyte. Homogenates were centrifugated with an acceleration of 20 000 g for 20 minutes. Three samples, obtained from different animals, were studied by two-dimensional electrophoresis in two variations of isoelectric focusing (IEF) and two methods of gel incubation after IEF. Figure 1 shows the experimental design.

Two-dimensional gel electrophoresis (2-DE)

IEF in the first dimension was performed at 3650 $V.h^{-1}$. The anodic and cathodic electrode solutions used for IEF were 0.01 M Phosphoric (V) acid and 0.02 M Sodium hydroxide, respectively, in 2.4 mm × 160 mm tube gels.

In the first classical version of IEF, the cathode buffer (0.02 M sodium hydroxide) was in the upper chamber of the electrophoresis cell, and the anode buffer (0.01 M orthophosphoric acid) was in the lower one. In the second variation of IEF, the electric current direction was changed: the anode buffer was in the upper chamber, and the cathode buffer was in the lower one.

After the IEF, gels were incubated in two different ways: extruded tube gels were incubated for 10 min, in 2.5 mL of equilibration buffer I (6 M urea, 20% w/v glycerol, 2% w/v SDS and 1% w/v Ditiothreitol in 375 mM Tris-HCl buffer, pH 8.8), followed by equilibration buffer II (6 M urea, 20% w/v glycerol, 2% w/v SDS and 4% w/v iodoacetamide in 375 mM Tris-HCl buffer, pH 8.8); extruded tube gels were incubated for 10 – 15 min, in 2.5 mL buffer A (5 M urea, 2% w/v SDS, 5% v/v mercaptoethanol, 62.5 mM Tris-HCl buffer, pH 6.8 and 0.01% w/v Bromophenol blue).

For SDS-PAGE (12% T, 2.6% C) equilibrated tube gels were transferred to a 12.5% polyacrylamide gel (170 mm × 180 mm × 1.5 mm). Electrophoresis was carried out with a gel running buffer containing 25 mM Tris-HCl, 192 mM glycine and 0.1% w/v SDS at 30 mA per gel until the bromophenol blue front had reached the lower edge of the gel. Experimental molecular weights were detected relatively to marker proteins – 250; 150; 100; 70; 50; 40; 30; 20; 15; 10; 5 kDa (Thermo Scientific, Lithuania).

Protein visualization and image analysis

Protein spots were visualized staining by solution Coomassie (0.05% w/v Coomassie Brilliant Blue G-250, 10% v/v Acetic acid and 25% v/v 2-Propanol) for 1 hour. The destaining procedure was carried out by incubating in 10% v/v Acetic acid for 15 minutes several times until the background of the gel became transparent.

For computerized densitometry, two-dimensional electropherograms were used in a wet state. Their full digital images and/or images of individual fragments were obtained using a Bio-5000 plus scanner (Serva, Germany). Scanned images were analyzed with ImageMaster™ 2D Platinum software powered by Melanie 8.0 (GE Healthcare and Genebio, Switzerland). Spots were detected and quantified automatically with minimum thresholds: saliency – 11, min area – 5 and smooth – 3. The relative optical density (OD) and relative volume were computed to correct for differences in gel staining. These measures take into account variations due to protein loading and staining, by considering the total OD or volume over all the spots in the gel. The digitized 2DE images of the cortex were then compared by the matching method **(Grove et al., 2006)**.

Protein spots on muscle tissue two-dimensional electropherograms were interpreted following the Swiss-Prot database **(O'Donovan et al., 2002)** and the Muscle organ proteomics database **(Kovaleva et al., 2013)**.

Statistical analysis

The experimental data were analyzed using ordinary one-way ANOVA (between gels, obtained with different variation IEF) by ImageMaster™ 2D Platinum software powered by Melanie 8.0 (GE Healthcare and Genebio, Switzerland).

A p value <0.05 was considered to indicate a significant difference. All results are presented as mean ± SD from at least three independent experiments.

RESULTS AND DISCUSSION

In most scientific works, IEF is performed using a thin layer of gel deposited on a plastic substrate (IPG Dry Strip) to speed up and simplify the process. **(Naveena et al., 2017; Di Luca et al., 2016; Lee, Saraygord-Afshari and Low, 2020)**. However, the glass-tube IEF, despite process complexity, has an advantage in the resolution and protein loading volume in the gel **(Matsumoto et al., 2019)**. Based on foregoing, for this experiment, we selected glass-tube IEF.

In accordance with the experimental design, depicted in Figure 1, four 2-DE variations were performed; the obtained electropherograms are presented in Figure 2.

A different distribution of pig muscle protein was noted for molecular weights (MW) and isoelectric points (pI).

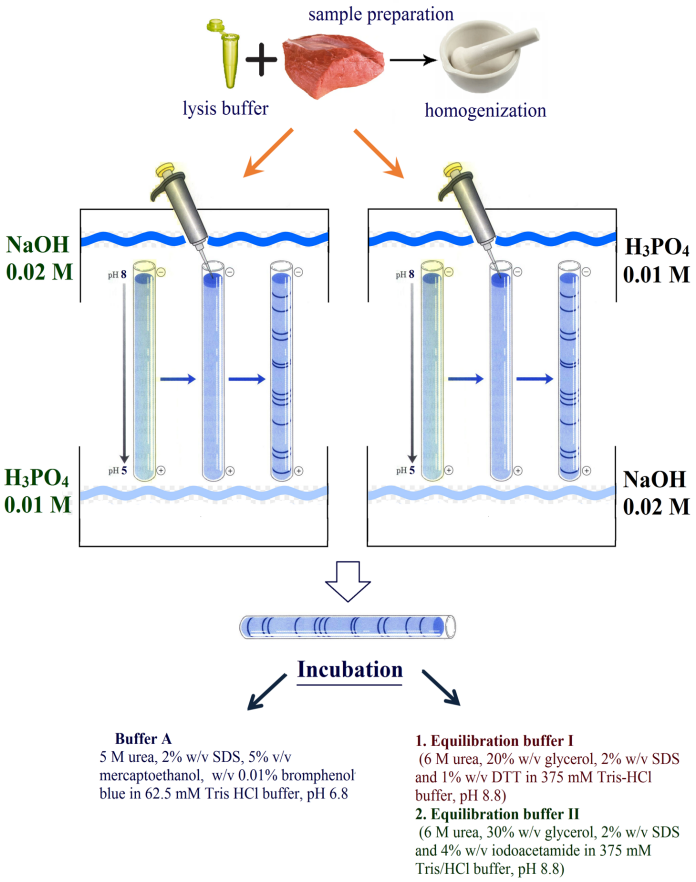

Figure 1 Experimental design of pig *L. dorsi* 2-DE.

Table 1 Results of the densitometry analysis.

	Name of gel

Note: Spot Vol** were normalized by total valid spot volume and mean of value from duplicate analytical gels from three replicates. Data represented are means ±SD of three independent experiments. *Significant differences were found between IEF variations in the distribution of values between gels within the same sample with p <0.05. **Vol: The volume of a spot is the sum of the background-subtracted gray values of all pixels delimited by the spot border. By default, the background is defined as the minimum gray value on the spot border.

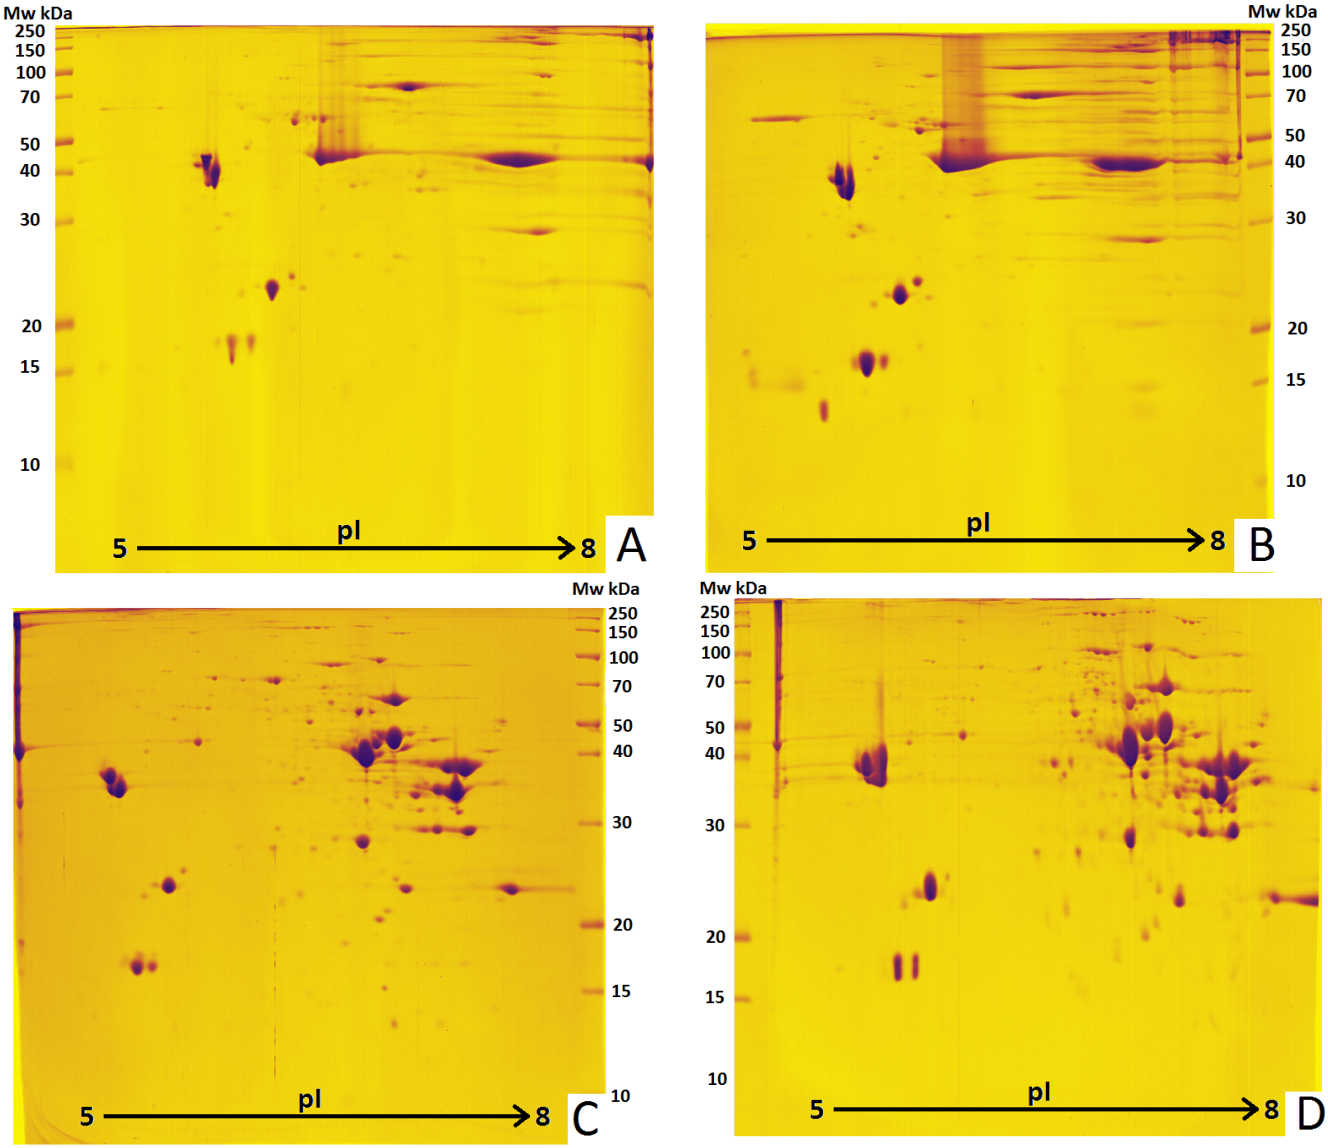

Figure 2 2-DE of pig *L. dorsi*. Note: A – 0.02 M NaOH were from above, 0.01 M H_3PO_4 from below, tube gels were incubated in equilibration buffer I. and II; B – 0.02 M NaOH were from above, 0.01 M H_3PO_4 from below, tube gels were incubated in buffer A; C – 0.01 M H_3PO_4 were from above, 0.02 M NaOH were from below, tube gels were incubated in equilibration buffer I and II; D – 0.01 M H3PO4 were from above, 0.02 M NaOH were from below, tube gels were incubated in buffer A.

In the classical version of IEF **(O'Farrell, 1975; Hirano, 1982; Kimura et al., 2003)**, when 0.02 M NaOH is in the upper chamber of the electrophoretic cell (Figure 2A), good protein separation is observed within a pI range of 5 to 6.5, such as tropomyosin beta chain (Mw 33.5 kDa, pI 4.80) **(D´Alessandro et al., 2011; Peng et al., 2013)**, tropomyosin alpha-3 chain (Mw 33.5 kDa, pI 4.71) **(Davoli et al., 2000)**, myosin light chain 3-like (Mw 22.0 kDa, pI 5.24) and myosin light chain 1/31 (Mw 21.0 kDa, pI 5.80) **(Montowska and Pospiech, 2012; Kovaleva et al., 2013)**.

Moreover, on two-dimensional electropherograms with incubation in buffer A (Figure 2B), these proteins are most clearly identified **(Ros et al., 2002; Montowska and Pospiech, 2007; Paredi, Mori and Mozzarelli, 2018)**. At the same time, in the alkaline zone of the gel, a blurred image of protein fractions is observed. A completely different gel was obtained when the current direction changed during the IEF, when 0.01 M orthophosphoric acid was in the upper chamber of the electrophoretic cell. Clear and well-defined protein spots were obtained with uniform distribution over the entire gel area **(Chernukha et al., 2017)**. Presumably, this was because proteins with acidic and neutral pI are more highly represented in muscle tissue, resulting in a higher proportion of positively charged proteins. Since the current always goes in the direction from "plus" to "minus", when changing the direction of the current flow, it is easier for positively charged proteins, which are always layered on top to move to the lower chamber of the electrophoretic cell, where a negative charge (cathode) is created **(Colangeli et al., 2018)**.

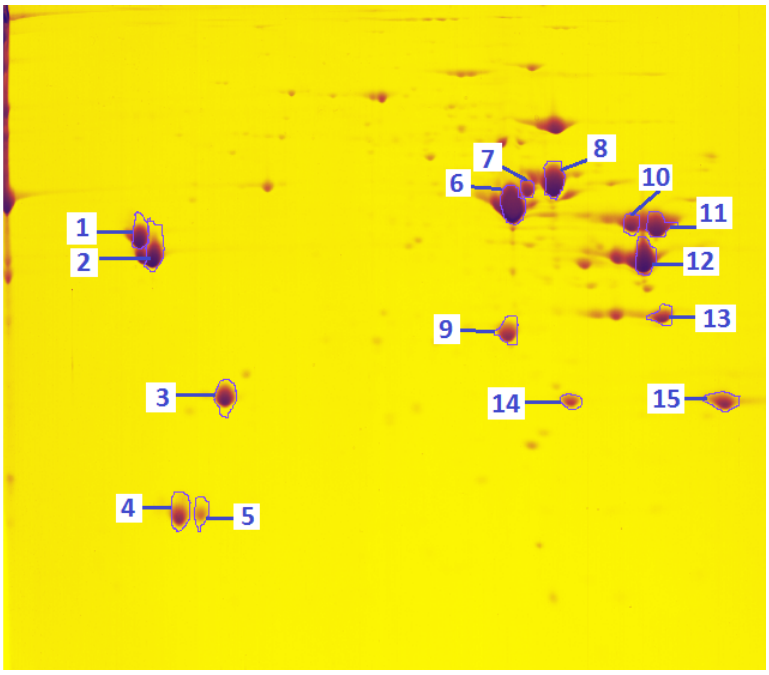

Figure 3 2-DE of pig *L. dorsi* with the designation of structural muscle proteins for densitometric assessment.

Interestingly, during incubation in equilibration buffer I and II (Figure 2C), protein spots with a molecular weight greater than 50 kDa were better visualized **(Vasilevskaya and Akhremko, 2019)**. In contrast, when incubated in buffer A (Figure 2D), protein spots with a molecular mass of less than 40 kDa were better visualized. The latter variation was used in a study by Kovalev **(Kovalyov et al., 2006; Zvereva et al., 2015)**, and analysis of the results found that this method, as in the case of incubation in equilibration buffers, allows the best detection of muscle tissue proteins.

Major structural proteins of pig muscle tissue (Figure 3) were found **(Montowska and Pospiech, 2012)** and subjected to densitometric analysis (Table 1). The Fold change index **(Persike et al., 2018**) was calculated. Fold change index is the ratio between the volume of protein spots with the highest average value and the lowest average value. Eight fractions were detected (≥2-fold change, p <0.05) with increased spot volume by at least 2 times compared with the classical version of the IEF (marked * in Table 1).

Thus, the variation of the IEF, when sodium hydroxide is in the upper chamber of the electrophoresis cell, has a lower resolution and does not properly detect protein fractions in the alkaline zone. So, in Figures 2A and 2B, proteins in the right half of the gel are noticeably out of focus. It is necessary to increase the number of volt-hours by at least 40% (up to 7 – 8 hours) for better protein separation in this area.

After changing the direction of electric current during the IEF, the process takes 4 hours. As a result, at least two times more protein spots are detected on 2-DE, including major structural muscle proteins, such as glyceraldehyde-3-phosphate dehydrogenase **(Han et al., 2019)**, troponins group **(Mora et al., 2016; Drousiotis et al., 2020)**, 3-hydroxyacyl-Coenzyme A dehydrogenase, beta-enolase and others **(Nolan et al., 2019)**.

CONCLUSION

The results of electrophoretic studies showed that the best option for the separation of meat proteins is to change the direction of the current. Thus, when the anode buffer (0.01 M orthophosphoric acid) is in the upper chamber of the electrophoretic cell, and the cathode buffer (0.02 M sodium hydroxide) is in the lower one, the most informative picture is obtained. Incubation in both buffer A and equilibration buffers can also be used.

Densitometric analysis showed that the use of new parameters allows us to identify a larger number of proteins (almost 2 times). An increase in the color intensity of certain fractions is also noted. Thus, the proposed variation of the IEF can be used as the main one for muscle proteins electrophoretic analysis, since it requires less time and has a higher resolution.

EVALUATION OF STORAGE METHODS OF BEEF BY MICROBIOLOGICAL AND CHEMICAL INDICATORS

Mykola Kukhtyn, Volodymyr Salata, Oleksandra Berhilevych, Zoya Malimon, Anatoliy Tsvihun, Bogdan Gutyj, Yulia Horiuk

ABSTRACT
Meat and meat products are a major part of a person's ration. However, due to their high nutritional value, they are a favorable environment for the development of microorganisms and require refrigerated storage. The purpose of this work was to evaluate the storage methods for refrigerated and frozen beef by microbiological and chemical parameters and to suggest criteria for evaluating beef by the content of psychrotrophic microorganisms. It was found out that the storage of beef meat with an initial mesophilic bacterial content of about 4.88 log CFU.cm^{-2} of surface and psychrotrophic bacteria 3.79 log CFU.cm^{-2} at temperature 0 °C is only possible for 8 days, further, the microbiological indices exceed the acceptable standards. Investigation of the dynamics of microflora reproduction during the storage of beef in the frozen state at temperature -2 to -3 °C for 20 days established a decrease in 1.3 times the number of mesophilic bacteria in 10 days of storage. At the same time, the number of psychrotrophic microorganisms during this storage time was increased in 4.5 times, and 20 days in 7.9 times and amounted to 5.3 log CFU.cm^{-2} of surface area. This indicates that the storage of meat in the frozen state inhibits or completely stops the development of mesophilic microorganisms for 20 days. It was found out that storing of beef in the cooled state at a temperature of 0 ±0.5 °C for more than eight days is impractical, as its biochemical indices are worsening and signs of spoilage are appearing. At the same time, storing of beef in the frozen state at a temperature of -2 to -3 °C for 20 days does not cause such significant biochemical changes as in beef stored in the cooled state at a temperature of 0 ±0.5 °C for 16 days. Therefore, we have experimentally substantiated the quantitative indicators of the content of psychrotrophic microorganisms on the surface of beef intended for storage in a cooled or frozen state. The proposed microbiological criteria will improve the safety of beef.

Keywords: psychrotrophic microflora; microbiological criteria; beef chilled; beef frozen; volatile fatty acids of meat

INTRODUCTION
Meat and meat products are a significant part of a person's ration as they are a source of complete proteins. Due to its high nutritional value, meat is a favorable environment for the development of microorganisms **(Alonso-Hernando, Alonso-Calleja and Capita, 2013; Dave and Ghaly, 2011; Gunvig, Hansen and Borggaard, 2013; Lerma et al., 2015)**. Therefore, during its storage, short-term (cooling), long-term (freezing), or long-term (freezing), different temperature regimes are used to stop microbiological and physico-chemical processes **(Bruckner et al., 2012; Jeremiah, 1997; Pennacchia, Ercolini and Villani, 2011; Pothakos et al., 2014)**. According to the definition of the British Institute of Research in the field of food technology (UK Institute of Food Science and Technology, IFST) the storage date of the food is the time during which the product remains safe, ie, meets all the proper organoleptic, chemical, physical, microbiological properties, as well as food and nutritional requirements.

The beef and half carcasses of the beef are kept cool at 0 to -1 °C at 85% relative humidity for 16 days. Freezing involves storing of beef meat at -2 to -3 °C at 90% relative air humidity for 20 days, and freezing at -12, -18, -20, -25 °C at 95% relative humidity for 8 months, 12 months, 14 months. and 18 months, respectively standard DSTU 6030:2008 **(DSTU, 2009)**.

In the **Commission Regulation (EC) No. 2073/2005** and DSTU 6030:2008 **(DSTU, 2009)** of beef and veal in carcasses, half-carcasses and quarters specify the parameters and terms of refrigerated storage of beef and veal, microbiological standards for the safety of meat in excess of which indicate the need to improve the hygiene of slaughtering and review of measures to control the technological process. However, even within the standard temperatures of refrigerated storage of meat, there is different intensity of reproduction for certain groups of microflora **(Bruckner et al., 2012; Casaburi et al., 2014; Cerveny, Meyer and Hall, 2009; Zhang et al., 2019)**.

Therefore, even if the microbiological parameters meet the standard requirements before cooling, freezing, or chilling the meat, they may well exceed these standards at the end of the storage period.

Normally, after animals slaughtering, micro-organisms should be detected only on the surface of the carcasses, this is due to exogenous contamination and meets the sanitary and technological requirements **(Bruckner et al., 2012; Kameník, 2013; Salata et al., 2017; Serraino et al., 2012)**. According to **Commission Regulation (EC) No. 2073/2005**, the number of colonies of aerobic mesophilic micro-organisms on cattle carcasses before cooling should be from log 3.5 CFU.cm^{-2} to log 5.0 CFU.cm^{-2} area, and the content of bacteria of *Enterobacteriaceae* ranges from log 1.5 CFU.cm^{-2} to log 2.5 CFU.cm^{-2}.

Scientific publications and regulatory documents pay more attention to the contamination of beef carcasses, mainly mesophilic aerobic facultative anaerobic microorganisms and bacteria of the genus *Enterobacteriaceae*, which are indicators of compliance with sanitation during the slaughter of animals **(Cantalejo, Zouaghi and Pérez-Arnedo, 2016; Commission Regulation (EC) No. 2073/2005; Leroy et al., 2009; Nyamakwere et al., 2016)**.

It is believed that microbiological changes in meat occur due to the reproduction of psychrotrophic microflora when stored beef in a cooled and frozen state. **(Ercolini et al., 2009; Nieminen et al., 2011; Pothakos, Samapundo and Devlieghere, 2012; Pothakos et al., 2014; Stellato et al., 2017)**.

However, in recent years there has been a tendency to increase consumption and use as raw material for the frosted meat food industry compared to frozen **(Kukhtyn et al., 2020; Wei et al., 2019; Zhang et al., 2019)**. In this regard, technologies are being advanced that aim to extend the term of storage of frosted meat without altering organoleptic, physico-chemical and microbiological parameters **(Hilgarth, Behr and Vogel, 2018; Adam, Flint and Brightwell, 2010; Kukhtyn et al., 2019; Moschonas et al., 2011; Robertson et al., 2013)**. However, the term of storage of any product cannot be implemented in the production technology without a comprehensive scientific justification for all parameters that influence safety.

Therefore, a properly selected storage regime should ensure the maximum term of storage of the food product without disturbing its organoleptic, physico-chemical, and microbiological characteristics. With this in mind, it is relevant to study the content of psychrotrophic microflora during refrigeration storage of beef.

The purpose of this work was to evaluate the storage methods for refrigerated and frozen beef by microbiological and chemical parameters and to suggest criteria for evaluating beef by the content of psychrotrophic microorganisms.

Scientific hypothesis

It is possible to use the psychrotrophic group of microflora to evaluate the hygiene of the technological process of cattle slaughtering and beef processing and the suitability of meat for storage in a cooled and frozen state.

MATERIAL AND METHODOLOGY

A sampling of beef and carcass washes was carried out at meat processing enterprises of Lviv and Ternopil region, preparation for the investigation was performed according to ISO 6887-1:2017 and ISO 6887-2:2017 **(ISO, 2017a; ISO, 2017b)**. One part of the beef (half-carcass) was stored in a refrigerated state at 0 ±0.5 °C for 16 days and the second in the frozen state at 2 – 3 °C for 20 days. At the beginning of the experiment (cooled beef) and in 8, 16 days of storage in the cooled state and 10 and 20 days of storage in the frozen state, samples were taken and microbiological and biochemical parameters were determined.

Microbiological investigations were carried out in the laboratory of the Stepan Gzhytskyj Lviv National University of Veterinary Medicine and Biotechnologies. To determine the number of psychrotrophic microorganisms was sown 1 cm^3 of flushing or its ten-fold dilutions in Petri dishes, poured 15 cm^3 of molten and cooled to 45 ±5 °C MPA, incubation of crops was carried out at a temperature of +7.0 ±0.5 ºC for 10 days, and to determine aerobic mesophilic microorganisms, the crops were incubated at 30 ±1 °C for 72 ±1 h. The identification of pure cultures was performed according to the morphological, tinctorial, cultural, and biochemical properties, which are described in the Bergey bacteria determinant **(Vos et al., 2011)**. Tests were also used for the biochemical identification of non-fermenting microorganisms "Neferm test-24" (Rliva-lachema, Czech Republic).

The amount of volatile fatty acids was determined by a method based on the isolation of volatile fatty acids, which are accumulated in the meat during storage and determination by the titration amount of the distillate obtained with a solution of caustic potassium (or caustic soda). Herewith meat was considered fresh in terms of volatile fatty acids 4.0 mg KOH; – doubtful freshness – from 4.1 to 9.0 mg KOH; stale more than 9.1 mg KOH. The content of lipid peroxidation products in beef meat was determined by conventional methods, so the concentration of TBK-active products in tissue homogenates was determined by the method of Korobeinikova, 1989. To precipitate proteins to 1 mL of tissue homogenate was added 4.5 mL of 20% phosphoric acid and the samples were centrifuged. The supernatant was drained and 1.0 mL of 0.8 th thiobarbituric acid (TBK) solution was added to the precipitate and was kept for 1 h in a water bath at 100 °C. The tubes were then cooled and centrifuged. In the obtained centrifuge, the absorbance was measured at 535 and 580 nm against a control sample that contained bidistilled water instead of the homogenate. Double absorption measurement eliminates the absorption of colored complexes of thiobarbituric acid by substances of non-lipid nature. The content of TBK-active products was calculated by regression equation:

$$C = 0.21 + 26.5\Delta D$$

where C is the concentration of TBK-active products; ΔD – indicator D535 – D580 in the centrifuge. Diene conjugates (DCs) in the meat were determined spectrophotometrically.

Statistical analysis

Statistical processing of the results was carried out using methods of variation statistics using the program Statistica

9.0 (StatSoft Inc., USA). Non-parametric methods of research were used (Wilcoxon-Mann-Whitney test). The arithmetic mean (x) and the standard error of the mean (SE) were determined. The difference between the comparable values was considered to be significant for $p < 0.05$.

RESULTS AND DISCUSSION

The results of research on the dynamics of the microflora of beef meat cooled during storage are shown in Figure 1.

As can be seen from Figure 1, that in compliance with all veterinary and sanitary requirements for the procurement of beef meat in meat processing plants, the microbiological indices of the meat meet the established standards of the Regulation EU No 2073/2005 (permissible content of mesophilic micro-organisms up to 5 log CFU.cm^{-2} of carcass surface). In 8 days of storage at 0 °C, the total number of mesophilic microorganisms on the surface of half-carcasses was increased into 16.6 times ($p < 0.05$), and in 16 days – into 3 350 times ($p < 0.05$) and exceeded the allowed level following the regulations by 1.3 times and 258 times, respectively. It can also be noted that the content of psychrotrophic microorganisms was increased into 350 times ($p < 0.05$) in 8 days of meat storage and 52 thousand times ($p < 0.05$) in 16 days. If you compare the content of psychrotrophic microorganisms with the number of mesophilic during the process of meat storage, you can find the following. Psychrotrophic microorganisms on the surface of the chilled meat are 12.4 times smaller than mesophilic, but due to the faster rates of reproduction at this temperature, their number in the eighth day of storage was already 1.7 times ($p < 0.05$) higher. Psychotrophic microorganisms of chilled meat during the storage process have been the main dominant microflora, and this indicates its major role in the occurrence of microbiological defects in meat.

In Figure 2 results are given due to the microbiological investigations on the dynamics of microflora during the storage of beef in the frozen state at temperatures of -2 to -3 °C for 20 days.

As can be seen from Figure 2, that the content of mesophilic microorganisms beef meets the established requirements for 20 days of storage at temperatures of -2 to -3 °C. A decrease of 1.3 times ($p < 0.05$) in the number of mesophilic bacteria were detected after 10 days of storage, and after 20 days of their content remained practically unchanged. This does not indicate that the storage of meat in the frozen state inhibits or completely stops the development of mesophilic microorganisms for 20 days. At the same time, psychrotrophs, which can withstand low ambient temperatures, under these conditions increased their number on the surface of the beef in 10 days of storage into 4.5 times ($p < 0.05$). During the next 10 days of storage, that is, for 20 days, their number was increased into 7.9 times ($p < 0.05$) and amounted to 5.3 log CFU.cm^{-2} of surface area.

To fully characterize the microbiological changes in frozen meat, we determined the generic composition of psychrotrophic microflora, which is dominant in the storage process of beef at low temperatures.

In Figure 3 the composition of the psychrotrophic microflora of chilled beef is shown.

The identification of psychrotrophic microflora revealed that most of the cooled meat were bacteria of the genus *Acinetobacter* spp. – 55.1 ±2.2% and the smallest 14.6 ±0.7% of *Pseudomonas* spp. At the same time, an increase in the number of detected bacteria in the composition of psychrotrophic microflora of chilled beef was detected after 16 days of storage. Among the already identified three genera from the beef are bacteria of the genus *Flavobacterium* spp. and *Aeromonas* spp., which were not identified in the cooled meat, their number was 1.7 ±0.2% and 1.4 ±0.1%, respectively. This indicates the development of these bacteria during the storage of the beef in a chilled state. It is also seen that bacteria of the genus *Acinetobacter* spp. represent almost half of all psychrotrophic microflora of the cooled and chilled meat after 16 days of storage – 55.1 ±2.2 and 42.4 ±1.7% respectively. Bacteria of the genus *Alcaligenes* spp. occupy a stable niche of microflora, both cold and frozen meat – from 30.3 to 26.2%. However, bacterial growth of the genus *Pseudomonas* spp. Into 1.9 times ($p < 0.05$) on the surface of chilled beef, compared to cooled was observed.

Identification of the composition of psychrotrophic microflora of frozen beef after twenty days of storage (Figure 4) revealed an increase in bacteria of the genus *Pseudomonas* spp. into 1.3 times. At the same time, bacteria of the genus *Alcaligenes* spp. were consistently high in both cold and frozen meat – 30.3 – 31.7% respectively. Half of all psychrotrophic microflora accounted for bacteria of the genus *Acinetobacter* spp. 55.1 – 48.6%.

The research of the chemical indices of refrigerated and frozen beef during storage is shown in Figure 5.

As can be seen from the data of Figure 5, that the beef, which was stored in chilled state for 8 days in the content of volatile fatty acids, was of dubious freshness, indicating the beginning of the fat hydrolysis process. After 16 days of chilled beef storing at 0 ±0.5 °C, a certain indicator indicates the deterioration of the meat. In particular, the number of volatile fatty acids was increased into 5.1 times ($p < 0.05$), indicating that the course of intensive biochemical processes of enzymatic hydrolysis of fat and beef with such indicators is characterized as not fresh.

Thus, researches indicate that storing beef in chilled state at 0 ±0.5 °C for more than eight days is impractical, as its chemical characteristics are getting worse and there are signs of spoilage.

Research of beef stored in a frozen state at the temperature -2 to -3 °C revealed that, after 10 days, the number of volatile fatty acids remained at the level characteristic of fresh meat. In 20 days of meat storage, an increase in the amount of volatile fatty acids was found to be 2.3 times ($p < 0.05$). According to these indicators, meat is characterized as doubtful freshness.

Therefore, storage of beef in the frozen state at a temperature of 2 to -3 °C for 20 days does not cause such significant biochemical changes as in beef stored in the cooled state at a temperature of 0 ±0.5 °C for 16 days.

The next part of our research was to determine the content of lipid peroxidation (POL) products in chilled and frozen beef. It is well known **(Vega et al., 2009)** that the content of POL in meat is increasing with prolonged storage, which negatively affects its quality – smell, taste, structure. The results of researches on the content of TBK-active products (TBKAP) and diene conjugates (DCs) in chilled beef during storage are shown in Figure 6.

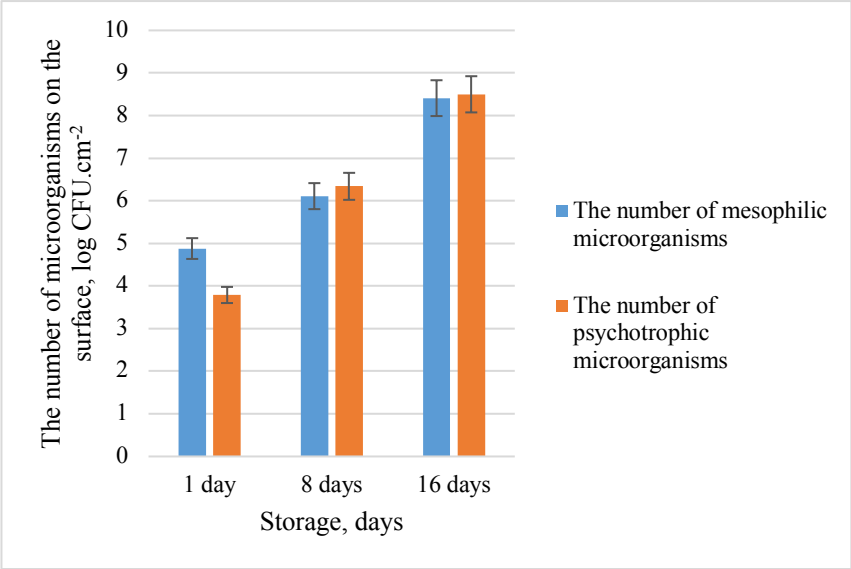

Figure 1 Changes of mesophilic and psychrotrophic microflora during storage of beef in a cooled state at a temperature of 0 ±0.5 °C.

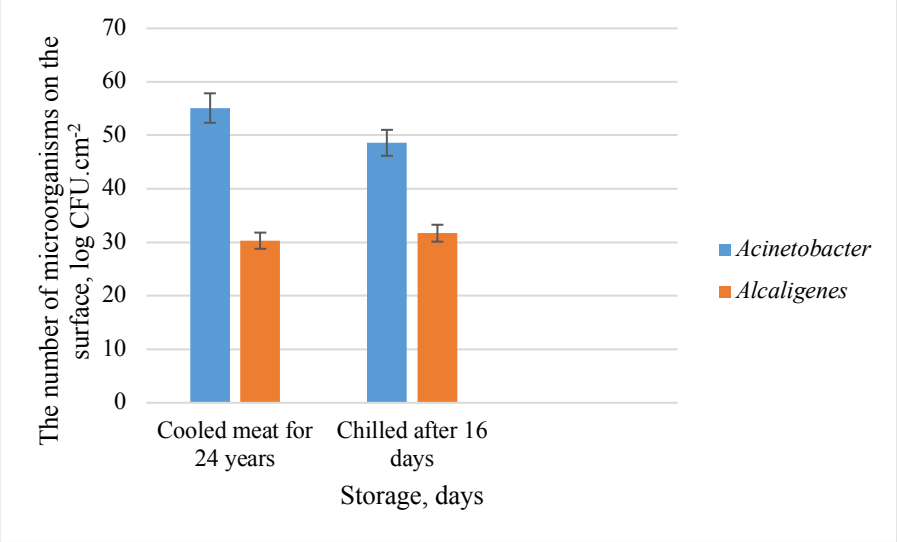

Figure 2 Changes of mesophilic and psychrotrophic microflora during storage of beef in the frozen state at temperatures -2 to -3 °C.

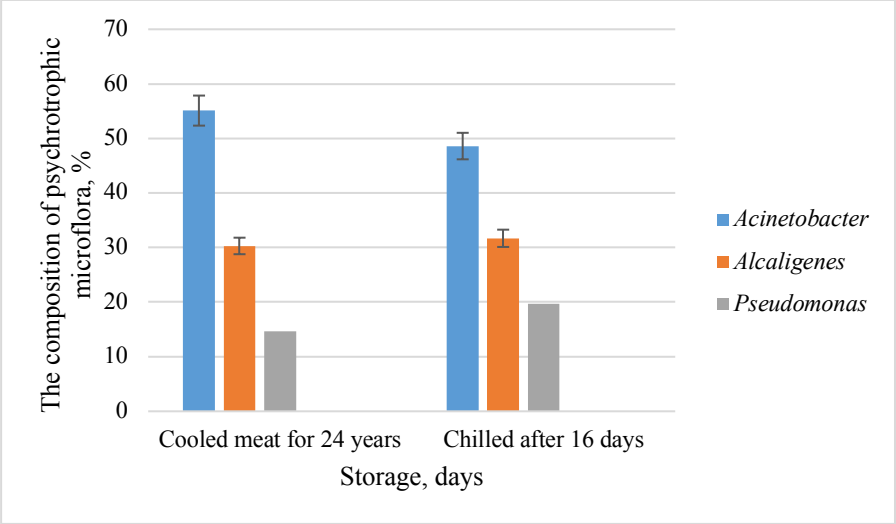

Figure 3 Generic composition of psychrotrophic microflora of beef during storage in a cooled state at a temperature of 0 ±0.5 °C.

As can be seen from Figure 6, that when the meat was kept refrigerated at 0 ±0.5 °C, no significant increase in the amount of TBKAP and DC on the eighth day was observed. On the 16th day of storage, there is a probable increase (p <0.05) in the number of TBKAP and DC compared to the first day.

When storing beef in the frozen state at a temperature of -2 to -3 °C, a probable increase into 1.3 times (p <0.05), compared to the first one, was noted only by the amount of DC for 20 days (Figure 7).

Thus, the obtained data are shown in Figure 6 and Figure 7 indicate that as the temperature of the refrigeration treatment of beef decreases, its resistance to oxidation increases, in particular the growth of TBKAP and DC.

The results indicate that the initial amount of microflora, especially the content of psychrotrophs, is crucial for the choice of beef storage temperature. Therefore, we are offered to evaluate the suitability of beef for storage in a cooled and frozen state according to the following hygiene criteria of the technological process (Table 1).

If a microbiological investigation of five beef samples before cooling from one batch reveals at least one sample of psychrotrophic microorganisms over 4 log CFU.cm^{-2} of area (≥M), then such beef is used immediately, and measures are taken to improve the hygiene of the technological process.

If three beef samples are detected, the number of psychrotrophic microorganisms from 3 log CFU.cm^{-2} area to 4 log CFU.cm^{-2}, (between m and M), then keep such batch in the cooled state at a temperature of 0 ±0.5 °C for not more than 8 days, or in the frozen state at a temperature of 2 to -3 °C for up to 20 days.

If a microbiological examination of five beef samples reveals a number of psychrotrophic microorganisms less than 3 log CFU.cm^{-2} of area (m), then such a batch is stored in chilled state at 0 ±0.5 °C for up to 16 days, or in the frosted state for 2 – 3 °C up to 20 days.

Thus, the proposed criteria for evaluating beef before storage allowed to scientifically justify the optimal cooling or freezing temperature to obtain, at the end of the storage period, meat with satisfactory organoleptic, physico-chemical and microbiological parameters.

The urgency of the issue of fresh meat and increasing the storage term is the primary purpose for meat industry professionals. Meat has a limited storage term, creating difficulties for both producers and consumers for whom a defective product is potentially dangerous **(Jeremiah, 1997; Nyamakwere et al., 2016)**. The biggest factor which causes spoilage of meat during its storage is microbiological **(Bruckner et al., 2012; Casaburi et al., 2014; Cerveny, Meyer and Hall, 2009; Pothakos, Samapundo and Devlieghere, 2012; Zhang et al., 2019)**. Therefore, first of all, it is necessary to minimize contamination by microorganisms from the moment of slaughter to processing and to inhibit the development of existing microflora through the use of refrigeration **(Bruckner et al., 2012; Dave and Ghaly, 2011; Kameník, 2013; Serraino et al., 2012)**. However, even during refrigerated storage (cooling, freezing) of beef meat, it is spoiled by the reproduction and activity of psychrotrophic microflora. **(Bruckner et al. 2012; Jeremiah, 1997; Pennacchia, Ercolini and Villani, 2011; Pothakos et al., 2014)**. Existing regulatory documents control the hygiene of the technological process of beef only by the content of mesophilic aerobic microorganisms and bacteria of the *Enterobacteriaceae* genus **(Commission Regulation (EC) No. 2073/2005)**.

Our investigations have found that the number of mesophilic microorganisms on fresh (24 h) beef carcasses was 12.4 times higher than the number of psychrotrophic microorganisms. During storage of the beef in chilled state at temperature 0 °C for 8 days, the number of aerobic mesophilic microorganisms was increased on the surfaces of the half-carcass by 16.6 times, and in 16 days – into 3 350 times and exceeded the admissible level (up to 5 log CFU.cm^{-2} of the carcass surface) into 1.3 times and 258 times respectively. At the same time, the psychrotrophic microflora during this period of storage increased 350 times in 8 days and in 52 thousand times in 16 days. That is, on the 8th day, the amount of psychrotrophic microflora already in 1.7 times outweighed the content of mesophilic microflora. In research **(Bruckner et al, 2012; Ercolini et al., 2009; Hassan et al., 2015; Pothakos, Samapundo and Devlieghere, 2012; Pothakos et al., 2014)** was also found a higher content of psychrotrophic microorganisms in chilled foods compared to the number of mesophilic aerobic bacteria. Researchers consider the use of mesophilic aerobic microorganisms as a parameter for estimating the storage term of chilled foods rather dubious **(Maas van Berkel, van den Boogaard and Heijnen, 2004; Hilgarth, Behr and Vogel, 2018; Salata et al., 2017; Zhou, Xu and Liu, 2010)**.

Overall, our results indicate that storage of beef meat with an initial mesophilic bacterial content of about 4.88 log CFU.cm^{-2} of surface and psychrotrophic bacteria 3.79 log CFU.cm^{-2} at temperature 0 °C is only possible for 8 days, further, the microbiological indices exceed the acceptable standards and half-corpuscles are unusable. Therefore, we believe that when storing chilled meat at temperature 0 °C, it is necessary to achieve a reduction in the initial inoculation of the carcasses by microorganisms by improving the sanitation conditions of meat provision at meat processing plants.

Investigation of the dynamics of microflora reproduction during the storage of beef in the frozen state at temperature -2 to -3 °C for 20 days established a decrease in 1.3 times the number of mesophilic bacteria in 10 days of storage. At the same time, the number of psychrotrophic microorganisms during this storage time was increased in 4.5 times, and 20 days in 7.9 times and amounted to 5.3 log CFU.cm^{-2} of surface area. This indicates that the storage of meat in the frozen state inhibits or completely stops the development of mesophilic microorganisms for 20 days. Therefore, we support the opinion of scientists **(Alonso-Hernando, Capita and Alonso-Calleja, 2013; Bruckner et al., 2012; Cerveny, Meyer and Hall, 2009; Jeremiah, 1997; Kameník, 2013; Pennacchia, Ercolini and Villani, 2011; Pothakos et al., 2014)**, which indicate that the temperature of refrigeration processing of meat has a significant influence on its storage term.

Thus, even though the meat complies with the standards by the content of mesophilic bacteria, the presence and development of psychrotrophic microorganisms in frozen meat is an integral part of the safety and quality control of beef.

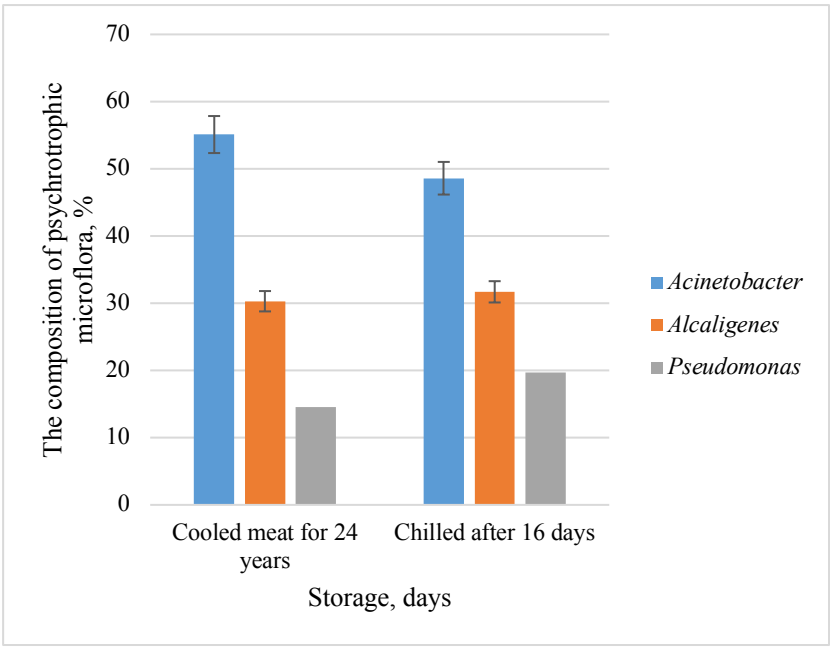

Figure 4 Generic composition of psychrotrophic microflora of beef during storage in the frozen state at temperatures -2 to -3 °C.

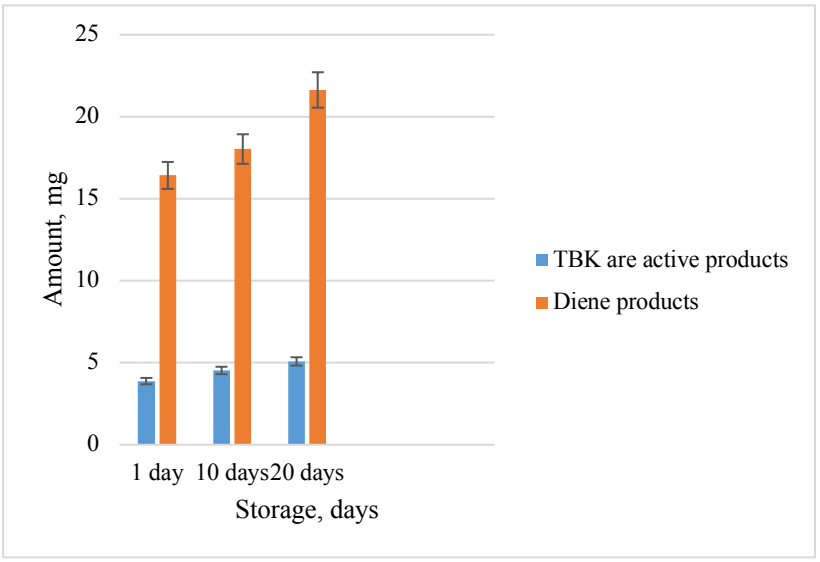

Figure 5 Changes in the content of volatile fatty acids during storage of beef in a cooled and frozen state at temperature. Note: KOH; – doubtful freshness – from 4.1 to 9.0 mg KOH; stale more than 9.1 mg KOH.

Table 1 Microbiological evaluation of chilled and frozen beef according to by the criteria of technological hygiene processes for the determination of psychrotrophic microflora.

Food category	Microorganisms	Sampling plan		Permissible limits		The stage where the metric is applied	Actions in case of poor results
		n[1]	c[2]	m[3]	M[4]		
Beef meat	Psychrotrophic	5	3	3 log CFU.cm^{-2}	4 log CFU.cm^{-2}	Before staging for refrigerated storage	improvement of slaughter hygiene and reviewing process control measures

Note: [1]n – number of samples taken from one carcass; [2]c – number of samples, parametric values, which are between *m* i *M*; [3]m – normative value of the content of microorganisms per 1 cm^2 of the carcass surface; [4]M – maximum content of microorganisms per 1 cm^2 of the surface.

An important factor that depends on the appearance of organoleptic defects in meat during its refrigerated storage is the microbial composition of the existing microflora because the production of aromatic substances and the decomposition of proteins, fats, and carbohydrates in different genera and species of microorganisms are different **(Cerveny, Meyer and Hall, 2009; Ercolini et al., 2009; Kameník, 2013; Adam, Flint and Brightwell, 2010; Pothakos et al., 2014; Stellato et al., 2017; Zhang et al., 2019)**. When identifying the psychrotrophic microflora of beef, it was found that bacteria of the genus *Acinetobacter* spp. make up almost half of all psychrotrophic microflora cooled and chilled after 16 days of storage 55.1 ±2.2 and 42.4 ±1.7% respectively. Bacteria of the genus *Alcaligenes* spp. occupy a stable niche of microflora, both cold and frozen meat – from 30.3 to 26.2%. However, bacterial growth of the genus *Pseudomonas* spp. was observed n 1.9 times on the surface of chilled beef, compared to cooling.

The identification of the composition of the psychrotrophic microflora of frozen beef after twenty days of storage revealed an increase in bacteria of the genus *Pseudomonas* spp. in 1.3 times. At the same time, the number of bacteria of the genus *Acinetobacter* spp. and *Alcaligenes* spp. in frozen meat was almost the same as in the cold. In research **(Doulgeraki et al., 2012; Ercolini et al., 2009; Stellato et al., 2017)** it is reported that the most responsible for the emergence of food defects during refrigeration storage are bacteria of the genus *Pseudomonas* spp. However, in large quantities stand out such psychrotrophic genus as *Acinetobacter* spp., *Brochothrix* spp., *Flavobacterium* spp., *Psychrobacter* spp., *Moraxella* spp., to a lesser extent *Staphylococcus* spp., and *Micrococcus* spp., lactic acid bacteria and genus Enterobacteriaceae **(Dave and Ghaly, 2011; Kameník, 2013; Pennacchia, Ercolini, and Villani, 2011)**.

Therefore, investigations indicate that bacteria of genus *Pseudomonas* spp. during the storage of beef in the cooled and frozen state show the highest intensity of development.

An assessment of the volatile fatty acid content of chilled beef found that after 8 days of storage, the meat was of dubious freshness, and after 16 days it was not fresh. In particular, the amount of volatile fatty acids was increased in 5.1 times by 16 days, indicating the course of intensive biochemical processes on enzymatic hydrolysis of fat and spoilage of meat. An investigation of frozen beef was found that after 10 days the amount of volatile fatty acids did not increase, and on the 20th day their storage their number was 2.3 times higher compared to the content in the cooled meat. With so many volatile fatty acids, the meat is considered to be of doubtful freshness.

Literary data **(Ercolini et al., 2009; Jay, Loessner and Golden, 2005; Mayr et al., 2003)** also indicate that during the storage process of meat and the development of the

microflora, there is a release of various aromatic compounds that cause organoleptic defects of meat. Therefore, we support the opinion of scientists that the amount of volatile fatty acids increases due to the microbial metabolism of psychrotrophic microflora **(Morales, Fernández-García and Nuñez, 2005; Padda et al., 2001; Popelka, Jevinová and Marcinčák, 2016)**.

CONCLUSION

Our investigations found that while storing meat in a refrigerated state, a probable increase in the amount of TBKAP and DC was detected by only 16th day compared to the first one. When storing beef in the frozen state, a probable increase in 1.3 times, compared to the first day, was noted only by the amount of DC on the 20th day. This indicates that active oxidation of polyunsaturated fatty acids in cell membrane phospholipids occurs in chilled beef meat after the eighth day of storage.

Thus, the investigations indicate that storing of beef in the cooled state at a temperature of 0 ±0.5 °C for more than eight days is impractical, as its biochemical indices are worsening and signs of spoilage are appearing. At the same time, storing of beef in the frozen state at a temperature of -2 to -3 °C for 20 days does not cause such significant biochemical changes as in beef stored in the cooled state at a temperature of 0 ±0.5 °C for 16 days. Also, to prevent the occurrence of organoleptic and biochemical beef defects during refrigeration, it is necessary to stop the development of psychrotrophic proteolytic and lipolytic microflora, which is possible by lowering the temperature.

Therefore, we have experimentally substantiated the quantitative indicators of the content of psychrotrophic microorganisms on the surface of beef intended for storage in a cooled or frozen state. The proposed microbiological criteria based on European approaches will improve the safety of beef.

Influence of maintenance technology in arid conditions on efficiency of marbled beef production

Ivan Fiodorovich Gorlov, Gilian Vasylevna Fedotova, Marina Ivanovna Slozhenkina, Elena Yurevna Anisimova, Ayzhan Andreevna Kaydulina, Vladimir Sergeevich Grishin, Olga Andreevna Knyazhechenko, Darya Aleksandrovna Mosolova

ABSTRACT
In recent years, Russia has been developing domestic single-purpose meat cattle breeding. Some livestock farms have focused on the production of high-quality grades of raw meat, i.e. 'marbled' beef. Meat of that kind is in great demand in the premium meat market. At the same time, production of beef without using steroids and hormonal drugs increases the competitiveness of this product on the world market in countries of the West and the Middle East. Within the framework of our study, an experiment was conducted on Kalmyk cattle in the arid conditions of OAO Kirovskij in the Republic of Kalmykia. Standardized methods of analysis were used. For the experiment, 10-month-old steers were selected and divided into two groups (Control and Test), 30 heads each. They were kept and fed according to different technologies until the age of 19 months. The Test group steers were kept tied up and fed with a diet developed by the Volga Region Research Institute of Manufacture and Processing of Meat-and-Milk Production; the Control group steers were kept according to conventional beef cattle production technology. The wide expansion range and popularity of this cattle breed are caused by the high productivity of steers whether kept tied up or allowed to graze free. The compared qualities of beef obtained from Kalmyk steers proved that keeping them tied up allows increased production efficiency of raw meat which is an important factor for meat production, being intensified in an unstable situation in agriculture.

Keywords: beef; feeding technology; grass-fed; 'marbled'; meat cattle breeding

INTRODUCTION
Meat is of great importance for the human diet, as it is a source of complete animal protein **(Avilés et al., 2015; Johnson et al., 2019)**. Research shows that most high-quality and balanced meat is obtained from cattle of meat breeds grown according to special fattening technology for the production of 'marbled' meat grades **(Culbertson et al., 2015; Kenny et al., 2018; Shumilina, Skvortsova and Grebenshchikov, 2012)**. The meat of various animal species can be marbled, i.e. cattle, small ruminants and pigs **(Belyaev et al., 2004; Burrow, 2001; Kayumov, 2008)**. The prospects of beef production and modern technologies for keeping and feeding cattle of different breeds in different regions of Russia and elsewhere in the world have been developed, investigated and scientifically substantiated by some scientists **(Adeyemi et al., 2019; Kelly et al., 2019; Lindholm-Perry et al., 2017; McIvor and Monypenny, 1995)**.

According to the literature, the Kalmyk breed has a genetic potential for the formation of marbled beef and is best adapted for the arid territories of southern Russia. Steers of this breed are widespread and popular in Russia due to their adaptive abilities **(Randelin et al., 2018)**. Currently, the Kalmyk breed of cattle is grown in 34 regions of Russia, i.e. in the regions of the North Caucasus, Southeast, Volga, Urals and the Far East.

The above-mentioned advantages of the Kalmyk breed caused its expansion into areas with severe agro-climatic conditions: Siberia, the Caucasus and Transbaikalia. Kalmyk cattle are kept and bred most often on pastures in natural habitat.

However, in recent years, there has been an insufficient number of pasture lands on farms, especially in regions with a severe harsh continental climate and features of desert invasion. For this reason, beef cattle are kept and raised tied up. In the absence of large pasture resources, this technology allows the production of raw meat in arid territories. At the present stage of cattle breeding, scientific investigations of the Kalmyk breed and the quality characteristics of the beef obtained do not pay attention to comparing the technologies under which livestock are kept: tied up or in free stalls. This led us to a scientific experiment aimed at comparing the productivity and quality characteristics of beef obtained by the technologies under which steers are kept and fattened either tied up or in free stalls in the arid conditions of the Republic of Kalmykia.

Scientific hypothesis

The maintenance technology and feeding animals with a specially formulated feed contributes to the rapid maturation and marbling of beef.

MATERIAL AND METHODOLOGY

Ethical approval

The authors confirm that the studies were conducted in accordance with internationally recognized ethical standards of the Helsinki Declaration on clinical researches.

Experimental design

The study was conducted on the territory of a farm in the South of Russia. We studied two groups of bull calves that were raised using different feeding and keeping technologies. An experiment was conducted to assess the process of forming marbled meat in the arid conditions of the Republic of Kalmykia. For this purpose, 60 animals of the Kalmyk breed, formed into two groups (experimental and control), were selected from the Kirovsky livestock farm. The animals of the control group were kept and fed according to the traditional technology without binding and on pastures, while the experimental group received green feed mown on specially designated areas of pasture on the farm and were kept on a leash in stalls. The rations for the experimental animals were developed using the Feed Optima Expert program by the standards and age.

Research materials were processed using graphical, trend and statistical analysis methods, as well as using the Microsoft Office software package. The paper uses generally accepted standardized methods of analysis of the studied objects.

Dynamics of live weight, and meat yield

The dynamics of live weight were studied by weighing experimental animals, calculating the absolute and average daily growth, and slaughter indicators: carcass weight, pulp, slaughter yield, etc., according to approved methods. The morphological composition of carcasses was studied by cutting them into cuts according to state standard no. 31797-2012 'Meat. Dressing of beef into cuts. Specifications'. To determine the quality indicators, average samples of the pulp and the longest back muscle were then selected. The meat index has the following formula:

$$\frac{\text{half - girth of the back}}{\text{height at the withers}} * 100\%$$

Histological analysis

Microscopy of samples of the longest back muscle of experimental bulls was performed using an electron microscope (Zeiss AxioImager.Z2), synchronized with a personal computer, having previously prepared a sample-a tool for preparing sections of a fixed 'Microtome' with the MS-1 system ('MicroM').

Statistical analysis

The experimental data on different variables were statistically analysed using the Statistica 10 package (StatSoft Inc.). The significance of differences between the indices was determined using the criteria of nonparametric statistics for the linked populations (differences with p <0.05 were considered significant: ***p <0.001; **p <0.01; *p <0.05; ns = not significant at p >0.05). Student's t-test was applied for the statistical analysis.

RESULTS AND DISCUSSION

Domestic and foreign scientists have shown the relevance of a comprehensive study of raw meat production technology in natural pasture conditions **(Asp et al., 2012; Fedotova et al., 2019; Shumilina, Skvortsova and Grebenshchikov, 2012; Troy, Tiwari and Joo, 2016)**.

The results of the experiment showed that steers gained live weight differently during the observation period from the 10th to 19th months of age, depending on the keeping and feeding technology.

It was determined that marbled beef is obtained from animals that are kept in stalls for a long time. It is obvious that by adjusting the percentage of intermuscular fat by changing the nutritional content of diets, you can win more consumers by producing various products with the necessary characteristics; this is confirmed by modern research **(Basarab et al., 2003; Luo et al., 2019)**. Marbling also depends on the time of feeding and the type of feed. The longer the cattle are fed high-calorie food, the more likely it is that they will have higher quality indicators, but significantly less marbled meat (as a percentage of the carcass, that is, the ratio of lean meat to marbled meat). The period after setting the animals to fattening lasts approximately 3 – 4 months and if the diet is not balanced it can lead to gastrointestinal pathology, so it is not recommended that the period of rearing livestock is extended **(Gorlov, Mokhov and Vorontsova, 2018; Samikshya et al., 2019)**. Feeding with a large amount of cereals, such as corn or barley, will change the colour of the fat from yellowish to white. Low physical activity is also a factor that affects marbling. In cows and steers that have grown up in tight stalls, the meat becomes softer than in free-grazing animals. Thus, animals that are restricted in movement easily accumulate intramuscular fat, and their meat becomes soft **(Adeyemi et al., 2019; Troy, Tiwari and Joo, 2016)**. The worldwide accepted technology for growing and fattening cattle to produce marbled meat is feedlots – platforms for final fattening with high-calorie diets for at least 120 days before slaughter, before animals graze free **(El-Khadrawy, Ahmed and Hanafi, 2011; Gorlov, Mokhov and Vorontsova, 2018)**.

The live weight (kg) and growth dynamics in the experimental groups of steers are presented in Table 1.

Assessment of the weight gain rate of steers showed that live weight gain in the Test group was faster, which affected the weight dynamics in different months. According to the study results in Table 1, higher live weight dynamics were shown by the Test group steers kept tied up and fed with the special recipe fodder developed by the Volga Research Institute **(Gorlov, 2018)**.

Comparing the dynamics of average daily live weight gain (kg) in the groups enabled observation of the maximum growth energy in Test steers at the age of 16 to 18 months. Therefore, we recommend raising steers to 18 months old (Figure 1, Figure 2).

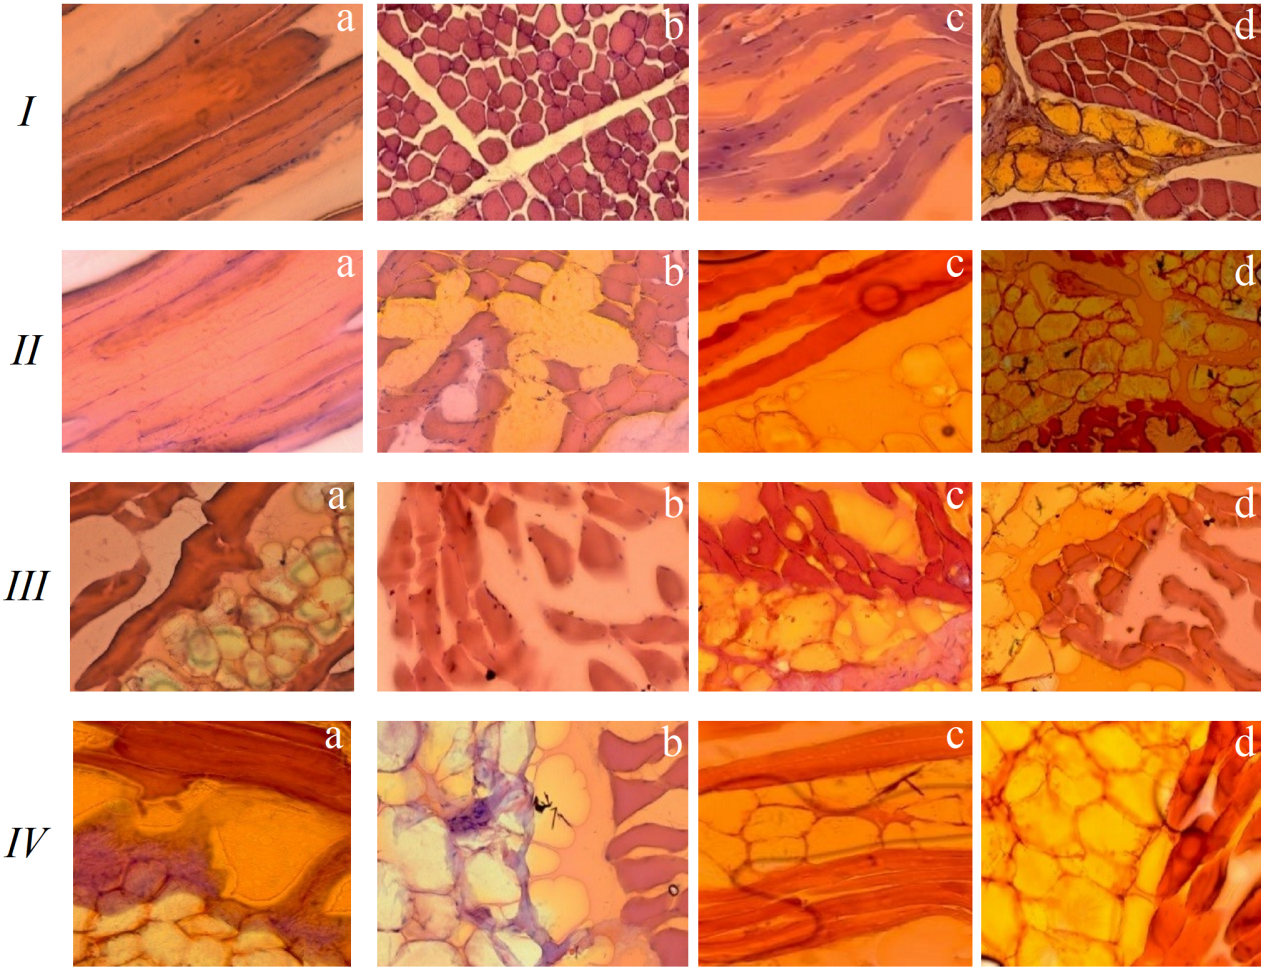

Figure 4 Microstructure of the *Longissimus* muscle of experimental steers at different ages: (I – 16, II – 17, III –18 and IV – 19 months; a, b – longitudinal section; c, d – cross section.

In the next stage of the experiment, steers at the age of 16, 17, 18 and 19 months were slaughtered in a slaughterhouse, to study the marble formation. The main indicators of the controlled slaughter of steers are presented in Table 2.

The control slaughters of experimental steers at different ages showed that the live weight dynamics in the Test group were higher than in the Control group by 8.3 – 10.5 kg, pre-slaughter weight by 8.5 – 11.3 kg, slaughter weight by 9.5 – 13.9 kg, chilled carcasses by 9.5 – 13.9 kg and flesh weight by 9.4 – 15.3 kg. The Kalmyk breed under consideration was characterized by high meatiness and hardiness with the meat index increasing for this keeping technology (Figure 3).

The morphological composition of the carcasses examined showed that in all steers, the most massive parts of the carcass are the hip cut, sternocostal and shoulder blade. In the Test group, these parts exceeded the weight of similar cuts of steers in the Control group (Table 3). Samples were taken from the rib-saddle part of Test steers to examine the microstructure of muscle tissue and assess the degree of marbling in the raw meat obtained. The results of the histological analysis are presented in Figure 4.

The muscle tissue samples were taken from animals at 16, 17, 18 and 19 months old in the Test group to establish the marbled structure of meat and its dynamic formation.

The unique ability of Kalmyk steers to accumulate reserve nutrients in the form of marbled layers gives high culinary qualities to their beef **(Prokhorov, Naumovich and Mulangi, 2016)**. Moreover, the value of this meat grade is due to its high content of vitamins and minerals, and a unique ratio between monounsaturated and saturated fats **(Makayev, 2005; Šulcerová et al., 2017; Yaremchuk and Rodin, 2011)**.

In assessing the microstructure of the muscle tissue, we found considerable fatty tissues in fibres, which characterized the degree of beef marbling. While some studies have shown that beef marbling is determined by the colour of muscle and fat tissue and marbling on the longest back muscle (*Longissimus dorsi*) of cattle **(Frank et al., 2016; Morozova, 2016; Yaremchuk and Rodin, 2011)**. Fat inclusions were found in the samples of all age groups, but the maximum marbling had been reached by 19 months; these results support some of the results of other studies **(Wang et al., 2019; Kayumov, 2008; Randelin et al., 2018)**.

Thus, it was proved that marbling is formed in the meat raw materials produced, depending on the feeding and keeping technology.

The tie-up keeping technology and feeding with a specially formulated feed mixture contributed to the early

maturation and marbling of beef. In addition, the proven experimental technology developed by the Volga Research Institute contributed to the rapid weight gain of steers and production of premium beef grades.

CONCLUSION

Single-purpose beef cattle breeding in the arid conditions of the South of Russia is the most promising direction for the development of agricultural production in these territories. The severe climatic conditions and waterless periods allow the breeding and keeping cattle of breeds best acclimatized to this area. The Kalmyk cattle breed grown in this area is the most promising in terms of the production of premium beef grades due to its genetic predisposition to marbling of the raw meat obtained. The wide expansion range and popularity of this cattle breed are caused by the high productivity of steers whether kept tied up or allowed to graze free. The compared qualities of beef obtained from Kalmyk steers proved that the tie-up keeping technology allowed increased production efficiency of raw meat.

EFFECTS OF SELENIUM ON MACRO- AND MICRONUTRIENTS AND SELECTED QUALITATIVE PARAMETERS OF OAT (*AVENA SATIVA* L.)

Ladislav Ducsay, Alexandra Zapletalová, Peter Hozlár, Ivan Černý, Ladislav Varga, Marek Slepčan

ABSTRACT

The article deals with the effect of foliar Se application on macro-and micro-elements and selected quantitative parameters (the content of ash, starch, and fat) in oat grains. The three-year experiments were carried out on Research and Breeding Station Vígľaš – Pstruša in the years 2014, 2015, 2016. The used oat variety was Valentin. The experiment was performed by a block method within a parcel size of 10 square meters (8 x 1.25 m) with the span of rows amounting to 0.125 m in four replications. Alfalfa was grown as forecrop. A potato and wheat production area (III-C2) with a height of 375 m above the sea level. The experimental area is characterized by warm, slightly wet weather with an average annual temperature of 7.8 °C and average annual precipitations of 666 mm. Basic fertilizing was planned before the sowing in the form of 100 kg of Ammonium nitrate containing dolomite (27% N), 100 kg of 60% KCl (60% of K_2O), and100 kg of MAP (Monoammonium phosphate 12% N and 52% P_2O_5). Selenium was foliar applied in doses 25 g and 50 g Se per hectare in a solution form of sodium selenate (Na_2SeO_4). The harvest was realized by a small plot harvester in BBCH 91. The results of the experiments showed a statistically non-significant effect on microelements and most macroelements. Only sulfur content in oat grains was statistically significantly influenced by Se foliar treatment. The contents of ash, starch, and fat in oat grains were monitored, which showed statistically significant effect only in fat. Se content in grains showed a statistically significant increase by both Se foliar treatments.

Keywords: selenium; macroelements; microelements; oat grain; quality

INTRODUCTION

Selenium is one of the essential mineral elements for human nutrition **(White and Brown, 2010)**. The Se deficiency is associated with various diseases such as hypothyroidism, cardiovascular disease, a weakened immune system, male infertility, cognitive decline, and increased incidence of various cancers **(Fairweather-Tait et al., 2011)**. Selenium is included in nearly 30 selenoproteins or selenoenzymes **(Rayman, 2012)**. The level of selenium in the body depends on its concentration in the food. The selenium gets primarily to the food chain from the soils and drinking water. Its content in plants is a function of the conditions of the soil-plant system. The daily intake of Se varies geographically. Worldwide, it is estimated that over one billion people ingest Se below the recommended dose of 55 $\mu g.day^{-1}$ **(Bañuelos, Lin and Broadley, 2017)**.

Selenium is chemically similar to sulfur (S) and the absorbed selenium replaces sulfur in some proteins of plants. The enzymes are unable to distinguish between Se and S until a critical value is reached after which Se becomes toxic to a plant **(Ferri, Favero and Frasconi, 2007)**.

Macro- and microelements are significant for the growth and reproduction of plants, and their role in the human diet has been intensively investigated. Quantification and control of the mineral composition of food plants are therefore important factors for the sustainability of culture conditions which aims to increase the content of selected substances in plants **(Combs, 2011)**.

Slovak soils are generally poor in selenium, which is related to its insufficient quantity in agricultural products. Content of selenium in the crops is constantly in the spotlight of the professional public. The biological value of grown food raw materials depends on a qualitative state of growing mediums – soils. Biogenic elements presented in the soils are taken by plants and thereby entering the food chain. Plants can receive the inorganic selenium added to the soil (in the form of selenate and selenite) and convert its part or all of it into the organic components. Agronomic biofortification through the application of fertilizers enriched with selenium is one of the possible ways of its content increasing in the soil. On the other hand, there is

a potential danger of soil contamination. Due to the selenium content increasing in edible parts of a plant its combination with other biofortification approaches is promoted, such as foliar biofortification, i.e. selenium application directly to the plant **(Graham et al., 2007)**. Foliar biofortification can provide a large-scale intake of minerals with antioxidant properties for human as well as an increase of certain biologically active substances as a result of their synergies **(Hegedűsová et al., 2015)**.

Scientific hypothesis

We expect a significant effect of foliar Se application on macro-and micro-elements and selected quantitative parameters (the content of ash, starch, and fat) in oat grains.

MATERIAL AND METHODOLOGY

Small field nutritional experiments were carried out at the Research and Breeding Station Vígľaš – Pstruša in the last decade of March in the years 2014, 2015, 2016. The used variety of oat (*Avena sativa* L.) was Valentin. The experiment was realized with the soil type Luvisol Pseudogley. The experiment was performed by a block method within a parcel size of 10 m^2 (8 x 1.25 m) in four replications. The seeding rate represented 5 million of germinating grains per hectare with the span of rows amounting to 0.125 m. Alfalfa was grown as forecrop.

A potato and wheat production area (III-C2) with a height of 375 m above the sea level. An experimental area is characterized by warm, slightly wet weather with an average annual temperature of 7.8 °C and average annual precipitations of 666 mm.

The influence of Se salts foliar applied was monitored for qualitative changes in oat grains during the small field experiment. The agrochemical analysis of soil is stated in Table 1. Basic fertilizing was planned before the sowing in the form of 100 kg of Ammonium nitrate containing dolomite (27% N), 100 kg of 60% KCl (60% of K_2O), and 100 kg of MAP (Monoammonium phosphate 12% N and 52% P_2O_5). 39 kg of Nitrogen, 49.8 kg of Potassium, and 22.9 kg of Phosphorus per hectare were applied by the used fertilizers. Selenium was foliar applied in doses of 25 g and 50 g Se per hectare in the solluted form of sodium selenate (Na_2SeO_4). The supplementary fertilization was realized by hand (dew machine STIHL). The spraying dose of solutions was 400 $L.ha^{-1}$. The application was planned during a growth phase of oat heading in BBCH 53 on 06 June 2014, 12 June 2015, and 07 June 2016. The experimental variants were the following:

Variants:

K – a control without foliar biofortification,
Se25 – an application of 25 g $Se.ha^{-1}$ in the form of an aqueous solution of sodium selenate in the stage of heading,
Se50 – an application of 50 g $Se.ha^{-1}$ in the form of an aqueous solution of sodium selenate in the stage of heading.

The harvest was realized by a small plot harvester in BBCH 91 (a growth staging scale of cereals – an over-ripe phase). Effect of fertilizing variants on Se content and selected Macro- and Micro – elements and content of ash, starch, and fat in oat grains were evaluated and analyzed after the harvest. Soil and grain analyses were determined by common methods.

The samples were mineralized by a microwave decomposition method during the increased pressure with used reagents (hydrogen peroxide and concentrated nitric acid) in the following conditions:
Max. power: 800
Power: 100%
Ramp time: 20 minutes
Temperature: 170 °C
Hold 15 minutes.

The achieved mineralizate was poured into a volumetric bank and deionized water was added to the capacity of 25 mL.

Se content in wheat grains was determined by ICP-MS method (inductivelycoupled plasma mass spectrometry).

Principles of measurement:

- introduction of the measured solution into the high-frequency plasma, where the energy transfer processes from the plasma cause evaporation of the solvent, atomization, and ionization of the elements,
- extraction of ions from plasma via an interface with built-in ion optics and from the separation of ions in a mass spectrometer based on their mass to charge ratio,
- ion transfer through a mass filter (quadrupole) and from electron multiplier detection.

Equipment model: ICP-MS Agilent 7900, the country of origin is Japan.

Statistical analysis

The achieved experimental results were statistically evaluated by standard methods using the Statgraphics plus 5.1 statistical software (Rockville, USA). A multifactor ANOVA model was used for the individual treatment comparison at $p = 0.05$, with separation of the means by the *LSD* multiple-range test.

RESULTS AND DISCUSSION

Gluten-free plants and their products are the subject of interest for nutritionists, food technologists, and people with longlife gluten-free diet suffering from coeliac disease. Oat belongs to 27 grains gluten-free crops in the European Union, especially to the gluten-free cereals such as corn, buckwheat, amaranth, rice, teff, and quinoa. Popular gluten-free cererals (corn, rice, buckwheat) contain 2.8 $\mu g.100g^{-1}$ of selenium on average and in less popular crops (amaranth, teff, and quinoa) the content of selenium content is 10.8 $\mu g.100g^{-1}$ on average **(Rybicka et al., 2015)**.

The concentrations of macroelements were determined in the oat grains. In the present study, the variation in the minerals (Ca, K, Mg, and P) that are essential for good preventive nutrition of humans **(Harmankaya, Özcan and Gezgin, 2012; Rayman, 2012)** are evaluated and discussed. Metabolic pathways of sulfur and nitrogen are influenced by assimilation of selenium in plants. A recent study was focused on influence of selenium treatment on nitrogen and sulfur secondary metabolites with expected health benefits **(Malagoli et al., 2015)**.

In Table 2 the results of macroelements N, P, K, Ca, Mg are stated, showing statistically nonsignificant influence,

but the Se25 foliar application confirmed a statistically significant effect increasing of sulfur content 1.00 g.kg^{-1}. The same tendencies are confirmed by a two-year experiment with maize grains, where a statistically nonsignificant effect on macronutrients N, P, K, Ca and Mg contents were signed **(Wang, et al., 2013)**. By contrast, a two-year experiment showed the results, in which Se foliar application at 50 g Se ha^{-1} confirmed statistically significant decrease of S, K, Ca in garlic **(Põldma et. al, 2011)**. Interesting results were achieved in the maize experiments, where contents of macronutrients in aerial parts of maize depended on a selenium concentration in the nutrient solution. Selenium at concentrations of 50 and 100 μmol.dm^{-3} caused a significant increase in phosphorus and calcium. Potassium significantly increased at the presence of 25 μmol Se·dm^{-3}, while decreasing under the influence of 100 μmol Se·dm^{-3}. The presence of selenium in the medium did not have a significant influence on magnesium. An excessive concentration of selenium affected the plant growth. A lower selenium concetration 5 μmol.dm^{-3} stimulated the process of root elongation positively, but higher doses of selenium concentration 50 and 100 μmol.dm^{-3} decreased not only a root tolerance index but also dry mass accumulation. Thus, from the above mentioned, it might mean that selenium in solution at high doses causes the disturbance of plant mineral balance.

$LSD_{0,05}$	0.13	0.08	0.12	0.12

Note: 0 – 0.0 g Se.ha^{-1}; 25 – 25 g Se.ha^{-1}; 50 – 50 g Se.ha^{-1}; the values in the columns with different letters are significantly different from each other at p <0.05.

The result is the increase of high amount of calcium and phosphorus in root shoot tissue **(Hawrylak-Nowak, 2008)**.

Selenium foliar application showed a statistically non-significant effect on the content of microelements Cu, Fe, Mn, and Zn in oat grains (Table 3). Three-year average values of microelement contents after Se foliar application were Cu 4.99, 5.38 $mg.kg^{-1}$, Fe 98.0, 129.0 $mg.kg^{-1}$, Mn 40.7, 41.7 $mg.kg^{-1}$ and Zn 58.0, 54.3 $mg.kg^{-1}$. In experiments with maize grains according to **Wang et al. (2013)** Se soil and foliar applications did not confirm statistically significant influence on monitored microelements (Fe, Mn, Cu, Zn).

Se is a microelement influencing a proper function of organism, but with a negative effect in dosage. It means that selenium disposes with a very interesting property, where the main sign is a very thin line between dietary deficiency and toxicity **(Kieliszek and Błażejak, 2013)**. Recent experiments have been focused on tracking the selenium content in selected crops intented for human consumption. A consumption of selenium affected products becomes the main source of selenium in human nutrition **(Chen et al., 2002; Hawkesford and Zhao 2007; Lyons, Stangoulis and Graham, 2004; Ramos et al., 2010; Schiavon et al., 2013)**.

Qualitative parameters in oat grains (ash, starch, and fat) after foliar applications were studied. The achieved values of these parameters are ash 4.10, 4.13%, starch 39.1, 39.9%, and fat 3.58, 4.01%. A statistically significant influence on selected qualitative parameters was achieved only between foliar Se applications. The statistically non-significant effect was shown between the control variant (without Se treatment) and variants with Se foliar treatment (Table 4). Similar results were described in the experiment according to **Havrlentová et al. (2013)**, where the qualitative parameter was β-D-glucan. A statistically significant difference was found between 2 variants of 5 by hulled oat. The application of fertilizers with selenium at naked oat grains was statistically non-significant. Other experiments with tomatoes showed interesting results in qualitative parameters, where foliar application of selenium had a positive effect on the increase of total polyphenol. The influence of Se biofortification on the content of vitamin C and carotenoids was not detected. Selenium foliar fertilization in dosage 150 $g.ha^{-1}$ is suitable way of tomato fruits enriching in polyphenols, without the negative effect on other antioxidants content **(Andrejiová et al., 2019)**.

Foliar application of Se is usually more efficient than soil application whenever the element is prone to be sorbed into soil particles **(Arthur, 2003)**, which is the case of Oxifact, Oxisols have positively charged surfaces that retain many anions **(Lopes and Guimarães Guilherme, 2016)**, including selenite and selenate, thus decreasing the availability of soil apsoil-appliedis interaction is especially strong for selenite, when compared with selenate. Irrespective of the form, in both cases (i.e., Se selenite or Se-selenate), since soil particles might absorb Se, the foliar application requires smaller doses and are more efficient **(Fernandes Boldrin et al., 2013; de Oliveira et al., 2018; Zhu et al., 2009)**. Se, best acceptable in the form of Na_2Se0_4 **(Eurola et al., 1990)**, is primarily transported into the chloroplast. SeO_4^{-2} then activates ATP-sulphurylase and forms of APSe by being reduced to selenite. This results in the production of amino acids, such as selenocysteine and selenomethionine. Selenium increases the content of amino acids, particularly isoleucine **(Duma and Karklina, 2008)**. Selenomethionine can be methylated to dimethylselenid through evaporation in the plant. It is particularly difficult and not easy to determine the levels of Se in the plant **(Brown and Shrift, 1982)**, as well as determine whether Se is essential for plant microelements. However, there is evidence that a higher content of Se (depending on the concentration of sulphur) has a positive impact, not only on levels of amino acids but also on plant growth and multiplication **(Ferri, Favero and Frasconi, 2007; Mora et al., 2015; Pennanen, Xue and Hartikainen, 2002; White and Broadley, 2009; White et al., 2007)**.

As expected, the Se content showed a statistically significant increase in oat grain after Se foliar treatment, as it is confirmed in Table 5. The average of years 2014 – 2016 in Se treatments were 0.28 ±0.12 $mg.kg^{-1}$ and 0.45 ±0.16 $mg.kg^{-1}$. Our achieved results of contents are comparable to multiple experiments **(Aspila, 2005; Galinha et al., 2012; Ventura, 2008)** with a positive effect on Se content in crops and vegetables after different application doses of selenium **(Galinha et al., 2012; Ventura, 2008)**.

Selenium is an essential mineral element for the well-being of animals and a beneficial element for plants. However, excess Se can be toxic to both animals and plants. There is considerable interest in understanding how plants acquire and accumulate Se, not only to facilitate appropriate dietary Se intakes for animal and humans, which often requires Se biofortification of edible crops but also to remediate the land contaminated anthropogenically by an excess of Se and to appreciate the ecology of native plants inhabiting seleniferous soils.

CONCLUSION

This study monitored the effect of Se foliar application on macro- and microelements and selected qualitative parameters in oat grains. In most cases a statistically nonsignificant effect of Se treatment on macroelements and microelements content in oat grains was found. The only sulfur amount increased 1.00 ±0.02 by foliar Se application in sodium selenate form in a dose of 25 g $Se.ha^{-1}$.

Qualitative parameters (ash, strarch, and fat) showed a statistically significant effect in fat content on both variants with Se treatment. Se contents in oat grains proved a statistically significant increase in both foliar Se applications, where the highest amount of Se 0.45 ±0.16was achieved on variants treated in dose of 50 g Se ha^{-1}.

ASSESSMENT OF A NEW ARTIFICIAL BUCKWHEAT SPECIES *FAGOPYRUM HYBRIDUM* AS A SOURCE OF PLANT RAW MATERIALS COMPARED TO *F. TATARICUM* AND *F. ESCULENTUM*

Elena Klimova, Ivan Fesenko, Elena Kuznetsova, Ján Brindza, Gyunesh Nasrullaeva, Olga Rezunova, Elena Kuznetsova

ABSTRACT

A promising way to increase the use of buckwheat is the wider introduction of technologies for its processing, including grinding of non-hulled grain. It requires the search for new plant materials with more suitable characteristics. In this work, the possibilities to use the grain of a new artificial buckwheat species *Fagopyrum hybridum* for flour production are studied in comparison with two cultivated species *F. tataricum* and *F. esculentum*. Some chemical characteristics of *F. hybridum* flour were evaluated. According to the size of the kernel fragments in different modes of milling within each species the significant differences were identified within *F. esculentum* and *F. hybridum* (p <0.001 and p <0.05, respectively); there were no significant differences within *F. tataricum* (p >0.1). Fragments of the seed hulls of *F. tataricum* and *F. hybridum* compared to ones of *F. esculentum* were distinguished by the absence of pronounced acute angles. For the cultivated species, amino acid compositions of grain protein of the studied samples manifest no strong deviations from earlier published results. The new species *F. hybridum* has the amino acid composition similar to ones of the both cultivated species with slight superiority in the content of all essential amino acids. So, the content of Cysteine, Tryptophan, Arginine, Lysine, Methionine, Leucine + Isoleucine, Threonine, Histidine and Valine in seeds of *F. hybridum* was 5.2, 15.0, 25.8, 30.2, 31.2, 36.0, 38.4, 41.1 and 46.2% higher compared to *F. tataricum* and 11.1, 43.7, 39.2, 3.7, 31.2, 15.2, 14.8, 20.0, 18.9% higher compared to *F. esculentum*. Using DPPH it was assessed the antioxidant activity (AOA) of whole grain flour of three buckwheat species and decreasing of the AOA during heating up to 100 °C. After water extraction the AOA was maximal for *F. tataricum* flour; *F. hybridum* and *F. esculentum* manifested similar values with the same decline dynamics during heating. After ethanol extraction the flour of *F. hybridum* shown higher AOA compared to both cultivated species before temperature treatment (1.3 times) as well as after heating to 100 °C (1.2 times). The results of the analysis of the fractional composition of flour from the whole grain of the three buckwheats shown the fragments of the seed hulls of *F. tataricum* and *F. hybridum* compared to ones of *F. esculentum* were characterized by the absence of pronounced acute angles. Additional experiments are needed to optimize the technology of whole-grain buckwheat flour. But the grain of *F. tataricum* and *F. hybridum* looks like more suitable for these purposes than the non-hulled grain of *F. esculentum.*

Keywords: buckwheat; grain; flour; food industry

INTRODUCTION

Buckwheat, a pseudo-cereal crop belonging to the family Polygonaceae, genus *Fagopyrum*, is a popular health food in Asian and European countries **(Kreft et al., 2003)**. Together with well-balanced chemical composition **(Bonafaccia, Marocchini and Kreft, 2003; Zhu, 2016)** including the optimal amino acid composition of seed storage protein **(Prakash et al., 1987; Jiang et al., 2007)** buckwheat manifests a high level of antioxidant activity due to the content of flavonoids **(Holasova et al., 2002)**. In buckwheat grain it was identified rutin, quercetin, and flavone C-glycosides **(Zielińska et al., 2012)**. It has several pharmacological functions such as anti-inflammatory, anti-diabetic **(Lee et al., 2016**; **Kamalakkannan and Prince, 2006)**, blood capillary strengthening properties **(Chua, 2013)**, and lipid-lowering activity **(Tomotake et al., 2015)**. Also, rutin has cardioprotective effects **(He et al., 1995**; **Wojcicki et al., 1995**; **Annapurna et al., 2009)**. It allows considering buckwheat as a functional food. Tartary buckwheat (*Fagopyrum tataricum* Gaertn.) contains approximately 100-fold higher amounts of rutin in its seeds compared to common buckwheat **(Fabjan et al., 2003)**. Sometimes buckwheat flour is used for the improvement of wheat-based products. So, wheat bread with buckwheat flour shown the level of antioxidant activity depends on the percentage of buckwheat flour, and the rutin content in such bread ranged from 7.76 to 26.90 mg kg^{-1} **(Lin et al., 2009**; **Bojňanská et al., 2009**; **Brindzová et al., 2009)**. Such products are recommended especially for people who

live in conditions of oxidative stress **(Kuznetsova et al., 2018)**.

In Russia, at present, the traditions of buckwheat consumption mainly as a groats crop promote cultivating only common buckwheat which grain is more suitable for groats production. In China and several other Asian countries where buckwheat grain is used mainly for the production of flour the Tartary buckwheat is also cultivated. Grinding of non-hulled grain is one of most perspective approach for use of buckwheat since it is a simple method which allows producing various types of flour for making noodles, pasta, bread, confectionery, etc. **(Steadman et al., 2001)**. Grinding grain with hulls reduces the relative content of nutrients in the flour obtained but increases the content of dietary fiber **(Dziedzic et al., 2012)**. Buckwheat grains can be milled using any equipment designed for grinding cereals, for example, the millstones or roller mill **(Mazza and Oomah, 2005)**. Millstones are more often used to produce whole grain flour for making pancakes at home. White flour can be obtained from such flour by removing the bran by sieving. The fineness of grinding with millstones can be different and is adjusted by changing the gap between them. Grinding with millstones is a one-step process, unlike grinding with a roller mill, where the process can be divided into several stages with the release of several flour fractions **(Ohinata et al., 2001)**.

It seems promising to search, create, and evaluate new buckwheat samples which could be more suitable raw materials for the development of deeper processing products. Using hybridization *F. tataricum* (4x = 32) × *F. giganteum* together with selection in late generations (F_{10} and later) recently was created a new buckwheat species *F. hybridum* **(Fesenko and Fesenko, 2010)**. The artificial species manifests competitive yield ability and may be considered for registration as a cultivar **(Fesenko et al., 2017)**.

An objective of this paper was the evaluation of *F. hybridum* grain properties, including amino acid composition, antioxidant activity, and characteristics of fragments of kernels and hulls after milling by both roller mill and millstones, compared to ones of *F. tataricum* and *F. esculentum*.

Scientific hypothesis

The whole grain of *F. hybridum* (a new species obtained using hybridization of tetraploid *F. tataricum* with artificial amphidiploid *F. giganteum* Krotov) and *F. tataricum* (Tartary buckwheat) is more perspective row material for the production of functional food in terms of deep processing technology compared to a whole grain of *F. esculentum* (common buckwheat) which usually used for groats production.

MATERIAL AND METHODOLOGY

The work involved one sample of each species. *F. tataricum* – an accession k-17 from the Federal Research Center N.I. Vavilov All-Russian Institute of Plant Genetic Resourses (VIR) collection (St.Petersburg); *F. hybridum* is a new species of hybrid origin which has been created at the Federal Research Center of Grain Legumes and Groats Crops, Orel, Russia **(Fesenko and Fesenko, 2010)**; *F. esculentum* was represented by cv. Devyatka (Federal Research Center of grain legumes and groats crops).

The grinding of the grain was carried out both on a millstone with gaps of 0.01 and 0.3 mm, and on roller mill with two frequencies of rotation, $6.5x10^3$ and $10x10^3$ turns per minute. Micrographs of the grains fragments were taken with an AxioCam MRc5 camera (Axio Imager microscope. Al, Carl Zeiss). The measurements were made using the AxioVision program.

Antioxidant activity (AOA) was measured using spectrophotometry in both alcohol and water extracts based on inhibition of the DPPH (2,2-diphenyl-1-picrylhydrazyl) radical **(Silva et al., 2005)**. Flavonoids were extracted with both 96% ethanol and water. 1g of milled grain was mixed with 25 mL of ethanol or water. Extraction was carried out for 24 hours with constant stirring. The extracts were filtered. 0.025 DPPH was dissolved in 100 mL of 96% ethanol. 10 mL of the solution was mixed with 90 mL of 96% ethanol. The optical density of the solution was measured after 30 minutes on a spectrophotometer in a cuvette with a thickness of 1 cm, at a wavelength of 515 nm. To determine the antioxidant activity of the studied extract, 0.1 mL of the filtrate was added to 3.9 mL of the solution of DPPH, mixed, and placed in a dark for 5 – 10 minutes. Then the optical density of the solution was measured using a spectrophotometer at a wavelength of 515 nm.

To determine the thermal stability of bioflavonoids, the extracts were gradually heated in a water bath (t = 20 – 100 ºC), and AOA was measured at 20, 40, 60, 80, and 100 ºC. The antioxidant activity (AOA) of the extracts is calculated by the formula $AOA = \frac{A1-A2}{A1} \times 100\%$, where A1 is the optical density of the DPPH solution before adding the investigated extract; A2 – optical density of the DPPH solution after adding the investigated extract.

The amino acid composition was evaluated using amino acid analyzer BIOCHROM (Biochrom Ltd., Great Britain).

Statistical analysis

Standard statistical analysis was conducted using MS Excell in combination with XLSTAT. The significance of differences between compared variants was analyzed using t-statistics (a two-sample *t*-test for independent samples); p-value is indicated where it is necessary.

RESULTS AND DISCUSSION

Results of different milling approaches

Millstones milling

The results of coarse and fine grinding were not entirely unambiguous. By the size of the hulls fragments, the maximum values were significantly higher for coarse grinding, but significant differences between the mean values were only for *F. hybridum* (t = 3.20; p = 0.02) (Table 1). Also, in the case of *F. tataricum*, the mean value of this trait was higher for fine grinding (albeit the difference was not significant). The maximal fragments of the kernel were larger in all cases on coarse grinding, but the average values were significantly higher only for *F. tataricum* (t = 6.14; p = 0.001) and *F. hybridum* (t = 2.04; p = 0.05).

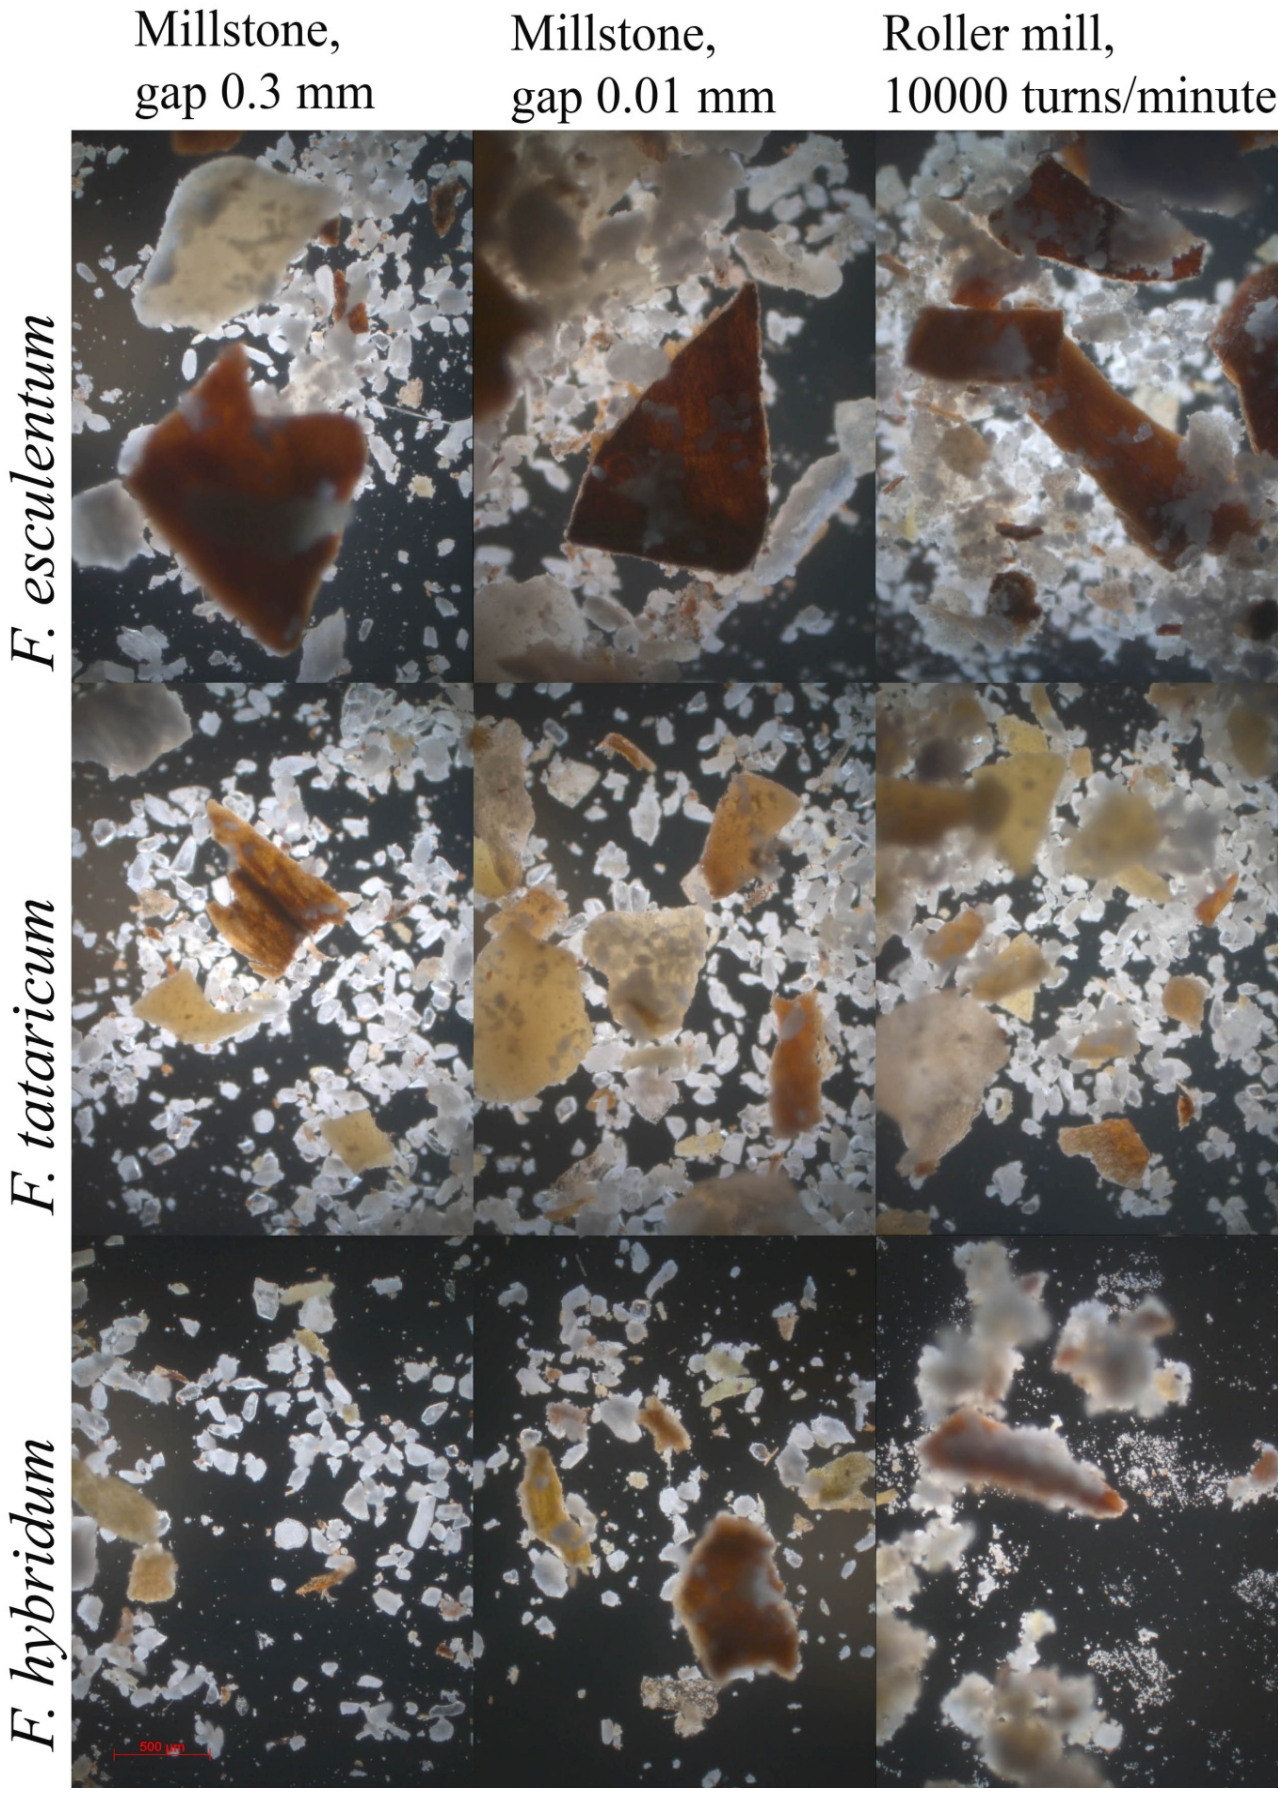

Figure 1 Kernels and hulls fragments of three buckwheat species after millstone (with gaps 0.3 and 0.01 mm) and rolling (10000 turns per minute) milling.

Table 1 Sizes (μm) of the kernels and hulls fragments of three buckwheat species after millstone milling.

Species	Fragments of	Gap = 0.01 mm		Gap = 0.3 mm	
		X ±m	Range	X ±m	Range
F. tataricum	**kernel**	66.1 ±1.7	21.4 – 158.9	90.0 ±3.5	46.7 – 298.8
	hulls	255.2 ±32.2	44.1 – 1429.0	207.7 ±33.1	14.6 – 2104.5
F. hybridum	**kernel**	90.9 ±4.1	27.4 – 641.7	108.5 ±7.6	46.2 – 851.0
	hulls	136.5 ±14.9	17.6 –675.9	207.2 ±16.3	20.7 – 1657.5
F. esculentum	**kernel**	128.6 ±7.6	29.6 – 936.9	96.0 ±7.1	24.3 – 1095.2
	hulls	271.9 ±78.2	22.4 – 1927.0	317.6 ±92.5	66.6 – 2527.0

Table 2 Sizes(μm) of the kernels and hulls fragments of three buckwheat species after milling by roller mill.

Species	Fragments of	Rotation frequency, turns per minute			
		$6.5x10^3$		$10x10^3$	
		X ±m	Range	X ±m	Range
F. tataricum	**kernel**	65.5 ±1.7	25.5 – 117.0	62.1 ±2.2	28.4 – 137.5
	hulls	172.8 ±11.3	41.9 – 625.5	233.9 ±55.3	48.3 – 1755.2
F. hybridum	**kernel**	70.1 ±4.6	32.3 – 154.7	59.0 ±3.1	13.2 – 208.6
	hulls	154.3 ±13.1	17.6 – 1066.8	116.6 ±16,3	10.7 – 557.7
F. esculentum	**kernel**	60.2 ±1.8	25.5 – 119.5	50.0 ±1.7	13.1 – 108.9
	hulls	347.8 ±84.4	43.2 – 1540.9	387.5 ±92.5	71.8 – 1397.1

In the case of *F. esculentum*, the fragments othe kernels were on average significantly larger on fine grinding (t = 3.13; p = 0.01). When comparing species on coarse grinding, in the size of the flour significant differences were found only between *F. tataricum* and *F. hybridum* (t = 2.21; p = 0.05). On fine grinding, no significant differences were found in the size of the hulls fragments between *F. esculentum* and the other two species, on average, although the maximal values were higher for *F. esculentum*. Fragments of the hulls of *F. tataricum* were significantly larger compared to *F. hybridum*. The fragments of the *F. tataricum* kernel were significantly smaller than in the other two species (p = 0.001). Fragments of the kernel of *F. esculentum* were larger than those of *F. hybridum* (t = 4.37; p = 0.001).

Roller milling

Grinding on a roller mill was carried out in two modes (Table 2). According to the size of the kernel fragments in different modes of milling within each species, the significant differences were identified within *F. esculentum* and *F. hybridum* (p <0.001 and p <0.05, respectively); there were no significant differences within *F. tataricum* (p >0.1). There were no significant differences in the size of hulls fragments in any case.

There were significant differences between *F. esculentum* and two other species in the size of the kernel fragments in all cases (the fragments of the *F. esculentum* kernels are smaller). The fragments of the *F. esculentum* hulls were noticeably larger than those of the other two species: only in comparison with *F. tataricum* when grinding at 10,000 turns per minute the differences were not significant. The differences between *F. tataricum* and *F. hybridum* in the size of the fragments of both the kernels and hulls were significant only when grinding at 10,000 turns.

It should be noted that the fragments of the seed hulls of *F. tataricum* and *F. hybridum* compared to ones of *F. esculentum* were distinguished by the absence of pronounced acute angles (Figure 1). Additional experiments are needed to optimize the technology of whole-grain buckwheat flour. But the grain of *F. tataricum* and *F. hybridum* looks like more suitable for these purposes than the non-hulled grain of *F. esculentum*.

Antioxidant activity (AOA) of flour and decline dynamics of the AOA during heating

Although some antioxidant activity (AOA) is characteristic of many plants **(Bandyukova and Sergeeva, 1974**; **Chua, 2013)**, including some wheat species **(Kuznetsova et al., 2018; Kuznetsova et al., 2019)**, buckwheat, especially Tartary buckwheat grain contains an outstanding amount of antioxidants, and it is one of the main advantages of the crop **(Kitabayashi et al., 1995a; Kitabayashi et al., 1995b**; **Ohsawa and Tsutsumi, 1995; Kreft et al., 1999**; **Holasova et al., 2002; Fabjan et al., 2003; Jiang et al., 2007; Zielińska et al., 2012; Kreft, 2016; Lee et al., 2016)**. The processing of grain into bread and confectionery products is usually associated with heat treatment at some stages; therefore it is necessary to evaluate the resistance of antioxidants contained in flour to heat. Using DPPH it was assessed the AOA of flour from whole grain of three buckwheat species and decreasing of the AOA during heating up to 100 °C. After water extraction the AOA was maximal for *F. tataricum* flour; *F. hybridum* and *F. esculentum* manifested similar values with the same decline dynamics during heating (Table 3). After ethanol extraction, the flour of *F. hybridum* shown higher AOA compared to both cultivated species before temperature treatment (1.3 times) as well as after heating to 100 °C (1.2 times). Since alcohol extracts antioxidants more efficiently compared water, the results of alcohol extraction reflect the ratios of their contents in different types of flour. The method used does not give an accurate estimate of the ratio of flavonoids in seeds of different species.

Table 3 Dynamics of antioxidant activity (AOA) of buckwheat flour extracts during heating.

Species	Flavonoid extraction with	Antioxidant activity (% inhibition of DPPH) after temperature treatment at				
		20 °C	40 °C	60 °C	80 °C	100 °C
F. esculentum	water	6.0 – 6.1	5.0 – 5.8	2.8 – 2.9	1.9 – 2.5	1.3 – 2.0
	ethanol	23.6 – 24.8	16.2 – 20.2	14.9 – 16.1	14.9 – 15.0	13.5 – 13.7
F. tataricum	water	29.6 – 30.6	25.5 – 26.0	22.5 – 23.5	19.8 – 20.8	17.9 – 18.4
	ethanol	41.7 – 42.8	34.2 – 34.5	29.2 – 30.1	28.4 – 28.8	26.8 – 27.2
F. hybridum	water	9.4 – 9.6	5.0 – 5.3	4.4 – 4.7	4.0 – 4.3	3.9 – 4.1
	ethanol	54.9 – 55.3	49.6 – 50.1	39.9 – 40.3	35.4 – 36.1	32.0 – 33.0

Table 4 Amino acid composition of *Fagopyrum* sp. (g.100g^{-1} flour).

Amino acid	*F.hybridum*	*F.tataricum*	*F.esculentum*
Arginine	0.78	0.62	0.56
Lisyne	0.56	0.43	0.54
Tyrosine	0.22	0.15	0.19
Phenylalanine	0.52	0.38	0.47
Histidine	0.24	0.17	0.20
Leucine+Isoleucine	0.83	0.61	0.72
Methionine	0.21	0.16	0.16
Valine	0.44	0.30	0.37
Proline	0.52	0.34	0.41
Threonine	0.54	0.39	0.47
Serine	0.55	0.44	0.47
Alanine	0.62	0.45	0.55
Glycine	0.52	0.37	0.46
Cysteine	0.20	0.19	0.18
Glutamicacid	2.26	1.67	2.02
Asparticacid	1.17	0.84	1.03
Tryptophan	0.23	0.20	0.16

It is known that differences in flavonoid content in seeds between *F. tataricum* and *F. esculentum* can be a hundredfold. However, these results correctly rank the test samples. *F. hybridum* in total AOA exceeds *F. esculentum* 2.2 – 2.3 times and *F. tataricum* 1.3 times.

The results of water extraction reflect the availability of antioxidants for enzymes that destroy them when using flour to make a dough **(Yasuda and Nakagawa, 1994; Suzuki et al., 2002, Suzuki et al., 2004, Suzuki et al., 2014)**. For *F. tataricum*, the maximum values of the efficiency of aqueous extraction were obtained: the AOA of an aqueous solution was 71% of the AOA of an alcohol solution. For *F. esculentum*, AOA of the aqueous solution was 25% of AOA alcohol. For *F. hybridum*, the AOA of the aqueous extract was only 17% of the AOA of the alcohol extract. Since the AOA of the alcohol extract of *F. hybridum* was maximal, this species is probably the most promising raw material for the production of products with high AOA. Lower AOA of aqueous extract of *F. hybridum* compared to *F. tataricum* can be elucidated either higher activity of antioxidants degradation enzymes or lower solubility of the antioxidants in water.

Amino acid composition

In spite of significant differences between the cultivated buckwheats, *F. esculentum* and *F. tataricum*, for the SDS PAGE spectra of seed storage proteins **(Rogl and Javornik, 1996; Lazareva and Fesenko, 2007; Lazareva et al., 2007; Li et al.,2008)**, both the species have a well-balanced amino acid composition of seed protein, with some variation among both species **(Prakash et al., 1987; Yang and Lu, 1992; Bonafaccia et al., 1994)**. *F. hybridum* has not been previously studied in this regard. We analyzed it for accessions studied in the work. The results are presented in Table 4.

The results manifest no strong deviations from earlier published results. The studied accession of new species *F. hybridum* has amino acid composition of seed protein similar to one of the cultivated species. In terms of the content of all essential amino acids, the sample *F. hybridum* is at least slightly superior to the samples *F. esculentum* and *F. tataricum* studied in our work. So, content of Cysteine, Tryptophan, Arginine, Lisyne, Methionine, Leucine + Isoleucine, Threonine, Histidine, and Valine in seeds of *F. hybridum* was 5.2, 15.0, 25.8, 30.2, 31.2, 36.0, 38.4, 41.1 and 46.2% higher compared to *F. tataricum* and 11.1, 43.7, 39.2, 3.7, 31.2, 15.2, 14.8, 20.0, 18.9% higher compared to *F. esculentum*.

CONCLUSION

So, the new species *F. hybridum* is better in some biochemical characteristics in comparison to cultivated buckwheats, *F. esculentum,* and *F. tataricum*. The total antioxidant activity of ethanol extract from *F. hybridum* flour was higher even compared to *F. tataricum*. Water extract from *F. hybridum* flour manifested only 17% AOA of ethanol extract. Probably, minimal efficiency of water extraction may indicate protection from dissolution by water and, accordingly, from the destruction of the flavonoids by enzymes, but the alternative explanation

about the higher activity of antioxidants degradation enzymes is not yet rejected. In terms of the content of all essential amino acids, the studied sample of *F. hybridum* exceeds the studied sample of *F. tataricum* by 5.2% (Cysteine) – 46.2% (Valine), and the studied sample of *F. esculentum* by 3.7% (Lisyne) – 39.2% (Arginine). The milling fragments of *F. hybridum* seeds hulls, as well as *F. tataricum* ones, have no pronounced acute angles, probably due to less compact structure of the hulls compared to *F. esculentum*. The non-hulled grain of both *F. hybridum* and *F. tataricum* is more suitable for production of whole-grain flour than the non-hulled grain of *F. esculentum*. Using the whole grain flour allows making the products with a high share of dietary fibers.

IMPROVING THE QUALITY OF MILK DISPERSION IN A COUNTER-JET HOMOGENIZER

Kyrylo Samoichuk, Dmytro Zhuravel, Nadiya Palyanichka, Vadim Oleksiienko, Serhii Petrychenko, Natalia Slobodyanyuk, Olga Shanina, Ivan Galyasnyj, Leonora Adamchuk, Vladyslav Sukhenko

ABSTRACT

Homogenization is a necessary process in the production of drinking milk and most dairy products. The specific energy consumption of the most common valve homogenizers reaches 8 kW $h.t^{-1}$. A promising way to reduce it is the introduction of more effective counter-jet homogenizers. The purpose of these studies is to increase the efficiency of machines of this type through fuller use of their kinetic energy. To achieve this, the design of a ring reflector was developed and experimental studies were carried out to determine its influence on the efficiency of milk fat dispersion in a counter-jet homogenizer. Calculations were made to determine the reflector's design parameters. An installation for experimental research has been developed, in which the required milk pressure is created with the help of compressed carbon dioxide. The dispersive indices of the milk emulsion were determined by computer analysis of milk sample micrographs obtained with an optical microscope and a digital camera using Microsoft Office Excel and Microsoft Visual Studio C# software using the OpenCV Sharp library. As a result of research, the formula for defining the angle of the reflector top has been determined analytically. Experimental studies proved its validity and allowed determination of the optimal diameter. A comparison of the dependence of the degree of homogenization on the excess pressure in a counter-jet homogenizer proves a 15 – 20% increase in the degree of dispersion when using a reflector. At the same time, specific energy consumption does not increase. Comparison of the distribution curves of milk fat globules by size after counter-jet homogenization and homogenization with a reflector suggests that the average diameter of fat globules for the experimental method decreases from 0.99 to 0.83 μm. This indicates the high quality of the dispersal characteristics of the milk emulsion after processing in a counter-jet homogenizer with a reflector.

Keywords: milk; homogenization; homogenizer; counter-jet homogenizers; reflector; degree of dispersion

INTRODUCTION

Homogenization is a necessary process in the production of drinking milk and most dairy products. The benefits of homogenized products are undeniable: reduced cream sludge, increased milk shelf life, improved taste and sensory properties of dairy products, increased digestion of milk fat and its even distribution throughout the product, etc. **(Dhankhar, 2014)**.

When milk is homogenized, its fat phase is dispersed (fat globules are crushed), as a result of which the average fat particle size decreases from 3 – 5 to 0.7 – 1 μm **(Walstra, Wouers and Geurts, 2006)**. This result can be achieved by exposing milk to pressure and velocity via ultrasonic, cavitation, vacuum and high-frequency electrical treatment **(Nuzhin and Gladushnyak, 2007; Samoichuk et al., 2016)**. Taking into account such a wide range of effects on the milk emulsion, dozens of types of homogenizers have been developed, which differ significantly from each other both in their design and principle of action **(Dhankhar, 2014; Fialkova, 2006)**.

A modern homogenizer must have a high efficiency (degree) of homogenization at low energy consumption. Moreover, the high degree of homogenization is crucial, which is confirmed by the fact that the vast majority of homogenizers in processing plants are valvular. When processing milk in such machines, the average diameter of fat globules is 0.75 μm, and the amount of energy consumed per unit of processed product is the highest among all existing homogenizers **(Rayner and Dejmek, 2015)**. Vacuum, ultrasonic, cavitation, mixing, electrohydraulic, screw, and spunbond devices for homogenization with significantly lower energy consumption have a lower degree of homogenization **(Dhankhar, 2014; Fialkova, 2006; Nuzhin and Gladushnyak, 2007)**. The degree of homogenization is close to that of valve rotor-pulsation and vortex

homogenizers. But a product that has been processed in a rotary homogenizer has a large fat content, which negatively affects the quality of dairy products made from such milk **(Fialkova, 2006)**.

Two types of high-efficiency jet homogenizers are distinguished, namely: jet, with a separate supply of fat phases **(Samoichuk et al., 2020)**, and counter-jet **(Samoichuk, 2008)**. Such homogenizers, the only ones among existing types, provide the highest speed of flow of the fat globule through the flow of milk plasma. After all, the Weber criterion depends on this value, which is a generalizing indicator for the main factors in the dispersion of the fat phase of milk **(Samoichuk et al., 2019)**. Weber's destruction coincides with the theories of homogenization by N. Baranovsky, P. Rebinder, A. Wittig and M. Oreshina, and by Innings' experimental studies **(Innings and Trägårdh, 2005; Oreshina, 2010)**.

A counter-jet homogenizer is not inferior to the valve type regarding the degree of dispersion of milk but has a specific energy consumption 4 – 5 times lower **(Samoichuk, 2008)**. This indicates a high potential for hydrodynamic dispersion, which is carried out when jets of milk emulsion collide.

In a study on such a homogenizer, it was found that the disruption of milk fat globules mainly occurs in the central part of the jet collision zone **(Samoichuk, 2008)**. After that, the jets divaricate in a fan shape (circularly). Their speed, and hence kinetic energy, is quite high. But this energy is not used for dispersion, so it reduces the efficiency of the homogenizer.

It is known that the disruption of milk fat globules occurs when a jet of milk collides with a hard surface **(Deynichenko et al., 2018; Nuzhin and Gladushnyak, 2007)**. Concerning counter-jet homogenizers, such a surface may be an annular reflector located in the path of milk flow after the collision.

Scientific hypothesis

This study hypothesizes that it is possible to increase the dispersion efficiency of a counter-jet homogenizer by installing an annular reflector.

This article aims to evaluate the effectiveness of dispersing milk in a counter-jet homogenizer with a reflector.

To achieve this aim, it is necessary to:

- develop the design of the annular reflector;
- experimentally determine the effect of the main parameters of the counter-jet homogenizer with a reflector on the degree of homogenization of milk;
- evaluate the dispersal indicators of the milk emulsion after homogenization.

MATERIAL AND METHODOLOGY

Experimental equipment

For experimental research, the reflector device was designed, the scheme of which is presented in Figure 1 **(Samoichuk, 2008)**.

The device consists of a chamber 15, in which the nozzles 16 are installed. The bottom of the chamber is conical with a slope to the centre, where the hole for removing milk after homogenization is placed. At the top, the chamber is closed with a transparent lid 10 to allow the process to be monitored. The sleeves 17 for adjusting the position of the nozzles with radially located screws allow the distance between nozzles to be changed and their alignment. Nozzles are collapsible and can be replaced.

c)

Figure 1 Scheme a), general view b) and chamber c) of the laboratory device for the study of counter-jet homogenization of milk: 1 – gas cylinder; 2 – discharge valve; 3 – air duct; 4 – outlet valve; 5 – manometer; 6 – filling valve; 7 – funnel; 8 – hose; 9 – tee; 10 – cover; 11 – cylinder; 12 – piston; 13 – main valve; 14 – hydraulic hoses; 15 – camera; 16 – nozzles; 17 – bushings for adjusting the position of the nozzles; 18 – reflector.

The creation of the required milk pressure is achieved by the gas cylinder 1 and cylinder 11, which are connected by the air duct 3. The pressure is controlled by the pressure gauge 5. The discharge valve 2 is used to fill the cylinder with gas from the cylinder. The milk is poured into the cylinder using the funnel 7, the hose 8, and the filling valve 6. The outlet valve 4 is necessary for the release of gas from the cylinder when it is filled with milk. The piston 12 prevents the diffusion of gas into the milk and, thus, a change in its properties.

The cylinder and nozzles are connected by hydraulic hoses 14. The division of the main milk flow from the cylinder into two equal flows is carried out in the tee 9. The main valve 13 is used to supply milk under the required pressure to the nozzles.

When performing the tests, the required volume of milk was poured into the cylinder through the funnel, with filling and outlet valves open. The main valve was kept closed. To create the necessary pressure in the cylinder, a GOST 8050-85 carbon dioxide cylinder was used. After opening the discharge valve (outlet and filling valves closed), carbon dioxide was supplied to the cylinder and the pressure in it increased to the required value. The device uses a manometer with a measurement limit of 100 kg/cm^2, accuracy class 0.75 according to GOST 2405-85. When the main valve was opened, the milk under the required pressure was sent to the nozzles, in which jets were formed. After homogenization, the milk was gravitationally discharged through a hole in the lower part of the chamber.

The main factors of the experimental studies were the excess pressure of the milk supply to the nozzles Δp and the diameter of the nozzle cone d_n. The distance between the nozzles *a* was taken to be equal to half the diameter of the nozzle cone **(Samoichuk, 2008)**. The temperature of milk during homogenization was assumed to be 60 – 70 °C **(Walstra, Wouers and Geurts, 2006)**. For counter-jet homogenization, the excess pressure is related to the modified Weber criterion We^{o-s} by the ratio:

$$We^{o-s} = \frac{6\rho_p \cdot \varphi^2 \cdot \Delta p}{10^6 \sigma_{f-p} \cdot \rho_m}, \quad (1)$$

Where: ρ_p, ρ_m – density of milk plasma and milk, kg.m^{-3}; φ – hydraulic coefficient of jet speed; σ_{f-p} – surface tension between milk fat and plasma, N.m^{-1}; Δp – excess milk supply pressure, Pa.

For the experimental studies, whole milk was used **(DSTU 8553, 2015)**, with a density of 1027 – 1023 kg.m^{-3}, and fat content of 2.5 – 4.4%.

Statistical analysis

The degree of homogenization of milk was determined by the formula **(Loncin and Merson, 1979; Nuzhin and Gladushnyak, 2007)**:

$$Hm = \frac{d_0}{d_k}, \quad (2)$$

Where:

d_0, d_k – average diameter of fat globules before and after homogenization, μm.

Average diameters of fat globules and other dispersive indices of the milk emulsion were determined by computer analysis of the micrographs of milk samples obtained with an optical microscope and a Mustek Wcam 300 digital camera (resolution 640×480) **(Samoichuk et al., 2020)**. Each experiment was repeated three times. From each experiment, three samples were selected and two dilutions were prepared from each sample. Six characteristic microscope field of view photos were selected from each dilution. Thus, 36 microscope fields of view were analysed to determine the statistical characteristics of milk.

The geometric characteristics of fat globules were analysed based on digital image analysis of the micrographs obtained.

The number of fat globules in the microscope field of view and their diameter were determined in the process of calculations. The average diameter of fat globules was determined by the statistical method of power average (arithmetic mean).

The qualitative uniformity of the measured data set was estimated by the coefficient of variation V. For dispersed indicators of milk fat globules, the coefficient of variation is sufficient for V >0.6 **(Haponiuk, Zander and Probola, 2015; Di Marzo, Cree and Barbano, 2016)**. When this condition is satisfied, the values of V are not given separately.

For this purpose, a software module has been developed that is implemented in Microsoft Visual Studio 2010 based on C# using the OpenCV Sharp library set 4.2.0. The exported numerical data and calculation of the sample statistics were performed in Microsoft Office Excel 2010.

A McBrain VA 318 electric wattmeter (Volga Region Power Equipment Plant, Russia) was used to record power.

RESULTS AND DISCUSSION

The rationale for the design of the reflector

For efficient operation of the annular reflector, the liquid flows after their collision with the annular reflector mustn't intersect with the main jets of milk (coming out of the nozzles) **(Fialkova, 2006; Innings and Trägårdh, 2005)**. Otherwise, there will be a violation of the continuity of the main jets and a decrease in the degree of dispersion of milk emulsions. To meet these requirements, the annular reflector in the radial cross-section must have the shape of an equilateral triangle, the vertex of which faces inwards of the annular reflector. With this design, the jets reflected from the surfaces of the reflector are removed outside the main jets of milk, which is necessary to prevent their crossing (Figure 2).

To prevent the intersection of the main jets of milk with those reflected from the reflector, it is necessary to calculate the angle β (Figure 3).

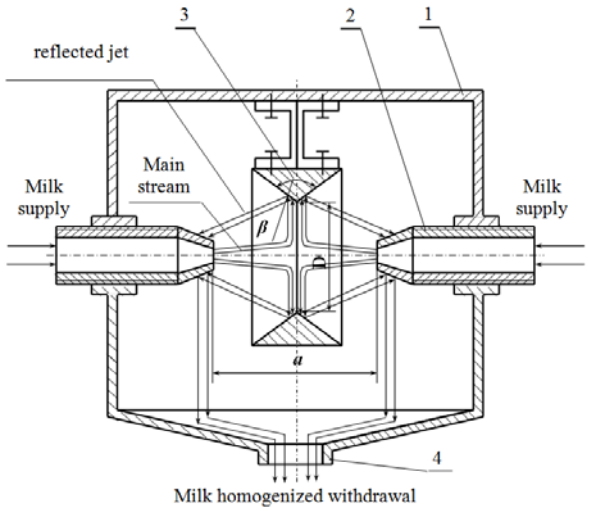

Figure 2 Scheme of the location of the annular reflector and direction of milk flows in the process of homogenization. Note: 1 – camera body; 2 – nozzle; 3 – annular reflector; 4 – hole for draining homogenized milk; D – diameter of the reflector; β – the angle of the reflector; *a* – the distance between the nozzles.

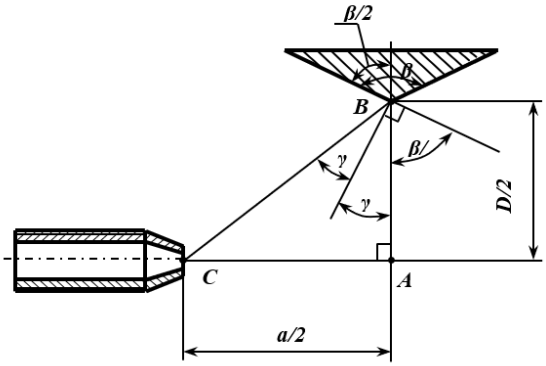

Figure 3 Calculation scheme for determining the angle β of the annular reflector.

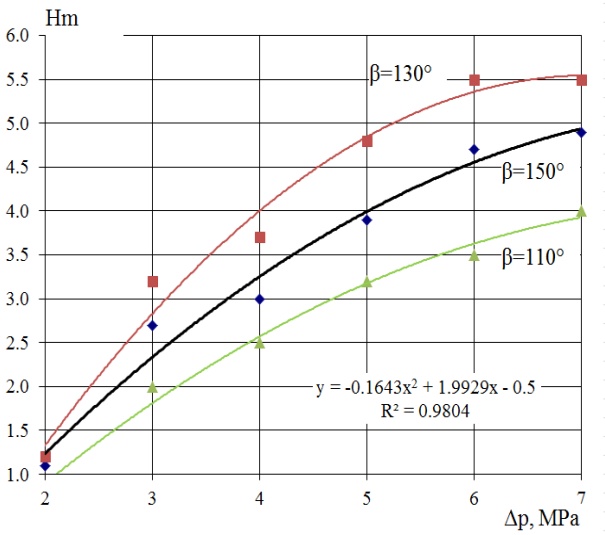

Figure 4 Dependence of the influence of excess pressure and angle of the reflector on the degree of homogenization at 70 °C.

$$\beta = 180^0 - \text{arctg}\frac{a}{D}. \quad (3)$$

The counter-jet homogenizer with a reflector works as follows. Whole milk is fed into the nozzles under the required pressure, which depends on the required degree of homogenization. After passing through the nozzle cones, the milk jets meet, while the fat fraction of milk is dispersed and mixed. The coaxial arrangement of the jets allows the fullest use of the kinetic energy of the fluxes for grinding the dispersed phase **(Huppertz, 2011; Samoichuk, 2008)**. After collision and homogenization, the product flow diverges in a fan shape perpendicular to the direction of the jets and hits the annular reflector. This results in the final grinding and partial mixing of the dispersed phase of the mixture **(Nuzhin and Gladushnyak, 2007)**. After contact with the annular reflector, the mixture is reflected from it and enters the housing of the homogenization device, where it is gravitationally removed from the machine. Moreover, due to the properly calculated angle of the annular reflector β, the product streams after contact with the annular reflector are reflected outside the jets coming out of the nozzles, so that there is no intersection of the flows of non-homogenized and homogenized products. Thus, in the counter-jet homogenizer with a reflector, dispersion of the fat phase of milk occurs in two stages: when the jets collide with each other and when the secondary jets collide with the reflector. This allows fuller use of the energy of the flow of milk.

Results of experimental studies

To determine the effect of excess pressure and the angle of the reflector on the degree of homogenization, an experiment was performed, the results of which are shown in Figure 4.

With increasing excess pressure, the degree of homogenization increases with parabolic dependence. At higher values of excess pressure, the growth of the response function (Hm) slows down. The prediction performed by the computer program Microsoft Office Excel 2010 **(Lawrence, Klimberg and Lawrence, 2009)** shows a maximum achievable degree of homogenization of 5.6 at an overpressure value of 7.4 – 7.5 MPa.

The optimal value of the angle of the reflector, calculated by the formula (3), is 130°. This achieves the highest degree of dispersion of the fat phase of milk – milk flow after reflection from the surfaces of the reflector is directed to the nozzle body and does not interfere with the free exit of the main jet from the nozzles. At an angle of the reflector β = 150°, the flow of milk strikes further on the body of the nozzles. In this case, due to the greater distance, the jet speed becomes smaller, so the efficiency of additional homogenization decreases. At an angle of the reflector β = 110°, the milk flow after the reflector intersects with the jets coming out of the nozzles, so the continuity of the milk flow is disturbed and its normal velocity component falls, so the decrease in the degree of homogenization is more significant.

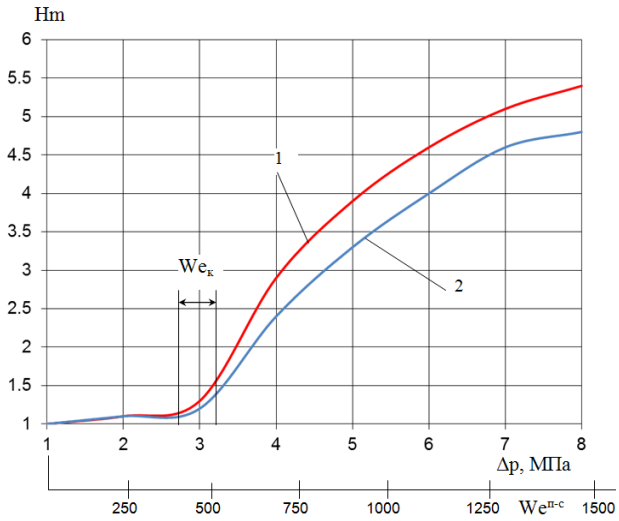

Figure 5 Comparison of the dependence of the degree of homogenization on excess pressure and the modified Weber criterion (at T = 70 °C, a = 0.56 mm, d_c = 1 mm): 1 – counter-jet homogenizer with a reflector; 2 – counter-jet homogenizer without a reflector.

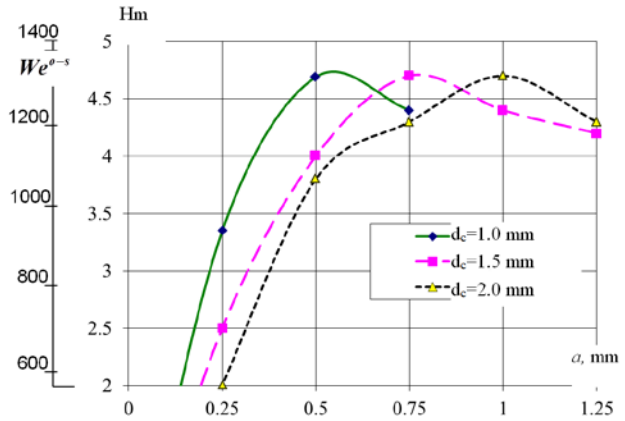

Figure 6 Dependence of the degree of homogenization and the modified Weber criterion on the distance between nozzle cones.

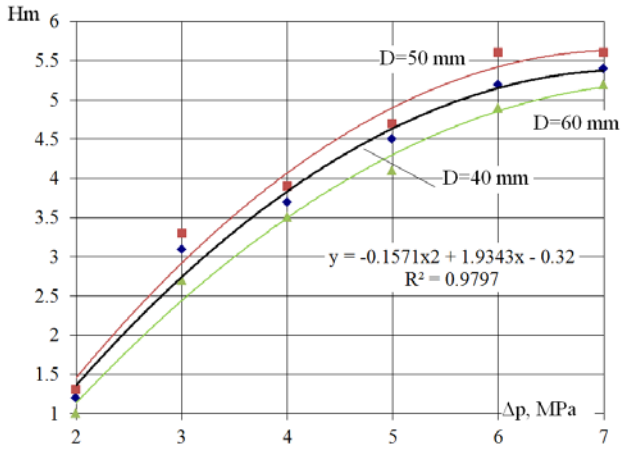

Figure 7 Results of experimental determination of the degree of homogenization depending on the pressure and diameter of the reflector.

The deviation of the values of the experimental curve of the modernized homogenizer in comparison to the homogenizer without a reflector is 15 – 20%. Indeed, the increase in the degree of homogenization with the reflector installed is due to more complete use of the kinetic energy of the milk flow in additional contact with the reflector and the nozzle housing.

Approximating the data of Figures 5 with a straight line, we obtain an expression that is identical in content to the known dispersion formula **(Loncin and Merson, 1979)**:

$$Hm = 0.9 \cdot 10^{-6} \Delta p \cdot \varphi^2 \qquad (4)$$

The coefficient of determination (R^2) in the range of 2.5 <Hm <6.0 is 95%, and at Δp = 5.0 – 6.0 MPa and a degree of homogenization of 4.5 – 5.2, the difference between theoretical and practical data is minimal. At Δp = 6.5 MPa, this difference reaches 6% and with a further increase in excess pressure, it is possible to predict its rapid increase. In the range Δp = 2 – 3 MPa, there is an intensive increase in the degree of grinding of the fat phase of milk. Here, the deviation of experimental data from the specified (approximated) dependence is maximal. At the value of Δp <2 MPa, homogenization practically does not occur.

The critical value of the Weber criterion (the beginning of the grinding of the fat phase) corresponds to the range of excess pressure of 1.8 – 2.2 MPa, at which We = 500 – 600.

Therefore, the optimal parameters of counter-jet homogenization for d_c = 1 mm are: a = 0.5 mm and T = 60 – 65 °C. The value of excess pressure depends on the required degree of homogenization and is Δp = 6.5 MPa at Hm = 5.0.

The results of experimental determination of the degree of homogenization and Weber criterion, with nozzle cone diameters of 1.0, 1.5, and 2.0 mm, depending on the distance between the nozzles cones, are shown in Figure 6. The diameter of the cone does not affect the maximum degree of homogenization.

It should be noted that at $a < d_c / 2$ the degree of homogenization is higher by 15 – 40% than that theoretically calculated **(Samoichuk, 2008)**, and the velocity of the jets at $a < d_c / 2$ corresponds to the calculated data. This can be explained by a more sudden change in the velocity of the fat globules after the collision of jets (which leads to an increase in the velocity difference between the fat globules and the surrounding plasma), due to the strict limitation of boundaries of the jet flow that is diverted by the edges of the nozzles **(Samoichuk and Kovalyov, 2013)**. Therefore, the optimal location of the nozzles is at a distance equal to half the diameter of the nozzle cone **(Samoichuk, 2008)**.

To determine the diameter of the annular reflector of the counter-jet homogenizer, the experimental study was conducted with reflector diameters D = 40, 50, and 60 mm. The results are shown in Figure 7.

It is optimal to use a reflector with a diameter of 50 mm as we obtain the maximum degree of fat dispersion. At D = 40 mm, the degree of homogenization decreases by 0.2 – 0.3, that is by 5%. This can be explained as follows. When using a reflector with a smaller diameter to comply

with the formula (3), the angle β decreases and the impact on the reflector becomes more sliding, which reduces the degree of homogenization. At D = 40 mm, the degree of homogenization decreases by 0.5 – 0.6, i.e. by 10%. This is due to the increase in loss of flow velocity before the collision with the reflector.

Changes in the fractional composition of fat globules after counter-jet homogenization **(Samoichuk, 2008)** (at T = 65 °C, Δp = 3.5 MPa) and comparing them with homogenization with a reflector (at a pressure of 4 MPa and T = 65 °C) and whole milk **(Dhankhar, 2014; Nuzhin and Gladushnyak, 2007; Oreshina, 2010; Haponiuk, Zander and Probola, 2015)** are graphically represented in Figure 8, and micrographs of fat globules are shown in Figure 9.

Milk before homogenization is characterized by the following parameters: average diameter of fat globules d_k = 2.49 mm, dispersion σ = 1.66, coefficient of variation

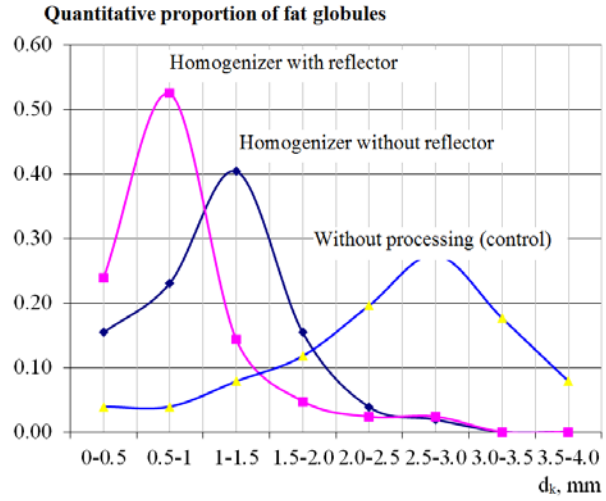

Figure 8 Differential distribution of fat globules of milk.

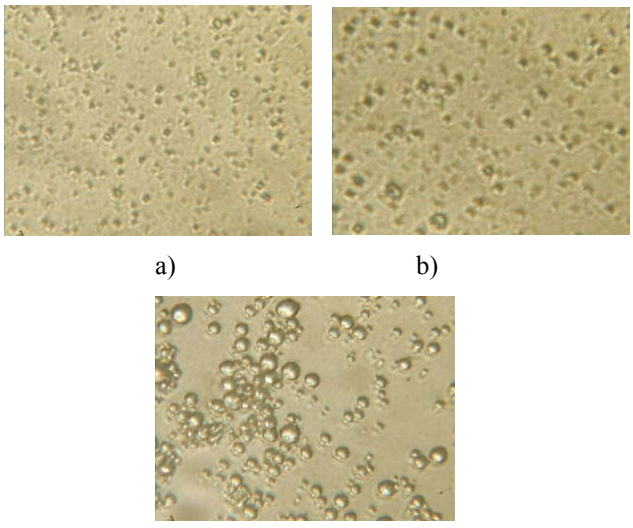

a) b)

c)

Figure 9 Photomicrographs of milk samples (400× magnification). Note: a) after counter-jet homogenization with a reflector at Δp = 4.0 MPa; b) after counter-jet homogenization at Δp = 4.0 MPa; c) raw milk.

(the share of scattering of the trait relative to the average) V = 67% **(Di Marzo, Cree and Barbano, 2016; Floury, Desrumaux and Lardieres, 2000; Hussain et al., 2017)**. Respectively for milk after counter-jet and countercurrent-jet homogenization with a reflector: d_k = 0.99 mm and 0.83 mm, σ = 0.51 and 0.47, V = 51% and 56%.

The value of the coefficients of variation indicates the reliability of the data sample.

The average diameter of the fat globules for the counter-jet homogenization treatment with the reflector decreased by 19% (from 0.99 to 0.83 μm) compared to that with the non-upgraded homogenizer. The dispersion value also decreased, which indicates the advantage of counter-jet homogenization with a reflector.

CONCLUSION

The design of the annular reflector has been developed to ensure the condition of free flow after collision with the surface of the reflector. The reliability of the theoretically obtained dependences for determining the angle of the reflector has been confirmed. It is proved that it is optimal to use a reflector diameter of about 50 mm.

When using a counter-jet homogenizer, it is possible to achieve a degree of homogenization of 5.6 at an excess pressure of 7.4 – 7.5 MPa. The degree of homogenization when installing an annular reflector increases by 15 – 20%. Moreover, such an increase in quality is provided without increasing energy consumption.

A comparison of the data on the distribution of milk fat globules by size after counter-jet homogenization and homogenization with a reflector suggests that the average diameter of fat globules for the experimental method is 19% smaller. The width of the particle size distribution is also smaller, which indicates better homogenization with the reflector installed.

BRYNDZA CHEESE OF SLOVAK ORIGIN AS POTENTIAL RESOURCES OF PROBIOTIC BACTERIA

Miroslava Kačániová, Petra Borotová, Margarita Terentjeva, Simona Kunová, Soňa Felšöciová, Peter Haščík, Ľubomír Lopašovský, Jana Štefániková

ABSTRACT

Bryndza cheese includes several predominant lactic acid bacteria. The aim of our study was the antagonistic effect of lactic acid bacteria supernatant isolated from ewes´ cheese bryndza against ten Gram-positive and Gram-negative bacteria. Isolated strains of bacteria were obtained from bryndza which were produced in five different regions of Slovakia. Isolated strains of lactic acid bacteria were identified with mass spectrometry MALDI-TOF MS Biotyper. A total of one hundred and thirty lactic bacteria include *Enterococcus faecalis, Enterococcus faecium, Enterococcus hirae, Lactobacillus brevis, Lactobacillus harbinensis, Lactobacillus johnsonii, Lactobacillus plantarum, Lactobacillus paracasei* ssp. *paracasei, Lactobacillus paraplantarum, Lactobacillus suebicus, Lactococcus lactis* ssp. *lactis, Lactococcus lactis,* and *Pediococcus acidilactici* were tested in this study against Gram-negative bacteria: *Escherichia coli* CCM 3988, *Klebsiella pneumoniae* CCM 2318, *Salmonella enterica* subsp. *enterica* CCM 3807, *Shigella sonnei* CCM 1373, *Yersinia enterocolitica* CCM 5671 and Gram-positive bacteria: *Bacillus thuringiensis* CCM 19, *Enterococcus faecalis* CCM 4224, *Listeria monocytogenes* CCM 4699, *Staphylococcus aureus* subsp. *aureus* CCM 2461, *Streptococcus pneumonia* CCM 4501 with agar diffusion method. Lactic acid bacteria showed activity 92% against *Yersinia enterocolitica*, 91% against *Klebsiella pneumoniae*, 88% against *Escherichia coli*, 84% against *Listeria monocytogenes*. The most effective bacteria against Gram-positive and Gram-negative bacteria tested was *Lactobacillus paracasei* ssp. *paracasei*.

Keywords: bryndza; Gram-positive and Gram-negative bacteria; lactic acid bacteria; probiotic effect; mass spectrometry

INTRODUCTION

Bryndza is a traditional Slovak natural white spreadable ripened cheese with Protected geographical indication status **(Commission Regulation (EC) No. 676/2008)**. Bryndza is made from ewes' or a mixture of ewes' and cows' milk and is a rich source of protein, vitamins, and minerals **(Toth et al., 2016)**. Bryndza is a dairy product that naturally contains a broad spectrum of microorganisms that has crucial importance on cheese properties, flavor, and aroma. Microorganisms are present during the whole process of cheese production, they are important in coagulation and ripening **(Andrade et al., 2008; Tilocca et al., 2020)**. Also, beneficial strains help to inhibit the growth of the pathogens and reduce the spoilage of the dairy products **(Arqués et al., 2015)**.

In previous research Gram-positive, Gram-negative bacteria, and yeasts were found and identified in bryndza **(Kačániová et al., 2019)**. The dominant group of bacteria in bryndza was lactic acid bacteria (LAB), mainly *Lactobacillus* species **(Kačániová et al., 2020)**. *Lactococcus, Pediococcus, Enterococcus, Streptococcus* were abundant in bryndza from different Slovak regions also **(Berta et al., 2009; Šaková et al., 2015; Sádecká et al., 2019)**. The probiotic properties of bacteria isolated from bryndza were observed in *Lactobacillus plantarum*, *Enterococcus faecium,* and *Enterococcus faecalis* strains. Researches claimed that these potentially probiotic strains can inhibit the growth of pathogenic bacteria, and some of them can survive in the acidic gastrointestinal environment, which is necessary for reaching the intestine of the host **(Belicová et al., 2011; Belicová et al., 2013)**.

Probiotic bacteria as an important part of intestinal microbiota helps regulate the immune responses, relieve the gastrointestinal tract dysfunction, alleviate the allergies, or lower cholesterol levels **(Dicks and Botes, 2010**; **Plaza-Diaz et al., 2019)**. Moreover, the anti-carcinogenic properties of probiotic bacteria have been described **(Zhong et al., 2014)**.

Our study aimed to evaluate lactic acid bacteria isolated from ewes´ bryndza and select the most active probiotic bacterial strain against pathogens and opportunistic pathogens.

Scientific hypothesis

Bryndza isolates possess probiotic activity. LAB can inhibit antagonistic activity against pathogens.

MATERIAL AND METHODOLOGY

Isolation of lactic acid bacteria

A total of 130 lactic acid bacteria were isolated from Slovak ewes´ bryndza. The bryndza samples were obtained from five producers in Slovakia. Before identification, the lactic acid bacteria colonies were subcultured on 90% of Trypton Soya agar and 10% of Main Rogosa (MRS) agar (Oxoid) at 30 °C for 18 – 24 h microaerobically. One colony of each bacterial isolate was selected for screening. Subsequently, an analysis of the bacteria identification was performed using the MALDI-TOF MS Biotyper.

Bacterial strains for testing

The bacterial strains of Gram-negative bacteria: *Escherichia coli* CCM 3988, *Klebsiella pneumoniae* CCM 2318, *Salmonella enterica* subsp. *enterica* CCM 3807, *Pseudomonas aeruginosa* CCM 1959, *Yersinia enterocolitica* CCM 5671 and five of Gram-positive bacteria: *Bacillus thuringiensis* CCM 19, *Micrococcus luteus* CCM 732*, Listeria monocytogenes* CCM 4699, *Staphylococcus aureus* subsp. *aureus* CCM 2461, *Streptococcus pneumoniae* CCM 4501 were obtained from the Czech collection of microorganisms (Brno).

Antibacterial activity of LAB isolate

The culture of lactic acid bacteria after 24 h of incubation in MRS broth (Oxoid, Basingstoke, UK) was centrifuged at 5500 g for 10 min at 4 °C and 2 mL of the supernatant was used for detection of antibacterial activity.

The well diffusion assay was used. Bacteria were spread on Petri dishes with MRS agar. LAB isolates were added into 6 mm diameter wells were created into the agar. The amounts of LAB and indicator bacteria were the same (100 µl, 10^8 CFU/mL) prepared from the broth culture of bacteria according to the 0.5 McFarland standard. After 48 h incubation at 37 °C in an aerophilically chamber, the inhibition zone diameter was measured for detection of the antagonistic effect of the LAB isolate against pathogenic bacteria.

Statistical analyses

The mean and standard deviation of inhibition zones was calculated for the detection of antagonistic effect against tested Gram-positive and Gram-negative bacteria.

RESULTS AND DISCUSSION

LAB antimicrobial products, such as bacteriocins, are very important in bioconservation of various foods. The diverse use of LAB bacteriocins, individually or as biopreservative combinations, may help to improve food safety, especially of traditional products **(Jamuna and Jeevaratnam, 2004; Mojgani and Amimia, 2007)**.

In our study 130, lactic acid bacteria isolated from ewes´ cheese bryndza (Table 1) were tested for antimicrobial activity and antagonistic effect against pathogenic gram-positive and Gram-negative bacteria.

Table 1 Number of LAB isolates.

Species of LAB	Number of isolates
Enterococcus faecalis	10
Enterococcus faecium	10
Enterococcus hirae	10
Lactobacillus brevis	10
Lactobacillus harbinensis	10
Lactobacillus johnsonii	10
Lactobacillus plantarum	10
Lactobacillus paracasei* ssp. *paracasei	10
Lactobacillus paraplantarum	10
Lactobacillus suebicus	10
Lactococcus lactis* ssp. *lactis	10
Lactococcus lactis	10
Pediococcus acidilactici	10
Total	130

In agar test, lactic acid bacteria isolated from ewes´ cheese bryndza demonstrated different antimicrobial activity with the inhibition the zone ranged from <1 to >5 mm. Altogether, 92% of LAB showed activity against *Yersinia enterocolitica*, 91% against *Klebsiella pneumoniae*, 88% against *Escherichia coli*, 84% against *Listeria monocytogenes*. Antimicrobial activity lower than 84% was observed against *Salmonella enterica* subsp. *enterica, Pseudomonas aeruginosa, Bacillus thuringiensis, Micrococcus luteus, Staphylococcus aureus* subsp. *aureus,* and *Streptococcus pneumoniae* (Table 2). **Belicová et al. (2013)** tested 125 acid resistant presumptive lactobacilli isolated from bryndza against *Listeria monocytogenes* CCM 4699, *Staphylococcus lentus* CCM 3472, *Acinetobacter calcoaceticus* CCM 4503, *Sphingomonas paucimobilis* CCM 3293, and *Salmonella enterica* subsp. *enterica*, serovar Typhimurium.

LAB produces metabolites such as organic acids (lactic and acetic acid), hydrogen peroxide, ethanol, diacetyl, acetaldehyde, acetoin, carbon dioxide, and bacteriocins that were classified as antimicrobial agents. Moreover, the production of organic acids resulted in low pH, which also inhibits the activity of pathogenic microorganisms **(Ponce et al., 2008; Šušković et al., 2010)**. Antibacterial activity of organic acids and bacteriocins was confirmed against various pathogenic Gram-positive and Gram-negative microorganisms **(Maragkoudakis et al., 2009)**.

A total of 20 LAB isolates showed strong inhibition zones (more than 5 mm) against *P. aeruginosa* and *M. luteus*. Nineteen of LAB isolates showed strong antimicrobial activity against *S. aureus*. Cell suspension of *Lactobacillus plantarum* inhibited *L. monocytogenes* growth **(Ennahar et al., 1998)**. *Lactococcus lactis* reduced levels of *L. monocytogenes* in Cheddar cheese **(Buyong et al., 1998)**. Lactococci developed by **Reviriego et al. (2005)** and **Reviriego et al. (2007)** reduced the number of *L. innocua, L. monocytogenes, S. aureus*, and *E. coli* in cheese **(Rodríguez et al., 2005)**. The intermediate inhibitory effect against Gram-negative and Gram-positive bacteria (1 – 5 mm) is shown in Figure 1. The most effective strains were *Lactobacillus paracasei* ssp. *paracasei* against all tested pathogens. This bacteria exhibited inhibitory activity against all 10 bacteria tested with 2 to 8 isolated were active against particular bacteria.

Table 2 Number of lactic acid bacteria isolates with antimicrobial effect against pathogenic bacteria in mm.

Inhibition zone	EC	KP	SEE	PA	YE	BT	ML	LM	SAA	SP
<1	5	4	10	15	5	15	20	6	11	15
1 – 5	115	118	105	95	120	105	90	110	100	101
>5	10	8	15	20	5	10	20	14	19	14

Note: EC – *Escherichia coli*; KP – *Klebsiella pneumoniae*; SEE – *Salmonella enterica* subsp. *enterica*; PA – *Pseudomonas aeruginosa*; YE – *Yersinia enterocolitica*; BT – *Bacillus thuringiensis*; ML – *Micrococcus luteus*; LM – *Listeria monocytogenes*; SAA – *Staphylococcus aureus* subsp. *aureus*; SP – *Streptococcus pneumoniae*.

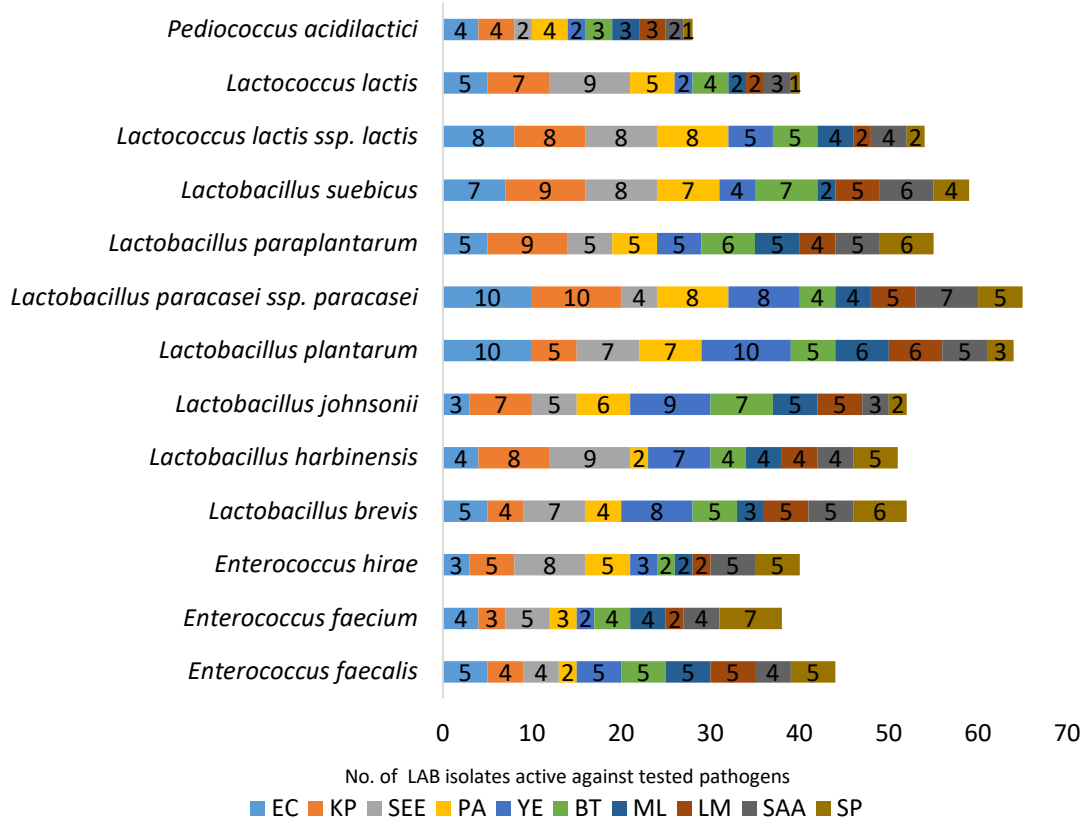

Figure 1 The inhibitory activity of the most active predictive lactic acid isolates against the pathogenic strains. Note: EC – *Escherichia coli*; KP – *Klebsiella pneumoniae*; SEE – *Salmonella enterica* subsp. *enterica*; PA – *Pseudomonas aeruginosa*; YE – *Yersinia enterocolitica*; BT – *Bacillus thuringiensis*; ML – *Micrococcus luteus*; LM – *Listeria monocytogenes*; SAA – *Staphylococcus aureus* subsp. *aureus*; SP – *Streptococcus pneumoniae.*

In total, inhibitory activity was expressed 64 times by 10 *L. paracasei* spp. *paracasei* isolates.

The most effective bacterial strain was *L. lactis* subsp. *lactis* against followed by *L. paraplantarum* against *S. enterica* subsp. *enterica*. The lowest antagonistic effect of lactic acid bacteria was found in *Enterococcus hirae* against *Bacillus thuringiensis* (Table 3).

Foodborne pathogens have become an important social topic and have received much attention from consumers and food safety regulatory agencies around the world because of frequent foodborne outbreaks. In previous studies, LAB showed a wide range of antimicrobial effects against many foodborne pathogens **(Soerjadi et al., 1981; Ennahar and Deschamps, 2000; Messens and De Vuyst, 2002; Dodd, 2012)**. Studies of interaction between LAB and
L. monocytogenes in various media and with various LAB strains have been performed, and in all cases LAB inhibited the growth of *L. monocytogenes* **(Tharrington and Sorrells, 1992; Zhang et al., 2011; Zhu et al., 2014)**.

However, **Kao and Frazier (1966)** obtained a mixed result when LAB was cocultured with *S. aureus*. Many researchers have found that LAB can inhibit *Salmonella* **(Keersmaecker et al., 2006; Zhang et al., 2016; Yang et al., 2017)** and that the bacteriostatic substances produced by LAB are thermally stable. The research focused on the inhibition of *E. coli* by LAB is more extensive compared to inhibition of the other bacteria. **Du et al. (2016)** found three strains of *Lactobacillus acidophilus* which could inhibit
E. coli ATCC 25922. Other investigations on *E. coli* O157:H7 proliferation control showed that LAB could effectively inhibit the growth of *E. coli* O157:H7 **(Brashears et al., 1998; Fooladi et al., 2014)**. *Klebsiella pneumonia, Bacillus cereus, Shigella flexneri* **(Sharma et al., 2017)**, *Staphylococcus epidermidis* **(Diepers et al., 2016)**, and *Candida albicans* **(Yu et al., 2006)** also can be inhibited by LAB.

Table 3 Antagonistic effect of lactic acid bacteria against Gram-negative and Gram-positive bacteria in mm (mean=zone of inhibition of 10 isolates ±*SD*).

CONCLUSION

In conclusion, the present study of lactic acid bacteria strains isolated from ewes´ cheese bryndza confirmed antagonistic effect against Gram-positive and Gram-negative bacteria.

In our study, the best results were found for *Lactococcus lactis* subsp. *lactis* against *Salmonella enterica* subsp. *enterica*. *In vitro* screening of LAB from Slovak bryndza ewes´ cheese have good potential for use as probiotic cultures.

ANALYSIS OF THE POSSIBILITY OF FISH AND MEAT RAW MATERIALS COMBINATION IN PRODUCTS

Nataliia Bozhko, Vasyl Pasichnyi, Vasyl Tischenko, Yuliia Matsuk

ABSTRACT

Aspects for the use of regional raw materials in ground food technology require further study of functional and technological properties to be able to predict them depending on the chemical composition of raw materials and processing methods. The aim of our research was to comparatively study the chemical composition, functional-technological, rheological properties of fish raw materials, and duck meat in terms of their possible compatibility in meat-containing products. The subject of our research was representatives of the regional aquaculture *Carassius gibelio* and *Hypophthalmichthys molitrix*, as well as the meat of Muscovy duck (*Cairina moschata*). It has been established that the nutritional value of freshwater aquaculture objects *Carassius gibelio* and *Hypophthalmichthys molitrix* is virtually identical in protein and fat content, making them interchangeable in terms of nutritional balance when developing the combined product. The ratio of protein and fat to water for duck meat is higher 3.54 – 4.88 times that of aquaculture, which can be used in the selection of components of the formulation of emulsified products, taking into account the nutrient balance. It has been confirmed that the addition of salt enhances water holding capacity, water binding capacity, and fat holding capacity. Water holding and water-binding capacities of minced fish are higher due to higher water levels, which, combined with the low-watering duck meat, can be predicted to create a forcemeat system with high functional-technological properties. The ability to emulsification and retain fat in the state of emulsion in minced duck meat has proved to be better, which when combined with fish minced meat can compensate for the ability to retain fat in the system of combined products. A combination of regional aquaculture with waterfowl meat will not only improve the functional and technological parameters of combined minced systems but also balance them by correcting the composition of proteins and fats.

Keywords: fish; meat; combination; analysis

INTRODUCTION

The problem of healthy nutrition is one of the most important issues facing society. Human health depends on the satisfaction of physiological needs for energy and nutrients **(Gibney et al., 2009**; **Waterlander et al., 2018)**. According to the WHO Regional Office for Europe, about 80% of all diseases are in one way or another related to nutrition, and for 41% of them, nutrition is a leading risk factor **(WHO, 2004)**. Violation of dietary recommendations leads to the development of pathological conditions of the body, especially with prolonged deviation from a balanced diet **(Hennig et al., 2018; Kimokoti and Millen**, **2016)**.

One of the reasons for the unfavorable conditions for human health is the lack of protein in the diet, which today is up to 30% for Ukrainians, especially for the protein of animal origin **(Prokopenko**, **2018)**. The main sources of animal protein are raw meat from slaughtering cattle and pigs. The volume of their production no longer meets the needs of the world population in protein and, therefore, in essential amino acids. Moreover, the methods used in agriculture for meat production have almost exhausted their potential **(FAO, 2018)**.

Aquaculture is of practical interest in filling nutrient deficiencies as promising components for creating new foods. The use of fish in conjunction with raw meat will significantly expand and diversify the range of high-quality protein products of high quality and create the possibility of designing products with a balanced nutritional composition. Furthermore, combining animal protein of different origins, in addition to the rational use of raw materials, will allow expanding the volume of biologically complete protein products, to ensure the economic efficiency of its production, by reducing the cost.

On the one hand, the range of meat products has been significantly expanded in recent years, in the formulation of which different ingredients of non-meat origin are used. On the other hand, aquaculture production has become an important source of food protein in many countries over the last decades **(Pauly and Zeller, 2017)**. This industry is developing rapidly, and its competitiveness is driven by the availability of raw materials to processing facilities, its rapid renewal, and low cost.

The nutritional and biological value of fish raw materials is the main indicator of its inclusion in the formulation of dietary foods. In the proteins of the muscle tissue of the hydrobionts, the high content of the compounds necessary for the human body, such as essential amino acids, polyunsaturated fatty acids, including the unique ones - docosahexaenoic and eicosapentaenoic **(Mohanty et al., 2016)**. Fish ranks first among animal protein products by methionine content **(Vidotti et al., 2003)**.

In addition to resource availability, an important criterion for the selection of aquaculture in food technology is its nutritional value, organoleptic, taste, and functional and technological characteristics. A sufficient number of works are devoted to the study of the chemical composition of freshwater aquaculture **(Abramova, 2005; Lebsjka and Gholembovsjka, 2014; Bozhko et al., 2018; Boghdanov, 2005)**.

In addition to the traditional indicators of the biological and nutritional value of fishery raw materials, **Tereschenko (2004)** suggested to supplement their characteristics with some critical coefficients and, first of all, with the coefficient of nutritional saturation (C_{ns}). According to the classification of **Tereschenko (2004)** fishery raw materials, depending on C_{ns} is divided into low saturated ($C_{ns} \leq 0.3$), medium saturated ($C_{ns} = 0.3 – 0.6$), and highly saturated ($C_{ns} > 0.6 – 1.5$).

As a result of studies of the biological efficiency, nutritional and biological value of fish muscle tissue, fish proteins have been found to have a high digestibility rate of 1.89 – 1.90, while for beef this figure is only 1.64 units **(Sidorenko, 2009)**.

However, there is a problem with aquaculture implementation, which is related to the peculiarities of the anatomical structure of the fish body. The presence of a large number of soft muscular bones, as well as the specific taste, necessitate the processing of fish for minced meat and combine it with other raw materials. At the same time, due to the wide variation of the components of the stuffing, it is possible to manufacture a wide range of products, including those with high biological value and certain physiological orientation **(Bozhko et al., 2018)**. Combining raw materials with different functional and technological properties (FTV) makes it possible to obtain products with a wide range of functional properties.

One of the pressing issues in the technology of combined food is the use of raw materials, which under the influence of technological processes forms a homogeneous system with directional-set properties. The production of high-quality products with a combined composition of raw materials requires information about the kinetics of the structure formation process, hydrodynamic properties of raw materials, which determine the degree of bound moisture, and, therefore, technological and consumer performance of products. Simultaneously selected components of the formulation should have sufficient technological properties, their maximum compatibility, or mutual compensation to ensure stable food emulsions.

At the same time, at each stage of the technological process, they take into account the characteristic functional properties of each ingredient and the influence of each of them on the formation of a stable emulsion and the qualitative characteristics of the finished products **(Kosoy et al., 2005)**. Thus, the prospects for the use of regional aquaculture in ground-based food technology require further study of functional and technological properties to be able to predict them, depending on the chemical composition of the raw material and the processing methods used.

Scientific hypothesis

We are expecting the confirmation of the high technological qualities of fish raw materials and the possibility of combining it with meat raw materials as part of the combined products. Therefore, the purpose of the research was to comparatively study the chemical composition, functional-technological, rheological properties of fish, and meat raw materials in terms of their possible compatibility in meat-containing products.

We are expecting that the chemical composition, high functional and rheological indicators, critical coefficients of *Carassius gibelio,* and Muscovy duck meat will improve the technological properties of combined meat systems, balance them by correcting the composition of proteins and fats.

MATERIAL AND METHODOLOGY

The subject of our research was representatives of the regional aquaculture *Carassius gibelio* and *Hypophthalmichthys molitrix*, as well as the meat of Muscovy duck.

Carassius gibelio weighing 250 – 350 g and a white carp (*Hypophthalmichthys molitrix*) weighing 1800 – 2000 g were purchased from the local supermarket in Sumy, Ukraine. The fish was stripped of the scales, the interior was removed, the meat was separated from the bones and ground into a meat grinder with a grid diameter of 2 – 3 mm. Samples of minced meat were divided into two groups, one of which was added 1.5% salt to the minced meat.

Muscovy duck (*Hypophthalmichthys molitrix*) weighing 2000 – 2500 g was purchased from the Sumy region local market from a poultry farm. Ducks were deboned and ground. For processing, the duck meat was minced through a 2 mm plate and then through a 3 mm plate of a meat grinder. Two types of forcemeat were prepared: 1 – without salt, 2 – with an addition of 1.5 % salt. The salt was added during mixing the minced meat. Samples were evaluated for different parameters.

Raw Protein Measurement

Protein measurements were performed using the Kjeldahl method **(ISO 937, 2007)**. 5 g of homogeneous fillet with 20 mL of concentrated sulfuric acid and 8 g of catalysts were placed in a special container and then heated at 350 °C for 30 min. After mineralization, the sample was quantitatively transferred to a solution of

NaOH at a concentration of 33%, sealed, and distilled off with the steam. The resulting steam distillate was transferred to a container containing several drops of the Tashiro indicator. The titration was performed with a solution of 0.01 N sulfuric acid.

Fat Measurement

Total fat was measured by the Soxhlet method **(ISO 1443, 2008)**. 4 g of the dried sample in a paper cartridge was placed in an extraction flask of a Soxhlet apparatus. Petroleum ether with a boiling point of 45 °C was used for the extraction. After multiple extractions, the weight of the test cartridge to constant weight was determined. The difference between the initial and final weight shows the percentage of fat.

pH measurement

The pH of the mincemeat was measured using a Partabell digital pH meter pcd650. Samples were prepared to measure pH based on the standard method **(Pasichnyi, 2013)**, and 10 g of minced meat in 100 mL of water were mixed.

Moisture analysis

Moisture was determined by the method of drying **(ISO 1442, 2008)**. 5 g of the sample was placed in a container, dried for 1 hour at 150 °C.

Cooking loss

Cooking losses were calculated by the difference of weight before and after cooking, and the moisture content was determined by drying the samples (4 g) at 150 °C.

Methods of measuring functional indicators

WBC (water binding capacity) of minced meat was determined by the pressing method **(Pasichnyi, 2013)**. WHC (water holding capacity) of minced meat was defined as the difference between the mass fraction of moisture in the minced meat and the amount of moisture released during the heat treatment. The following procedure was used to determine the emulsifying capacity (EC). The stability of the emulsion was determined by heating at 80 °C for 30 min. and cooling with water for 15 min followed by centrifugation and measuring the ratio of the emulsion layers **(Pasichnyi, 2013)**.

Determination of critical coefficients

Critical coefficients were determined by the method **(Kosoy et al., 2005)**. Coefficient of protein watering (Cw) was calculated as a ratio between moisture content and total protein; protein-water factor (PWF) as the ratio between total protein and moisture content; lipid-protein coefficient (LPC) - as the ratio between fat content and protein content; food saturation factor (FSF) as total protein, total fat and moisture content.

The coefficient of chemical composition (CCC) was calculated according to the formula (1):

$$CCC = [F/M] \times P \qquad (1)$$

Where: F – total fat, %; M – moisture content, %; P – total protein, %.

Definition of rheological indicators

Rheological indices of minced systems were determined using a rotational viscometer. RV-8m viscometer was used with a corrugated rotor (2 mm corrugation step) with an inner cylinder (Rc) of 0.605 cm, and an outer rotor radius of Rn – 1.9 cm, the length of the rotor was equal to 8 cm. on a scale using a stopwatch. The processing of the obtained results was performed according to the method **(Pasichnyi, 2013)**.

Statistical analysis

The data statistical analysis was produced by Microsoft excel and Statistica 15. All experiments were carried out in triplicate and the results reported are the results of those replicate determinations with standard deviations. The Student t-test was used for the statistical analysis of the obtained results. Data are presented as mean ±standard error of the mean (SEM). The smallest acceptable difference for probes from the one sample was pointed at 5%. Probes with more differences were not considered.

RESULTS AND DISCUSSION

Adherence to the theory of balanced nutrition has allowed substantiating a holistic system for determining the nutritional and biological value of products based on their chemical composition **(Pasichnyi, 2002)**. In turn, based on chemical composition data of food introduced the concept of different value categories. The term "nutritional value of the product" is used to determine the percentage of chemical composition conformity of the product under study to the formula of balanced nutrition, that is, the term reflects the completeness of the useful qualities of the product **(Bohrer, 2017; Sándor et al., 2011)**. On the other hand, the chemical composition of raw materials, namely the quantity and quality of proteins, the content of fat fraction and water, are responsible for the functional and technological properties of the food products created from it **(Kinsella, 1982; Sikorski, 2001)**.

In the development of combined products, the key is the selection of recipe composition, which is carried out on the basis of the chemical composition of raw materials and taking into account the compatibility of components from a technological point of view. Therefore, the first step in developing a new product is to analyze the nutritional value and chemical composition of the raw ingredients.

The results of the study of the chemical composition of two fish species: silver carp (*Carassius gibelio*) and silver carp white (*Hypophthalmichthys molitrix*) and Muscovy duck (*Cairina moschata*), presented in table 1.

The analysis of the table shows that the freshwater fish studied belong to the low-fat protein raw material. The crude protein content of the muscle of the silver carp was 18.60 – 18.78% depending on the season of the catch. Protein concentration in silver carp meat was slightly lower and amounted to 17.60 – 17.70%. High levels of protein in muscle in both marine and freshwater aquaculture have been identified by several researchers **(Tacon and Metian, 2013)**. Also, the results of studies **(Pilon et al., 2011; Rudkowska et al., 2010)** confirm the benefits of fish protein in human nutrition.

Protein and fat content in the muscle tissue of aquaculture and duck turned out to be almost identical.

Thus, the concentration of crude protein in duck muscle was 17.36 ±0.09%. Similar data were obtained by **(Mazanowski, Kisiel and Gornowicz, 2003)**. The crude fat of fish and duck muscles was almost the same, at 3.20 – 3.60%, while the total fat of the silver carp was 25.9% higher on average. The moisture content of all three study object objects varied between 75 – 79%, which is described by authors **(Ali, et al., 2007; Tilami and Sampels, 2018)**.

Moisture and protein content in muscle tissue determines the consistency, taste, and yield of the finished product. The moisture content also has a significant effect on the structure of the functional groups of the protein molecules, their stabilization and space configuration, and, thus, on the functional and technological properties of the meat system as a whole **(Huff-Lonergan and Lonergan, 2005)**. A certain prediction of the functional and technological properties of the muscle tissue of aquaculture objects can be made by the indicators of structural-critical coefficients, as C_w, PWF, and LPC. They complement the overall picture of rheological properties, such as effective viscosity. The chemical composition coefficient and the food saturation factor allow us to determine the technological suitability of the resulting mince and to determine possible variants of its combination or rational enrichment.

Table 2 shows the results of the coefficient calculation based on the study of the chemical composition of freshwater fish and Muscovy duck.

C_w of muscle tissue proteins of *Carassius gibelio* is 7.3% and 2.3% higher, depending on the season of catching than the silver carp. This indicates that in muscle tissue of *Carassius gibelio* one part of the protein accounts from 4.31 to 4.36 weight parts of moisture, most of which are insufficiently bound by hydrophilic protein components. Such muscle tissue is more elastic and gel-forming, as well as heat and mechanical resistance, which should be taken into account when selecting the processing method and modes. The moisture and protein ratio in the duck muscles is more balanced and is 3.73.

LPC of the muscle tissue of both the silver carp and the white silver carp had no significant differences. At the same time, some dependence of the values of this indicator on the catching season is traced. Both aquaculture species had LPC above in the autumn catching period, which also indicates a more tender and dense consistency of muscle tissue. Also, the value of LPC can predict the food saturation of raw materials. For duck meat, this figure is more than 3.54 – 4.88 times, which can be used in the selection of components of the formulation of emulsified products, taking into account the balance of nutrients.

The protein-water factor of the muscle tissue of the silver and white silver carp is in the range of 23.17 to 24.4, which indicates the ability to produce products with a gentle and juicy texture. On the other hand, the value of this figure for duck meat is 26.79, which indicates a denser texture. Therefore, the investigated raw material by the size of the PWF is close to the raw material with high molding properties, for which the value of the specified coefficient is normalized in the range from 26 to 30 units.

The calculation of the coefficients of the chemical composition and food saturation showed that the raw material is medium saturated, for which the value of this parameter is determined within 0.3 – 0.6 **(Tischenko, Bozhko and Pasichnyi, 2017)**.

Minced meat is a complex heterogeneous system. Its functional and technological properties depend on the ratio of tissues and their content of specific proteins, fats, moisture, and added components.

Sodium chloride content is one of the main components of the ground beef systems that affect the functional properties of proteins. Its contents and the way of incorporating it into the structure may have different effects on the water-binding capacity of the ground meat systems and, accordingly, on the organoleptic characteristics and yield of the finished products **(Hermansson and Akesson, 1975)**.

The ability of the muscle tissue of fish to bind and hold moisture depends on many factors, including storage temperature, pH, degree of grinding, and more. The size of

the WHC muscle tissue is determined by the content of immobilized moisture in it.

Maintaining of WHC of fish meat in the process of processing at the level of fresh fish indicators is of great practical importance, as it allows increasing the yield and improving the quality of finished products.

With the increase of WHC, the stickiness and elasticity of the forcemeat increases, the shear stress decreases, and the functional properties improve **(Borresen and Alsted, 1983)**.

Salt gives the ground meat some flavor and improves rheological characteristics **(Smith, 2001)**. Thus, the introduction of up to 3% NaCl mincemeat mass increases the solubility of myosin-type proteins **(Bandman, 1999; Chen et al., 2017)**.

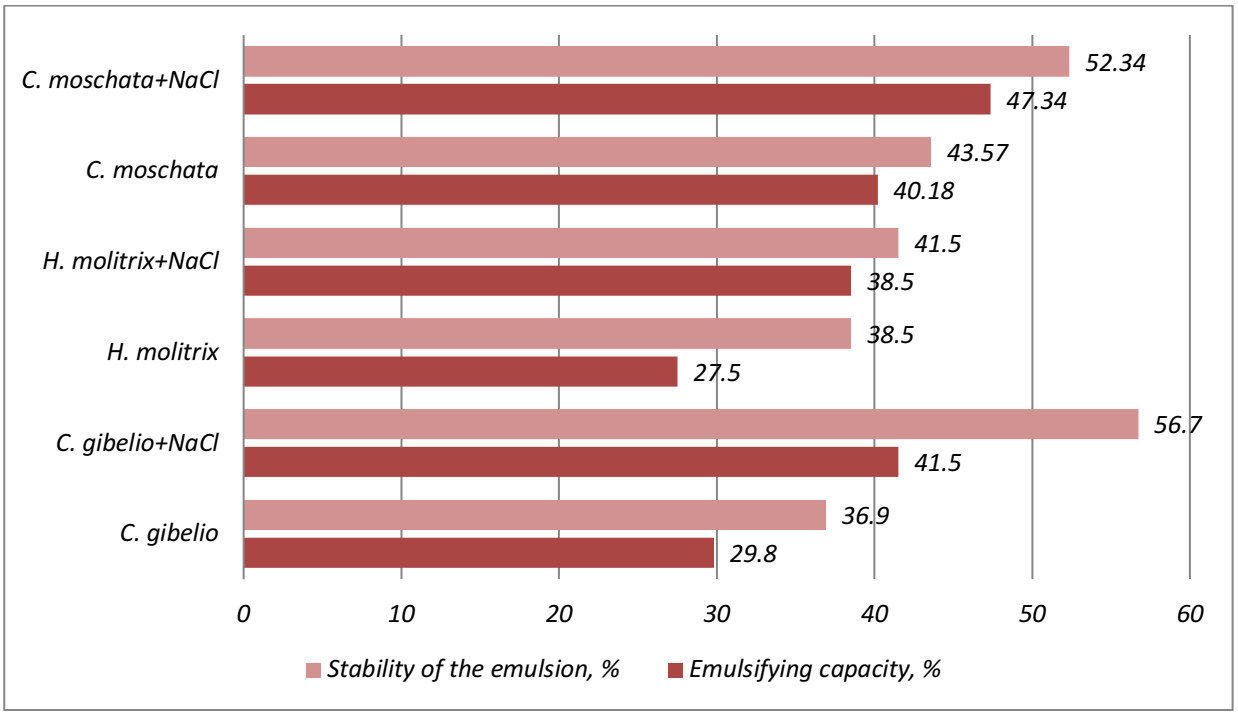

Figure 3 Emulsifying properties of experimental forcemeat samples.

At the same time, it is not recommended to introduce less than 1% NaCl into minced meat, since in this case, it acts as an oxidant **(Tischenko, Bozhko and Pasichnyi, 2016; Mariutti and Bragagnolo, 2017)**.

Table 3 summarizes the results of the functional properties study of minced meat of freshwater aquaculture and waterfowl.

The analysis of the table shows that the introduction into the structure of minced meat of 1.5% of salt has influenced the indicators of WHC and WBC.

The slightly higher indices of moisture-binding and moisture-holding capacity of minced meat in the presence of NaCl can be explained by the increased hydration of muscle tissue. This occurs by a mechanism where functional groups of proteins with electrostatic properties attract water dipoles and thereby increase hydration and WHC. **Ruusunen and Puolanne (2005)** explained in the work that chlorine ions, joining positively charged groups of proteins, support them in a state of swelling.

Good molding properties have forcemeat systems with WHC above 53%. All experimental samples of minced meat had an index of WHC by 10.7 – 13.9% higher than the minimum value, which is consistent by **Petrova and Bogdanov (2019)**.

Shear stress and effective viscosity of aquaculture and duck meat are shown in Figure 1 and Figure 2.

Plastic fluidity of forcemeat with the addition of salt begins at the size of the shear stress 519 Pa of muscle tissue of the crucian, which is 39.8% lower than in forcemeat without salt. It should be noted that there is a general tendency to improve the elastic-mechanical properties of minced meat with the addition of sodium chloride. The lowest viscosity of 195.0 and 205.5 Pa.s are minced without the addition of NaCl, indicating a profound disturbance of their structure and smear consistency.

When mixed with forcemeat 1.5% sodium chloride, there is a significant increase in their viscosity. Thus, the effective viscosity of *Carassius gibelio* muscle tissue increased by 42.8% and amounted to 430.5 Pa·s, and forcemeat of white carp – by 92.2% and became 390.5 Pa·s. The effective viscosity of duck meat was higher than fish and was 409 – 513 Pa·s, increasing with the addition of salt. So, it makes sense to combine fish forcemeat with waterfowl to increase effective viscosity, especially in the presence of NaCl. Analysis of rheological processes in minced meat will allow the use of the results obtained to evaluate and plan the technological processes in the production of combined food.

Results of the physical properties study of hydrobiota minced meat compared to waterfowl meat is shown in Figure 3.

The higher emulsifying capacity of the muscle tissue of *Carassius gibelio* is due to the values of the coefficients C_w and PWF, as well as the content of bound moisture. EC and SE of forcemeat are higher when NaCl is added. The values of these indicators are consistent with the indicators of WHC and WBC of minced fish and are caused by the increased content of water-soluble and salt-soluble fractions of proteins of the muscle tissue of hydrobionts **(Rembeza and Rechina, 1990)**. For this reason, only mobile and flexible macromolecules of proteins can form adsorption layers at the interface of two phases and to form a helical structure of the gel in a continuous phase **(Xiong and Brekke, 1989)**. According to **(Yakubchak, 2006)** the emulsifying capacity of minced poultry meat is 75%, and the emulsion stability is about 70%, which when combined with this raw material with multicomponent functional mixtures based on animal proteins **(Strashynskiy et al., 2016; Yancheva, Dromenko and Grinchenko, 2017)** will allow to effectively develop meat products with a combined composition raw materials.

CONCLUSION

It has been established that the nutritional value of freshwater aquaculture objects, namely *Carassius gibelio* and Muscovy duck, is identical in protein and fat content, making them interchangeable in nutritional balance when developing the combined product.

The ratio of protein, fat, and water for duck meat is higher 3.54 – 4.88 times then for aquaculture, which can be used in the selection of components for the formulation of emulsified products, taking into account the nutrient balance. The protein-water factor of muscle tissue of *Carassius gibelio* and white carp is in the range from 23.17 to 24.4, which indicates the possibility to produce products with a gentle and juicy consistency. PWF for duck meat is 26.79, which indicates a denser consistency. All types of raw materials under study have high molding properties, which indicate the possibility of combining them.

A comparison of the functional and technological properties of fish and duck forcemeat confirms that the addition of salt enhances WHC, WBC, and FHC. At the same time, WBC and WHC of fish are higher due to higher water levels, which, combined with low-watering duck meat, can be predicted to create a high-fat forcemeat system. A comparative analysis of the rheological properties of samples allows suggests that the combination of high-viscosity fish will compensate for the low fluidity of Muscovy duck meat.

The ability to emulsify and holding fat in the state of emulsion in minced duck meat has proven to be better. A combination with fish minced meat can compensate for the ability to retain fat in the system of combined products. Thus, due to the basic functional properties of raw materials and chemical composition, regional aquaculture, combined with waterfowl meat, will not only improve the technological properties of combined meat systems but also balance them by correcting the composition of proteins and fats.

EFFECT OF MODELLED STRESS AND ADAPTOGENS ON MICROSTRUCTURAL CHARACTERISTICS OF PORK FROM FAST-GROWING HYBRID ANIMALS

Anastasia Semenova, Tatyana Kuznetsova, Victoria Nasonova, Roman Nekrasov, Nadezhda Bogolubova

ABSTRACT
This research aimed to study the effect of modelled technological stress and the introduction of selenium and dihydroquercetin (DHQ) into pig diets on the microstructure of *M. longissimus dorsi* muscle tissue. The *in vivo* experiment was carried out on 36 hybrid young barrows (Large White x Landrace) x Duroc) with an initial live weight of 34 – 36 kg until they reached a weight of not less than 110 kg. The animals were divided into four groups: 1 (C-) – pigs did not receive adaptogens and were not subjected to modelled technological stress; 2 (C+) – pigs did not receive adaptogens but were subjected to stress via relocation of animals; 3 (C+Se) – pigs were subjected to stress and received 0.2 mg $Se.kg^{-1}$ feed as selenium proteinate in addition to their diet; 4 (C+DHQ) – pigs were subjected to stress and received 32 mg $DHQ.kg^{-1}$ feed in addition to their diet. The best results regarding the muscle tissue condition were recorded in *the musle L. dorsi* samples were taken from the carcasses of group 4 (C+DHQ). Analysis of variance using the Fisher–Snedecor test confirmed that addition of adaptogens led to an improvement of the pH_{24} value (at $p = 0.05$, $f_{observed} = 5.90 > f_{critical} = 4.17$) and moisture-holding capacity (at $p = 0.05$, $f_{observed} = 3.04 > f_{critical} = 2.92$). The effect of long-term addition of DHQ to pig diets (78 days) on the condition of muscle tissue was studied for the first time, which allowed us to conclude its role in the prevention of myopathic changes in the muscle fibre structure.

Keywords: pork; muscle tissue; myopathy; adaptogen; stress

INTRODUCTION
It is known that the development of degenerative (myopathic) changes in the muscle tissue structure which affect pork quality is a consequence of lifetime stress on the animal and/or inadequate nutrition **(Semenova et al., 2019)**. All types of mammals are exposed myopathic changes **(Herraez et al., 2013)**. Pig breeding and poultry farming have the most economic losses due to myopathic. On poultry farms, up to 70% of the poultry stock is affected by myopathy, which manifests itself on the breast muscles **(Kijowski and Kupinska, 2012)**. Hybrid fast-growing pigs are more sensitive to stress. In these animals, nodes, and bands of super contraction (or hyper contraction), the appearance of which leads to deterioration of pork technological and consumer quality, are seen in muscles after slaughter.

Therefore, the aim of this research was to study the effect of modelled technological stress and the introduction of adaptogens (selenium and dihydroquercetin (DHQ)) into pig diets on the muscle tissue microstructure of *M. longissimus dorsi*.

Scientific hypothesis
The muscles of fast-growing hybrid pigs are characterized by signs of myopathy, which develop in conditions of limited animal movement and under the influence of stress. Destructive changes in muscle tissue leading to a decrease in meat quality. Use adaptogens into feed can reduce the severity of signs of myopathy.

MATERIAL AND METHODOLOGY
The experiment was carried out *in vivo* on 36 hybrid young barrows (F-2 hybrids: (Large White x Landrace) x Duroc)) with an initial live weight of 34 to 36 kg. The animals were kept in the physiological yard of the L.K. Ernst Federal Science Center for Animal Husbandry (VIZh) from May 21 to September 28, 2019. Animals in all groups were kept under the same conditions (temperature, humidity and light regimes, the gas composition of the air inside the building), which corresponded to the zoohygienic norms in all groups. Animals were fed according to the norms of VIZh **(Nekrasov, Golovin and Makhaev, 2018)**. The animals were selected according to the pair-analogue principle and divided into four groups with nine animals in each group:

- control group 1 (C-) – pigs did not receive adaptogens and were not subjected to modelled technological stress;
- control group 2 (C+) – pigs did not receive adaptogens but were subjected to stress after the nursery period until slaughter;
- experimental group 3 (C+Se) – pigs were subjected to similar stress and received selenium proteinate in an amount of 20 mg.kg^{-1} feed (or 0.2 mg Se.kg^{-1} feed) additionally to their diet throughout the experiment until slaughter;
- experimental group 4 (C+DHQ) – pigs were subjected to similar stress and received the dihydroquercetin preparation in an amount of 40 mg.kg^{-1} feed (or 32 mg DHQ.kg^{-1} feed) additionally to their diet throughout the experiment until slaughter.

To create a stress factor in groups C+, C+Se and C+DHQ, the animals were kept in three pens with three pigs in each and were subjected to relocation after 14 days, which resulted in new "neighbors" in a pen (Table 1). In control group 1, animals were also kept in pens with three pigs per pen, but they were not relocated. Each pen corresponded to the norms of pig keeping (concrete floor (1.5 × 2.0 m) with a rubber cover (1.5 × 1.0 m) and was equipped with a nipple drinker and a group feeder with two dividers.

The period of pig fattening consisted of two stages with a diet corresponding to the physiologicalrequirements of animals. The duration of the stages were 42 and 36 days, respectively. Animals were slaughtered using the so-called "peasant method" after they reached a live weight of not less than 110 kg under the conditions of the physiological yard. The pigs were immobilized with a powder-charged handheld captive bolt stunner with a shortened bolt. Samples of muscle tissue were taken from the *M. longissimus dorsi* of chilled carcasses at the level of the last thoracic vertebra and the 6th and 7th lumbar vertebrae.

The following methods were used in the study:

- live weight and weight of hot carcasses were measured by weighing each animal (hot carcass) on REUS-A-PK brand and an error of weight measurement (scale interval) of 0.1 kg; weighing scales with a possible load range of 0 to 300; weighing scales with a possible load range of 0 to 300 kg;
- backfat thickness was measured using a ruler according to **GOST 427-75 (1977)** by measuring backfat thickness over spinous processes between the 6th and 7th thoracic vertebrae without counting hide thickness;
- carcass category was determined depending on carcass weight and backfat thickness according to **GOST 31476 (2012)**;
- pH was measured by the potentiometric method using a pH meter "Teslo 205" with a measurement error of ±0.02. Chilled carcasses were sorted by the mean pH value obtained after statistical processing of the results of not less than five parallel measurements in *M. longissimus dorsi*;
- moisture-holding capacity (MHC) was determined using the press method by Grau and Hamm with the modifications of Volovinskaya **(Zhuravskaya, Alekhina and Otryashnikova, 1985)**;
- microstructural investigations were carried out according to **GOST 19496-93 (1995)**; muscle tissue types were determined using Sudan black staining.

The research was approved by the bioethical commission of the V.M. Gorbatov Federal Research Center for Food Systems of the Russian Academy of Sciences (protocol #03/2019, dated May 31, 2019).

Statistical analysis

Statistical analysis was carried out by least-squares mean comparisons using the PDIFF option of the general linear model procedure (SAS, 2002; SAS Inst. Inc., Cary, NC, USA). Each pig was considered as an experimental unit in measuring growth performance, while an individual sample of pork muscle tissue was used as an experimental unit for analyzing functional technological indices and ratio of different muscle fibre types in *M. longissimus dorsi*. The differences in MHC between groups were confirmed statistically using the Fisher–Snedecor test (F-distribution at $p = 0.05$, degrees of freedom: 3 and 31; $f_{observed} = 3.04$, $f_{critical} = 2.92 \Rightarrow f_{observed} > f_{critical}$). Statistical differences were considered highly significant at $p < 0.01$, significant at $p < 0.05$ and as a tendency between $p \geq 0.05$ and $p \leq 0.10$.). The obtained experimental data were processed biometrically with STATISTICA (vers. 10, StatSoft, Inc., 2011).

RESULTS AND DISCUSSION

During fattening, all four pig groups showed good results expressed as intensive growth; therefore, animal groups did not display statistically significant differences in live weight at any fattening stage nor in hot carcass weight (Table 2).

The fact that live animal weight and carcass weight in all four groups, including the animals that received adaptogens, did not show significant differences and all carcasses were assigned to the 2nd category is in good agreement with the results of foreign studies from different years **(Mahan, Cline and Richert, 1999; Ivanova et al., 2019)**.

Table 2 Live weight of the experimental pigs, weight of hot carcasses and backfat thickness in the control and experimental groups.

Item	Mean value for groups			
	Control group 1, C-	Control group 2, C+	Experimental group 3, C+Se	Experimental group 4, C+DHQ
Live weight at the beginning of fattening, kg	34.71 ±1.24	34.64 ±1.68	34.89 ±0.96	34.51 ±1.11
Live weight at the end of the 1st period, kg	74.33 ±1.85	74.90 ±2.45	73.59 ±0.98	74.43 ±1.85
Live weight at the end of fattening, kg	116.19 ±1.83	115.42 ±1.51	113.03 ±0.56	115.77 ±1.39
Live weight after fasting, kg	109.86 ±1.54	109.76 ±1.36	106.90 ±0.90	109.61 ±1.34
Hot carcass weight, kg	80.04 ±1.48	78.31 ±2.68	78.71 ±0.84	79.91 ±1.09
Backfat thickness, mm	20.44 ±1.45	20.78 ±0.20	20.44 ±1.40	21.33 ±2.05

Note: * – without head, legs, tail, internal organs and internal fat, ** – between the 6th and 7th thoracic vertebrae of the left half-carcass without hide thickness.

Uniformity of the studied animals by weight was important for the following investigation of the effect of stress and adaptogens on muscle tissue microstructure. For example, when studying myopathy in fast-growing chickens and turkeys, it was established that poultry weight affected the frequency of manifestation of pathological changes in muscle tissue **(Kijowski and Konstanczak, 2009)**. In experiments on pigs, not only animal carcass weight but also the backfat thickness and the content of muscle tissue in a carcass (leanness) were assigned to risk factors **(Minvielle et al., 2001)**.

Moreover, non-uniformity of hot carcasses by weight and leanness leads to problems with their chilling after slaughter, which, in turn, can be reflected in post-mortem formation of muscle tissue microstructure **(Petracci and Cavani, 2012)**.

Therefore, significant differences in animal weight and leanness were undesirable as they could influence the development of myopathic changes in muscle tissue, "blurring" the picture of an effect of technological stress and adaptogens. It was noted in our experiment that control group 2 (C+) showed the lowest value of hot carcass weight, and experimental group 3 (C+Se) was distinguished by the lowest values of live weight beginning from the end of the 1st period of fattening up to slaughter. However, firstly, these differences in groups were not statistically significant; secondly, all carcasses obtained as a result of the slaughter of pigs from the control and experimental groups were assigned by weight and backfat thickness to the second category according to the existing Russian standard **(GOST 31476, 2012)**. It was noted in our experiment that control group 2 (C+) showed the lowest value of hot carcass weight, and experimental group 3 (C+Se) was distinguished by the lowest values of live weight beginning from the end of the 1st period of fattening up to slaughter. However, firstly, these differences in groups were not statistically significant; secondly, all carcasses obtained as a result of the slaughter of pigs from the control and experimental groups were assigned by weight and backfat thickness to the second category according to the existing Russian standard **(GOST 31476, 2012)**. The frequency of myopathy manifestation can be linked to reduced pH values in chilled pork. However, many researchers paid attention to the fact that there is a difference between meat with the signs of PSE and meat with the signs of myopathy **(Minvielle et al., 2001; Minvielle et al., 2001)**. The obtained data suggest that the carcasses from groups 1, 2, 3, and 4 did not display statistically significant differences in the average pH_{24} value (Table 3). Moreover, analysis of variance using the Fisher–Snedecor test (F-distribution at $p = 0.05$, degrees of freedom: 3 and 35) confirmed the invalidity of the hypothesis about the presence of differences in the control and experimental groups by the pH_{24} value ($f_{observed} = 2.00$, $f_{critical} = 2.92 \Rightarrow f_{observed} < f_{кр}$).

Quite low pH_{24} values (5.41, 5.40, 5.49 and 5.47) in groups 1, 2, 3, and 4, respectively, were explained by stress in animals directly at slaughter (peculiarities of "peasant slaughter") and indicated distinct manifestation of PSE properties in all meat samples. With that, a trend towards less pronounced PSE properties was observed in the experimental groups that received adaptogens compared with the control. Verification of this statistical hypothesis (at $p = 0.05$, degrees of freedom: 1 and 35) showed its validity ($f_{observed} = 5.90, f_{critical} = 4.17 \Rightarrow f_{observed} > f_{critical}$). This conclusion is in agreement with the results of many studies, which found a positive effect of organic selenium **(Mahan, Cline, and Richert, 1999; Mateo et al., 2007; Li et al., 2011; Calvo et al., 2016; Calvo et al., 2017; Jiang et al., 2017)** and DHQ **(Vlahova-Vangelova et al., 2019)** on the ultimate pH value of pork. The mean values of MHC for control groups 1 and 2, and experimental groups 3 and 4 were 62.61%, 67.05%, 69.18%, and 69.49%, respectively (Table 3). The differences in MHC between groups were confirmed statistically using the Fisher–Snedecor test (F-distribution at $p = 0.05$, degrees of freedom: 3 and 31; $f_{observed} = 3.04, f_{critical} = 2.92 \Rightarrow f_{observed} > f_{critical}$). Thus, the samples from all four groups were different regarding functional-technological properties in the absence of significant differences in muscle tissue pH in chilled pork.

The obtained results showed that the modelled technological stress during animal fattening and the use of adaptogens positively affected pork MHC. Similar conclusions regarding adaptogens were drawn by other studies **(Mahan, Cline, and Richert, 1999; Mateo et al., 2007; Li et al., 2011; Calvo et al., 2016; Calvo et al., 2017; Jiang et al., 2017; Vlahova-Vangelova et al., 2019; Kremer, Stahly and Sebranek, 1998)**.

Differences in MHC in the absence of differences in pH_{24} could be associated with different ratios of the main muscle fibre types in pork.

Note: (n = 5)

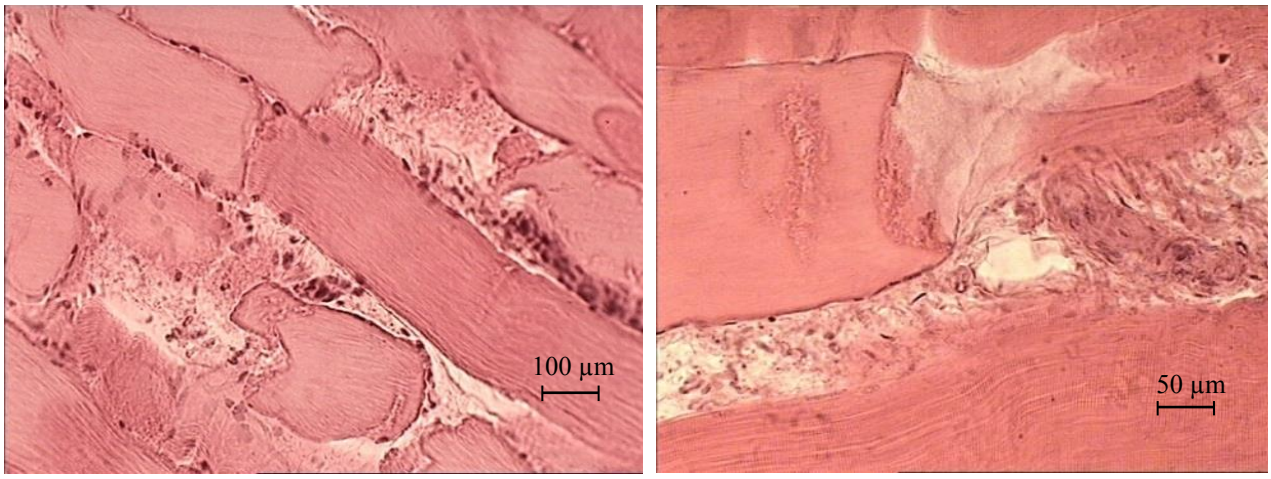
Muscle fibres are dynamic structures, which can change from one type to another under certain conditions **(Listrat et al., 2016)**.

The proportions of type I fibres (red, slow, oxidative), type II fibres (white, fast, glycolytic) and intermediate types depends on many factors, including muscle function, animal species, breed, age, physical activity, ambient temperature, nutritional and so on.

It is known that porcine skeletal muscles, especially in fast-growing hybrids, show a tendency towards an increased content of type II muscle fibres **(Lefaucheur et al., 1998)**. With that, several studies show that destructive changes in muscle tissue, including the development of myopathy and meat quality deterioration, are linked with the prevalence of type II fibres **(Realini et al., 2013; Kim et al., 2018; Lee et al., 2012)**. The highest content of type II fibres is typical for *M. longissimus dorsi*. In this context, it is recommended that this muscle be sent for histological investigations to diagnose myopathic conditions in pigs **(Realini et al., 2013; Cooper and Valentine, 2015)**.

The proportion of type II (glycolytic) fibres influences a tendency in meat tissue towards post-mortem development of nodes and bands of hypercontraction (so-called "giant fibres"), which are formed during the pig's lifetime and directly linked with poor quality meat **(Kim et al., 2018; Schubert-Schoppmeyer et al., 2008)**.

In our experiment, microstructural investigations of *M. l. dorsi* (Table 4) showed that the ratio of the main muscle fibre types was within the range of literature data (78.4% to 78.6%). According to the results of similar studies **(Listrat et al., 2016; Sales and Kotrba, 2013)**, the proportion of white fibres in *m. L. dorsi* of fast-growing hybrids can be up to 90%. As a rule, red and intermediate fibres on average account for 10% each. Our results are in agreement with these tendencies.



a) b)

Figure 1 Microstructure of muscle tissue with signs of myopathy. Note: Longitudinal section. Non-uniform cross-striation (samples from groups 1 and 3). a) – nodes and bands of supercontraction with ruptures of myofibrils with a length of up to 800 µm. b) – formation of fine-grained protein mass at the sites of muscle tissue destruction as a result of damage to the sarcolemma integrity.

As follows from the data in table 4, some differences in the content of red and intermediate fibres were observed between the samples from the control and experimental groups. For example, the samples from experimental group 4 were characterized by the highest content of red fibres (11.9%) and the lowest content of intermediate fibres (10.2%), which likely had a positive effect on the functional-technological characteristics of muscle tissue but do not fully explain them.

During microstructural investigations of sections stained with haematoxylin and eosin, the complex of morphometrical indices of muscle tissue was determined, including the characteristics of white muscle fibres (Table 5).

Minimum and maximum sarcomere length in samples of *m. Longissimus dorsi* from animals of all groups were characterized by a rather wide range of values. The most stable sarcomere sizes were observed in sections of the samples from group 4. All samples from carcasses of animals subjected to the stress factor (groups 2, 3 and 4) showed a tendency towards an increase in the thickness of the connective tissue layers (perimysium) and an increase in the thickness of the fat tissue layers. The latter tendency was most pronounced in the muscle tissue samples from animal carcasses of groups 3 and 4, which received adaptogens. The mean diameter of muscle fibres without signs of supercontraction in the samples of all groups was quite uniform and corresponded to the animal species and characteristics of the muscle that was chosen for investigation (*M. longissimus dorsi*).

At the same time, all samples showed signs of myopathy, which were manifested in peculiarities of generative changes in the structure of white muscle fibres. In the samples of control group 1, the diameter of nodes of contraction in the cross-sections was 60 to 80 µm. The bands of super contraction with multiple ruptures of myofibrils with a length of up to 800 µm with non-uniform cross-striation were observed in the longitudinal sections. The fine-grained protein mass was found at the sites of muscle fibre destruction as a result of damage to the sarcolemma integrity.

Similar changes in the structure of white muscle fibres were also observed in the muscle tissue samples from the third group of animals, which received selenium. With that, the fibre diameter in the nodes of contraction was 80 to 100 µm.

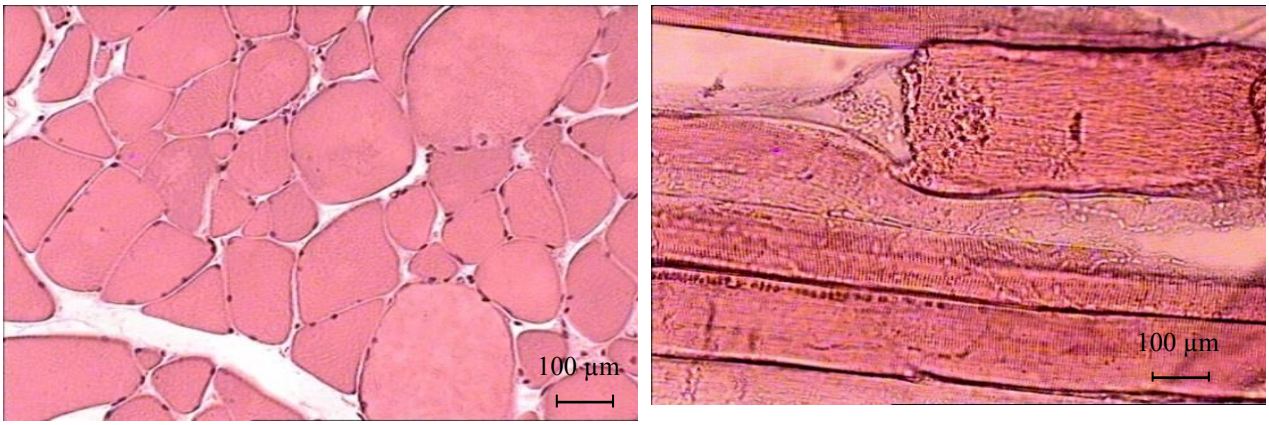
The revealed pathological changes in the samples from groups 1 and 3 corresponded to the picture of myopathy (Figure 1 and Figure 2).

In the samples from group 2, upon similar sizes of white fibres in nodes of contraction (80 to 100 µm), the bands of super contraction with the lengths of not more than 400 µm were observed in the longitudinal sections, which allowed diagnosis of only moderate myopathy.

In the samples from group 4, bands of super contraction had a maximum length of not more than 350 µm, which undoubtedly facilitated better retention of pork functional-technological properties and partly explained the high results obtained in MHC measurement. On the other hand, a higher proportion of red fibres was found in the samples from group 4, which can also facilitate higher MHC values. The pathological changes revealed in the samples from groups 2 and 4 corresponded to the picture of moderate myopathy (Figure 3).

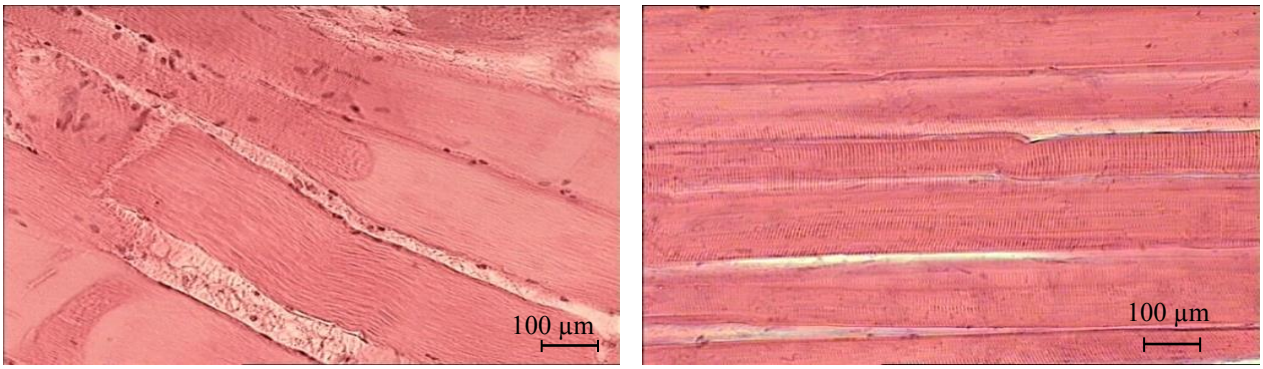
A comparison of the results of microstructural investigations showed that supplementation of animal diets with DHQ had a greater effect on the condition of pork muscle tissue than the use of selenium in the diet. These results are in good agreement with the data of other researchers.

For example, it was concluded in three studies **(Calvo et al., 2016; Falk et al., 2018)** that the addition of selenium, irrespective of the source, in the diet did not influence the muscle tissue condition. However, it was suggested that during meat aging selenium could enhance destructive changes in muscle tissue caused by an increase in the activity of tissue enzymes. It is necessary to note that data on the effect of DHQ on the condition of pork muscle tissue w not found in the available scientific literature.



a) b)

Figure 2 Microstructure of muscle tissue with signs of myopathy (samples from groups 1 and 3). Note: a) – nodes of supercontraction with the round shape in the cross section and a diameter more 100 µm; b) – nodes of supercontraction of myofibrils with pronounced longitudinal striation and ruptures of the sarcolemma more 100 µm in the longitudinal section.



a) b)

Figure 3 Microstructure of muscle tissue with signs of moderate myopathy (samples from groups 2 and 4). Longitudinal section. Note: a) – nodes of supercontraction of myofibrils with ruptures of sarcolemma and pronounced longitudinal striation with a length near 400 µm. Non-uniform cross-striation; b) – transversal bands of myofibril supercontraction in the muscle fibre structure Muscle fibres with the straight shape and pronounced cross-striation lay loosely in relation to each other.

However, the results of recent studies on laboratory animals have shown that long-term addition of quercetin (analogue of DHQ) reduces muscle damage **(Hollinger et al., 2015; Mukai et al., 2016).**

Therefore, the combination of modelled technological stress during animal fattening with the addition of DHQ into a diet partly leveled pork quality deterioration caused by an effect of pre-slaughter stress in animals, allowing the production of meat with moderate signs of myopathy and, consequently, with higher functional-technological characteristics.

CONCLUSION

A decrease in pork functional-technological characteristics, such as MHC, is not always conditioned to the full extent by the pH value of muscle tissue. The manifestation of myopathy, which is expressed in destructive changes in muscle tissue, is typical for fast-growing hybrid animals fattened under conditions of industrial enterprises. The results of this study showed that the presence of such modelled technological stress factors as the relocation of animals during fattening positively influenced the muscle tissue microstructure after slaughter. At the same time, additional incorporation of DHQ as an adaptogen reduced the development of myopathy signs to a greater extent. DHQ showed better results in this regard than selenium as a distinct manifestation of destructive regions in muscle tissues was lower in the group of animals that received DHQ in the diet for a long time. In the future, accumulation and systemization of scientific data on the manifestation of pathological changes in the muscle tissue structure and methods for their prevention will allow more effective management of the process of lifetime formation of pork quality.

IDENTIFICATION OF THE NEEDS OF PRIMARY MILK PRODUCERS IN THE NEW COMMON AGRICULTURAL POLICY 2021 – 2027

Petronela Švikruhová, Zuzana Kapsdorferová, Radka Kataniková, Zuzana Poláková, Pavol Grman

ABSTRACT

Although Slovakia belongs to the smallest milk producers in the EU, we have to bear in mind the importance of the milk industry for the economy of Slovakia. Current expectations in Slovakia are that primary milk producers are able to produce milk at the lowest possible price, with state support on the same level as in other EU states, processing companies have a good purchasing price for the raw materials, retailers are able to share margins and to increase the market share of Slovak dairy products and last but not least that consumers buy milk and dairy products produced in Slovakia. Milk production in primary production has a profound ecological and social benefit for our countryside but the most important is the contribution of milk and dairy products to human health. The Slovak dairy sector has experienced three dairy crises and one butter crisis in the last ten years, what caused that up to 37% of milk producers in Slovakia cease their production. Currently, there are 401 approved primary milk producers in Slovakia. This sector is in long-term condition weakened by market fluctuation and by previous crises. Slovakia has a large investment debt in this sector. That is why in order of food security and maintaining employment it should be in the interest of the new government to do everything possible to stabilize this sector. Therefore, the primary objective of this scientific paper is to identify the needs of primary milk producers in Slovakia in relation to the strategic objective – to increase the competitiveness of the milk producers. The research aims to transform the voice of primary milk producers into the new programming documents for the upcoming period of the Common Agricultural Policy (CAP) for the years 2021 – 2027.

Keywords: milk; primary milk producers; dairy sector; common agricultural policy

INTRODUCTION

The importance of milk and dairy products to human nutrition has been repeatedly confirmed by nutritionists around the world. Milk, as the most complex food, has been one of the main foods since ancient times. The existence of human society cannot be imagined without the milk. Its composition makes milk irreplaceable for a healthy diet.

Milk is a highly nutritious food containing many macro- and micronutrients that are essential for the growth and maintenance of human health **(Iqbal et al., 2015)**. The main biological components of milk include protein, fat, lactose, minerals (calcium, phosphorus, potassium, magnesium) as well as essential nutritional substances, vitamins and other important substances, which form a comprehensive balanced food for all age categories of the population **(De la Fuente and Juárez, 2015; Šimo, Mura, and Buleca, 2016)**.

Milk proteins present in the milk are made of casein and whey proteins which are nutritionally and technologically essential and represent an irreplaceable amino acid intake for humans **(Bartošovičová, 2011)**. Milk proteins contain 18 out of 22 essential amino acids that cannot be created by the human body itself and that are inevitable for running of the human body; and are divided into two basic groups, i.e. caseins and whey proteins. Milk is rich in vitamins, namely vitamin A, B (especially B1, B2, B3, B6, and B12), C, D, E, and K **(Gonda, 2009)**.

Other essential nutrition components of milk are carbohydrates (especially lactose) and fats. Lactose is a hydrocarbon that can only be found in milk and has a significant role in energy production. Lactose is simply a certain kind of sugar presented in milk **(Kurajdova and Táborecká-Petrovičová, 2015)**. Milk fat, representing an easily digestible emulsion containing lecithin and a relatively low level of cholesterol, is another important ingredient in milk **(Kubicová, Predanocyová and Kádeková, 2019)**.

Besides the fact that milk has a notable positive nutritional impact on the human body, it is characterized by a pleasurable effect on health and disease prevention. Although a lot of various researches and studies on health aspects and disease prevention effects of drinking milk and consuming milk products are still in progress, there are

several interesting conclusions and findings which came to light.

The most recent scientific evidence supports the consumption of cow's milk and dairy products as part of a balanced diet. Current scientific literature suggests that appropriate consumption of milk and its derivatives may be beneficial at all ages, except specific medical conditions such as lactose intolerance or milk protein allergy **(Marangoni et al., 2019)**.

Scientific hypothesis

This research paper aims to identify the needs of primary milk producers in Slovakia in relation to two strategic objectives (to increase the competitiveness of the milk producers and their position in value chains) and transform their voice into the new programming documents for the upcoming period of the Common Agricultural Policy for the years 2021 – 2027.

Several hypotheses were formulated:

Hypothesis 1: There exists a dependence between the legal form of business and land area.

Hypothesis 2: There exists a dependence between the legal form of business and the number of dairy cows.

Hypothesis 3: There exists a dependence between the legal form of business and number of employees.

Hypothesis 4: There exists a dependence between the region and average milk yield per cow.

MATERIAL AND METHODOLOGY

In order to fulfill the stated objectives, we chose a questionnaire survey as the main method. This method was chosen mainly because the questionnaire generally represents a series of different types of questions that are answered by respondents. The content, number, and type of questions are determined by the purpose of the survey and the target group for which the questionnaire is intended. The questionnaire is suitable for obtaining data from many people. Due to the uniformity of the formulations, the data can be processed, and the responses of different groups can be easily compared. In general, the questionnaire is an "economical" tool in terms of data collection and processing (depending on the type of questions).

The questionnaire survey aimed to gather information from primary milk producers, to analyse the current situation and identify the needs of primary milk producers in the new CAP 2021 – 2027. For this purpose, the questionnaire consisted of two parts:

1) The current state of the primary milk producers.
2) Identification of the needs in the new CAP 2021 – 2027 concerning the strategic objective – to increase the competitiveness of the milk producers

The survey was carried out in September – November 2019 by sending a link to an electronic questionnaire by e-mail but mainly by personal inquiry of the Slovak primary milk producers.

The criteria for determining the survey sample were all primary milk producers in Slovakia. Out of a total of 401 primary milk producers in Slovakia, we managed to reach 104 primary milk producers, who represent 27% of the total number of respondents surveyed. In Figure 1 below, we can see the legal form of the respondents surveyed.

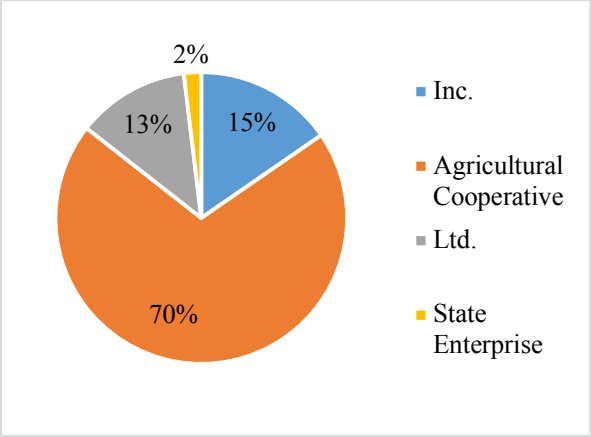

Figure 1 The legal form of the respondents surveyed. Note: Own processing based on questionnaire survey.

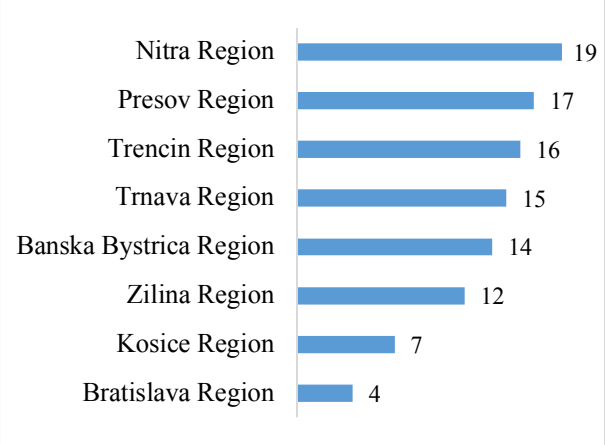

Figure 2 Regional representation of enterprises. Note: Own processing based on questionnaire survey.

Table 1 Number of dairy cows as of 31/08/2019 in Slovakia.

Indicator	Total SR (pc)	Analyzed (pc)	Share in SR (%)
Number of dairy cows as of (31/08/2019)	124 030	40 713	33%

Note: Own processing based on Statistical Office of Slovak Republic.

The largest share of respondents was represented by agricultural cooperatives (70%).

Figure 2 shows the regional representation of the respondents surveyed. The largest share of respondents was from the Nitra region.

In Table **1** below the number of dairy cows can be seen. In Slovakia, there are registered in a total of 124 030 dairy cows as of 31/08/2019. Together our analysed sample had 82 303 all cattle categories and out of this number, our analysed sample had in total 40 713 dairy cows which represent 33% share in Slovakia. The smallest enterprise had just 103 dairy cows and the largest enterprise had 3 146 dairy cows.

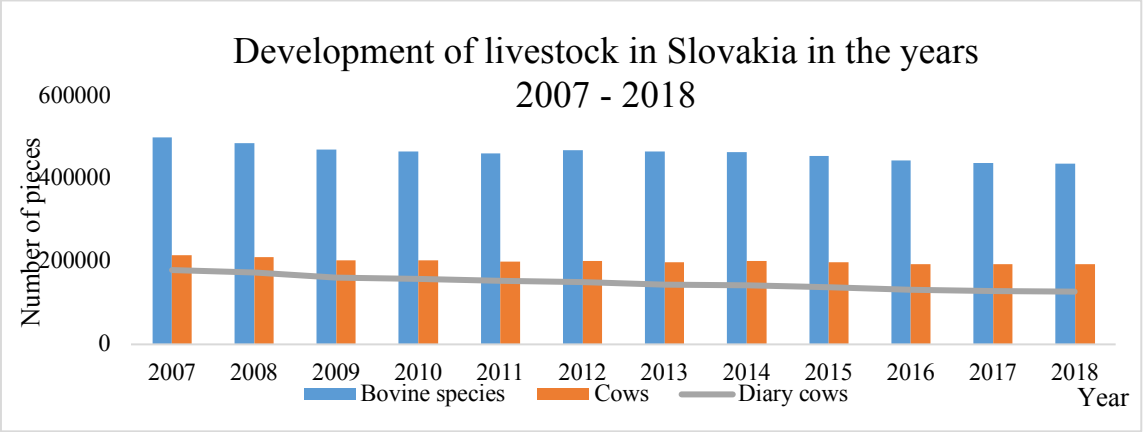

Figure 3 Development of livestock in Slovakia in the years 2007-2018. Note: Own processing based on Statistical Office of Slovak Republic.

Table 2 Development of the Consumption of Milk and Dairy Products in kg per capita in the SR (2007 – 2017).

	Year										
	2007	**2008**	**2009**	**2010**	**2011**	**2012**	**2013**	**2014**	**2015**	**2016**	**2017**
Milk and dairy products (kg)	153.4	153.0	153.8	162.8	156.9	158.6	158.5	166.8	169,2	176,2	174,6
Milk (kg)	52.4	48.3	49.5	54.5	53.1	54.3	49.3	48.3	48.1	46.5	46.4

Note: Own processing based on Statistical Office of Slovak Republic.

After analysing the number of dairy cows we also decided to analyse milk deliveries of our analysed sample.
In Table 2 the share of analysed enterprises in the milk deliveries in Slovakia can be seen. In our survey, we analysed 40% of the whole milk deliveries in the Slovak Republic.

Statistical analysis

The selection of tests is designed particularly because of variables in research. The attention is paid to the formulation of hypotheses (null and alternative) and to determine the level of significance. The collected data were processed by using Microsoft Excel and subsequently evaluated in the statistical program XL Stat. The formulated hypotheses were tested by applying the following statistical tests:

1) Shapiro–Wilk test
2) Chi-square contingency test
3) ANOVA test
4) Kruskal Wallis test

In hypothesis testing, if the p-value is lower than a significant level, in the case of XL Stat software by Addinsoft (version 2019.3.2), it is 0.05, the null hypothesis was rejected and the alternative hypothesis was confirmed.

RESULTS AND DISCUSSION

Raw cow milk represents one of the most important commodities in the agricultural market. The Slovak agro-food foreign trade is characterized by a substantial increase in the commodity trade, monitoring of competitiveness is therefore very important **(Šimo, Mura, and Buleca, 2016)**. The major part of the milk production is represented by the cow milk. Other milk types such as the sheep, goat, and milk of other species have specific properties as well as the use in human and animal consumption **(Matić et al., 2014; Gavurová et al., 2014)**.

In Slovakia, there are currently approved 401 primary milk producers that process milk. The Slovak dairy sector has experienced three dairy crises in the last ten years. The Slovak dairy sector is weakened and financially undersized due to large fluctuations in the market. In the interests of food security and maintaining employment, it is important to do everything possible to stabilize the dairy sector.

Cows' breeding can be considered as strategic, especially concerning other categories of cattle and its connectivity to arable land and permanent grass-land. Cattle breeding represents a crucial condition to maintain a balance between the plant production and breeding processes of agricultural business activities **(Siničáková, 2012)**.

In the reporting period, we can observe a decline in livestock in Slovakia (Figure 3). Likewise, the decreasing character can be observed in the number of cows together as well as in the number of dairy cows. It is interesting to note that on the 1st April 2015, when milk quotas were abolished, the number of cows in Slovakia did not increase. However, in recent years Slovakia has had an annual milk production quota of 1 billion litters, which has not been fulfilled.

Table 3 Milk deliveries for the year 2018 (kg) of the analyzed sample.

Indicator	**Total SR (kg)**	**Total Analysis (kg)**	**Share in SR (%)**
Milk deliveries	817 000 000	326 352 835	40%

Note: Own processing based on Statistical Office of Slovak Republic.

The decline in livestock in Slovakia may also be due to a decline in the reproduction and reproductive characteristics of cattle (the indicators of reproduction of the basic herd and reproductive characteristics of cattle decline year-on-year).

By applying the Chi-square contingency test, hypothesis 2 was confirmed that there exists a statistically significant dependency between the legal form of business and the number of dairy cows (p = 0.05). The testing criteria F is higher than the table value χ^2, therefore we reject the null hypothesis.

In the last year in the reported period, the percentage of heifers and cows fertilized and the proportion of heifers transferred to cows decreased.

On the other hand, the percentage of cows culled as a result of cow mortality has decreased. Deaths of calves were slightly increasing year-on-year. Similarly, fertility indicators deteriorated year-on-year. The number of calves born per 100 cows and the number of calves raised per 100 cows decreased by up to 2.71. The average daily weight gain of fattening cattle increased year-on-year by 0.019 kg/KD, reaching 0.765 kg per head per day per year.

In general, the dairy sector is very labour intensive and people are not interested in working there. According to our analysis, on average one employee takes care of 48 dairy cattle. Hypothesis 3 assumed dependency between the legal form of business and the number of employees. By applying the Chi-square contingency test, hypothesis 3 was not confirmed and there is no statistically significant dependency between the legal form of business and the number of employees (p = 0.05). This means that we do not reject the null hypothesis.

Milk, as one category of dairy products, belongs to the group of basic daily-consumed products characterized by relatively high purchase frequency **(Kurajdova, Táborecká-Petrovičová, 2015)**. Based on their nutritional values, milk and dairy products have an irreplaceable role in daily consumption. On the other hand, the consumption of milk and dairy products is experiencing a certain negative trend in Slovakia compared to other countries in Central Europe.

In Table 3, we can see the development of milk and dairy products consumption in 2007 – 2017 (per capita/year). The consumption of milk and dairy products in Slovakia is increasing from year to year but we are still below the recommended consumption by the World Health Organization (WHO).

According to the WHO, the recommended consumption of milk and dairy products is at least 220 kg per person per year. However, the actual average consumption in Slovakia is currently significantly lower. On average it is only 178 kg per person per year. The average consumption in Europe is over 320 kg per person per year. This means that according to the WHO recommendation, each person should consume at least a glass of milk or a cup of sour milk products such as yogurt or acidophilic milk, plus a portion of butter and 100 g of cheese or cheese products daily.

Even though Slovakia belongs to the smallest milk producers in the EU, we have to keep in mind the importance of the milk industry for the economy of Slovakia. Application of the Chi-square contingency test, as well the hypothesis 1 was not confirmed and there is no statistically significant dependency between the legal form of business and land area (p = 0.05). This means, that we do not reject the null hypothesis.

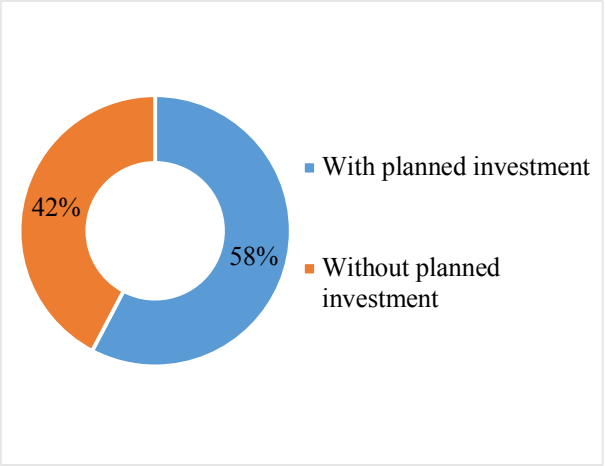

Figure 4 Investments into the housing. Note: Own processing based on questionnaire survey.

The current situation in Slovakia is complicated. We expect:

1) milk producers to be able to produce milk at the lowest possible price,
2) state support at the same level as in other EU states,
3) processing companies to have a good purchase price for the raw material,
4) retailers to be able to share margins and to increase the market share of Slovak dairy products, and
5) consumers to buy milk and dairy products originating in Slovakia.

One of the most important issues within the CAP is the support of milk production **(Folmer, et al., 2013)**. The present experience with the CAP that was introduced into the milk market did not result in the anticipated effects. The price of milk is highly volatile, and the production is changing. The demand for milk has been changing with people consuming less milk per capita worldwide. The success of any future policy affecting the milk market depends on communication between policy makers and farmers **(Alpmann and Bitsch, 2017)**.

Dairy farmers need to invest in keeping their farms in good condition, maintain competitiveness on the market, increase the rate of technology adoption, and improve labour productivity **(Pouch and Trouvé, 2018)**.

For this reason, we decided to identify the needs of primary milk producers and transform their voice in the new CAP 2021 – 2027. Investments realized in dairy farms allow the implementation of new technologies and involve benefits associated with an increase in efficiency, a reduction in costs, an improvement in the quality of products and a reduction in the adverse impact on the environment, and an improvement in animal welfare **(Bewley, 2010)**.

Based on this, in this paper, we focused on analysing the investments of dairy farmers into housing, milking, feeding, water feeding and water supply, storage capacity, pasture system, waste management, and welfare. Firstly, we analysed the investments into the housing – objects for cattle. In Figure 4 it can be seen that 58% of respondents plan the investments into the housing of cattle in the next year. These investments were divided into two main

categories, the reconstruction of the old objects and the construction of the new ones.

Up to 68% of respondents are planning the reconstruction of existing buildings and just 32% of respondents plan to build a new stable for cattle.

Respondents with planning investments into the reconstruction mostly plan the complete reconstruction of the building such as the reconstruction of the roof, electricity, water, replacement of windows, reconstruction of sanitary facilities, isolation), some of them plan just small construction work such as demolition of the side walls to increase the volume of fresh air, to build ventilation slots or to install or replace stall ventilation. In terms of animal housing responders plan to replace fences, bed mattresses, drinkers.

As shown in Figure 5 above, our respondents plan housing in total for 31 545 different categories of bovine species in 2020. These animals are planned for both stables, for the new ones as well as for the reconstructed ones. The highest number of planned animals is represented by cows (17 700 pc.) followed by heifers (5 830 pc.), young cattle (4 850 pc.), and the smallest number is represented by calves (3 165 pc.).

The planned volume of investment for housing by our respondents is approx. 75 million €. Our estimated volume

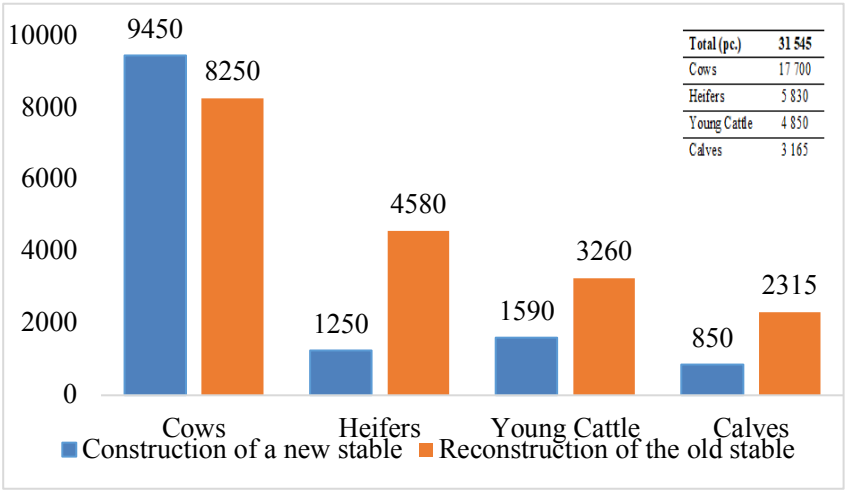

Figure 5 Planned capacity for different categories of bovine spieces. Note: Own processing based on questionnaire survey.

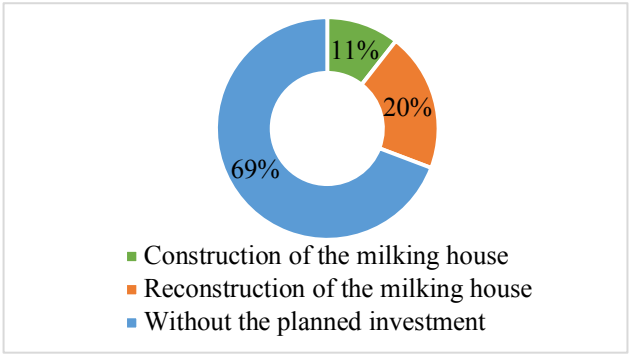

Figure 6 Objects for milking technology. Note: Own processing based on questionnaire survey.

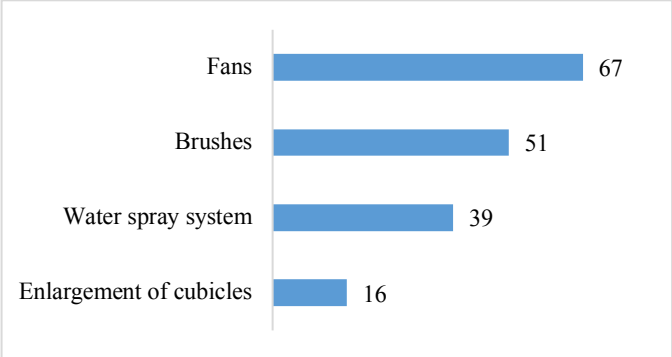

Figure 7 Planned welfare investments of primary milk producers in 2020. Note: Own processing based on questionnaire survey.

of housing investments in Slovakia is approx. 200 million €.

The investment in housing is really necessary for Slovakia because stables in which milk is produced are often in a bad condition. During our research, we found out that up to 77% of all stables were built between the years 1950 – 1990. These objects often do not fulfil the conditions for sufficient animal welfare, which may cause lower milk yields and thus affect milk deliveries.

Talking about Milking - objects for milking technology up to 69% of the respondents in 2020 do not plan investments, 20% of respondents plan to do some reconstruction and just 11% of respondents plan to build a new one (Figure 6).

Based on the survey, we found out that primary milk producers plan to invest in the purchase of milking robots (up to 10% of the respondents) in a total of 46 pieces in 2020. Milking robots are automatic milking systems where milking is performed without the direct participation of an operator **(Andrews, Davison and Pereira, 2016)**. It seems that milking robots are becoming popular systems also among Slovak farmers. This system relies on the use of the computers and the special herd management software, which means reducing labour cost from the partially manual milking.

However, according to **Shortall et al. (2016)** any decision to invest in automatic milking should consider several factors, such as the availability of skilled labour, lifestyle sought by the farmer, the interest in technology, and the initial capital investment requirement by the milking system.

The planned volume of investment for milking by our respondents is approx. 14 million €. Our estimated volume of objects for milking technology in Slovakia is approx. 35 million €.

Talking about investments in feeding and water feeding, we found out that most primary milk producers plan to invest in the fodder mixing wagon in 2020. On the contrary, the least interest is in investment into feeding robots. In recent years, great success has been made in the field of autonomous robotics. To date, autonomous robots have already been widely used in dairy farming that is a labour-intensive industry involving many tasks such as feeding, milking, livestock management, etc. Gradually, these robots appear to become huge advantages especially in aspects of increasing productivity, improving accuracy and decreasing labour costs **(Cheng, 2016).** In Slovakia, feeding robots are not popular among Slovak primary milk producers yet.

The planned volume of investment for feeding by our respondents is approx. 9 million €. Our estimated volume of feeding investments in Slovakia is approx. 25 million €.

In terms of the type of investments in technology and equipment to provide water for animals, our responders mainly utilize the water pumped from bored or dug wells or from free-flowing natural groundwater springs so their planned investment is primarily into water well drilling, reconstruction of hydro-globes (water towers), extension or construction of water distribution from an existing well or construction of a public water connection.

The planned volume of investment for water security by our respondents is approx. 1 million €. The estimated amount of investment for water security in Slovakia is 3 million €.

Regarding storage capacity, our analysed sample plans to invest in the reconstruction or construction of forage warehouses, feeding troughs, and hay-lofts. The estimated volume of investment of the analysed sample in the storage capacity is 9 million €. Our estimated amount of investment in the storage capacity in Slovakia is 20 million €.

Last but not least part of our research was animal welfare. In recent years, the animal welfare debate in livestock farming has continued to grow, including dairy cattle farming **(Koik, Thiele and Enneking, 2019)**.

According to **Buller and Morris (2003),** discussions about animal welfare generally begin with an often-unarticulated ethical assumption that it is morally acceptable for humans to use animals so long as they ensure that animals are free of physical and mental stress and able to experience positive feelings. On the other hand, animal rights movements consider any use of animals to be morally objectionable and argue for the development of dairy and meat alternatives **(Garner, 2016)**.

Understanding of animal welfare tends to include consideration of three aspects: (1) that welfare comprises animals' essential health and functioning (i.e. absence of disease and injury); (2) the need to consider animals' 'affective states' (such as pain, distress, and pleasure) and how positives and negatives add up to a quantitative indicator of well-being; and (3) animals' freedom to pursue 'natural' behaviours (e.g. grazing in the open air), including their ability to exercise control in a given situation to remove themselves from 'poor' situations and place themselves in more positive mental and physical states **(Fraser 2008; Ohl and Van der Staay 2012; Arnott, Ferris and O'Connell, 2017)**.

In literature about the welfare of animals, different authors have tended to emphasize different concerns. Given the complexity to understand the concept of animal welfare we understand it as a summary of three key points:

1) welfare comprises animals' essential health and functioning (i.e. absence of disease and injury);
2) the need to consider animals' 'affective states' – states like pain, distress, and pleasure as positive or negative add up to a quantitative indicator of well-being; and
3) the ability of animals to live reasonably natural lives by carrying out natural behaviour and having natural elements in their environment (e.g. grazing in the open air) **(Fraser 2008; Ohl and Van der Staay 2012)**.

An inadequate environment and breeding techniques mean that a significant proportion of livestock is in a state of chronic stress which greatly reduces the resilience, viability, longevity, production, and reproduction of genetically high-value animals. We must, therefore, respect the demands of animals to create the conditions for them to live and produce.

The number of days with extremely high temperatures in Slovakia is constantly increasing and according to the forecast, it is going to increase. Global warming significantly affects the animal's life which also affects how they are bred. Most breeders in Slovakia are not prepared for this. Therefore, they plan investment into modern technologies to reduce this negative impact of climate extremes. Appropriate ventilation is one such solution.

As you can see in Figure 7 primary milk producers plan to invest in different combinations of methods and practices of welfare in 2020. Respondents are most interested in fans. In

extreme summer conditions, when the air flow in the stables decreases and the air exchange is inadequate, breeders use fans to support the air flow. The second of planned welfare investment were brushes which improve the health of cows and have a very beneficial effect on blood circulation. At the same time, they increase the comfort and convenience of the cows, which affect milk production. Many responders also plan to invest in the water spray system to form an aerosol substance that cools the air. There were many answers with a combination of water spraying systems with fans which is a suitable solution to enhance the effect of air cooling. The responders are not certainly interested in the enlargement of cubicles (Figure 7).

The dairy sector is undergoing major structural changes in the EU. Current changes in the dairy sector affect farm efficiency, profitability, and long-term economic sustainability **(Cabrera, Solis, and Del Corral, 2010)**.

Dairy farmers need to invest to keep their farms in a good condition, maintain competitiveness in the market, increase the rate of technology adoption, and improve labour productivity **(Schick and Hartmann, 2005; Pouch and Trouvé, 2018)**.

In our research, we also identified the other forms of support to increase the competitiveness of Slovak milk producers such as:

1) Support investment in livestock production and new technologies of livestock production. Farm investment support is one of the EU Rural Development Programme policy instruments provided to enhance farm productivity, agricultural production efficiency and thus farm competitiveness **(Hurňáková, Bartová, and Fandel, 2016)**.
2) Create the same conditions for all EU milk producers. We believe that the new programming documents of the new CAP 2021 – 2027 will reflect this requirement. A new CAP delivery model should lead to a more results-based policy and greater flexibility in its implementation while preserving its common dimension **(Rossi, 2018; Matthews, 2018)**.
3) Linking science with practice and better cooperation with universities (educational and consulting activities, analyses, benchmarking). Many respondents would be interested in collaboration with universities. The biggest advantage of cooperation they see in the preparation of project documentation as well as in the analysis of various data.
4) Assistance in natural disasters. Natural conditions are one of the important factors affecting the economic competitiveness of dairy farming in relation to other agricultural activities **(Bórawski et al., 2020)**.
5) To raise awareness regarding the importance of milk production and milk consumption in the Slovak Republic. Milk production is important for society as a whole, both in terms of the economy of the state and the employment of the rural population. It is a traditional economic sector that due to its very favourable conditions promises a very viable future **(Gurčík, et al., 2016)**.

Finally, we would like to look at the last tested hypothesis, hypothesis 4. In **Error! Reference source not found.** below, we can see that the F-value is lower than the F-critical value for the alpha level selected (p = 0.05). Therefore, the null hypothesis is valid and sample means are equal, or they do not have any significant difference. Based on the One- way ANOVA we can say with a probability of 95% that the average milk yield per cow does not depend on the region.

Even though nonparametric methods show less power compared to parametric methods, we have decided to use the Kruskal-Wallis test for testing the last hypothesis. Similarly, the Kruskal-Wallis test did not confirm the existing differences between a region and an average milk yield per cow.

Within the individual regions of Slovakia, there is a different level in the development of the average milk yield per cow. Based on available data from previous years, Bratislava and Nitra regions significantly influence the achieved level of milk yield in Slovakia. On the contrary, in the east of Slovakia, the number of dairy cows is increasing every year.

On the member-farm level, the abolition of the EU milk quota system opened up new entrepreneurial options for farm growth. At times when milk prices were relatively high, such as in the years 2011 – 2014, many farmers invested in the expansion of their milk production.

Table 4 Anova:Single Factor.

Source of Variation	SS	df	MS	F	*p*-value	F crit
Between Groups	38035074.27	7	5433582	1.957673	0.068965	2.107506
Within Groups	263675400.6	95	2775531			
Total	301710474.8	102				

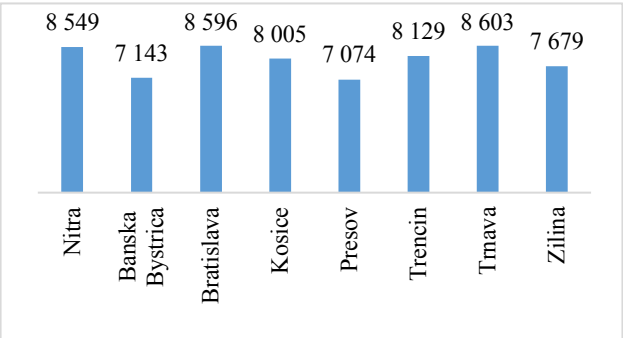

Figure 8 Anova: Single factor. Note: Own processing based on questionnaire survey.

However, when prices steeply declined in 2015 and 2016, the same farmers were not ready to accept the low prices offered to them by their cooperatives **(Nagy and Jámbor, 2019)**. The Slovak dairy market has been in an unfavourable situation in recent years. Long-term low prices of raw cow milk led to the liquidation of primary milk producers **(Váryová et al., 2019)**. The year 2019 was one of the better years for primary milk producers. After some time, the situation has improved, mainly thanks to the recovery of milk purchasing prices (32.6 cents per kilogram over the year) but also thanks to some support **(Štefániková, 2020)**.

CONCLUSION

Although the situation in the milk sector is improving, not all primary milk producers achieve the balanced cost of milk production. No one is producing milk at the same cost. Several factors affect milk production. It is different to produce milk in mountainous areas and the flat south, so natural conditions also affect it.

In our research, we pointed out the current situation and needs of milk producers in Slovakia in relation to the strategic objective – to increase the competitiveness of the milk producers. The sample we examined plans to increase the number of milk deliveries by 2.6% in 2020. This fact is very positive for the sector. On the other hand, costs have risen again, either because of rising energy prices or because of rising labour costs caused by the government measures and the conditions in which the milk is produced are insufficient. The oldest stables in which dairy cattle are kept exist on average 50 years. We certainly need to make our primary milk producers more competitive. In the upcoming period, we need a government that will prioritise and support the development of the dairy sector.

CONSUMER PREFERENCES AND DECISION-MAKING DETERMINANTS FOR THE PURCHASE OF SHEEP'S MILK AND ITS PRODUCTS

Ľudmila Nagyová, Andrej Géci, Elena Horská

ABSTRACT

When observing consumer behaviour, we find that the consumer carries out the process of purchasing decisions under the influence of several factors. These factors come from the external environment, from its individual characteristics, and also from the specific purchasing situation. The above facts show that consumer preferences and understanding of the behaviour is a very demanding process. This is mainly because consumers may behave differently, i.e. they may have different consumer behaviours that depend on their needs and desires. Therefore, it is necessary to know the factors that influence consumer behavior or the purchasing decision for certain market commodities. The presented research document is focused on the issue of consumer behavior and decision-making in sheep's milk and its products. Sheep's milk has a long tradition and is one of the basic building elements of human food. Consumer behaviour is constantly evolving, their needs and desires are changing as well as factors that influence their shopping behaviour. The main goal of the research is to draw attention to the personality of the consumer, to selected personality characteristics and social factors, and, subsequently, to evaluate their impact on purchasing behaviour and making purchasing decisions on the market of sheep's milk products. Primary data were obtained from a survey conducted on a sample of 796 respondents. Most of the respondents were classified in the sanguine group based on temperament - an emotionally stable extrovert. When buying sheep's milk and its products, they make emotional decisions (57.17%). The most important factor in buying these products was their quality (47.16%). Assumptions were formulated for deeper analysis, which was subsequently verified by the means of a statistical test - Chi-square of the square contingency. The degree of dependence between the examined variables was determined by the means of the Cramer contingency coefficient.

Keywords: consumer; sheep´s milk; sheep´s milk products; consumer behaviour; decision-making determinants

INTRODUCTION

Humans develop during their lives. They learn new things, come up with new ideas and thoughts, and ultimately change their behaviour **(Christensen et al., 2014)**, behaviour towards other people in their lives but also their behaviour when buying common goods of daily consumption. On the one hand, shopping methods, preferences, tastes are changing, and on the other hand, the determinants of the influence on their shopping behaviour are constantly changing **(Yadav and Pathak, 2017)**. In general, consumers develop over their lifetime. Currently, most consumers are becoming rational and conscious, as they live in a very fast period **(Vuelvas and Ruiz, 2017)**. Recent years have shown that consumers pay close attention to what they put in their shopping cart when shopping **(Ertemel and Ammoura, 2019)**. The authors **Rana and Paul (2017)** claim that in recent years there has been a growing consumer demand for healthy and especially high-quality food. This interest is causing a positive year-on-year growth in the market for organic products.

Consumer, their behaviour and decision-making

A consumer is every person whose primary task is to satisfy needs and desires through the purchase of various goods and services **(Javornik, 2016)**. These needs and desires can be his/hers but also another family member. In this case, when a family member buys goods and consumes them at the same time, we are talking about the consumer **(Biswas and Roy, 2015)**. According to **Lemon and Verhoef (2016)**, there is another type of consumer and that is the customer. For them, only a shopping act is typical. The customer does not get to the consumption and satisfaction of needs through purchased goods **(Dabholkar, 2014)**. On the contrary, a person who only consumes pre-purchased goods and products without purchasing activity is called a consumer **(Goodman and Paolacci, 2017)**. Each person has gone through all phases

of purchase and consumption in their lives. Based on the above, consumer behavior is a constantly changing process, the basis of which is the reflection of external but mainly internal attributes **(Trudel, 2018)**. Consumer behaviour is defined by **Drossos et al. (2019)** as the intentional conduct of individual purchasers, whose primary task is to satisfy their needs. They try to meet these needs at the highest possible level **(Coronel et al., 2019)**.

Determinants of consumer behaviour

Various factors play a role in enabling consumers to make the right purchasing decisions. These factors often operate at the unconscious consumer level **(Victor et al., 2018)**. One of the main influences on the consumer when buying is still the price of goods or services. The monetary expression of the value of goods is perceived most among consumers whose incomes do not reach high numbers **(Malc et al., 2016)**. According to **Roux et al. (2017)**, however, solvent customers are much less prone to the pricing value of goods and services. Another important determinant is the product brand. Consumers are fond of reaching for familiar and already tried and tested products. If they are satisfied with a particular good or service, it is very difficult to get their affection to focus their attention on a competing product and to buy and try it **(Godey et al., 2016)**. In the research by **Madzharov et al. (2015)**, who discussed the relationship between the fragrance and space, the increased interest in premium and branded products was confirmed. The authors state that the smell influences the spatial perception of consumers in the shopping environment, which affects the feeling of the power of customers and thus the preferences of individual products and, ultimately, their shopping behaviour. Impulsive behaviour is also a very important determinant. **Holly (2019)** states that while this form of shopping behaviour will bring greater satisfaction to the seller, in the end, consumer behaviour is satisfied at a lower level. Very important determinants of the impact on consumer behaviour are consumer preferences, food trends, and also eating habits. In recent years, as a result of the growing interest in health, there is a preference for quality and organic products **(D´Amico et al., 2016)**. Last but not least, the basic determinants include sufficient information that determines the purchase. **Jiang and Yang (2018)** argue that when looking for basic information about the products, the consumer's purchase is influenced by their needs, values, and interests. Therefore, individual companies need to build a certain competitive advantage. To achieve such an advantage, consumers must receive food products of different quality and the necessary information, which would allow consumers to make their choice easier **(Gracia and Magistris, 2016)**. An important step in the decision-making process is also the attention that is a prerequisite for the consumer to thoroughly process the information **(Drexler et al., 2017)**. Consumers also have the opportunity to use heuristics (methods of problem-solving) to simplify their decisions, through which they do not pay the required attention to all product features **(Loo et al., 2015)**. Based on the above factors, it is interesting to analyze consumer determinants that lead to justification and understanding of consumer behaviour **(Aquilani et al., 2015)**.

Sheep's milk and its products

The present document also deals with the consumption of sheep's milk, in particular with the cheeses made from this type of milk. In general, we can encounter various reasons why people do not consume this milk **(Kurajdová et al., 2015)**. The most important reason is the content of lactose in milk and its products. The lactose content is higher in cow's milk products, as it decomposes in individual product processing processes. This process does not take place in sheep's milk products and therefore the milk and its products are also intended for people suffering from lactose intolerance **(Balthazar et al., 2017)**. Concerning the content of fat and vitamins, the fat of sheep's milk is twice as high and the content of vitamins is higher than that of cow's milk **(Revilla et al., 2017)**. A negative attitude towards the consumption of sheep's milk products may also stem from one's own beliefs but also the lifestyle of consumers **(Griebler et al., 2016)**. The development of sheep breeding in Slovakia is constantly changing. Since 2013, it has been constantly declining. In 2019, the number was at the level of more than 351 thousand head of sheep. Compared to the previous year, this is a decrease of more than 14,000 head **(Horalová, 2019)**. Based on the decline in sheep farming, it is clear that sheep milk production is also declining. According to **Horalová (2018)**, consumption in 2018 was at the level of 1.3 million kg. As for world sheep milk production, it is headed by Greece, followed by Spain, Italy, and Romania **(Palo, 2015)**. According to the **Ministry of Agriculture and Rural Development of the Slovak Republic (2019)**, the estimated consumption of sheep's milk per capita is on average around 2 kg (in 2018 it was 1.96 kg per capita). The average selling prices of sheep's milk according to **Huba et al. (2018)** for the year 2018 are around 1 Euro (specifically 0.98 EUR per liter of sheep's milk).

Scientific hypotheses

Assumption n. 1: We assume that there is a relationship between the age of the respondent and the consumption of sheep's milk.

Assumption n. 2: We assume that there is no relationship between the respondent's temperament and the factor that most influences them when buying sheep's milk.

Assumption n. 3: We assume that the personality in terms of emotional stability/lability has an impact on the emotional behaviour and decisions of consumers on the food market.

Assumption n. 4: We assume that the consumer's extroverted/introverted personality does not affect their emotionality in food market behaviour and decisions.

Assumption n. 5: We assume that the type of consumer temperament influences their emotional behaviour and decision-making in the food market.

MATERIAL AND METHODOLOGY

Based on the findings of consumer behaviour on the market of sheep's milk and its products, a questionnaire method was used. The survey was conducted online using the Google Forms tool. Data acquisition was carried out at the turn of two years (2019 – 2020) and took place in the Slovak Republic. The sample was 796 respondents. The survey was divided into four parts. The first part focused

on the Eyesenck personality test, which determines the temperament, emotional lability/stability as well as extroversion/introversion. The second part focused on factual issues related to consumer behaviour when buying food. This part focused on consumer behavior on the market, i.e. whether they act emotionally or rationally. The third part focused on specific-factual issues, which were focused on the consumption of sheep's milk, consumer preferences, and also on the factors influencing the purchase. The last part of the questionnaire survey was focused on classification questions. In the beginning, it was necessary to process and evaluate Eyesenck's personality questionnaire. To evaluate the test, a publicly available and in practice used evaluation method was used - tabular application of values in a template, which is based on the horizontal and vertical axes.

Table 1 Rating scale intervals – temperament.

Type of temperament	Rating scale on the Y-axis	Rating scale on the X-axis
Melancholic	<13 – 24>	<0 – 11>
Choleric	<13 – 24>	<13 – 24>
Phlegmatic	<0 – 11>	<0 – 11>
Sanguine	<0 – 11>	<13 – 24>
Uncertain	= 12	= 12

Table 2 Rating scale intervals – emotionality.

Consumer	Rating scale
Rational	<1 – 24>
Emotional	<24 – 40>

Table 3 Characteristics of Respondents.

Category of Respondents	%	Place of Residence	%
Male	34.30	City	51.88
Female	65.70	Village	48.12
Age Structure	**%**	**Net monthly income (€)**	**%**
Up to 26 years	41.33	Up to 500	41.08
27 – 33 years	16.33	501 – 800	28.77
34 – 45 years	18.84	801 – 1 000	14.20
46 – 55 years	14.07	1 001 – 1 500	10.43
56 – 62 years	4.77	1 501 and more	5.53
63 and more years	4.65		
Education	**%**	**Economic activity**	**%**
Primary school	4.40	Student	26.88
Vocational school	6.91	Employed	59.92
Secondary school	43.47	Unemployed	6.66
University	45.23	Retired	6.53

The position of the resulting point (Table 1) represents the location in one of the four quarters, with each quarter representing a different temperament.

This was followed by a survey of consumer behaviour to assess consumers' emotional reactions, views, and attitudes in the sheep's milk market. The finding is based on a scale as an attitude test. It includes 8 items for which the respondents indicate the degree of their agreement or disagreement with the above statements concerning behaviour and decision-making when purchasing food products. A Likert 5 point scale was used (1 – strongly disagree, 2 – disagree, 3 – don't know, 4 – agree, 5 – strongly agree). Within this assessment, a gross emotionality score has been calculated, which can be in the range of 1 to 40. The higher the score, the higher the tendency of the consumer to behave emotionally. Individual respondents were evaluated based on a specified interval of the rating scale (Table 2).

The structure of the obtained data according to the gender was as follows - 65.70% of women and 34.30% of men. The age structure was divided into 6 age categories. The age structure up to 26 years had the largest share (41.33%). The highest achieved education was at the university level (45.23%). Regarding the economic status of the respondents, most of them (59.92%) are employed. Within the net monthly income per respondent, the largest interval turned out to be an income not higher than EUR 500 (41.08%). Most of the respondents stated the city as their residence and most respondents live in the Nitra region. More information on the structure of respondents is given in Table 3.

Statistic analysis

At the beginning of the questionnaire survey, the scientific assumptions were set, the validity of which would be verified using selected statistical methods. Contingency tables were applied to the obtained primary data and subsequently, the data were evaluated by the means of qualitative statistics - the Chi-square test of good agreement. The degree of dependence between the examined variables was determined by the means of the Cramer contingency coefficient.

If the calculated test criterion $\chi 2$ is higher than or equal to $\chi 2$ for the significance level $\alpha = 0.05$ and degrees of freedom (r-1) * (s-1), then the H_0 hypothesis is rejected, which means that there is a relationship between the given variables. Conversely, if the calculated test criterion $\chi 2$ is less than $\chi 2$ for the significance level $\alpha = 0.05$ and degrees of freedom (r-1) * (s-1), then H_0 hypothesis is accepted, which means that there is no dependence between the given variables.

RESULTS AND DISCUSSION

The research was implemented to identify the temperament, extroversion/introversion of the respondent or emotional stability/lability, and then define their impact on emotional or rational behaviour on the sheep's milk market and also to ascertain consumer attitudes towards the sold milk products. Therefore, it was necessary to categorize respondents at the beginning of the research. The sorting was carried out based on the question of whether they consume sheep's milk and sheep's milk

products. Thus, the respondents who answered positively to the above question continued. 642 respondents (80.65%) answered this question in the affirmative. The first part of the research was focused on determining the temperament, extroversion/introversion, and also on emotional stability/lability through Eyesenck's personality questionnaire. Figure 1 shows approximately the same proportion of unstable and stable individuals in the sample of respondents. Emotionally stable people predominate (345 respondents), which is 54.33%. On the contrary, in a smaller proportion (297 respondents), the respondents are emotionally unstable.

Based on the above-obtained results, we can state that a large number of people do not have neurotic tendencies, i.e. they are emotionally stable. They are characterized by less sensitivity and suspectivity to other people. They are characterized by endurance and resistance, they react calmly and are not subject to impulsive reactions. They consider decisions precisely and have their emotions and feelings under control. On the other hand, there are people with neurotic tendencies, which represent their lability. They are more sensitive and easier to be swayed. Almost identical results were found in a research document by **Rybanská (2015)**. The author discusses the fact that both groups of people are important for marketing research, as it is necessary to properly set up and target a marketing strategy along with communication to a selected segment of consumers.

The statistical observation was made on an assumption whether the personality in terms of emotional stability / lability has an impact on the emotional behavior and decision-making of the consumer on the food market.

H_0: We assume that personality in terms of emotional stability/lability does not influence the emotional behavior and decisions of consumers in the food market.

H_1: We assume that personality in terms of emotional stability/lability has an impact on the emotional behavior and decisions of consumers in the food market.

We have used the Chi-square test of square contingency to verify the hypotheses. In this case, the tabular value was at the level of 3.84 and the test characteristic was calculated at the level of 12.20, which means that we reject the null hypothesis. We accept the alternative hypothesis and claim that the personality in terms of emotional stability / lability influences the emotional behavior and decisions of consumers on the food market. Based on the test results, we consider the assumption to be correct. The strength of the observed dependence was subsequently investigated with the use of the Cramer correlation coefficient (0.17), based on which it can be stated that there is only a small correlation / weak dependence between the analyzed variables.

Figure 2 shows approximately the same proportion of introverted and extroverted respondents. Out of the total number of filtered respondents, we refer to 347 respondents as extroverts. The remaining more than 45% of respondents can be ranked based on a personality test among introverts (295 respondents).

Based on the above results, we can conclude that a larger number of respondents are extroverts. Impulsive action is typical for this type of personality (they act first and then

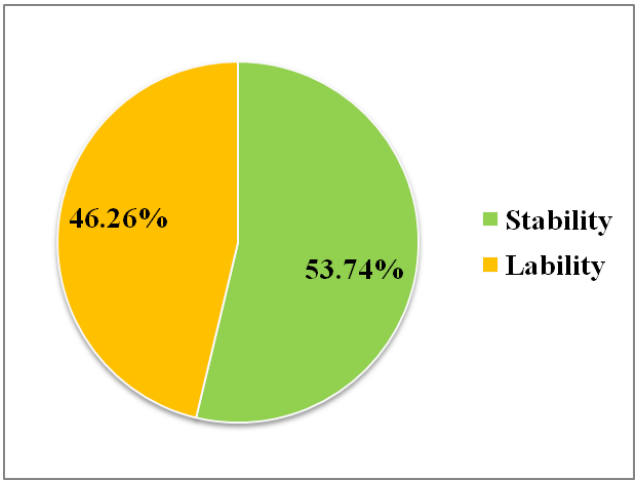

Figure 1 Structure of respondents according to the scale of extraversion.

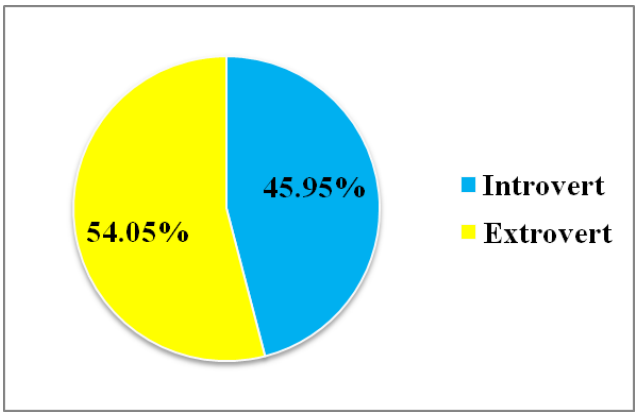

Figure 2 Structure of respondents according to the scale of extraversion.

think), they have a strong need for contact with the external environment. They also like diversity, they are open and motivated towards other people and things. On the contrary, the introverts are motivated internally, they are trying to establish an authentic connection with the others. The team of authors **Lu et al. (2015)** concluded that even with this division of people, one mentioned group of people in marketing research cannot be forgotten, as their response to stimuli is different.

A statistical observation was made on the established assumption that the extroverted / introverted personality of the consumer does not influence his emotionality in behaviour and decision-making on the food market.

H_0: We assume that the consumer's extroverted/introverted personality does not affect his/her emotionality on food market behaviour and decision-making.

H_1: We assume that the consumer's extroverted/introverted personality influences his/her emotionality on food market behaviour and decision-making.

To verify the hypotheses, we have used the Chi-square test of square contingency. In this case, the tabular value was equal to 3.84 and the test characteristic was calculated at 0.18, which means that we reject the alternative hypothesis. We accept the null hypothesis and claim that

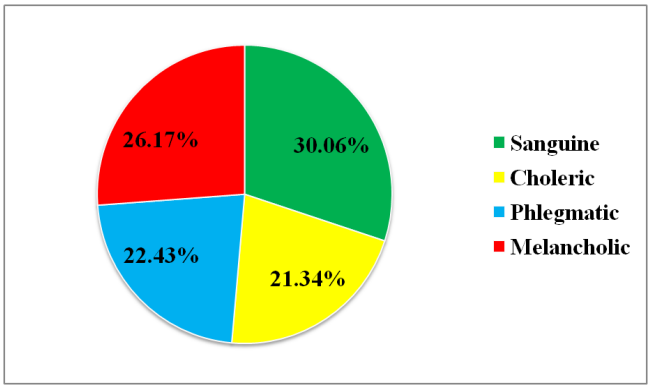

Figure 3 Structure of respondents according to temperament.

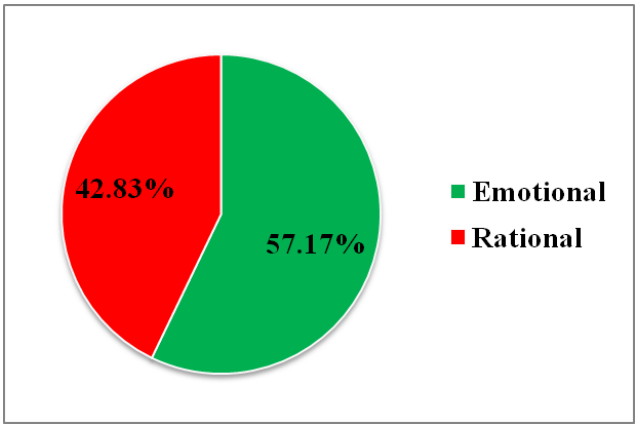

Figure 4 Emotional vs. rational consumer behavior.

the consumer's extroverted/introverted personality does not affect his/her emotionality on food market behavior and decision-making. Based on the test results, we consider the assumption to be correct.

If we reconcile the above dimensions of the personality test (emotional stability/lability and extroversion / introversion), Hippocrates' 4 types of temperament (phlegmatic, sanguine, choleric, and melancholic) can be confirmed. The distribution according to temperament is shown in Figure 3.

The most represented group among the evaluated respondents are sanguine, who is represented by 193 respondents in the total number. The team of authors **Ul Islam et al. (2017)** claims that they are characterized by high mental activity and performance, but also by a rapid appearance and alternation of emotions. The second most represented type of temperament is melancholic (168 respondents). This type is characterized by a slow course of emotions, but with great intensity and longer duration. The third group of temperament was a phlegmatic (144 respondents). Low levels of mental activity are typical for phlegmatic. The last group of temperaments is choleric people (137 respondents), who are characterized by a high level of mental activity, energetic action, sharpness, short temper, the strength of movements, fast, pace and irascibility.

The second part of the survey was focused on identifying the emotionality manifested in the consumer behaviour of respondents. The task was to classify the respondents into two groups, namely emotional and rational consumers (Figure 4). In this section, 8 statements were presented, in which the respondents had to mark their answers in the form of a Likert scale (assign points from 1 to 5).

Figure 4 shows that emotional consumers (367 respondents) are more represented in the research sample. They are characterized by the fact that they are strongly influenced by emotions when making purchasing decisions, their rational choices remain slightly in the background. The second group is rational consumers (275 respondents). Emotions do not have a significant effect on this type of person The team of authors **Dwivedi et al. (2019)** states in their research that the fact of how they feel when buying remains in the background. It is typical of them that they consistently consider all possible alternatives and carefully compare them.

A statistical observation was made on the established assumption - that the type of consumer temperament influences his/her emotional behaviour and decision-making on the food market.

H_0: We assume that the type of consumer's temperament does not influence his/her emotional behaviour and decision-making in the food market.

H_1: We assume that the type of consumer's temperament influences his/her emotional behaviour and decision-making in the food market.

To verify the hypotheses, we use the Chi-square test of square contingency. In this case, the tabular value was 3.84 and the test characteristic was calculated at 18.30, which means that we reject the null hypothesis. We accept the alternative hypothesis and claim that the type of consumer temperament influences his/her emotional behavior and decision-making in the food market. Based on the test results, we consider the assumption to be correct. The strength of the detected dependence was subsequently investigated with the use of the Cramer's correlation coefficient (0.18), based on which it can be stated that there is only a small correlation or weak dependence between the analyzed variables.

The last part of the research was focused on consumer behaviour on the market of sheep's milk and its products. In this part, we investigated consumer behaviour to the purchase of specific types of sheep products, reasons for consumption, the places of purchase, factors influencing the purchase, and also factors that would increase the consumption of these specific types of food. The first question in this part was focused on the specific types of sheep 's milk products purchased (Figure 5).

It follows from the above figure that most respondents prefer sheep cheese (197 respondents), other popular and consumed products are parenica (steamed cheese), nite (string cheese), and korbáčiky (braided string cheese), which were mentioned by 164 respondents (12.81%). Oštiepok (cheese preserved by smoked cure) was purchased by 138 respondents, i.e. 17.34% of the total number of respondents. This was followed by hard and lump cheeses – 164 respondents (20.60%), sour milk (sheep´s whey) – 69 respondents (8.67%) and yogurts (76 respondents). The least interest among consumers is in sheep's milk, which is bought by only 6.28% of respondents (50 respondents).

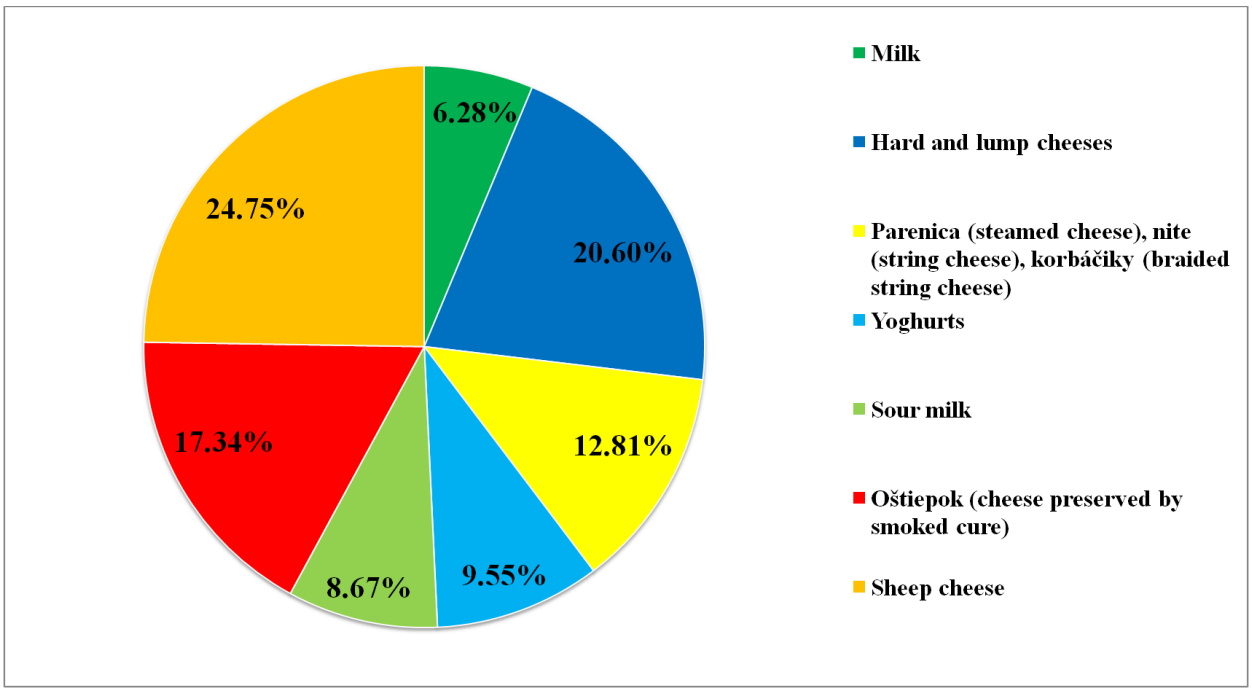

Figure 5 Purchased types of sheep products.

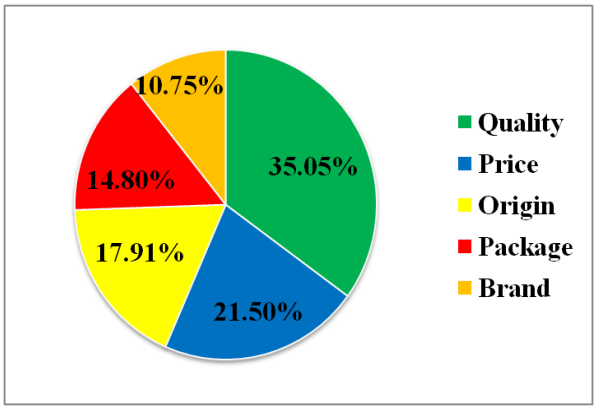

Figure 6 Factors influencing the consumer when buying sheep products.

A statistical observation was made on the established assumption - whether there is a relationship between the age of the respondent and the consumption of sheep's milk.

H_0: We assume that there is no relationship between the age of the respondent and the consumption of sheep's milk.
H_1: We assume that there is a relationship between the age of the respondent and the consumption of sheep's milk.

To verify the hypotheses, we use the Chi-square test of square contingency. In this case, the tabular value was 11.07 and the test characteristic was calculated at 39.40, which means that we reject the null hypothesis. We accept the alternative hypothesis and claim that there is a relationship between the age of the respondent and the consumption of sheep's milk. Based on the test results, we consider the assumption to be correct. The strength of the observed dependence was then investigated using the Cramer correlation coefficient (0.34), based on which it can be stated that there is a small almost medium correlation / dependence between the analyzed variables.

Another issue dealt with the reasons for consuming sheep's milk and sheep's milk products. Most respondents answered that the reason for consuming these products is their taste (55.76%). This was followed by the health factor (23.21%), nutritional value (19.47%), and finally other reasons for consumption, which were identified by 10 respondents (most often they reported consumption based on support for sheep breeding in Slovakia).

This was followed by a question that focused on the specific purchase of sheep's milk and its products. We, therefore, asked where specifically (which store) consumers buy these products. They most often make purchases in retail chains (48.44%). The main advantage of retail chains is time availability, which is a very important criterion for more and more buyers. Discounts and supermarkets, as a modern type of store in the vicinity, are gaining in importance, and buyers shop here more often. On the contrary, the importance of small and counter stores is declining and specialized stores are defending their position only with difficulty **(Silver et al., 2016)**. Another shopping place is local stores (29.13%) and the last place was a specialized store (22.43%).
The penultimate question of inquiry followed, and these were the factors that influence the consumer when buying sheep products (Figure 6).

The most significant influence on the purchase of sheep products is quality (225 respondents). Then the price (138 respondents), origin, and packaging follow. In the last place was the brand factor, which was marked by 69 respondents.

A statistical observation was made on the established assumption – whether there is some dependence between the respondent's temperament and the factor that most influences them when buying sheep's milk.

H_0: We assume that there is no relationship between the respondent's temperament and the factor that most influences them when buying sheep's milk.

H_1: We assume that there is a relationship between the respondent's temperament and the factor that most influences them when buying sheep's milk.

To verify the hypotheses, we use the Chi-square test of square contingency. In this case, the tabular value was at the level of 21.03 and the test characteristic was calculated at the level of 11.54, which means that we reject the alternative hypothesis. We accept the null hypothesis and claim that there is no relationship between the respondent's temperament and the factor that most influences them when buying sheep's milk. Based on the test results, we consider the assumption to be correct.

Most respondents know that the consumption of sheep's milk and sheep's dairy products is low in Slovakia. Therefore, the last question was focused on the reasons that would lead to higher consumption of sheep's milk and its products. Most respondents stated that the reason that would increase their consumption is the greater availability of products (25.86%). The second factor was a lower price (24.61%), followed by better promotion (22.43%) and higher quality (17.91%). Other respondents indicated a different option saying they would not be motivated by anything.

CONCLUSION

The survey showed that more than half of the respondents are emotionally stable (53.74%). Within the personality type, there is a higher proportion of extroverts (54.05%). The sanguine was most represented within the temperament (30.06%) and emotional types of respondents predominate (57.17%) within decision-making based on emotions.

In 2016, the Commodity Council for Sheep and Goats of the Ministry of Regional Development of the Slovak Republic stated that consumer interest in sheep products is increasing. Based on the results, it can be stated that the consumption of sheep's milk and sheep's products is not so high in Slovakia. More than 80% of respondents in the study consume sheep's milk and sheep's milk products. The rest of the respondents do not consume these products and the most common reasons were unpopularity, preference for cow's milk over sheep´s milk, health reasons such as the allergy or intolerance, as well as high prices or unavailability. The most frequently consumed and also purchased sheep product is sheep cheese (24.75%), which is considered a traditional Slovak product. Other popular and consumed products among people are cheeses (20.60%), oštiepok (cheese preserved by smoked cure) – (17.34%). The research also found that consumers in the market of sheep's milk products use mainly retail chains as a place of purchase (48.44%). According to the respondents, the most important factor that affects the purchase of these products was their quality (35.05%). According to consumers of the survey, the price also has a significant impact (21.50%). An important finding was to obtain information about what would motivate consumers or would lead to higher consumption of sheep's milk and its products. The research shows that most respondents would welcome more accessibility (25.86%), followed by a lower price (24.61%) and better promotion (22.43%).

FUNCTIONAL PROPERTIES OF THREE NATIVE STARCHES AND THEIR MODIFIED DERIVATIVES

Funmilayo Deborah Adewumi, Labunmi Lajide, Abayomi Olagunjoye Adetuyi, Olajide Ayodele

ABSTRACT

Starches were isolated from cocoyam (*Xanthosoma sagittifollium*), white yam (*Dioscorea rotundata*) and bitter yam (*Dioscorea dumentorum*). Starch modification was carried out using acetic anhydride and phthalic anhydride. The native and modified starches were characterized using Fourier Transformed Infra-red Spectroscopy (FTIR) for identification of the functional groups. Functional properties such as water absorption capacities, oil absorption capacity, swelling power, solubility, gelation temperature, least gelation capacity, amylose content and pH were determined using standard procedures. Acetylation increased the water absorption capacity, oil absorption capacity, swelling power, amylose content, and solubility of the starches while phthalation decreased water absorption capacity, oil absorption capacity, swelling power, and solubility of the starches. Native cocoyam starch has the highest gelation temperature (85 °C) while Acetylated bitter yam has the lowest gelation temperature (74 °C). The pH of the native and modified starches was within the range of 4.14 − 6.55. Phthalation and acetylation increased the bulk density of the starches. Native cocoyam, white yam, and bitter yam starches had the lowest gelation concentration (6%). Modification of native starches will improve the usage of starch in food and non-food applications.

Keywords: native starch; phthalation; gelation; amylose; pregelatinized starch

INTRODUCTION

Starch is one of the most available natural polymers is a starting material or an intermediate for many chemical industries **(Yadav and Garg, 2013)**. Starch is a useful raw material for adhesive industries because of its availability and abundance **(Yu et al., 2009)**. Starch has been applied as a filler and bonding agent in the making of tablets, it is also used as an additive to improve the shelf life of soaps and detergents. Other uses of starch are in the rubber and foam industries **(Tonukari, 2004)** and the food industry **(Dura and Rosell, 2016)**.

In the food sector, starch is being used to give divers functionalities which include stabilizing, gelling, encapsulating, thickening, texturing, and shelf-life elongation. Despite the numerous advantageous properties in chemical industries, however, many starches in their crude form have limited applications in industrial processes as they have a high level of retrogradation which limits their application in food processing industries **(Singh, Kaur and Singh, 2004)**. However, it is necessary to modify crude starches to incorporate some specific properties which thereafter make them useful in the industrial sector **(Torruco-Uco and Betancur-Ancona, 2007)**.

Cocoyam (*Colocasia esculenta*) which is an ancient tuber of *Araceae* family originated from South-East, Asia, and has been cultivated for over 2000 years **(Wang, Truong and Wang, 2003)**. It has both red and white varieties. White yam (*Dioscorea rotundata*) is widely cultivated in Africa as an edible tuber with economic importance **(Omonigho and Ikenebomeh, 2000)**. Bitter yam (*Dioscorea dumetorum*) belongs to *Dioscoreacae* family. It is rich in phyto-nutrients such as proteins **(Medoua et al., 2005)**; still, it remains one of the underutilized tropical tubers in the world **(Owuamanam et al., 2013)**.

The present study focuses on the modification of four different starches using acetylation and phthalation processes, and also the determination of the functional properties of both native and the modified starches.

Scientific hypothesis

This research evaluated the significance of chemical modifications of native starches and the subsequent effects by comparing the characterizations and properties with their modified derivatives.

MATERIAL AND METHODOLOGY

Materials

Cocoyam, white yam, and bitter yam (Figure 1) were bought from a local market in Ado-Ekiti, Ekiti State, Nigeria. All the reagents used were of analytical grade.

Figure 1 Pictorial representations of cocoyam (A), white yam (B) and bitter yam (C).

Starch Isolation: The starches were isolated using the wet extraction method as described by **(Shujun et al., 2006)**. The tubers were thoroughly washed with water, cut into small sizes, and homogenized blended for about five minutes. The produced slurry was transferred into a muslin cloth and released into a bucket with distilled water. The content was continuously squeezed to eject the starch into the bucket of water, the starch was allowed to settle overnight and the supernatant was decanted. The product was rinsed continuously to remove soluble impurities until the supernatant was clear, the final product was spread on a flat substrate and air-dried.

Preparation of acetylated starches

The method of **(Sathe and Salunkhe, 1981)** was employed in the acetylation process. 100 g of starch was measured and dispersed in 500 mL distilled water, the resulting mixture was magnetically stirred for 20 min. The pH of the obtained slurry was adjusted to 8.0 using 1 M NaOH. 10.2 g of acetic anhydride was added for a period of 1 h, and the reaction was allowed to proceed for 5 min after the addition of acetic anhydride. The pH of the slurry was then adjusted to 4.5 using 0.5 M HCl. The product was filtered, washed several times with distilled water, and air-dried.

Preparation of Pregelatinized Starch Phthalate

Pre-gelatinized Starch Phthalate was prepared using the method of **(Surini, Ssputri and Anwar, 2014)**. Two basic steps were involved: gelatinization and esterification. Gelatinization was carried out by heating starch solution at 70 °C, the gel was then oven-dried, ground, and sieved. The esterification reaction was done by reacting 10% pre-gelatinized starch in distilled water with 16.7% solution phthalic anhydride in 96% ethanol. 10 M NaOH was added continuously during the reaction to keep the pH between 8 and 10. Anhydrous sodium sulphate was added to absorb excess moisture. Stirring was carried out at 1000 rpm, the stirring was continued for 30 more minutes and allowed to stay for 24 h. The mixture pH was adjusted to 6.5 − 7.0 using HCl solution. 50% Ethanol was added into the neutralized solution to wash the un-reacted phthalate. The final precipitate was dried, ground, and sieved to obtain pre-gelatinized starch phthalate (PCSP) powder.

Fourier Transform Infrared (FT-IR) Analysis

The functional groups of native and modified cocoyam, bitter yam, and white yam starches were obtained using Fourier Transform Infra-Red (Shimadzu Model FTIR – 8201PC).

FUNCTIONAL PROPERTIES

Water absorption capacity (WAC)

Water absorption capacity was carried out using the method described by **(Omojola et al., 2010)**. One gram of the sample was mixed with 10 mL distilled water for 5 min. The sample was allowed to stay for 30 min, centrifuged at 3000 rpm for 30 min, the volume of the supernatant was measured. Assuming the density of distilled water was 1 $g.mL^{-1}$.

Swelling power and solubility

Swelling power and solubility were determined using the method described by **(Awokoya et al., 2011)**. One gram of native starch was weighed and transferred into a clean and dried test tube (W1). The native starch was dispersed in distilled water (20 mL). The obtained slurry was heated at 60 ºC for 30 min in a calibrated water bath. The mixture was centrifuged at 3000 rpm for 20 min, the supernatant was decanted and the swollen granules were weighed

(W2). 10 mL of the supernatant was oven-dried at 120 °C. The residue obtained on drying the supernatant indicates the quantity of starch solubilized. The swelling and solubility are calculated as follows:

$$Swelling\ of\ starch\ (g/g) = \frac{W_2 - W_1}{weight\ of\ starch}$$

$$Solubility\ of\ Starch\ (g/g) = \frac{weight\ of\ dried\ aliquot}{weight\ of\ starch}$$

Gelatinization temperature (GT)

Gelatinization temperature was determined by the method described by **(Attama et al., 2003)**. About 1 g of starch sample was transferred into a beaker and 10 mL of distilled water was added. The dispersion was heated on a hot plate. The gelatinization temperature was then taken with a thermometer suspended in the slurry.

Determination of least gelation concentration

The method of **(Sathe and Solunkhe, 1981)** was used with slight modification. Appropriate sample suspensions of 2, 4, 6, 8, 10, 12, 14, 16 w.v^{-1} were prepared in 5 mL distilled water. The test tubes containing the suspensions were heated for 1 h in boiling water cooled under running tap water. The least gelation concentration was determined as concentration when the sample from the inverted test tube did not fall down or slip.

Determination of bulk density

Bulk density was determined using the procedure of **(Gbadamosi and Oladeji, 2013)** with slight modification. The sample (10 g) was put into a 100 mL graduated cylinder. The cylinder was tapped forty times and the bulk density was calculated as weight per unit volume (g.mL^{-1})

$$Bulk\ density\ (g/mL)\frac{W_2 - W_1)}{V}$$

pH Determination

The pH was determined using the procedure of **(Omojola et al., 2012)**. 20 g of the sample was shaken in 100 mL of distilled water for 5 min and the pH was determined using a pH meter.

Amylose content

The amylose content of the samples was determined by the colorimetric measurement of the blue amylose-iodine complex **(Mir, Srikaeo and García, 2013)**. In summary, 100 mg of sample was weighed into a 100 mL volumetric flask, mixed with 1 mL ethanol and 9 mL of 2 M NaOH. The samples were diluted and the iodine solution was added. After 10 min incubation at room temperature, the absorbance at 620 nm was analyzed using UV-spectrophotometer (Beckman DU640 UV/Vis Spectrophotometer) and the amylose content was calculated based on the standard curve. The samples were analyzed in triplicate.

Statistical analysis

All the analyses were done in triplicate and the data were statistically subjected to Analysis of Variance (ANOVA) using SPSS (IBM Statistics 21). Results are means of replicates (determined on a dry weight basis) ± standard deviation, significantly different at p <0.05.

RESULTS AND DISCUSSION

FTIR spectroscopy was used to verify the changes in the chemical structures of starch molecules resulting from acetylation and phthalation. The FTIR spectra of native, acetylated and phthalated cocoyam starches are presented in Figure 2, Figure 3, and Figure 4. In the spectrum of native starch, the peak at 3421.72 cm^{-1} and 2929.87 cm^{-1} correspond to O-H and C-H stretching, while the peaks at 1654.92 cm^{-1} and 1458.18 cm^{-1} correspond to O-H and C-H bending. Acetylated starches show new strong absorption bands at 1732.08 cm^{-1}; this indicates C=O stretching of acetyl group. **Mano, Koniarova and Reis (2003)** submitted a similar report. Phthalated starch showed new absorption bands at 1849.73 cm^{-1}, this new absorption indicates that phthalated starches were formed during the esterification process.

The FTIR spectra of native, acetylated and phthalated white yam starches are presented in Figure 5, Figure 6, and Figure 7. For the native starch, the peak at 3423.65 cm^{-1} and 2929.87 cm^{-1} correspond to O-H and C-H stretching, while the peaks at 1653.00 cm^{-1} and 1458.18 cm^{-1} correspond to O-H and C-H bending. Acetylated and the phthalated white yam starch did not show a new absorption band.

The FTIR spectra of native, acetylated and phthalated bitter yam starches are presented in Figure 8, Figure 9 and Figure 10. For native starch, the peaks at 3394.72 cm^{-1} and 2929.87 cm^{-1} correspond to O-H and C-H stretching, while the peaks at 1654.92 – 1637.56 cm^{-1} and 1438.18 cm^{-1} corresponds to O-H and C-H bending. Acetylated starches show new strong absorption bands at 1909.53 cm^{-1}; this indicates C=O stretching of acetyl group. Phthalated starch showed new absorption bands at 1703.14 cm^{-1} due to the carbonyl group of esters.

The results of the functional properties of native and modified starches are presented in Table 1. Native cocoyam starch has a water absorption capacity (WAC) of 8.70 ±0.02 g.g^{-1}, the value was increased after acetylation (9.37 ±0.15), and reduced after phthalation (6.50 ±0.30). The WAC values for native white yam and bitter yam starches were 8.17 ±0.15 and 8.94 ±0.05 g.g^{-1}, respectively, however, the values were increased (8.87 ±0.15, 8.50 ±0.01 g.g^{-1}) after acetylation and decreased (5.33 ±0.50 and 4.56 ±0.21 g.g^{-1}) after phthalation. Acetylated white yam starch showed the highest water absorption capacity while the phthalated bitter yam showed the least WAC. Acetylation increased the WAC of all the starches compared to their corresponding native starches, whereas phthalation decreased the WAC. A similar increase in the WAC upon acetylation was obtained in acetylated starches of sweet potato **(Lee and Yoo, 2009)** and corn **(Diop et al., 2011)**. The increase in the WAC in acetylated starches could be associated with the introduction of acetyl groups that impeded intermolecular chain associations, causing structural disorganization that facilitated water access in the amorphous region **(Xu, Dzenis and Hanna, 2005)**.

A decrease in WAC in phthalated starches could be that phthalation reinforces the structure of starch granules and limit water absorption which restricts the mobility of starch chain in the amorphous region **(Gunaratne and Corke, 2007)**. An increase in water absorption capacity of acetylated starches gave it the advantage of being used as a thickener in liquid and semi-liquids foods, it could be used in the development of confectionery products such as hard candies, the acetylated starches could also be used to produce absorbent materials such as disposable diapers and female napkins. The decreased water absorption capacity of phthalated starches suggests that they could be used in biodegradable films because of their reduction in hydrophilic property.

In the case of oil absorption capacity (OAC), Native cocoyam starch has an OAC of 2.57 ±0.21 which increased after acetylation (3.33 ±0.42 g.g-^{1}) and reduced after phthalation 1.63 ±0.25 g.g^{-1}. The OAC of the native white yam and bitter yam were 3.47 ±0.06 and 3.62 ±0.20 g.g^{-1}, respectively. However, the OAC values increased after acetylation and decreased after phthalation. Acetylated white yam starch showed the highest oil absorption capacity and phthalated cocoyam showed the least OAC. Acetylation increased the OAC of all the starches compared to their corresponding native starches, whereas phthalation decreased the OAC. This result suggested that acetylation enhanced the hydrophobic tendencies of the starches. A similar result was reported by **Uzomah and Ibe, (2011)**. WHO indicated that Acetylated starches had the strongest affinity for oil absorption. The obtained results showed that acetylation could be used to improve the oil absorption capacity of native starches.

Swelling power and solubility centre on the interaction between starch chains within the amorphous and crystalline regions, and the results are presented in Table 1. The swelling power of the native cocoyam, white yam, and native bitter yam starches increased after acetylation and decreased after phthalation. Acetylated bitter yam showed the highest swelling power while (4.63 ±0.15 g.g^{-1}) while phthalated white yam starch (1.64 ±0.04 g.g^{-1}) has the least swelling property. Increase observed in the swelling power of acetylated starches may be due to the weakening and disrupting of intra- and inter molecular hydrogen bonds in the starch chains, which may increase the accessibility of the starch granules to water. **(Lee and Yoo, 2009; Olu-Owolabi et al., 2014)**. Similar reports on swelling power after modifications have been documented **(Olayinka, Adebowale and Olu-Owolabi, 2013)**. The reduction in swelling power after phthalation could be linked to the possible structural disintegration within the starch matrix as a result of the modification. **Lawal (2004)**; **Adebowale and Lawal (2003)** reported that the lower swelling power of phthalated starches denotes the stability of starch granule. Starch swelling power is very important in the formulation of tablets and capsules, it is conceived that disintegrant works through swelling action **(Adebayo and Itiola, 1998)**. Consequently, starch with high swelling power is expected to release active pharmaceutical ingredients at a faster rate. Also, high swelling power leads to high digestibility which suggests improved dietary attributes **(Nuwamanya et al., 2010)**. The reduction in the swelling power of phthalated starches is an important property for their applications in biodegradable films.

Table 1 shows the water solubility of native and modified starches. Native cocoyam starch has a solubility of 1.56 ±0.06 g.g^{-1} which then increased after acetylation to 2.25 ±0.25 g.g^{-1}, and reduced after phthalation to 0.54 ±0.04 g.g^{-1}. The water solubility values for native white yam and bitter yam starches were 2.58 ±00.06 and 2.18 ±1.26, respectively. There was an increase in the values after acetylation, a reduction in value was however observed after phthalation. The increase in water solubility of acetylated form could be due to the structural rearrangement which weakens the granules and improves amylose leaching **(Lawal, 2004)**. Similar reports on water solubility on African yam bean and corn were submitted by **(Akintayo and Akintayo, 2009)** and **(Ayucitra, 2007)** starches. A decrease in water solubility after modification of Acha starch has been reported by **Olu-Owolabi et al. (2014)**.

The gelatinization temperatures of the native, acetylated and phthalated starches, are presented in Table 2. Acetylated and phthalated starches (cocoyam, whiteyam, and bitter yam) have lower gelatinization temperature compared to their corresponding native starches. These observations are in agreement with previous studies **(Lawal, 2011; Lee and Yoo, 2011)**. A decrease in gelatinization temperatures could be traced to the phthalation and acetylation processes in the starch polymer backbone, which permits improved flexibility **(Singh, Chawla and Singh, 2004)**. A decrease in gelatinization temperature is useful as a thickening agent in various industries, whereby the starch will form a gel at a lower temperature. Hoewever, thermal treatment reduced anti-nutritional agents **(Lauková et al., 2020)**.

The pH values for acetylated and phthalated starches were found to be slightly lower than their corresponding native starches, but still fall within the pH range of 3 − 9 obtained for most starches used in pharmaceutical, domestic, and food industries. The reduction in pH of native starches after acetylation and phthalation can be attributed to the modification processes thereby increasing the acidity of starch molecules. The amylose content of native cocoyam starch (20.90% ±0.06) was reduced (18.73% ±0.64) after acetylation, and increased after phthalation (30.31% ±0.17), amylose content of the native white yam(21.53% ±0.30) and bitter yam (22.73% ±0.31) decreased (18.63% ±0.17; 31.37% ±0.15) after acetylation, and increased (28.67% ±0.38; 27.53% ±0.38) after phthalation. Phthalated cocoyam starch showed the highest amylose content while acetylated white yam starch showed the least amylose content. The decrease in amylose content of acetylated starch was in agreement with the report of **Lawal (2004)**, on the reduction of amylose content of new cocoyam starch after acetylation. **Reddy, Haripriya and Suriya (2014)** also submitted a similar report on acetylated banana starch. Increased amylose contents of phthalated starches were in consonance with the report submitted by **Singh, Chawla and Singh (2004)** on modified potato and corn starches. Amylose content undergoes changes upon modification, also, structural differences between amylose and amylopectin can be considered as one of the most important factors of starch properties. Low amylose level makes starch a good source of food for diabetic and other

Table 1 Functional properties of native and modified starches.

Sample	WAC ($g.g^{-1}$)	OAC ($g.g^{-1}$)	SWP ($g.g^{-1}$)	Solubility ($g.g^{-1}$)	Gelation temp. (^oC)	Amylose content (%)	pH	Bulk density ($g.mL^{-1}$)	Amylopectin %

health conscious beings **(Agbo and Odo, 2010)**. However, high amylose content often leads to retrogradation.

Table 1 shows the bulk density of native and modified starches. Native cocoyam starch has a bulk density of 0.61 ±0.08 $g.g^{-1}$, which decreased after both acetylation and phthalation to 0.45 ±0.05 and 0.32 ±0.06 $g.g^{-1}$. The bulk density values of the native white yam and bitter yam starches (0.65 ±0.22 and 0.51 ±0.04 $g.g^{-1}$) decreased after both acetylation (3.00 ±0.08 and 3.24 ± 0.17 $g.g^{-1}$,) and phthalation (1.50 ±0.16 and 1.56 ±1.24 $g.g^{-1}$). Native white yam starch has the highest bulk density of 0.65 ±0.22 $g.g^{-1}$, while phthalated cocoyam starch (0.32 ±0.06) has the least bulk density. Acetylation and phthalation reduced the bulk density of the starches. The higher bulk density of a material, the more the quantity which can be packaged in a confined space **(Fagbemi, 1999)**. Materials with high bulk density are regarded as heavy.

The results of the least gelation of native and modified starches are presented in Table 2. The lowest gelation concentration for native cocoyam, white yam, and bitter yam starches was 6%. However, none of the starches showed positive results at the concentrations of 2 and 4%. At 8% concentration, all the native and modified starches formed a gel, all other higher concentrations showed positive results. It was observed that an increase in concentration leads to gel formation. A similar increase in the least gelation concentration upon acetylation was obtained in acetylated starches of African yambean starch **(Akintayo and Akintayo, 2009)** and sweet potato starch **(Diop et al., 2011)**. Thus, the results suggested that the native starches are better gelating food additives than acetylated and phthalated starches.

CONCLUSION

It can be concluded that phthalation of native starches reduced water absorption capacity, swelling capacity, solubility, oil absorption capacity, swelling power, amylose content of the starches which are better properties of biodegradable polymers while acetylation increased

water absorption capacity, oil absorption capacity, swelling power and solubility of the starches which make the starches to be useful in confectioneries. This study, apart from establishing the characterization differences between native and modified starches has also provided information that the modified starches have more and improved applications in food industries.

SPONTANEOUS FERMENTATION IN WINE PRODUCTION AS A CONTROLLABLE TECHNOLOGY

Radim Holešinský, Božena Průšová, Mojmír Baroň, Jaromír Fiala, Petra Kubizniakova, Vít Paulíček, Jiří Sochor

ABSTRACT

This study focuses on the isolation of a consortium of microorganisms from spontaneously fermenting must that naturally contain lactic acid bacteria, non-saccharomyces yeasts, and saccharomyces yeasts. To collect the greatest diversity of microorganisms, the consortium was taken from the point of micro-sparkling. Based on the growth curves, isolation was performed using individual special nutrient media, and the isolates were subsequently multiplied in the nutrient medium. Individual isolates were then used for fermentation tests to monitor the percentage of fermented sugar and hydrogen sulphide production. The highest fermentation abilities were achieved in the isolates containing *Saccharomyces cerevisiae* and *Zygosaccharomyces bailii*. The smallest amount of ethanol was formed from the isolates containing *Hanseniaspora uvarum*, while *Candida sake* isolate produced the lowest amount of hydrogen sulphide and *Zygosaccharomyces bailii* produced the highest. The other isolates produced an average amount. Based on these results, a consortium containing the given isolates in a certain ratio was compiled.

Keywords: spontaneous fermentation; yeast cultivation; yeast isolation; growth curves

INTRODUCTION

Saccharomyces cerevisiae (*S. cerevisiae*) is a type of yeast that performs alcohol fermentation and is widely used as a fermentation starter. During the alcoholic fermentation of grape must, *S. cerevisiae* becomes the dominant species with the increasing ethanol concentration **(Mas, Guillamón and Beltran, 2016)**. Therefore, the isolation of natural *S. cerevisiae* is generally carried out from must be fermented by spontaneous fermentation **(Versavaud et al., 1995; Valero et al., 2007; Clavijo, Calderón and Paneque, 2010; Cordero-Bueso et al., 2011; Viel et al., 2017; Crosato et al., 2018)**, suggesting that *S. cerevisiae* is common on grapes. Recently, **Taylor et al. (2014)** reported that *Saccharomyces* sp. makes up less than 0.00005% of the yeast population on ripe grapes.

Similarly, **Fleet (2003)** reported its presence at concentrations below 10 – 100 cfu.g^{-1}, and **Fleet (2003)** and **Martini, Ciani and Scorzetti (1996)** reported that the total number of cells never exceeds 10 cfu.g^{-1} on grape berries (cfu - colony forming units).

The diversity and quantity on grapes always vary depending on the variety, stage of ripening, terroir, vintage, vineyard age, soil type, the geographical location of the vineyard, climatic conditions, diseases, pests, and vineyard work used **(Pretorius, 2000; Mannazzu, Clementi and Ciani, 2002; Valero et al., 2007; Barata, Malfeito-Ferreira and Loureiro, 2012; Setati et al., 2012; Bokulich et al., 2014)**.

Equally important is the secondary microbial process of malolactic fermentation (MLF), which is when malic acid is converted into nicer-tasting lactic acid. Lactic acid bacteria (LAB) are involved in this process **(Bauer and Dicks, 2004)**, and this microbial development is also associated with the release of other metabolites that are capable of affecting wine quality **(Campbell-Sills et al., 2016)**.

Model microorganisms for alcoholic and malolactic fermentation are *Saccharomyces cerevisiae* and *Oenococcus oeni*. The selected strains belonging to these two species have been used to design starter cultures that are useful for promoting alcoholic fermentation (AF) and MLF, thus making the fermentation process more manageable **(Garofalo et al., 2016; Berbegal et al., 2017; Petruzzi et al., 2017)**.

MLF can also occur spontaneously, but its course is often unpredictable. It can take place over several months after the end of AF or fail due to unfavorable conditions in a wine based on the wine's pH, ethanol, and SO_2 content **(Berbegal et al., 2016; Lucio et al., 2017)**.

Another risk of spontaneous MLF is the formation of undesirable by-products, colour reduction, and higher synthesis of biogenic amines **(Guo et al., 2015; Henríquez-Aedo et al., 2016)**.

Oenococcus oeni is generally the main species used as an MLF starter due to its easy adaptation to wine conditions. New strains such as *L. plantarum* are currently being discovered, however, that can also survive and adapt well to the viticulture. These strains also have more favorable biological properties compared to *O. oeni*, such as higher growth rate, creation of a more complex aromatic profile, and the prevention of undesirable by-product formation **(du Toit et al., 2011; Brizuela et al., 2017)**.

Therefore, the aim of this study was to isolate yeast and lactic bacteria from the vineyard and carry out a fermentation experiment using these isolates.

Scientific hypothesis

Each vineyard has its own wine of microbiota, which affects the quality of the resulting wine. Separation and cultivation methods can be used to characterization and multiplying individual microorganisms. Based on the fermentation and H_2S production tests, the resulting consortium can be assembled, which can be used for fermentation, thereby promoting both the fermentation process and the terroir of the wine.

MATERIAL AND METHODOLOGY

The aim was to obtain a functional consortium of wine microorganisms that was characterized in terms of biotechnology and taxonomy. This consortium was separately cultivated to achieve the required amounts and then used to inoculate a drained batch of Hibernal must in which fermentation and H_2S production were monitored.

Materials

MEA+T Malt Extract Agar with Tetracycline (a broad-spectrum antibiotic against both gram-positive G+ and gram-negative G- bacteria). Only eukaryotic microorganisms grow on this medium.

Composition: agar – 15 $g.L^{-1}$, malt extract – 30 $g.L^{-1}$, mycological peptone – 5 $g.L^{-1}$, (manufacturer: Sigma Aldrich)

WLN: Wallerstein Nutrient Agar for counting and culturing yeast and bacteria.

Composition: agar – 20 $g.L^{-1}$, bromocresol green – 0.022 $g.L^{-1}$, calcium chloride – 0.125 $g.L^{-1}$, casein enzymic hydrolysate – 5 $g.L^{-1}$, dextrose – 50 $g.L^{-1}$ (manufacturer: Sigma Aldrich).

MRS (Agar according to DeMan, Rogosa, and Sharpe): Nutrient agar for the determination of lactic bacteria.

Composition: Agar – 12 $g.L^{-1}$, diammonium bicarbonate – 2 $g.L^{-1}$, potassium hydrogen phosphate – 2 $g.L^{-1}$, D (+) – glucose – 20 $g.L^{-1}$, magnesium sulphate – 0.1 $g.L^{-1}$, manganese sulphate – 0.05 $g.L^{-1}$, meat extract – 5 $g.L^{-1}$, sodium acetate – 5 $g.L^{-1}$, universal peptone – 10 $g.L^{-1}$, yeast extract – 5 $g.L^{-1}$. (manufacturer: Sigma Aldrich)

YPD (Yeast extract Peptone Dextrose) agar: Solid medium for yeast multiplication.

Composition: Bacteriological peptone – 20 $g.L^{-1}$, yeast extract – 10 $g.L^{-1}$, glucose – 20 $g.L^{-1}$, agar – 15 $g.L^{-1}$. (manufacturer: Sigma Aldrich)

ME (M-enterococcus) agar: Agar consists of tryptose; yeast extract; glucose; disodium hydrogen phosphate; sodium azide; 2, 3, 5-triphenyltetrazolium chloride; agar; and distilled or deionized water. (manufacturer: Sigma Aldrich)

BIGGY (Bismuth Sulphite Glucose Glycine Yeast Agar): Selective and differential medium with addition of bismuth salt for H_2S detection. Bismuth reacts with the resulting sulfane to form a precipitate that colours the agar below the colony.

Composition: Glucose – 10.0 $g.L^{-1}$, glycine – 10.0 $g.L^{-1}$, bismuth ammonium citrate – 5.0 $g.L^{-1}$, sodium sulphite – 3.0 $g.L^{-1}$, yeast extract – 1.0 $g.L^{-1}$, agar – 13.0 $g.L^{-1}$. (manufacturer: Sigma Aldrich)

The must of the Hibernal variety: This variety was developed in Germany in 1944 as a hybrid of Seibel 7053 (Chancellor) and Riesling. The must be clarified by sedimentation (after 24 hours). The turbidity value of the must after clarifying was approx. 400 NTU and this was not adjusted. The sugar content was 16 °NM, pH was 3.51, titratable acid content was 6.48 $g.L^{-1}$, and assimilable nitrogen content was 321 $mg.L^{-1}$.

Isolation of yeasts

The must of the Hibernal variety was fermented spontaneously. During this spontaneous fermentation, 20 mL of the matrix (must, fermentation must, wine) was taken at selected monitoring points (must, micro-sparkling, 4 and 8 vol. % ethanol, end of fermentation). The sample obtained was subsequently diluted using the so-called decimal series. From each dilution, 250 mL was pipetted onto Petri dishes with MEA+T, WLN, and MRS culture medium, and a microbiological rod smear was performed. The Petri dishes were then placed in a thermostat (30 °C; WLN and MEA+T – 3 days; MRS – 7 days).

At the end of the cultivation, the total number of microorganisms and individual colonies was enumerated. Based on a combined analysis of phenotypic characters (macroscopic and microscopic properties), a sampling point was selected (the most suitable was the micro-sparkling point - the diversity of technologically important microorganisms was evaluated – saccharomyces and non-saccharomyces yeasts and lactic bacteria) to serve as a source for consortium acquisition.

Determination of growth characteristics of individual isolates of the 2018 Wine Microorganism Consortium (growth curves)

The aim was to determine the growth characteristics of individual isolates. Individual isolates of microorganisms were pre-cultured in standard media (yeast – YPD; lactic acid bacteria - MRS) with the following culture conditions: 30 °C; shaking 120 rpm; yeast 24 h; and lactic acid bacteria 72 h. The obtained cell suspensions were centrifuged (10 mins; 10 °C; 10,000 rpm), washed with saline solution, and then resuspended in the selected media (yeast – YPD, ME, YPD_{mod}; lactic acid bacteria – MRS, YPD, and YPD_{mod}) so that the resulting optical density value of the suspension was 0.2 at a wavelength of 600 nm.

The obtained suspension was then pipetted onto Bioscreen C culture plates (Oy Growth Curves Ab Ltd). Each arrangement (microorganism x medium) consisted of five repetitions to ensure the achievement of relevant results.

Table 1 Results of the operational microbiological monitoring of the fermentation process.

Sampling time interval	MEA+T (cfu.mL^{-1})	WLN (cfu.mL^{-1})	MRS (cfu.mL^{-1})
Must	3.80E +05	4.00E +05	4.00E +02
Micro-sparkling	1.75E +06	2.35E +06	7.00E +03
EtOH 4 Vol. %	8.00E +06	5.00E +06	5.00E +02
EtOH 8 Vol. %	9.00E +06	1.20E +07	1.20E +02
End of fermentation	5.00E +04	4.00E +04	0

Note: cfu - colony forming units.

The culture conditions of the Bioscreen C device were set as follows: 30 °C; shaking every 3 mins; duration of one shaking cycle = 1 min; and the so-called wide band of wavelengths – WB (420 – 620 nm). The maximum growth rate μ (h^{-1}) was then calculated from the measured data, and the maximum optical density OD_{MAX} was determined. These data, along with the course of growth curves, served to assign culture media to individual isolates.

Identification of microorganisms

The MALDI TOF (matrix-assisted laser desorption/ionization coupled with time of flight mass spectrometry) method was used to identify microorganisms. It is a very accurate, simple method, able to determine high molecular weight substances, proteins, peptides, lipids, nucleic acids, carbohydrates **(Huong et al., 2014)**.

An essential part of the MALDI TOF measurement was the preparation of fresh α-cyano-4-hydroxycinnamic acid. The organic solvent was prepared by mixing 500 μL of acetonitrile (100%), 475 μL of distilled water, and 25 μL of trifluoroacetic acid. Before use, 250 μL of organic solvent was added to the plastic tube. The contents of the tube were vortexed until the complete dissolution of the crystals. α-cyano-4-hydroxycinnamic acid was stored in the dark place and its preparation is ideal the day before the measurement.

The cultures were applied to the clean metal plate for MALDI TOF and the culture was allowed to dry on the plate. It was then covered with 1 microliter of α-cyano-4-hydroxycinnamic acid. At the same time, it was important to homogenize the sample and matrix **(Jarolímková, 2017)**.

Unlike the analysis of bacteria, preprocessing of the yeast isolates was required to extract fungal proteins. The protein extraction method used to process yeast isolates for MALDI-TOF MS was adapted directly from established methods used to identify difficult bacterial isolates. Specifically, 1 to 5 colonies of an isolate were inactivated in 75% ethanol, pelleted, and then suspended in a 1:1 mixture of 70% formic acid and acetonitrile. The resulting supernatant was then analyzed by MALDI-TOF MS **(Marklein et al., 2009; Bader et al., 2011; Dhiman et al., 2011)**. The results of the identifications are in Table 5.

Optaining pure cultures: Separation and lyophilisation

This procedure aimed to cultivate individual isolates of technologically important microorganisms and preserve them using the lyophilization method. Separate cultivation of individual microbial isolates was performed based on the information obtained from the growth characteristics. Individual taxa were first pre-cultured in 250 mL Erlenmeyer flasks (100 mL medium volume; orbital stirring 120 rpm; 20 °C). The media and the culture times are shown in (Table 3). The pre-cultured cell suspension was examined microscopically (cell morphology, elimination of contamination) and centrifuged (10,000 rpm; 10 mins; 10 °C).

After separating the supernatant, the pellet was washed with saline solution and re-centrifuged (10,000 rpm; 10 mins; 10 °C) and resuspended in the pure culture medium. The prepared suspension served as the inoculum for the second cultivation stage, which was carried out in 2,000 mL Erlenmeyer flasks (1,000 mL medium volume; orbital stirring 100 rpm; 30 °C). The media and the culture times used for the individual isolates are shown in (Table 5).

After the cultivation was complete, the suspension was repeatedly centrifuged and washed as described in the previous step. The obtained biomass was mixed with cryoprotective medium and shock-frozen (70 °C; 24 h). The frozen suspension was then lyophilized. The viability of the obtained dehydrated biomass was then determined, and according to the qualitative and quantitative microbiological analysis (Table 2) and the cell viability in the lyophilisate, the 2018 Wine Microorganism Consortium was compiled.

Fermentation tests using a consortium

Fermentation tests

Individual yeast isolates were initially cultured in 50 mL Erlenmeyer flasks (25 mL medium volume; orbital stirring 120 rpm; 30 °C). The media and the culture times used for the individual isolates are shown in (Table 5). In the obtained cell suspension, the cell density was determined by microscopic cell counting in a so-called Bürker chamber. The calculated amount of this suspension was then pipetted to a final concentration of 10^8 cells.mL^{-1} in a 250 mL Erlenmeyer flask (100 mL YPDm medium volume; without shaking; 25 °C). Fermentation was monitored by the gravimetric method, and weight loss due to the metabolic conversion of fermentable sugars to carbon dioxide and ethanol was observed.

H_2S production

Individual isolates were inoculated onto a BIGGY agar identification medium using a microbiological loop. Individual Petri dishes were statically cultured at 30 °C for 3 days. Based on the visual evaluation, the individual isolates were marked as low, medium, and high producers of H_2S.

BiGGY, Bismuth Sulphite Glucose Glycine Yeast Agar, is based on the formulation developed by **Nickerson (1953)** and mainly used for the isolation and presumptive identification of *Candida* species. In a study of sulphite

reduction by yeasts, the ability of many yeasts to reduce a bismuthyl hydroxy polysulphite was noted. Growth on an acidic or neutral medium containing bismuth sulphite produced black colonies because of the extra-cellular reduction of the bismuth sulphite, to bismuth sulphide. The bismuth sulphite complex confers a high degree of selectivity to the medium, and most strains of bacteria are inhibited on BIGGY Agar. In this study, BIGGY agar was used as a simple and rapid method to compare the rate of H_2S production between pure yeast isolates.

Statistical analysis

Statistical analyses and figures were generated using Excel 2007 software packages (manufactured by Microsoft Office, USA) and Statistica 10 statistical software (Copyright © StatSoft). The Statistica 10 software was used to process growth curves data and create their line graphs.

RESULTS AND DISCUSSION

Isolation of yeasts

The results of the microbiological analysis are shown in (Table 1). These data are comparable with the normal course of fermentation of the grape must. Based on the phenotypic analysis, a consortium was selected from the point of micro-sparkling.

The quantitative parameters of the individual taxa of the 2018 Wine Microorganism Consortium are given in (Table 2). The individual values in (Tables 1 and Table 2) were averaged from three measurements.

Through the application of microbiological techniques, the 2018 Wine Microorganism Consortium was obtained from the spontaneous batch, which was characterized in qualitative and quantitative terms.

Growth curves

The growth curve courses are shown in (Figures 1 and Figure 2), while the numerical parameters of the growth characteristics are shown in (Tables 3 and Tables 4). The growth characteristics of individual isolates were determined based on the growth curves of different types of media. These characteristics were used to assign culture media and culture times to individual isolates (Table 3).

Obtaining pure cultures: Separation and lyophilisation

To culture and lyophilise the 2018 Wine Microorganism Consortium, 30 g of the consortium was prepared and used for fermentation for 100 litres of must. The representation of the individual isolates can be seen in Table 4.

The growth curves, fermentation tests, and H_2S production results were used to inform the composition of the consortium so that the entire mixture exhibited the best fermentation capabilities, including the desired strains of lactic acid bacteria. Isolates Y03, Y06, and Y07 had the largest mass representation as characterized by a looser fermentation process but had the ability to ferment alcohol to 6.98, 9.37, and 7.20% vol. alc., respectively. These isolates showed low, medium, and high H_2S-producing ability. Isolates Y02 and Y05 had the second largest mass representation of the resulting consortium as characterized by high sugar fermentability up to an alcohol content of 13.28 and 13.30% vol. alc., respectively. The fermentation process was not gradual, however, which could negatively affect the quality of the wine. Both isolates showed mean H_2S production capacity. The isolate Y04 had a low mass representation. It showed the lowest sugar fermentability to an alcohol content of only 2.98 and had a medium ability to produce H_2S.

Table 5 contains the identification of individual isolates. The consortium consists of 2 strains of lactic acid bacteria and 7 strains of saccharomyces and non-saccharomyces yeast. The most abundant yeast strains of Consortium are *Hanseniaspora uvarum*, *Zygosaccharomyces bailii* and *Candida sake.*

Fermentation using isolates

Fermentation tests

Based on the results of the fermentation tests (Figure 3 and Table 6), we can conclude that there was some similarity between isolates from the 2018 Wine Microorganism Consortium. For example, between isolates Y02 and Y05 and isolates Y01 and Y07. For the Y03 and Y06 strains, there was always a certain deviation that distinguished them from the other isolates, and isolate Y04 showed a completely different course of fermentation compared to the other yeast microorganisms tested. Based on these data, we were also able to divide the strains into high fermentation strength strains (Y02 and Y05) and medium fermentation strength strains (Y01, Y03, Y06, and Y07).

Figure 3 shows the different fermentation progress of individual isolates. The consortium mixture was composed of isolates that showed different fermentation ability. The selection also included the incorporation of saccharomyces and non-saccharomyces yeast, which contribute to the sensory expression of the wine. Isolates Y03, Y06, and Y07 are characterized by a slower fermentation process. Isolates Y02 and Y05 were characterized by high sugar fermentability up to an alcohol content of 13.28 and 13.30% vol. alc., i.e. with a faster fermentation process. Y04 isolate showed the lowest sugar fermentability to an alcohol content of only 2.98, but the fermentation process was the most gradual.

H_2S production

Low, medium, and high sulfane productivity occurred during the monitoring of H_2S production by yeast isolates (Figure 4, Table 7). Most isolates (Y01, Y02, Y03, Y04, Y05) had medium sulfane productivity.

H_2S production was also monitored during the testing of a suitable fermentation strain, and strains with low, medium and high H_2S production were found. The Y07 strain showed low production; the Y01, Y02, Y03, Y04, and Y05 strains showed medium production; and the Y06 strain showed high production. Y02 and Y05 also showed high fermentation strength and medium H_2S production, while the Y07 strain produced a low amount of H_2S and had a medium fermentation capacity.

Discussion

This study focused on the isolation of yeasts and lactic acid bacteria representing the given vineyard. From the isolated microorganisms and growth curves, the most suitable culture media and required culture times were determined. The isolation was realized from the point of micro-sparkling of spontaneous fermentation due to the strain diversity. The study found that at an ethanol concentration stage of 4.5 – 5%, naturally, present non-saccharomyces yeasts die and ethanol-*tolerant S. cerevisiae* begins to act. Previous studies have also reported that many different strains occur at the beginning of fermentation, but only a few dominate in the later stages of wine fermentation **(Torija et al., 2001)**. Subsequently, fermentation tests were carried out to monitor the fermentation process and the fermentability of sugars to ethanol in individual isolates. Differences were found between individual isolates due to the isolation of microorganisms from the point of micro-sparkling when yeast diversity was greatest. During the fermentation tests, the differences in fermentability were shown, allowing us to select the yeast strain most suitable for fermentation.

Some similarities were found in the sugar fermentability of different isolates, specifically isolates Y02 and Y05 and Y01 and Y07. In the strains Y03 and Y06, there was always a certain deviation that distinguished them from the second group, and isolate Y04 showed a completely different course of fermentation compared to the other yeast microorganisms tested. Based on these data, we were also able to divide the strains according to strains with high fermentation strength (Y02 and Y05) and those with medium fermentation strength (Y01, Y03, Y06).

During spontaneous fermentation, different yeast species and strains interact with each other differently depending on the changing conditions of the fermenting must **(Albergaria and Arneborg, 2016; Ciani et al., 2016; Morrison-Whittle and Goddard, 2018)**. The medium becomes increasingly selective and this corresponds to the proportion of individual yeasts and bacteria **(Bisson, 2012; Perrone et al., 2013; Ciani et al., 2016; Brice et al., 2018; Henriques et al., 2018)**. Various studies indicate the prevalence of *S. cerevisiae* over non-saccharomyces, which usually initiate fermentation. *Saccharomyces* strains have greater tolerance to ethanol and temperature changes **(Goddard, 2008; Salvadó et al., 2011; Alonso-del-Real et al., 2017)**.

Ganucci et al. (2018) reported the effect of ethanol and temperature on the dominance of various *S. cerevisiae* strains occurring in multiple spontaneous fermentations carried out on an industrial scale. Another study by **Tofalo et al. (2013)** examined the prevalent strains of *S. cerevisiae*, which were differentiated by the RFLP-mtDNA method and according to their isolation frequency. The results obtained by an analysis of 637 isolates

confirmed the genetic polymorphism expected in the *S. cerevisiae* population in spontaneous wine fermentation and the high variability between isolation frequencies of different strains. **Schuller et al (2012)** evaluated intraspecific genetic diversity of fermentative vineyard-associated *S. cerevisiae* strains and evaluate relationships between grape varieties and geographical location on populational structures. Similar results are shown in the study **(Bisson, 2012; Schuller et al., 2012; Tofalo et al., 2013)**.

The study by **Ganucci et al. (2018)** further found that independent of the grape variety, five of the six wineries in the study only had one predominant *S. cerevisiae* strain with an isolation frequency ranging from 32 to 74%, while the variable number of strains (from four to 14) was characterized by an isolation frequency of less than 10%. This finding is consistent with those reported by other authors **(Versavaud et al., 1995; Gutiérrez et al., 1997; Egli et al., 1998; Sabate et al., 1998)**, although in some cases the predominant strains of *S. cerevisiae* were not found by the fermentation process **(Vezinhet et al., 1992)**.

To select the most suitable yeast strain for fermentation, H_2S production was also monitored on a special nutrient medium: BIGGY. The obtained isolates showed varying degrees of H_2S production, ranging from low, medium to high H_2S production. These results confirm those presented by **Perrone et al. (2013)** and **Pérez-Torrado et al. (2017)**, which state, inter alia, that the dominant behavior of yeast strains is due to differential H_2S production and killer factor resistance.

It is noteworthy that in the high-frequency strains that were tested by **Ganucci, Guerrini et al. (2018)**, no killer factor was detected and no significant differences in H_2S production were found. The degree of competition of each strain, which determines the ability of one strain to compete with another, is influenced by other factors, however, including pH, temperature, ethanol, osmotic pressure, and available nitrogen **(Ciani et al., 2016)**.

Ganucci et al. (2018) study looking at the effect of ethanol and temperature on growth performance and condition advantage of high-frequency *S. cerevisiae* strains showed that these two factors can play an important role in determining the dominance of one strain over another during wine fermentation. A single action of ethanol on the growth performance led to the high-frequency strains showing significantly lower inhibition than the low-frequency strains.

According to **Arroyo-López, Querol and Barrio (2009)**, an even more accurate indicator of total yeast growth is the percentage of inhibition as this parameter is indirectly related to the delayed phase but linearly related to both the maximum specific growth rate (μmax) and the maximum cell density at the end of growth. Consequently, there is an advantage of condition, which according to **Salvadó et al. (2011)**, represents the difference in μmax between competitors for specific environmental conditions. This leads to higher concentrations of high-frequency strains, indicating their enhanced adaptability to increasing ethanol concentrations compared to low-frequency strains. Each *S. cerevisiae* strain can exhibit different stress reactions to ethanol because the effects of increasing ethanol concentrations on the yeast cell include various changes, such as membrane composition and gene expression, synthesis of heat shock proteins, increase in chaperone proteins, etc.**(Ding et al., 2009)**.

Another study of four commercial wine yeast strains recently highlighted that fermentation temperature may be an important factor in determining the dynamics of a population of *S. cerevisiae* strains **(García-Ríos et al., 2014)**. Ethanol and high temperature synergistically affect membrane integrity and permeability, causing a decrease in yeast population growth **(Alexandre, Rousseaux and Charpentier, 1994; Albergaria and Arneborg, 2016)**.

CONCLUSION

The outcome of this study was the 2018 Wine Microorganism Consortium, which was obtained from the spontaneous fermentation that characterizes the given vineyard and supports the 'terroir' of the wine. At the same time, inoculation with this mixed culture helps to prevent problems with stagnant fermentation, which is often associated with spontaneous fermentation. Isolates of lactic acid bacteria and non-saccharomyces and saccharomyces yeasts were obtained and the resulting consortium was formed from these isolates. The obtained consortium was then used for fermentation tests where the percentage of fermented sugar and hydrogen sulphide production were monitored.

The Y03, Y06, and Y07 isolates had the largest mass representation and were characterized by a looser fermentation, but with the ability to ferment alcohol to 6.98, 9.37, and 7.20 vol. % alc. These isolates showed low, medium, and high ability to produce H2S. Y02 and Y05 isolates had the second largest mass representation of the resulting consortium and were characterized by high sugar fermentability up to an alcohol content of 13.28 and 13.30% vol. alc., but the fermentation process was not gradual, which could negatively affect the quality of the wine. Both isolates showed medium ability to produce H2S. Y04 isolate also has a low mass representation and showed the lowest ability to ferment sugar to an alcohol content of only 2.98 and a medium ability to produce H2S.

The Y03, Y06, and Y07 isolates had the largest percentage in the resulting consortium. These isolates formed 80% of the total weight of the consortium. The LAB 01 and LAB 02 isolates represented 7% of the consortium. Lactic acid isolates do not participate in alcoholic fermentation and are in the consortium to start malolactic fermentation.

ASSESSMENT OF THE INTAKE OF SELECTED MINERALS IN POPULATION OF PREMENOPAUSAL WOMEN BASED ON SPECIFIC SOCIO-DEMOGRAPHIC INDICATORS

Kristína Jančichová, Marta Habánová, Jana Mrázová, Martina Gažarová, Jana Kopčeková

ABSTRACT

Eating behavior interventions are a modifiable risk factor for chronic diseases. The aim of this study was to monitor the intake of selected minerals – calcium, phosphorus, zinc, copper, selenium, and chromium in the diet of premenopausal women (n = 30) and to highlight the possible adverse effects of disbalanced intake of these elements. At the same time, we investigated whether socio-demographic factors and choice of food store have an impact on the intake of these substances. We assessed the intake of selected minerals using three-day nutritional protocols and subsequently processed the data. The participants were women between 40 and 50 years old, from districts of Partizánske and Prievidza, for whom menopause has not yet begun. Women provided information about their place of residence (urban or rural area), type of home they live in (family house or apartment), and the type of food store where they grocery shop. The results indicate an impact of the place of residence: higher intake of zinc ($p = 0.012$) and selenium ($p = 0.020$) were observed in the participants from the urban area. The impact of the type of home was proven on the intake of chromium ($p = 0.049$), copper ($p = 0.048$), and carbohydrates ($p = 0.021$) with higher intake in the apartment-dwelling group. The impact of food store choice has not been confirmed. Based on the observed values, we conclude that the observed population might be at a higher risk of skeletal disorders and osteoporosis due to deficient calcium intake and the unfavorable ratio of Ca:P; increased Zn and Se intake levels may stimulate the development of cardiovascular risk factors and may also elevate the risk for type 2 diabetes mellitus.

Keywords: minerals; intake; diet; menopause; place of residence; type of home; type of food store

INTRODUCTION

The basic need of the human body is food intake. Food supplies building material and energy and contains immune-system-promoting substances. Macronutrients (proteins, fats, and carbohydrates) and micronutrients (minerals and vitamins) are introduced into the body through food **(Svačina et al., 2008)**. Macronutrients supply energy and material to ensure the entire body composition. Micronutrients are required to maintain continuous design and reconstruction processes. The micronutrient requirements of an organism vary depending on individual needs **(Biesalski and Tinz, 2018)**. The primary functions of micronutrients in human metabolism and physiology are to maintain and optimize health and prevent disease. Adequate intake is essential to maintain homeostasis, physiological functioning, and normal growth and development of a young organism **(Shergill-Bonner, 2017)**. All vitamins and minerals can be obtained from a balanced diet that includes all food groups from the food pyramid. It has been known since the 18th century that diseases may result from low-quality food **(Combet and Buckton, 2019)**. Micronutrients are essential dietary ingredients with preventive effects. **Shergill-Bonner (2017)** states that chemical reactions in different metabolic pathways may not be able to continue their natural pathway if a critical micronutrient is missing. Normal metabolic regulation of the organism will be impaired and poor health can develop due to the lack of specific micronutrients. The physiological functions of micronutrients include acting as coenzymes in key metabolic reactions, antioxidants to control damage caused by reactive oxygen species, gene transcription modulators, enzyme components and cofactors, and structural tissue components **(Combet and Buckton, 2019)**.

From the publication "Slovakia: country health profile 2019" we learn that the most frequent cause of death of women in Slovakia is cardiovascular diseases (50% of deaths) and cancer (24%) **(OECD, 2017)**. During menopause, the female body undergoes changes that gradually increase the risk of developing diseases. The production of endogenous estrogens with anti-atherosclerotic and anti-inflammatory properties is decreasing, maintaining pancreatic insulin response to glucose **(Svatikova and Hayes, 2018; Wedisinghe and**

Perera, 2009). According to **Harvey, Coffman and Miller (2015)**, loss of estrogen contributes to the increased development of hypertension, ischemic heart disease, congestive heart failure, and cerebrovascular disease. Of the micronutrients, selenium, zinc, and copper are particularly critical in preventing cardiovascular disease (CVD). Severe selenium deficiency is a known cause of reversible heart failure – Keshan disease. In patients with CVD, a disbalance is often observed – increased copper levels and concurrently reduced levels of zinc and selenium in the body **(Koşar et al., 2006; McKeag et al., 2012; Salehifar et al. 2008)**. Calcium is also important in the prevention of chronic diseases; it is a modifiable risk factor for osteoporosis **(Skowrońska-Jóźwiak et al., 2016)**, reduces the risk of hypertension and colon cancer **(Ong et al., 2017)**, and normalizes blood levels. Its low intake is associated with pathogenesis of obesity, hypertension, insulin resistance, and type 2 diabetes **(Skowrońska-Jóźwiak et al., 2017)**. In addition to Ca, phosphorus is also essential for bone tissue – together they form hydroxyapatite **(Itkonen et al., 2017)**. Furthermore, plasma levels of P inversely correlate with body weight **(Zohal et al., 2019)**.

Zinc is a trace element that plays a role in over 300 biological processes. It plays an important metabolic role in the metabolism of proteins, carbohydrates, lipids, and nucleic acids. It affects the action of insulin and is an integral part of many antioxidant enzymes. Its deficiency damages the synthesis of these enzymes, which increases oxidative stress **(Zohal et al., 2019)**. A high incidence of Zn in the brain (amygdala, hippocampus, neocortex) has been observed and found to have several important effects on the CNS. It is believed that inadequate Zn intake may be associated with various changes in mental functions (e.g. behavior, cognition, and mood) **(Dome et al., 2019)**.

Copper is a cofactor of redox enzymes (ceruloplasmin in iron metabolism), participates in antioxidant defense, neuropeptic synthesis, and immune responses, and it is also important in wound healing and haematopoiesis **(Bost et al., 2016; Uzzan et al., 2017)**. Higher copper intake may increase the risk of stroke, other cardiovascular diseases, and overall CVD mortality. The exact mechanism is unknown, but it is believed that copper can be incorporated into the molecule instead of zinc or other metals during protein biosynthesis, also oxidizing LDL-cholesterol, thereby increasing its atherogenicity. Copper can also be considered a risk marker of inflammation through its relationship with the acute phase reactant, ceruloplasmin. Cu overload is associated with insulin resistance: high serum copper levels have been found in patients with type 2 diabetes **(Eshak et al., 2018)**.

Current data support the beneficial effects of selenium on hypertension, coronary artery disease, cancer, and inflammatory diseases **(Asemi et al., 2015)**. Studies have shown a significant decrease in serum insulin levels and a reduction in insulin resistance in obese women after supplementation with 200 $mg.day^{-1}$ Se, added to a hypocaloric diet enriched by legumes **(Alizadeh et al., 2012)**. Se deficiency is a factor in the development of cardiovascular and neurodegenerative diseases, aging, and immune system damage due to oxidative stress **(Wang et al., 2014)**.

Chromium (Cr^{3+}) supplementation improves insulin sensitivity and blood glucose levels in animals and humans with impaired glucose tolerance, insulin resistance, and diabetes **(Staniek and Wójciak, 2018)**. In contrast, Cr^{6+} is very toxic and has a high ability to enter cells, causing a wide range of damage – DNA damage, chromosome aberrations, changes in epigenome, and microsatellite instability **(Bjørklund et al., 2017)**. It causes various types of cancer; exposure to Cr^{6+} can result in asthma and damage to the nasal epithelium and skin, and the effect of Cr^{6+} on the thioredoxin system likely has widespread consequences for cell survival and redox signaling in cells **(Kaprara et al., 2015)**.

Scientific hypothesis

The female organism undergoes changes during menopause resulting from a gradual decrease in estrogen production that increases several health risks. Considering these risks, we selected 6 micronutrients, the intake of which we will evaluate. We assume that women living in a city environment, mostly in apartments, will show a higher intake of micronutrients. We also examine whether the choice of shopping place influences the intake of selected minerals or energy intake.

MATERIAL AND METHODOLOGY

We monitored the intake of selected minerals in the diet of premenopausal women and highlighted the possible adverse effects of disbalanced intake of these elements. At the same time, we investigated whether socio-demographic factors and choice of food store have an impact on the intake of the mineral substances. 30 women aged between 40 and 50 years old (44.79 ±2.04 years), from the districts of Partizánske and Prievidza, were involved in the research. Eating habits and intake of monitored nutrients were determined using 3-day dietary records, which included 2 workdays and 1 non-workday. All participants reported a weekend day, mostly Sunday (23 of 30). We collected the nutritional protocols from October 2018 to January 2019. For BMI determination self-reported weight and height were used. All participants participated in the research voluntarily, were acquainted with the way of processing the provided data, and provided their consent to their processing.

The assessed nutritional parameters included the intake of energy and essential macronutrients – carbohydrates, protein and fat, and intake of selected micronutrients – calcium, phosphorus, zinc, copper, selenium, and chromium, which affect the health of the participants in relation to certain health risks arising from the upcoming menopause. The study was aimed at nutritional intake, therefore the level of physical activity was not a necessary criterion.

We evaluated the data using Mountberry nutritional and fitness software (2011, version 1.1). This software is designed for a complete analysis of food, meals, and recipes based on the composition of the raw ingredients. Using the updated food database, it is possible to adjust the software outputs in terms of nutrient intake, health ailments, dietetic principles, and individual user needs. Dietary regime analysis evaluates energy and nutrient balance and the intake of selected nutrients and compares

the values with the recommended standard. If the food listed in the nutritional protocol was not contained in the software database, we added the nutritional data manually into the database. We also proceeded in cases, in which, in order to add the food into the database, we had to consult with the participant about the exact recipe.

Statistical analysis

Statistical analysis was carried out using MS Excel 2010 (Los Angeles, CA, USA) in combination with XLSTAT (Version 2019.3.1). Mean, standard deviation, minimum and maximum, and median were calculated. Statistical significance was determined using a two-sample t-test when comparing subgroups of the population and a paired t-test when comparing the nutritional intake of the entire population during a workday and weekend. Differences at $p < 0.05$ were considered significant.

RESULTS AND DISCUSSION

Workday vs. weekend

Significant adverse effects on the intake of basic nutrients and energy were observed on workdays and non-workdays, for which all participants provided a weekend day (Table 1).

On weekdays, women tend to receive lower amounts of total energy, protein, carbohydrates, and fats compared to a weekend day. According to the calculated mean values, the recommended daily allowance (RDA) (57 g) was met only for protein intake, both on weekdays (62.89 ±27.33 g) and over the weekend (75.47 ±25.76 g).

We observed that the average values of the monitored group did not meet the RDA guideline **(MHSR, 2015)**, which are 8800 kJ of energy, 306 g of carbohydrates, and 72 g of fats. At the same time, there are obvious differences in the intake of the selected minerals on a workday and weekend day.

Haines et al. (2003) described high energy intake from alcoholic beverages over the weekend, especially on Saturday, in the 19 – 50 age group, as did **An (2016)** and **Jahns et al. (2017)**. In addition to alcohol, energy intake was also increased by the increase in the proportion of fats in the weekend diet, which was richer than during workdays by an average of 115 kcal (481.28 kJ).

Haines et al. (2003) observed similar results as the study of **An (2016)**, which examined the differences in the nutrition of 11 646 adults over 18 years in the United States during workdays and weekends. In comparison with the average values on workdays and on Saturday, the weekend intake was increased, especially in the case of total energy, by 181.04 kcal, approximately 757.5 kJ. Food quality on Saturday was lower than on other monitored days.

Jahns et al. (2017) also found a higher energy intake of macronutrients over the weekend in a population of middle-aged women (49.4 ±5.8 years). In 75% of these women, they noticed increased energy intake by an average of 158 kcal (661.23 kJ) over the weekend. The increase in intake was provided mainly by carbohydrates, as in our results. The least variable nutrient were fats; their intake was very similar during the week, contrary to our results. In our research, we observed very small differences in protein intake.

From our results, on workdays, the recommended nutritional quantities of protein intake were met only in 56.67% of cases, and those of fat intake in 6.67% of cases in a population of thirty. None of the participants from the observed group met the recommended intake of energy and carbohydrates. Weekend intake was higher for all four endpoints (Tables 1), with recommended energy intake met by 23.33%, protein intake by 73.33%, carbohydrates intake by 16.67%, and fat intake by 40.0% of the participants.

Table 1 Average intake of monitored nutrients, working day vs. weekend day.

Parameter	Work day		Weekend day		*p*-value[1]
	Mean ± SD	median	Mean ± SD	median	
Energy (kJ)	4989.75 ±1283.91	4906.86	7440.07 ±2504.7	7101.47	0.000001[2]
Protein (g)	62.89 ±27.33	59.73	75.47 ±25.76	66.83	0.011115[2]
Carbohydrates (g)	153.83 ±39.86	151.11	231.68 ±74.81	217.22	0.000001[2]
Fats (g)	44.5 ±16.49	44.23	68.47 ±28.32	64.26	0.000074[2]
Ca (mg)	613.62 ±241.37	564.89	657.28 ±325.62	560.64	0.25
P (mg)	913.71 ±282.62	824.05	1024.28 ±290.86	999.69	0.07
Zn (mg)	25.85 ±12.46	23.63	25.99 ±14.02	22.70	0.47
Cu (mg)	1.39 ±0.82	1.16	1.31 ±0.46	1.18	0.28
Se (µg)	177.13 ±106.46	180.34	163.37 ±102.15	165.04	0.15
Cr (µg)	38.00 ±12.57	37.62	41.88 ±26.42	37.85	0.25

Note: [1] statistically significant differences were verified using paired t-test; [2] $p < 0.05$ was considered statistically significant.

Table 2 Average values of monitored parameters, living in urban vs. rural area.

Parameter	Urban area (n = 17)		Rural area (n = 13)		*p*-value[1]
	Mean ± SD	median	Mean ± SD	median	
	23.76 ±4.27	22.68	23.32 ±3.16	23.38	0.38
Energy (kJ)	5733.78 ±1531.09	5540.84	5901.62 ±1317.57	5833.61	0.38

Cr (µg)	36.00 ±11.15	36.77	43.05 ±10.64	45.28	0.049[2]

Note: [1] statistically significant differences were verified using two-sample t-test; [2] $p < 0.05$ was considered statistically significant.

Several authors **(Haines et al., 2003; Ruopeng, 2016; Jahns et al., 2017)** have observed lower nutritional quality of the diet over weekends – reduced intake of fruits, vegetables, and fiber, and increased consumption of fast food. Our results, on the other hand, show better nutritional status over the weekend, especially in terms of total energy, carbohydrate, and fat intake, but participants also received higher amounts of almost all minerals (except Cu and Se). Based on the average intake of the selected nutrients, we find that the intake of micronutrients over the weekend is almost the same as on weekdays. The biggest differences were in the intake of energy, carbohydrates, and fats, which is explained by the fact that during the weekend, the participants had time to consume more meals per day compared to a workday (average of 4.5 meals on a weekend day; an average of 4.1 on a workday). Of those involved, 53% received at least one meal more during the weekend than on weekdays.

Evaluation of the intake of monitored nutrients by place of residence (urban vs. rural area)

Urbanization interacts with several key determinants of food consumption. It is believed that the self-production of food is not very common in urbanized areas, which also affects dietary habits **(Cockx, Colen and De Weerdt, 2018)**.

From the monitored population of 30 women, 13 women lived in a village and the remaining 17 lived in a city. Based on average values of the group (Table 2), intake of minerals, zinc, copper, selenium, and chromium were met in both groups of women, even exceeding the

recommended amounts given in the RDA guideline **(MHSR, 2015)**.

In the "urban" group, we observed that the average BMI was higher than in the "rural" group, mainly because most overweight (>25 kg.m^{-2}) and obese (>30 kg.m^{-2}) women lived in the city (Table 3). Although BMI above 30 kg.m^{-2} was observed only in 2 participants in our study, several studies of women of similar age categories show the prevalence of higher BMI in urban women, often in association with waist circumference (≥88 cm) **(Okop, Levitt and Puoane, 2015; Rothman et al., 2018)**. In addition, **Okop, Levitt and Puoane, (2015)** reported a higher proportion of excessive body fat in urban women (47.6 ±11% body fat) compared with women living in rural areas (44.10 ±10% body fat), differences in BMI parameters (34.7 ±9 and 31.4 ±8 for city and village, respectively), and waist circumference (100.1 ±16 cm in the city and 93.7 ±17 cm in the village). The percentage of women in the 35 – 49 age group (n = 429) with high measured endpoints was 10% higher for BMI, 6% higher for waist circumference, and 4% higher in the urban group compared to the rural. Conversely, **Trivedi et al. (2015)** are critical of the rural group in the American population, in which they observed a higher prevalence of obesity due to poor eating habits and lower physical activity. The prevalence of female obesity was 33.4% in the rural area and 28.2% in the urban area (p <0.01). The nutritional risk factors associated with an increased risk of obesity were lower fruit consumption, higher protein intake (mainly from meat and beans), and skipping breakfast.

Both groups met the requirements for the recommended intake of phosphorus ingested – the intake exceeded the RDA by more than 200 mg. However, in the case of calcium, the intake was almost 400 mg below the RDA in both groups. Women living in the village environment received a higher amount of Ca, which is surprising given that the intake of other minerals was lower than in the urban group. However, on average, this amount was still insufficient, and less than 30 mg higher than that of the women from the city district. **Rothman et al. (2018)**, in their study of 452 women (aged 45 to 54 years), observed a higher intake of milk and dairy products (Ca sources) in the diet of the urban population compared to the rural population and assumed that calcium intake is directly proportional to the consumption of these foods. They refer to an insufficient intake of these foods and thus calcium as a risk factor in the development and progression of osteoporosis.

Average zinc intake was elevated almost 2.5 to 3 times the recommended daily dosage, which may be counterproductive and may disrupt the homeostasis of the body. However, the mean value was not within the range of 50 – 300 mg.d^{-1}, and therefore we assume that chronic toxicity manifestations of this element should not be present **(EFSA, 2006)**. The dietary intake of copper according to the RDA guideline **(MHSR, 2015)** is 900 µg and 1.6 mg according to the Mountberry nutritional software used; therefore, the values obtained from the nutritional records of the population were optimal. Again, we observed a higher intake of both elements in the group of participants living in the city.

Ilow et al. (2011) also reported lower zinc intake in urban areas, although our average values were 3 to 4 times higher than those reported, mainly attributed to the size of our sample (n = 30) and the sample size of **Ilow et al. (2011)** (n = 2572). However, copper intake in their study was higher in rural areas by an average of 0.1 mg, while we observe a higher intake of 0.25 mg in the urban population. In both cases, copper intake exceeds the recommended daily quantities.

A phenomenon similar to that of zinc intake is also observed for selenium intake. The urban part of the population receives a higher amount than women living in the village, and the intake is 2 – 3 times higher than recommended by the Ministry of Health. If the participants consistently received that much selenium, as in the case of zinc, their organisms could be damaged. Chromium intake only slightly exceeds the recommended intake in women living in a village and can be said to be optimal compared to Cr intake in the city where we observe a slightly higher average intake value. Nutritional intake is again higher in the urban group.

Table 4 Average values of nutrition parameters, supermarket vs. different food source.

Parameter	Different food source (n = 18)		Supermarket (n = 12)		p-value[1]
	Mean ± SD	median	Mean ± SD	median	
BMI (kg.m^{-2})	24.1 ±4.45	22.46	22.77 ±2.45	22.51	0.16
Energy (kJ)	5765.41 ±1408.54	5718.56	5868.17 ±1495.54	5597.32	0.43
Protein (g)	63.30 ±18.47	62.29	73.27 ±28.75	66.68	0.16
Carbohydrates (g)	180.94 ±43.41	170.13	177.54 ±43.34	184.97	0.42
Fats (g)	56.28 ±22.63	54.04	50.78 ±15.99	51.73	0.23
Ca (mg)	644.03 ±237.46	555.72	604.39 ±187.61	595.82	0.31
P (mg)	923.76 ±212.40	916.74	990.99 ±225.56	933.49	0.22
Zn (mg)	23.60 ±11.34	21.99	29.34 ±12.60	26.39	0.12
Cu (mg)	1.21 ±0.28	1.17	1.58 ±0.91	1.27	0.11
Se (µg)	156.91 ±105.50	137.68	196.00 ±85.44	182.83	0.15
Cr (µg)	36.69 ±11.81	38.13	43.20 ±9.73	45.28	0.06

Note: [1] statistically significant differences were verified using two-sample t-test; [2] p <0.05 was considered statistically significant.

Similar findings were present in the Polish population, with higher Se intake in cities (77.3 ±31.3 μg per day) compared with rural areas (72.9 ±23.6 μg per day). The authors attributed the size of the standard deviation to different numbers of participants (n = 1786 for the urban population and n = 786 for the rural population) **(Ilow et al., 2011)**.

The differences in the diets can be explained by the fact that urban areas are characterized by a significantly different food supply environment, affecting the availability and price of food. The possibilities of eating away from home or buying semi-finished or ready-made meals are more prevalent and more diverse in urban areas because there are mini-markets, supermarkets, and fast-food chains with easy availability of food **(Cockx. Colen and De Weerdt, 2018)**.

Evaluation of the intake of monitored nutrients by type of home (family house vs. apartment)

The participant group comprised of 16 women living in a family house with a garden and 14 living in an apartment. The average intake of minerals was similar to the previous criterion of evaluation, namely that the intake of all selected micronutrients was sufficient except for calcium, intake of which was deficient in both groups regardless of the type of housing (Table 3).

We observed a higher intake of Ca in participants living in a family house with a difference of over 100 mg. Six women from this group achieved the recommended intake, but none received more than 1000 mg twice or more in 3 monitored days. In the group of women living in apartments, we have seen such values only in 4 women, also only one day from the three-day nutritional protocol. Phosphorus intake was met according to RDA limits but may be of concern due to low calcium intake. The calcium to phosphorus intake ratio in the "family house" group was 1:1.58, while in the "apartment" group the Ca:P ratio was 1:1.45. **EFSA (2015)** reports an optimal Ca:P ratio of 1.4:1 to 1.9:1 and may therefore be a risk factor at a later age or after menopause, particularly in relation to osteoporosis.

The mean value of Zn intake was 27.60 ±11.57 mg in the group of women living in apartments and 24.40 ±12.52 mg in family houses. The actual intake was more than triple the RDA, but this amount should not cause any health risks according to **EFSA (2006)**.

Comparing the intake of copper in both groups, we can see that the individual average received quantities are higher than those stated by the **MHSR (2015)** in the RDA for SR, therefore, the intake was sufficient. However, according to the limits in Mountberry software, which recommends an intake of 1.6 mg Cu per day for the selected age group, intake would be inadequate, especially in the "family house" group.

The average Se intake in the "apartment" group was more than three times the RDA. For women living in a family home, we also see a higher daily intake, but to a lesser extent. Selenium intake is high throughout the population regardless of assessment criteria, which may have an adverse effect on the cardiovascular system, as reported by **Grotto et al. (2018)** and **Vinceti et al. (2019)**. **Grotto et al. (2018)** reported that high intake induces changes in blood pressure: an increase in systolic blood pressure. Their experiments were performed in mice which they had been feeding increased amounts of selenium for 85 days via drinking water (2 and 6 $mg.L^{-1}$) in the form of sodium selenite; the first changes in blood pressure were observed after 42 days. Although several authors report 400 μg a day as a critical intake of Se in humans, and according to the recorded average values, the respondents' health should not be in danger, we do not recommend a multiple increase in the intake of this mineral.

According to the RDA, the intake of chromium is adequate in both groups, with a more optimal value in the "family house" group, where the difference from RDA is on average 1.01 μg, while in women living in apartments, the actual intake exceeds RDA by less than 23%. Overall, we note that the intake of Cr and Cu shows the most optimal values in relation to the recommended daily allowances set by the Ministry of Health of the Slovak Republic **(MHSR, 2015)**.

We can see from Table 3 that the intake of all nutritional parameters was higher in women living in apartments. **Cockx. Colen and De Weerdt (2018)** suggest that smaller living space and a lack of storage and cooking facilities could contribute to increased dependence on foods that require less or no preparation. This phenomenon may encourage more frequent shopping and more varied food choices, depending on the individual's current preferences.

Evaluation of the intake of monitored nutrients by food source (supermarket vs. mixed source)

Several studies point out that the choice of grocery store affects food intake and nutritional composition. We anticipated that total energy intake would be higher in the supermarket group, due to the increased availability of semi-prepared foods and ready-made meals that tend to contain more salt, saturated and trans-fatty acids, and sugar **(Albuquerque et al., 2018)**.

Most women (18) reported different sources of food than the supermarket, which included local producers, vendors, farmers, or their food production. The second group consisted of women (12) who identified supermarkets as their only food source – they did not buy food in other establishments.

We observed that the intake of minerals, except Ca, is higher in the group buying food in several stores of local farmers and producers or growing and producing the food themselves (Table 4). In this group we also see a better ratio of calcium to phosphorus intake, numbering 1:1.43 compared with 1:1.64 in the supermarket only group. From this point of view, women buying only in supermarkets could be at a higher risk of breaching bone homeostasis. Regardless of the Ca: P ratio, calcium is deficient in the diet of the participants of both groups. This is not true of phosphorus intake, which seems excessive compared to RDA in both groups and reaches 141.57% of RDA in the supermarket group and 131.97% RDA in the "different food source" group.

Zinc intake is excessive in both subgroups but is significantly higher in women shopping at the supermarket. Zinc, due to its role in the human body, is nowadays one of the elements by which food, for example, breakfast cereals or flour, is fortified, especially to prevent its deficiency in the body **(Brown, Hambidge and Ranum, 2010; Shah et al., 2016)**. The likelihood of availability of such enriched foods in local farm shops is

lower than in the supermarkets. Again, the average amounts received are within the range recommended in the RDA and Mountberry (0.9 – 1.6 mg per day), leading us to conclude that the diet intake is optimal.

The amounts of selenium and chromium received from the diet were met in terms of the recommended daily intakes in both groups. Again, as with most previous micronutrients, higher quantities were received by women shopping in the supermarket.

In our representative sample of women, it was not confirmed that the choice of food source had an impact on the intake of the micronutrients monitored, as the differences between the groups are slight and statistically inconclusive (Table 4). These findings are consistent with **Cummins, Flint and Matthews (2014)**, who reported that they did not find significant changes in endpoints when changing the typical grocery shopping place in the American population. However, **Liese et al. (2017)** noted the relationship between BMI and the primary grocery store. Their research involved 459 respondents (80% women), with 61% listing a supermarket as their primary point of purchase. Their results pointed to an interesting association: higher BMI values of 2.6 $kg.m^{-2}$ were found in people who regularly and primarily shopped in large stores (supermarkets) and discount halls compared to shoppers in small local operations.

In the group of women shopping in supermarkets, we observed a slightly higher energy intake compared to the second group, but the nutrient intake did not change significantly, which may mean that these participants received more low-nutrient but high-energy foods. This, according to **Cohen et al. (2015)**, can reflect in changes in body weight and consequently an increase in BMI. More frequent consumption of such foods is also helped by the marketing strategies of the producer or retailer: lower price, bigger packaging, and advantageous offers (2 in 1). Based on the results (Table 4) we can say that the choice of food source does not play a significant role in the intake of minerals. We observe minor abnormalities in the intake of macronutrients, but given the uneven distribution of the population with a higher number of participants on the mixed food source side (n = 18) than on the supermarket side only (n = 12), we conclude that these differences are due only to the food preferences of the women.

Several strengths and limitations exist in the current study. We focused strictly on the intake of selected nutrients and did not consider physical activity, which may increase the body's need for some nutrients. Another limitation might be the sample size. On the other hand, the strength of the study is the age group and the quality of the obtained nutritional data. Collected 3-day dietary records were responsibly filled by participants and we completed the dietary records with an interview about used groceries and food processing.

CONCLUSION

We assessed the impact of a diet in premenopausal women in relation to the risk factors for chronic non-communicable diseases, the development of which is related to the menopausal period.

Mineral intake was adequate with average values higher than the RDA guideline by MHSR, except for calcium. Based on the place of residence, we observed a higher intake of macronutrients and macroelements (Ca and P) in participants living in the village, but the intake of other minerals was lower compared to the urban group. There were statistically significant differences in the intake of Zn ($p = 0.012$) and Se ($p = 0.020$), but the place of residence did not affect the intake of other nutrients. The effect of the type of home was statistically significant only in the case of intake of Cr ($p = 0.049$) and Cu ($p = 0.048$) with higher intake in participants living in an apartment. An increase was also observed in carbohydrate intake ($p = 0.021$). In the case of shopping place location, there was no statistically proven effect on the intake of minerals or macronutrients.

Based on the current intake of the monitored nutrients and assessment criteria, we conclude that the study group is at risk for the development of osteoporosis due to overall insufficient Ca intake in the entire population sample. We also take into account the risk of developing type 2 diabetes mellitus due to abnormal Se and Zn intakes and an increased risk of cardiovascular complications that may facilitate the development of metabolic syndrome in the future, especially in women living in the city.

PREPARATION OF PROTEIN PRODUCTS FROM COLLAGEN-RICH POULTRY TISSUES

Aneta Polaštíková, Robert Gál, Pavel Mokrejš, Jana Orsavová

ABSTRACT

Chicken stomachs are by-products obtained from the poultry processing in slaughterhouses. Their amount has been gradually increasing as a consequence of a continually rising poultry consumption. Since these animal tissues are still rich in proteins, mainly collagen, fat, and minerals, it is essential and beneficial to investigate the appropriate management and further processing. Collagen could be extracted from chicken stomachs and used as a raw material in the food, cosmetic, medical, and also pharmaceutical industry. This paper is to investigate possibilities of such extraction of collagen products, gelatines, or alternatively hydrolysates, from chicken stomachs after prior biotechnological treatment with the proteolytic enzyme Protamex. In this experiment, non-collagenous proteins were removed from stomachs using 0.03 M NaOH and 0.2 M NaCl. Subsequently, the tissue was defatted applying acetone and the enzyme Lipolase. Purified and dried collagen was then treated with the proteolytic enzyme Protamex. In the last step, gelatine was extracted from the tissue in hot water. The influence of selected processing parameters on the extraction efficiency and final product quality was monitored. The extraction conditions included the amount of the added enzyme (0.1 – 0.4%) and the extraction temperature of between 60 and 65 °C. The total gelatine yield ranged from 43.80 to 96.45% and the gel strength varied from 2 ±0 to 429 ±8 Bloom. The enzymatic treatment of the raw material is an economical and ecological alternative to traditional acid or alkaline treatments. Extracted gelatine with the gel strength of 100 – 300 Bloom would be suitable for the applications in the food industry in the production of confectionery, marshmallow, aspic or dairy products.

INTRODUCTION

The consumption of poultry meat has been consistently increasing. The current status in the Czech Republic is approximately 27 kg per person per year. Such a situation emphasizes the importance of management and processing of slaughter by-products **(Český statistický úřad, 2019)**. The poultry slaughter process produces two forms of edible and inedible waste, solid and liquid. Solid waste includes skin, feathers, intestines, offal, glands, limbs, and bones and liquid involves blood and various adipose tissues **(Seong et al., 2015; Ockerman and Hansen, 2000)**. Poultry waste comprises up to 30% (in several cases even 40%) of the live weight of the animal. Considering their proteinaceous nature and the fact they are produced in large quantities, they must be managed to avoid environmental pollution. However, inedible parts of poultry are mostly incinerated or landfilled. That is undesirable waste management producing up to 100 million tonnes of waste worldwide **(Borowski and Kubacki, 2015; Xiong et al., 2016; Ferraro, Anton and Santé-Lhoutellier, 2016)**. Blood is used as an additive in certain food products and in the production of feed meal. Bones and skins are applied in the production of hydrolysates, gelatine, fertilizers, and feed for livestock; furthermore, in the leather industry in the leather production and in the production of meat-and-bone meal. Adipose tissues are employed in the production of biofuels, industrial lubricants, oils, soaps, and as a functional additive for cosmetic products **(Lee, Lee and Song, 2015; Cruz-Fernández et al., 2017; Sarbon, Badii and Howell, 2013)**. Keratin hydrolysates obtained from feathers are used as growth promoters, feed additives, and functional additives in cosmetic products **(Ockerman and Hansen, 2000; Barbut, 2015; Dikeman and Devine, 2014; Wan Omar and Sarbon, 2016)**. Other wastes aim for the production of biofuels, composting, anaerobic digestion, or the isolation of valuable substances contained in animal by-products **(Borowski and Kubacki, 2015; Alibardi and Cossu, 2016; Xiong et al., 2016)**. The best solution would be to eliminate waste. Even though this is unfortunately very difficult to achieve, the optimal waste management must be pursued. To use slaughter by-

products efficiently, several criteria are vital to be accomplished. Primarily, a process recycling such a material to produce new products must be developed. Equally important is to provide a sufficient amount of slaughter by-products in the locality of new products manufacture together with the appropriate technological and economical background. A potential market where to offer these products is also essential. One of the ideal solutions appears to be the processing of slaughter waste, such as chicken stomachs, into further protein products containing significant amounts of collagen, vitamins, and minerals **(Rafieian, Keramat and Shahedi, 2015; Lee, Lee and Song, 2015; Khalid et al., 2011)**. It is important to explain that in the countries of Central Europe (the Czech Republic, Slovakia, Poland, and Hungary) poultry stomachs are considered to be edible offal. However, in Western Europe and America, these animal tissues are not included in a diet and are generally regarded as a slaughter waste. A suitable alternative to the utilization of chicken stomachs is in collagen products of gelatines and hydrolysates possible to apply in the food, pharmaceutical, cosmetic and medical industry. This would facilitate the management of an undesired and unused slaughter waste **(Alao et al., 2017; Toldra, 2006; Schreiber and Gareis, 2007; Rousselot gelatin, 2019)**.

Poultry slaughtering produces by-products having extraordinary physico-chemical properties **(Ockerman and Hansen, 2000; Ferraro, Anton and Santé-Lhoutellier, 2016)**. The chicken stomach is a part of the digestive system functioning as a smooth muscle bag divided into a muscular and glandular part. Only the muscular part is edible. The chicken stomach represents about 3% of the total weight of poultry. Since stomachs contain a significantly large amount of collagen, suitable methods of extracting gelatine from them have been investigating. Regrettably, chicken stomachs are composted or incinerated rather than used for the consumption in these regions so far **(Marvan, 2017; Huda et al., 2013; Kosseva, 2013).** The viscera, including chicken stomachs, provides extraordinary nutritional value and is highly appreciated in many parts of the world, such as in China, Japan, and India **(Bakar and Harvinder, 2002)**.

In practice, type A and type B gelatines are encountered. Type A gelatine is obtained by acid treatment of the raw material, while type B gelatine is extracted using a base. Currently, the extraction is performed using beef and pork skins and bones. This study examines the gelatine extraction after the prior enzyme treatment which seems to be the most convenient method of obtaining gelatine in terms of time and energy savings. Type B gelatine is treated for up to 6 months, type A gelatine for up to 40 hours, but enzyme extracted gelatine is treated for only up to 24 hours.

What is more, this form of gelatine is considerably well digested and absorbed in the gastrointestinal tract **(GMIA Standard Testing Methods for Edible Gelatin, 2019; Schreiber and Gareis, 2007; Mokrejš et al., 2019)**.

The aims of this study

As chicken stomachs are solid poultry by-products containing large amounts of collagen **(Marvan, 2017; Ockerman and Hansen, 2000)**, this study is to contribute to the investigation of suitable methods for the collagen extraction from such a slaughter waste. To our best knowledge, extraction and application of gelatine obtained from chicken stomachs by enzymatic treatment of the raw material have not been reported yet. Therefore, the aim of this paper is to assess the possibilities of extracting gelatine from chicken stomachs after the preceding biotechnological treatment of tissues with the proteolytic enzyme Protamex. It continues in the previous research "Preparation of protein products from collagen-rich poultry tissues" and "Utilization of protein by-products from poultry slaughterhouses for the preparation of collagen" **(Polaštíková et al., 2019a; Polaštíková et al., 2019b)**. This study focuses on monitoring the influence of selected technological conditions on the process efficiency and the final quality of extracted gelatine. The examined factors include the amount of the added Protamex proteolytic enzyme (Factor A; 0.1, 0.25, and 0.4%) and the extraction temperature (Factor B; 60, 62.5, and 65 ° C). Furthermore, it characterizes prepared gelatine by its gel strength and ash content.

Scientific hypothesis

Gelatine with a high gel strength of approximately 200 – 300 Bloom can be extracted from chicken stomachs.

MATERIAL AND METHODOLOGY

Material

Chilled chicken stomachs were provided by Raciola Uherský Brod, the Czech Republic. Stomachs were minced and homogenized to the particle size of 3 mm. The dry matter content was 19.10 ±0.05% and the composition in dry matter was as follows: protein content of 75.6 ±0.8%; fat content of 21.70 ±0.01% and mineral content of 3.900 ±0.005%.

Appliances, tools and chemicals

P-22/82 meat mincer Braher (Brather Internacional, Spain), LT2 shaker Kavalier (Kavalier, Czech Republic), Kern 440 – 47 electronic analytical scale, Kern 770 electronic analytical scale (Kern, Germany), pH meter Multical pH 526 (WTW, Weilhein, Germany), heating block LTHS 250 and 500 (Merci, Czech Republic), WTB Binder E28-TB1 driver (Binder, Germany), Memmert ULP 400 drying device (Memmert GmbH + Co. KG, Germany), SLR heating board with a magnetic stirrer (Schott Gerate GmbH, Germany), Stevens LFRA Texture Analyser for measuring gelatine gel strength (Leonard Farnell and Co Ltd., England), magnetic stirrer IKA Labortechnik PCT Basic with a heating and magnetic stirrer (IKA-Werke, Germany), differential scanning calorimeter DSC 1 (Mettler-Toledo, Germany), Mora hot air oven (Mora, Czech Republic), Nabertherm L9/11 muffle furnace (Nabertherm, Germany), desiccator (Kavalier, Czech Republic), EBA 20 centrifuge including a rotor (Hettich, Germany), vertical mixer ETA 0010 New Line (ETA, Czech Republic), KRUPS grinder and Samsung refrigerator (KRUPS, Czech Republic).

Erlenmeyer flasks of the volume of 2 L and 0.5 L; 2 L PET bottles with a screw cap; 25 mL, 200 mL, 250 mL and
1000 mL graduated cylinder; Petri dishes; pipettes;

weighing bottles; low-density filter papers; metal sieves; sprays with distilled water; scissors; gel strength flasks; non-stick drying pads; PA fabric; silicon crucible; 1 mm and 2 mm metal sieves; laboratory spoons and sticks; beakers; laboratory tongs; self-closing PE bags; funnels; metal sheet and adhesive tape.

Enzym Protamex (*Bacillus* protease complex developed for the hydrolysis of food proteins; declared activity of 1.5 $AU.g^{-1}$), distilled water, 0.03 M and 0.06 M NaOH, 0.2 M HCl, acetone, chloroform, ethanol, the enzyme Lipolase. The enzyme was provided by the Danish company Novozymes and the all chemicals used were provided by the Czech company Verkon.

Factor analysis

Factor analysis refers to a trial method describing the effect of individual factors on the total yield. It is a more time-consuming optimization method sensitive to measurement errors. It provides an extensive range of information; it monitors the impact of several factors on the sample. Factor analysis enables to evaluate not only one factor but also a complex of factors affecting the studied sample. Factor schemes of 2^2 or 2^3 are the most common. The analysis is a matrix creating a combination of input values. And the number of experiments depends on the number of variables **(Antony, 2014; Erge and Zorba, 2018)**. In this study, a factor scheme of 2^2 was applied for the experiments, for two levels and two examined quantities. The factors were as follows: the amount of Protamex enzyme added (Factor A; 0.1, 0.25 and 0.4%) and the extraction temperature (Factor B; 60, 62.5, and 65 °C). The enzymatic treatment of the raw material and the extraction time were constant for all laboratory experiments, 30 h, and 2 h, respectively.

Testing of functional properties gelatines

The extraction efficiency was calculated according to the following equation:

$$HY = \frac{m_1}{m_0} . 100$$

$$GY = \frac{m_2}{m_0} . 100$$

$$\eta = HY + GY$$

Where:

HY is the hydrolysate yield (%), m_0 is the weight of the defatted raw material (g), m_1 is the weight of the hydrolysate, GY is the gelatine yield (%), m_2 is the weight of gelatine (g) and η is the total yield (%).

Gelatine analysis providing ash content and gel strength was performed according to the Standard testing methods for edible gelatine **(GMIA Standard Testing Methods for Edible Gelatin, 2019)**. The melting temperature of gelatine gel was determined using a differential scanning calorimeter (DSC). After weighing 15 – 30 mg of the sample onto the DSC aluminum dish, it was sealed with a lid. Subsequently, the sample was placed into the measuring cell together with the reference sample. First, the DSC dish was cooled to 5 °C and maintained at this temperature for 5 min. Then, the dish was heated at a heating rate of 5 °C/1 min to the final temperature of 50 °C. Afterward, it was cooled to the initial temperature of 5 °C following the cooling rate of 5 °C/1 min. The melting temperature reflected an endothermic peak during the sample heating **(Höhne, Hemminger and Flammersheim, 2003)**.

Preparation of chicken stomach gelatines

Preparation of pure collagen

The purpose was to remove non-collagenous proteins and fat from the raw material to obtain isolated collagen which was then processed in gelatine extraction. First, the raw material was washed in water which removed albumins from the raw material. The treatment in 0.2 M NaCl at the ratio of 1:6 for 1.5 h followed to remove globulins. Then, the treatment with 0.03 M NaOH at the ratio of 1:6 for 20 h removed glutelins. And finally, the treatment with the enzyme Lipolase (the amount of 5% enzyme) with water 1:10 for 3 days defatted the material. Afterward, the defatted tissue was dried at 35 ±1 °C in the oven for 24 h. Thereafter, solvent defatting of the material was performed using acetone at the ratio of 1:9 for 20 h. This was followed by grinding pure collagen on a vertical mixer to the particle size of 1 mm.

Extraction of gelatine from pure collagen

The purified raw material was mixed with distilled water at the ratio of 1:10 and gently shaken at room temperature for 45 min. Then, the pH was adjusted to 6.5 – 7.0. Subsequently, the Protamex enzyme was added in the amount following *Factor A*, which is 0.1% or 0.25% or 0.4% of the enzyme (Table 1). The enzymatic treatment time of 30 h was constant for all experiments. In the next step, the raw material was filtered through a metal sieve, which was provided with 3 layers of PA fabric, and washed thoroughly with water to inactivate the enzyme partially. The material was then subjected to gelatine extraction. First, the washed material was placed into a beaker and mixed with distilled water at the ratio of 1:8. Subsequently, it was heated to the temperature of 60 °C, 62.5 °C, or 65 °C following *Factor B*. After reaching a defined temperature, the gelatine was extracted for 2 h. Finally, 200 mL of gelatine solution was poured onto a 330 cm^2 sheet provided with a non-stick film and dried in an air circulation drier at the temperature of 45 ±1 °C for 2 days.

Table 1 provides the list of experiments including the technological conditions, process characterization, and the list of prepared gelatines following the factor scheme of 2^2.

Statistical analysis

The results of all experiments were processed in MiniTab® 17.3.1 software (Fujitsu Ltd., Tokyo, Japan) for Windows. The statistical significance of the investigated process factors within the observed limits was evaluated on the significance level of p = 95%. Factors with a value lower than α = 0.05 influenced the evaluated variables with a 95% significance. The lower the p value, the greater the influence of process factors on the sample. Subsequently, the coefficient of determination characterizing the quality of the regression model was established and the data was graphically expressed.

Table 1 Characteristics of the experiments defining technological conditions, process characterization and attributes of prepared gelatines.

Exp. No.	Factor A Enzyme addition (%)	Factor B Extraction temperature (°C)	Yield of hydrolysate, η_H (%)	Yield of gelatine (main fraction), η_G (%)	Yield of gelatine (minor fraction), η_G (%)	Total extraction efficiency, $\sum\eta$ (%)	Gel strength, F ±SD (Bloom)	Ash content, AC ±SD (%)
1	0.10	60.0	7.76	24.39	32.70	64.85	192 ±10	1.87 ±0.04

5	0.25	62.5	7.76	63.19	9.67	80.62	96 ±4	1.40 ±0.30

RESULTS AND DISCUSSION

The evaluated variables included the degree of conversion, i.e. the percentage of conversion of the raw material into collagen products, the degree of purity of the final products in terms of ash content, and the quality of the extracted gelatine expressed in gel strength in Blooms.

The equation (1) of total extraction efficiency was:

$$\sum\eta = 177 + 139.5\,A - 2.16\,B \qquad (1)$$

The amount of added enzyme performed a statistically significant (p = 0.035) influence on the total extraction efficiency, whereas the extraction temperature showed no statistical significance (p = 0.309); R^2 = 93.58%.

Figure 1 depicts the effects of factors A and B on the total extraction efficiency. It reveals that the overall yield is the least (less than 50%) with the enzyme addition of 0.1% and the extraction temperature of 65 °C. Conversely, the highest total efficiency of more than 90% was recorded with the enzyme addition of 0.4% and the extraction temperature of 60 and 65 °C. At the temperature of 62.5 °C, the yield declined below 90% again. In general, the total efficiency increases with a rising amount of added enzyme and growing extraction temperature. Thus, the highest efficiency of 96.45% was monitored when 0.4% enzyme was added and the extraction temperature was 60 °C; the lowest efficiency of 43.80% was determined with 0.1% added enzyme and the extraction temperature of 65 °C.

The yield of the gelatine extraction from chicken stomachs varied between 23.84 and 88.69%. **Du et al. (2013)** treated chicken and turkey heads in acetic acid and

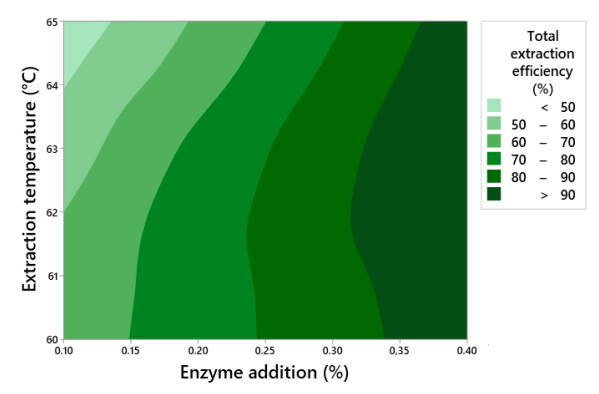

Figure 1 The impact of the amount of added enzyme and extraction temperature on the total extraction efficiency.

achieved gelatine yields ranging from 21.1 to 38.0%. Lower gelatine yield of 21.1% was obtained for chicken gelatine extracted at 60 °C and higher gelatine yield of approximately 38.0% was established for turkey gelatine extracted at 50 °C. In both studies, a lower gelatine yield was established if compared to the present experiment. **Almeida, Calarge and Santana (2013)** treated chicken feet at 120 °C for 20 min and extracted gelatine with a yield of about 36% which is in accordance with the yields determined in this study. **Cheng et al. (2009)** treated chicken feet in hydrochloric, acetic, and lactic acid and established the gelatine yield of 5.6 (HCl), 7.3% (acetic acid), and 8.3 (lactic acid) which is less than in this experiment. **Sarbon, Badii and Howell (2013)** extracted gelatine from chicken skin using both the acid and alkaline method with the total yield of only 16%. Therefore, it is evident that the acid and alkaline method may not be optimal to apply for skin processing. A higher yield of gelatine was achieved using the enzymatic treatment of the raw material **(Mrázek et al., 2019)**. Duck gelatine yield examined by **Huda et al. (2013)** was 28.4% which is a lower yield compared to the chicken gelatine yield of 31% achieved by **Liu, Lin and Chen (2001)**. **Abedinia et al. (2017)** treated duck feet using the acid, alkaline and enzymatic methods with the yields of 12.76, 11.39, and 17.94%, respectively. Even though their study confirmed the highest yield of gelatine by enzymatic treatment, it is still less than it was established in this experiment.

The equation (2) of gelatine gel strength was as follows:

$$F = -1044 - 1018\,A + 23.1\,B \qquad (2)$$

The amount of added enzyme and the extraction temperature did not show a statistically significant (p = 0.084; p = 0.346) influence on gel strength; R^2 = 85.69%.

Figure 2 depicts the impact of Factor A and B on gelatine gel strength. It is evident that to obtain high values of gelatine strength it is essential to apply higher extraction temperatures together with a lower amount of the enzyme. With 0.1% of the added Protamex enzyme and extraction temperature of 65 °C (Experiment 2), gelatine with the gel strength of more than 400 Bloom was extracted which is significantly high. Generally, the gel strength grows with a decreasing amount of enzyme and rising extraction temperature. In this study, it ranged from 2 ±0 to 429 ±8 Bloom. The lowest gel strength value was recorded with 0.4% of the added enzyme and at the extraction temperature of 65 °C. The highest values of gel strength

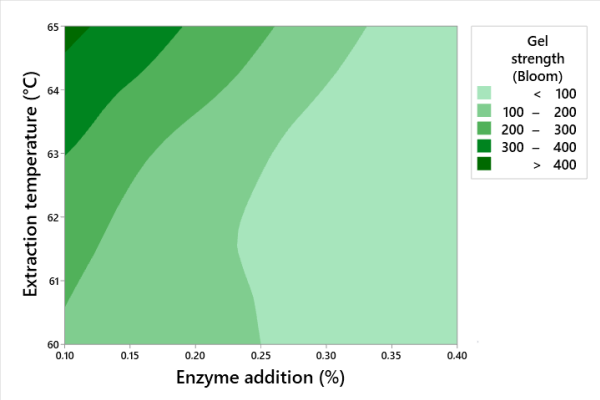

Figure 2 The impact of the amount of added enzyme and extraction temperature on the gel strength.

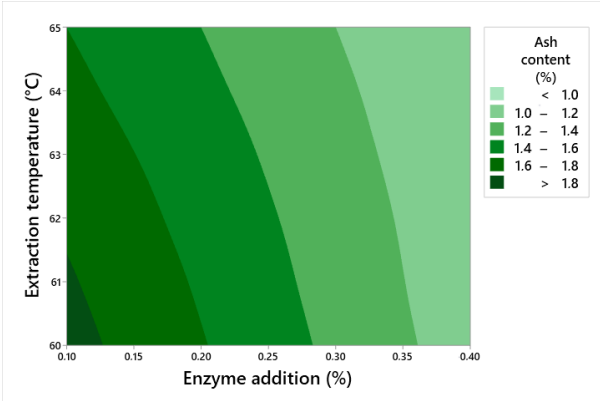

Figure 3 The impact of the amount of added enzyme and extraction temperature on the ash content.

were achieved in the extraction conditions of Experiment 2.

Du et al. (2013) extracted gelatine from turkey and chicken heads with a prior treatment in acetic acid and established the gel strength of 367 Bloom of turkey gelatine extracted at the temperature of 50 °C and the gel strength of 248 Bloom of chicken head gelatine extracted at the temperature of 60 °C which corresponds with this study. **Sarbon, Badii and Howell (2013)** stated bovine gelatine gel strength of 229 Bloom and chicken gelatine gel strength of 355 Bloom. High gel strength values ranging between 320 and 550 Bloom were established in the study by **Rafieian, Keramat and Kadivar (2013)**. **Rafieian, Keramat and Shahedi (2015)** examined chicken bone waste of mechanically deboned meat and determined the gel strength of 520 Bloom which exceeded the results of this experiment. **Sarbon, Badii and Howell (2013)** extracted chicken skin gelatine using both acidic and alkaline extraction methods and recorded the gel strength of 355 Bloom. Such a gel strength value confirms they have obtained the gelatine of considerably good quality. Compared to other alternative gelatine sources, such as fish, chicken gelatine achieves higher gel strength values; mackerel gelatine showed the gel strength of 280 Bloom and tilopia gelatine of about 220 Bloom **(Bakar and Harvinder, 2002)**. In the last decade, an interest in both poultry and fish gelatines has increased. Gel strength of fish gelatines may reach up to 420 Bloom. Such a significant gel strength was measured in gelatine extracted from tuna skin according to the study by **Zhou, Mulvaney and Regenstein (2006)**.

The equation (3) of the ash content in gelatine was as follows:

$$AC = -4.277 - 2.283\,A - 0.0370\,B \qquad (3)$$

For the ash content, the amount of added enzyme was statistically significant (p = 0.008). In contrast, the extraction temperature was statistically insignificant (p = 0.092); R2 = 98.58%.

Figure 3 shows the effects of Factors A and B on ash content. It is evident that to obtain a low amount of ash content in % it is vital to apply a lower/higher extraction temperature and a higher amount of the added enzyme. With 0.4% of the added enzyme Protamex and the extraction temperature of 60 and 65 °C, the ash content is approximately 1.1%. The ash content generally grows with a decreasing amount of the added enzyme and rising extraction temperature. The highest value corresponds with 0.1% of the added enzyme and the extraction temperature of 60 °C which reflects the extraction conditions in Experiment 1.

In the present study, the ash content ranged from 1.0 ±0.3 to 1.87 ±0.04%. **Du et al. (2013)** published a smaller ash content of only 0.03 to 0.06% in turkey and chicken gelatine extracted at 50 °C and 60 °C. **Almeida and Lannes (2013)** established the ash content in chicken feet gelatine of 1.9%. According to **The United States Pharmacopeial Convention (2018)** the maximal content of ash in gelatine must not exceed 2.0%; therefore, this factor has been accomplished in this study. **Bueno et al. (2011)** determined approximately 0.3% of ash in pork gelatine and **Sarbon, Badii and Howell (2013)** established 1.1% of ash in beef gelatine. In contrast to this study, **Rafieian, Keramat and Shahedi (2015)** recorded the ash content in chicken bone waste of 2.6%. **Sarbon, Badii and Howell (2013)** affirmed a lower ash content of 0.4% in chicken skin gelatine extracted using both acid and alkaline methods. **Huda et al. (2013)** extracted gelatine from duck feet using 5% lactic acid in the rate of 1:8 and established the ash content of 28.6% which is fourteen times higher than the required limit for gelatine application in the food industry.

Melting temperatures of gelatine gels

Figure 4 depicts DSC curve of gelatine gels melting temperatures. Experiment 4 (the gel strength of 2 ±0 Bloom) failed to identify the melting temperature of the gel since a hydrolyzate was formed. The gelatine of Experiment 1 (0.1% of the added enzyme and the extraction temperature
of 60 °C) performed a gelatine gel melting temperature of approximately 35 °C (the gel strength of 192 ±10 Bloom). Very similar melting temperature was achieved in Experiment 5 (0.25% of the added enzyme and the extraction temperature of 62.5 °C; the gel strength of 96 ±4 Bloom). The melting temperature of 36 °C was recorded in Experiment 3 with the gel strength of 8 ±0 Bloom (0.4% of the added enzyme and the extraction temperature of 60 °C). The highest melting temperature of gelatine gel with a strength of 429 ±8 Bloom (40.5 °C) was identified in Experiment 2 (0.1% of the added enzyme and

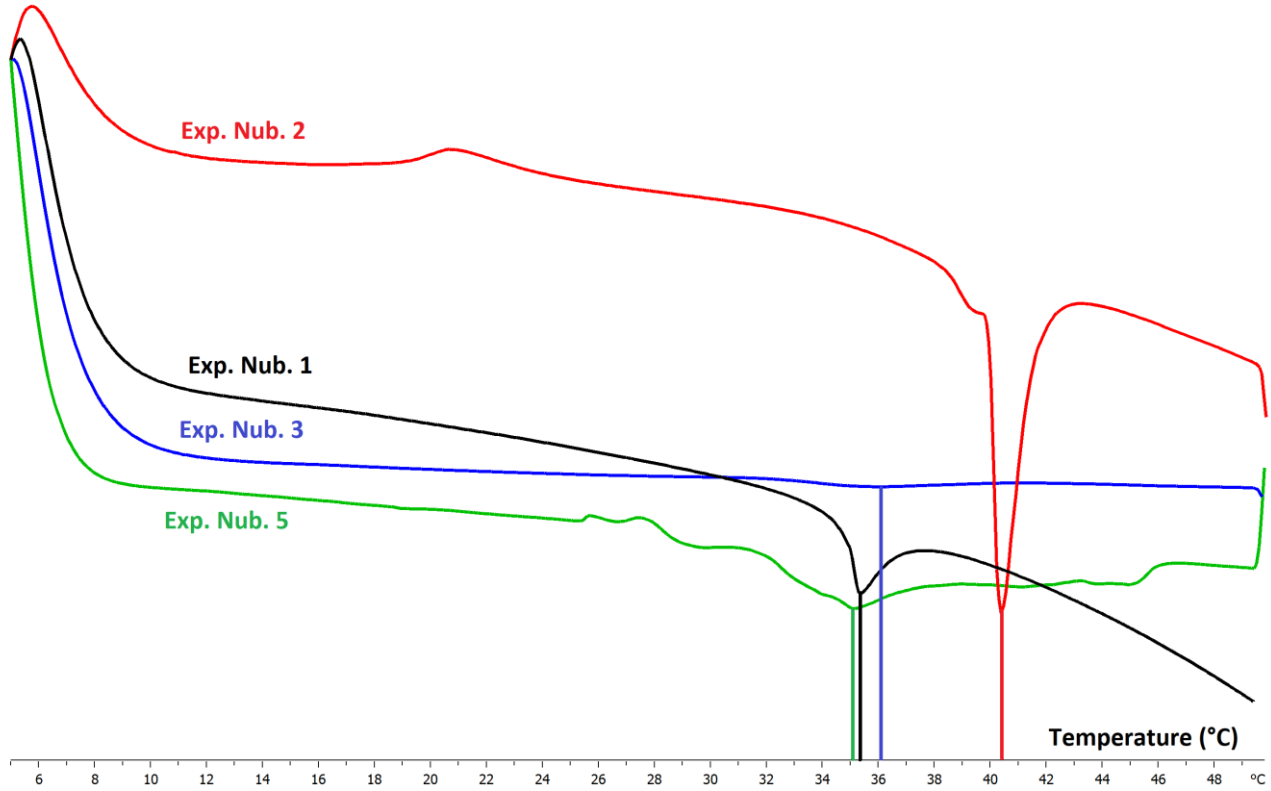

Figure 4 DSC curve of gelatine gel melting points.

the extraction temperature of 65 °C). Melting temperatures of commercial gelatine gels vary in the range from 30 to 40 °C. Their values are important not only from a technical point of view, but also considering the particular application of gelatines influencing various factors, such as the management of gelatine products, maintanance of the final shape of gelatine products and the stability of the products during the storage. Concerning gelatines extracted from chicken stomachs, their melting temperatures ranged from 35 to 40 °C which is comparable with commercial gelatines **(Schreiber and Gareis, 2007)**. **Du et al. (2013)** determined the melting temperature between 33.7 and 34.2 °C. That is slightly lower than the melting temperature of 35 – 40 °C established using DSC in this study reflecting the trend that melting temperature increases with a rising gelatine gel strength.

CONCLUSION

The study examines the possibility of extracting gelatine from chicken stomachs after the prior treatment by the proteolytic enzyme Protamex. The main objective was to propose technological conditions for processing stomachs into collagen products, either gelatines or hydrolysates, with a maximum yield. The influence of Factor A and B on the final efficiency and quality of extracted gelatine was monitored. Factor A represents the amount of added enzyme of 0.1, 0.25 and 0.4% and factor B represents the extraction temperature of 60, 62.5 and 65 °C. The extraction time of 2 h was constant. The final extraction efficiency ranged from 43.83% with 0.1% of added enzyme and the extraction temperature of 65 °C to 96.45% with 0.4% of added enzyme and the extraction temperature of 60 °C. The highest gel strength of about 430 Bloom was measured within the conditions of the enzyme addition of 0.1% and extraction temperature of 65 °C. On the other hand, the lowest gel strength of 2 Bloom was established with the enzyme addition of 0.4% and extraction temperature of 65 °C. The ash content in prepared gelatines was less than 2%; it ranged between 1.0 (0.4% of added enzyme and the extraction temperature of 65 °C) and 1.9% (0.1% of added enzyme and the extraction temperature of 60 °C). Edible gelatine with the gel strength of 96 Bloom (with the yield of 63%) is suitable for the applications in the production of confectionery, such as meringues, toffee, licorice and also deposited marshmallow. To produce jelly, gummy bears, aspic and dairy products it is preferable to employ gelatine with a higher gel strength (192 Bloom) despite its lower yield (approximately 24%). Both types of gelatine performed the ash content lower than 2.0% and the melting temperature of about 35 °C which means that such gelatines would be soluble in the mouth and simultaneously it would maintain the product shape during the storage, particularly during the summer months. Gelatine with a high gel strength of more than 220 Bloom is applicable in the production of desserts, extruded marshmallow, fish aspic and reduced fat spreads and in the pharmaceutical industry in the production of soft gelatine capsules.

This study has proved that it is possible to obtain high quality gelatine from chicken stomachs with the gel strength of up to 430 Bloom if appropriate technological conditions are set. The method applied in this study is quite prompt and efficient. Therefore, it has also confirmed that effective processing of valuable poultry slaughter by-products is accesible.

SURVEY OF MYCOBIOTA ON SLOVAKIAN WINE GRAPES FROM SMALL CARPATHIANS WINE REGION

Soňa Felšöciová, Miroslava Kačániová, František Vrábel

ABSTRACT

A total of 13 samples of grapes (bunches) without apparent fungal contamination were analyzed. The samples were collected during the 2019 harvest from Vrbové village in the Small Carpathian region of Slovakia. For the isolation of fungi were used the direct plating technique on DRBC plates. The plates were incubated aerobically at 25 ±1 °C for one week in the dark. The data obtained from the cultivation of the grape berry samples revealed a high diversity of fungal species (a total of 1044 isolates were obtained). *Alternaria* and *Rhizopus* were the main components of the wine grape mycobiota of the Vrbovský subregion at harvest time (92%, each), followed by *Cladosporium* (85%), *Penicillium* (77%), *Botrytis* and *Epicoccum* (54%, each). The most abundant genera found by descending order were *Penicillium* (25%), *Alternaria* (24%), *Cladosporium* (20%), and *Rhizopus* (12%) and only in minor percentage by *Aspergillus* (3%) among others. The main fungal species isolated from genera *Penicillium* and *Aspergillus* were *Penicillium expansum* (57% RD) and *A.* section *Nigri* (97% RD). Of 17 analyzed *Penicillium* strains, 65% were able to produce at least one of the six mycotoxins analyzed in *in vitro* conditions by means of thin-layer chromatography method: citrinin, griseofulvin, patulin, cyclopiazonic acid, penitrem A, and roquefortin C.

Keywords: grape; filamentous fungi; *Penicillium*; mycotoxin; Slovakian vineyard

INTRODUCTION

Viticulture is an important activity in many countries **(Einloft et al., 2017)**. Vine growing and viticulture have a very long tradition in Slovakia and are parts of the country's cultural and historical heritage. Hundreds of years of viticulture and viniculture have created a specific type of landscape **(Bezák et al., 2010)**, with unique cultural and aesthetic values **(Salašová and Štefunová, 2009)**. In total there exist six viticultural regions in Slovakia with forty areas and wine-growing villages **(ÚKSÚP, 2019a)**. Slovakia features almost 660 producers growing around 13.500 ha of vines (of a potential 15.300 ha) **(ÚKSÚP, 2019b)** for a production of about 300.000 hL annually, which is primarily sold within the national market.

The microflora of the grapes is highly variable, mostly due to the influence of external factors as environmental parameters, geographical location, grape cultivars, and application of phytochemicals on the vineyards **(Pretorius, 2000; Pinto et al., 2014)**. A variety of fungal genera, mainly *Botrytis*, *Alternaria*, *Aspergillus*, *Penicillium,* and *Cladosporium*, can contribute to grape spoilage before harvest **(Bellí et al., 2006; Magnoli et al., 2003; Medina et al., 2005)**. Filamentous fungi impact negatively in the production, sensory quality, and safety characteristics of the wine in several ways. Their development in wine grapes brings significant yield losses for winemaking, alters the chemical composition of wine grapes, and produces secondary fungal metabolites and enzymes that together adversely affect wine flavor and color as well as yeast and lactic acid bacteria growth during vinification **(Fleet, 2003)**. Among them, it is of great concern the presence of toxicogenic fungi in wine grapes capable of producing mycotoxins that could persist during the winemaking process up to wine, being a high risk for consumer's health **(Paterson et al., 2018; Prendes et al., 2015)**.

The genus *Alternaria* is ubiquitously distributed and includes both saprophytic and opportunistic plant-pathogenic species, which may affect crops in the field or cause harvest and postharvest decay of plant products. Moreover, several *Alternaria* species are known to produce toxic secondary metabolites, *Alternaria* mycotoxins. The major *Alternaria* mycotoxins are the tetramic acid derivate, tenuazonic acid, and the dibenzopyrone derivates, alternariol (AOH), and alternariol monomethyl ether (AME) **(Prendes et al., 2015)**. Despite the toxic effects of the *Alternaria* toxins and their documented occurrence, they have not yet received the same attention as others mycotoxins and up to now, there is no regulation about them **(EFSA, 2011)**. As an opportunistic pathogen, it has the potential to cause a grape berry rot in the field under high disease pressure

situations. Strikingly, *Alternaria* has not been extensively studied in wine grapes as a hazardous genus.

P*enicillium* has gained attention as grapevine pathogens. *Penicillium expansum* can cause rot in grapes, but does not usually attack grapes before harvest. Aside from losses in fruit, this species is regarded as the major producer of patulin, although this species produces many other toxic metabolites such as citrinin, roquefortine C or chaetoglobosins among others **(Andersen, Smedsgaard and Frisvad, 2004)**.

Scientific hypothesis

Some of the fungal species occurring on grapes and grape products can produce mycotoxins, so species identification is critical to predicting the potential mycotoxin contamination of grapes and wine.

MATERIAL AND METHODOLOGY

Study area

Village Vrbové is located in the Vrbovský subregion in the Small Carpathian wine region. The Small Carpathian wine region is the most extensive of the six wine regions in Slovakia (vineyards are covering 4175 hectares) and is located in the southwestern part of Slovakia **(ÚKSÚP, 2019b)**. Vines have been grown on the south-facing slopes of the Small Carpathian mountains in locality Záhorie for more than three thousand years. This region has a medium climate and abundant moisture.

Last year, as a whole, was extremely warm. The year 2019 had the same average annual temperature in Hurbanovo 12.42 °C as in 2018. This value is a record high for Hurbanovo since the record began. During the whole year, 2019 was only one month of the territory temperature below normal. It was May **(Beránek and Faško, 2020)**.

Grape sampling

A total of 13 samples were taken: 3 from red varieties (Alibernet, Cabernet Sauvignon, and Blaufränkisch) and 10 from white varieties (Palava, Green Veltliner, Seteasca Regala, Chardonnay, Rheinriesling, Welschriesling, Sauvignon, Pinot Blanc, Irsai Oliver, and Müller Thurgau). The sampling was conducted at the 2019 vintage, at the end of September. Two diagonals crossing the vineyards were delimited, and five healthy and undamaged bunches from each diagonal were obtained. Each bunch was collected in a sterilized plastic bag and sent to the laboratory chilled on ice.

Mycological analysis

Fifty berries were selected randomly from each sample (totaling 650 berries) and placed in Dichloran Rose Bengal Chloramphenicol agar (DRBC) **(Samson et al., 2002)**. Plates were incubated at 25 ±1 °C for 7 days in darkness. Genera identification was conducted according to microscopic and macroscopic criteria using the key of **Pitt and Hocking (2009)**. *Aspergillus* strains were isolated and cultivated on MEA (Malt extract agar) **(Samson et al., 2010)**, CYA (Czapek yeast extract agar) **(Samson et al., 2010),** and CY20S (Czapek yeast extract with 20% sucrose) **(Pitt and Hocking, 2009)**. The *Aspergillus* colonies were identified to species level according to micro and macroscopic criteria, using the keys of **Klich (2002)** and **Pitt and Hocking (2009)**. *Penicillium* strains were isolated and cultivated on MEA, CYA, Creatine-Sucrose agar (CREA) **(Samson et al., 2010)** and Yeast Extract agar (YES) **(Samson et al., 2010)**. The *Penicillium* colonies were identified to species level according to **Pitt and Hocking (2009)** and **Samson and Frisvad (2004)**.

Mycotoxin production

Toxinogenity of selected isolates was screened in *in vitro* conditions by means of thin-layer chromatography (TLC) according to **Samson et al. (2002)**, modified by **Labuda and Tančinová (2006)**. Extracellular metabolites – citrinin griseofulvin and patulin were carried out on YES agar and intracellular cyclopiazonic acid, penitrem A, and roquefortin C on CYA agar. At 14 days of incubation, five agar plugs (4 mm diameter) were cut from the edge of a colony (extracellular metabolites) or cut from a colony (intracellular metabolites) from each Petri plate and placed in an Eppendorf tube. The plags were extracted in 500 µL of chloroform-methanol (2:1, v/v) (Reachem, Slovak Republic). The content of the tubes was stirred for 5 min by Vortex Genie ® 2 (MO BIO Laboratories, Inc. – Carlsbad, CA, USA). The extract of liquid phase 30 µL along with 10 µL of standards (Sigma, Germany) was transferred to the TLC plate (Alugram ® SIL G, Macherey – Nagel, Germany). The plate was put into TEF solvent (toluene:ethyl acetate:formic acid – 5:4:1, toluene – Mikrochem, Slovak Republic; ethyl acetate and formic acid – Slavus, Slovak Republic). After elution, the plate was air-dried. The identification of the metabolites was done by comparison with metabolite standards. Cyclopiazonic acid was visible directly in daylight after spraying with the Ehrlich reagent as a violet-tailed spot. Penitrem A was visible after spraying with 20% $AlCl_3$ in 60% ethanol and heating at 130 °C for 8 min as a dark blue spot. Roquefortin C was visible after spraying with $Ce(SO_4)_2$ x 4 H_2O as an orange spot. Patulin detection was achieved by spraying with 0.5% methylbenzothiazolone hydrochloride (MBTH) (Merck, Germany) in methanol and heating at 130 °C for 8 min and then detected as a yellow-orange spot under visible light. Citrinin was detected directly as an intense yellow-green streak under ultraviolet light (365 nm) as well as griseofulvin, which was visible as a blue spot.

Statistical analysis

The obtained results were evaluated and expressed according to relative density (RD) and isolation frequency (Fr). The relative density (%) is defined as the percentage of isolates of the species or genus, occurring in the analyzed sample **(Guatam, Sharma and Bhadauria, 2009)**. These values were calculated according to **González et al. (1999)** as follows:

RD (%) = (ni/Ni) x 100

where ni – number of isolates of a species or genus; Ni – total number of isolated fungi.

The isolation frequency (%) is defined as the percentage of samples within which the species or genus occurred at

least once. These values were calculated according to **González et al. (1999)** as follows:

Fr (%) = (ns/N) x 100; where ns – number of samples with a species or genus; N – total number of samples.

RESULTS AND DISCUSSION

Fifteen fungal genera were identified from the grape samples: *Alternaria, Aspergillus, Aureobasidium, Botrytis, Cladosporium, Epicoccum, Fusarium, Mucor, Penicillium, Phoma, Rhizopus, Syncephalastrum, Trichoderma, Trichothecium,* and *Ulocladium*. About 2 % of the isolated fungi did not produce conidiophores or conidia on the tested conditions and were nominated as non-sporulated fungi *Mycelia sterilia*. The number of isolates within the several genera found on grapes from different varieties are shown in Table 1. The highest number of isolates (from 101 to 199) with 7, 8, or 9 genera were isolated from varieties Müller Thurgau (13), Irsai Oliver (12), Blaufränkisch (3), Palava (4), and Alibernet (1). The lower number of isolates (26, 28, respectively) were isolated from the white variety Rheinriesling (8) with the number of genera 6 and Pinot Blanc (11) with the number of genera 4. It is interesting to note the absence of isolates belonging to microscopic filamentous fungi in one sample Green Veltliner (5). This wine grape was colonized only by yeasts. All samples (except sample 5) were colonized by genera *Alternaria* and *Rhizopus*. Genus *Alternaria* was dominated in samles Palava (4), Cabernet Sauvignon (2) and Welschriesling (9), genus *Rhizopus* in sample Alibernet (1), genus *Penicillium* in samples Müller Thurgau (13), Irsai Oliver (12), Blaufränkisch (3) and Welschriesling (9) and genus *Cladosporium* in samples Irsai Oliver (12) and Sauvignon (10).

Thirty of the 32 *Aspergillus* isolates were identified as *A.* section *Nigri* and 1 isolate as *A. ochraceus.* Sixteen black aspergilli were isolated from the Blaufränkisch variety (3), 6 from Cabernet Sauvignon (2), 5 from Irsai Oliver (12), 2 from Palava (4), and 1 from Chardonnay (7). Among section *Nigri, A. carbonarius* is considered the predominant species responsible for the occurrence of OTA in wine grapes and derivatives **(Ponsone et al., 2010; Visconti et al., 2008)**. A low occurrence of this fungus was previously reported in Argentina **(Chiotta et al., 2009; Ponsone et al., 2010),** Brazilia **(Einloft et al., 2017)** and Lebanon **(El Khoury et al., 2006)**, and the absence of this fungus was observed in cold regions, like Germany, North Hungary, Czech Republic and Portugal **(Abrunhosa et al., 2001; Ostrý et al., 2007; Varga et al., 2005)**.

Three species of *Penicillium* were isolated from grapes. Species *Penicillium expansum* were dominated from the Müller Thurgau variety (13), Blaufränkisch (3), Seteasca Regala (6), Rheinriesling (8), and Palava (4). *Penicillium expansum* has a high incidence in certain wine regions such as bordering regions of North Portugal and Galiza (Spain) **(Serra et al., 2006)**. The incidence of *P. expansum* in some wine regions is high, but the attack of this fungus to vineyards, is rare, being *B. cinerea* the most common disease. **Morales et al. (2013)** observed that, *in vitro*, the presence of *P. expansum* spores enhanced *B. cinerea* growth, while the latter avoided patulin accumulation.

The data in Table 2 obtained from the cultivation of the berry samples revealed a high diversity of fungal species (a total of 1044 isolates were obtained). *Alternaria* and *Rhizopus* were the most frequently occurring genera (92%, each), followed by *Cladosporium* (85%), *Penicillium* (77%), *Botrytis,* and *Epicoccum* (54%, each). *Penicillium* spp. was predominant in terms of relative abundance (25%), followed by *Alternaria* (24%), *Cladosporium* (20%), *Rhizopus* (12%), and *Botrytis* (6%). Besides, a minor portion (<5%) of *Aspergillus* and other genera was found.

Alternaria genus was the main component of the wine grape mycobiota of the Vrbovský subregion (Small Carpathian wine-growing region) at harvest time, which is in agreement with previous studies carried out in several winemaking regions worldwide, e.g. from Uruguay **(Garmendia and Vero, 2016)**, Argentina **(Magnoli et al., 2003; Prendes et al., 2015)**, Spain **(Medina et al., 2005)**, Slovakia **(Felšöciová et al., 2015c; Felšöciová, Mašková and Kačániová, 2018; Felšöciová and Kačániová, 2019a; Felšöciová and Kačániová, 2019b)**.

It was followed by *Penicillium*, which recorded a frequency of 77% and a high relative density of 25%. From the previous study by **Felšöciová and Kačániová (2019a)**, *Penicillium* contributed a small proportion (21% Fr, <1% RD) from mycobiota associated with grapevine in Vrbové. The *Botrytis* genus, which is regarded as the main spoilage cause in wine grapes, was isolated in this study, but the absence of this genus has already been reported by **Magnoli et al. (2003)** in Argentina, and **Medina et al. (2005)** in Spain. Grey mold *Botrytis cinerea* is responsible for severe economic loss. Musts obtained from botrytized grapes are more liable to oxidation because of the polyphenol oxidizing activity of *B. cinerea* laccase and are not suitable for wine production **(Morales et al., 2013)**.

Aspergillus was one the less common genera (46% Fr, 3 % of all fungi). These results differ from those obtained by other authors, who reported a much higher frequency from this genus, ranging from 70% to 95% **(El Khoury et al., 2008; Magnoli et al., 2003; Medina et al., 2005)**.

Data in Table 3 show that, 32 *Aspergillus* species were identified from grape samples. The section *Nigri* was predominant within the *Aspergillus* genus, representing 94% of species isolated from this genus with 38% frequency. Certainly, the *Aspergillus* species are present worldwide, in all the grape products and under all environmental conditions **(Somma, Perrone and Logrieco, 2012)**. From the 12 vineyards in the Small Carpathian area (14 samples), 79% of the samples were coloniezed by the genus *Aspergillus* **(Felšöciová et al., 2015c)**. During the 3 years survey (2011, 2012, and 2013), 37 isolates belonging to 7 *Aspergillus* species (*A. clavatus, A. flavus, A.* section *Nigri, A. ostianus, A. parasiticus, A. versicolor* and *A. westerdijkiae*) were isolated. The main occurring *Aspergillus* species of the samples were *A.* section *Nigri* (64%), as in our research. On the other hand, the most species were not been isolated from any of the samples analyzed in the present study.

Table 1 Fungi identified in Slovak wine grapes from exogenous mycobiota in 2019 by direct plating method.

Table 5 Toxinogenity of selected *Penicillium* strains, isolated from exogenous mycobiota of wine grapes.

Species	**C**	**G**	**P**	**CA**	**PA**	**RC**
P. crustosum					1/1	0*/1**
P. expansum	13/14		11/14			9/14
P. griseofulvum		2/2	2/2	1/2		1/2

Note: * – number of isolates with ability to produce mycotoxin, ** - number of tested isolates, C – citrinin, G – griseofulvin, P – patulin, CA – cyclopiazonic acid, PA – penitrem A, RC – roquefortin C.

Data in Table 4 show 3 different *Penicillium* species from the 264 fungal strains. *Penicillium expansum* was predominant within the *Penicillium* species, representing 57% of the isolates and 54% frequency, which agrees with previous publications by **Felšöciová and Kačániová (2019a)**, **Felšöciová and Kačániová (2019b)**. The predominant species of *Penicillium* isolated from grapes differs between vineyards. For example, *Penicillium expansum* is the species most frequently isolated in South Slovak wine region (28% RD) **(Felšöciová et al., 2017)**, *P. aurantiogriseum* in East Slovak wine region (34% RD) **(Felšöciová et al., 2015a)**, *P. chrysogenum* in Small Carpathian wine region (64% RD) **(Felšöciová et al., 2015c)**, in Nitra wine region (28% RD) **(Felšöciová et al., 2013)**, in Central Slovak wine region (53% RD) **(Felšöciová et al., 2014)** and Tokaj (39% RD) **(Felšöciová et al., 2015b)**. *Penicillium expansum* was found frequently in botrytized grapes **(Morales-Valle et al., 2011)**. This species was the second frequent (after *P. chrysogenum*) in Tokaj (33% RD).

The toxicogenic profile of the 17 *Penicillium* isolates representing *P. crustosum, P. expansum* and *P. griseofulvum* from the Slovak grapes is shown in Table 5.

The 65% of the 17 analyzed *Penicillium* strains were able to produce at least one of the six mycotoxins tested (citrinin, griseofulvin, patulin, cyclopiazonic acid, penitrem A, and roquefortin C). Citrinin was the toxin produced by the majority of the strains *P. expansum* (93%). It was followed by patulin produced by 79% of the strains *P. expansum*, and roquefortin C produced by 64% of the strains. *Penicillium crustosum* produced only penitrem A, did not produce roquefortin C. Two strains of *Penicillium griseofulvum* produced griseofulvin and patulin, the production of cyclopiazonic acid and roquefortin C was confirmed by one isolate.

Almost 100% of *Penicillium expansum* strains are patulin producers **(Andersen, Smedsgaard and Frisvad, 2004; Morales et al., 2008)**, which does not fully correspond to our results. *Penicillium expansum* is commonly associated with apple rot, production of geosmin − a well-known compound with a strong earthy smell, and patulin contamination in apple derivatives **(Morales-Valle et al., 2011)**. However, patulin has been reported in grapes **(Moake, Padilla-Zakour and Worobo, 2005)**, processed grape juice **(Scott, Fuleki and Harwig, 1977),** and fermenting wine **(Majerus, Hain and Kölb, 2008; Bragulat, Abarca and Cabañes, 2008)**, although the occurrence in wine is low because it is well-known to be degraded partially by the fermentation process **(Moss and Long, 2002)**. Patulin mainly induces gastrointestinal disorders including ulceration, distension, and bleeding. The compound provokes congestion and oedema of pulmonary, hepatic, and gastrointestinal blood vessels and tissues. Subcutaneous injection of patulin produced local sarcomas in rats and is classified in group 3 as not classifiable as to its carcinogenicity to human by IARC **(Varga et al., 2015)**.

CONCLUSION

Our results indicate a high diversity of fungal species with a high incidence of *Alternaria* genus. Out of 17 potentially toxigenic *Penicillium* strains isolated from exogenous mycobiota, namely *P. crustosum, P. expansum* and *P. griseofulvum*, 65% produced at least one mycotoxin by thin-layer chromatography method. The occurrence of the potentially toxigenic fungus *Aspergillus* was overall very low what indicates the high quality of the wine grapes produced in Slovakia.

SENSORY ACTIVE SUBSTANCES CAUSING OFF-ODOR IN LIQUID WHEY DURING STORAGE

Mariana Hanková, Helena Čížková

ABSTRACT

Liquid whey is a nutritious product with high water activity and neutral pH. Therefore, it is very susceptible to microbiological spoilage that results in undesirable off-odors. Additionally, minimally processed foods are the recent trend so setting an appropriate shelf life is essential. The commonly used microbiological methods are lengthy and time-demanding, so a quick and early identification of microbial degradation would be a significant benefit. Here we tested a solid-phase microextraction, gas chromatography with mass spectrometry coupled with olfactometry analysis (SPME-GC-MS/O) on samples of sweet unpasteurized liquid whey stored at 6 °C, 12 °C and 25 °C for a week. We compared the common methods – plate methods, measurement of pH, and dry matter determination with our proposed SPME-GC-MS/O. We have identified seven sensory active compounds while octanoic acid and a compound not reliably identified by the MS detector (with main m/z observed 133 (100), 151 (65), and 135 (26)) being the most prominent. Microbiological methods proved irreplaceable for proper setting of storage conditions (with the growth of coliforms being significant (p <0.001) at 25 °C). However, SPME-GC-MS/O was able to identify volatile substances responsible for off-odors and can be used as a powerful tool to detect the cause of undesirable chemical and microbial changes in whey beverages.

Keywords: whey; SPME-GC-MS/O; off-odor; analysis

INTRODUCTION

Sensory characteristics, such as appearance, taste, and aroma, are the basic parameters for evaluating the quality of many products. While traditional sensory analysis continues to be a valuable method of food and beverage analysis, it is not without its limitations in the evaluation of certain defects. Recently, we found this to be the case when presented with the problem of identification of the off-odor in real samples of liquid whey.

Whey is the leftover liquid when coagulating milk to produce cheese or the released liquid after the fermentation of other dairy products, most often Greek-style yogurts or skyrs. After the coagulation of milk with enzymatic rennet in the production of cheeses, sweet whey is produced, while the use of lactic acid in the production of curd results in acid whey. These two types differ slightly in their composition **(Karagul-Yuceer, Drake and Cadwallader, 2003)**.

While both types mostly consist of water, lactose, proteins, minerals, and fat, acid whey contains more minerals (especially calcium) and less proteins and lactose than sweet whey **(Kilara, 2015)**. Lactose makes up more than 75% of the total solids and is also the main reason why whey is considered as one of the most polluting food streams. On the other hand, the contained proteins and peptides (mainly α-lactalbumin, β-lactoglobulin, serum albumin, and immunoglobulins) are of exceptional biological and functional value and thus offer a wide range of whey utilization **(Anand, Khanal and Chenchaiah, 2013; Smithers, 2008)**.

Dried or concentrated whey and products where some ingredients, especially proteins, are isolated or concentrated (whey protein hydrolysate (WPH), whey protein concentrate (WPC, 34 – 89% protein) and whey protein isolate (WPI, >90% protein)) are widely used as a food ingredient for human consumption **(Evans et al., 2009)**. Liquid whey drinks are gaining popularity, either native, demineralized, or further processed (fermented, carbonated) and flavored in various ways **(Francis, 1999)**.

Liquid whey beverages are very susceptible to microbial spoilage and associated undesirable qualitative deviations because of their rich nutritional content and high water activity. Their shelf life is ensured either by heat treatment (pasteurization or sterilization) or by fermentation and subsequent cold storage **(Lo et al., 2016)**.

Microorganisms generally spoiling whey are the ones that typically spoil milk. Raw and pasteurized milk, exposed to secondary contamination, is most often contaminated by gram-negative bacteria of the genus *Pseudomonas*, while pasteurized milk is most often spoiled by thermoduric spore-forming microorganisms of the *Bacillus* and *Paenibacillus* species. Since whey is easily subjected to lactose fermentation to produce ethanol, acetic, lactic, and propionic acid (which is formed from

lactic acid by the bacteria of the genus *Propionibacterium*), the naturally present lactic acid bacteria – LAB (e.g, *Streptococcus, Lactobacillus* and *Lactococcus*) form a variety of aromatic active compounds such as 2,3-butanedione (diacetyl), acetoin, acetaldehyde or acetic acid from pyruvate, an intermediate in lactose fermentation **(Lo et al., 2016)**. When preparing alcoholic whey beverages, mainly yeasts of the genus *Kluyveromyces (K. fragilis* and *K. marxianus*) are used. These beverages are characterized by the presence of volatile compounds, including higher alcohols (mainly isoamyl alcohol, isobutanol, and 1-propanol), ethyl esters (mainly ethyl acetate), as well as acids and acetals **(Dragone et al., 2009)**. All of these substances contribute to the natural aroma of whey, but at higher concentrations to an undesirable odor. However, the main contributors to the off-odor of both liquid and dry whey are lipid oxidation products namely aldehydes, ketones, alcohols, and alkanes **(Carunchia Whetstine et al., 2003)**.

Sensory properties have traditionally been described and evaluated via sensory analysis, which can be loosely divided into two groups: discriminant methods and descriptive methods. The purpose of discrimination testing is to indicate whether a tested sample is perceived as being significantly different from a standard one (e.g. Triangle or Duo-Trio test). Descriptive methods, such as the flavor profile method or quantitative descriptive analyses, are more similar to chemical analysis in that they aim to determine the presence or intensity of a particular characteristic **(Kilcast, 2010)**. The problem is that while descriptive methods can characterize a particular off-odor, they are not able to link it to the specific compound, or compounds, responsible for certain occasional defects. That is where instrumental methods come in.

However, instrumental methods are best used in combination with sensory analysis. For example, GC-MS is able to identify the most abundant volatile compounds in a sample but cannot provide clear information on whether the substances are sensorially active. And the most sensitive physical detectors (MSD, ECD, FID) only have detection limits ranging from 1 to 10 pg, whereas human noses can readily detect to 0.05 pg **(Muñoz et al., 2010)**. Gas chromatography with an olfactometric detector (GC-O) combines the high resolution of capillary gas chromatography with the high selectivity and sensitivity of the human nose to detect and identify the compound, or compounds, responsible for an off-odor. The assessors sniff the eluate from the gas chromatograph using a special olfactory port to detect the presence of sensory-active compounds. Recently, solid-phase microextraction with gas chromatography/mass spectrometry coupled with olfactometry (SPME-GC-MS/O) has been used to identify substances in a variety of matrices, including coffee, cheeses, milk powders, orange juice, cashew apple (*Anacardium occidentale*) juice, yogurt, and even chocolate. **(Zellner et al., 2008; Gocmen et al., 2005; Semmelroch and Grosch, 1995; Zepka et al., 2014)**

Scientific hypothesis

The determination of sensory active substances allows for quick and early identification of microbial degradation and lipid oxidation.

MATERIAL AND METHODOLOGY

Samples

Samples of unflavoured, unpasteurized sweet liquid whey, with a fat content of up to 1%, sold in 1 liter PET bottles were purchased for the analysis. Recommended storage at a temperature from 4 °C to 8 °C and up to 4 days. Individual whey samples in the original packaging were analyzed (for pH, dry matter, and microbiology) 1 day after production (at time T0) and after 1 week stored in thermostats at 6 °C, 12 °C and 25 °C. This shelf-life study was conducted in two batches, and each sample was stored in each temperature in duplicates. Therefore, we obtained 4 sets of data for each storage temperature.

Methods

Microbiological

Samples were analyzed using plate methods **ISO 7218 (2007)** for coliforms according to **ISO 4832 (2006)** using VRB agar (Merck) and yeasts and molds according to **ISO 21527-1 (2008)** using YGC agar (Merck).

pH

The pH was measured using an Inolab pH meter (Thermo Scientific).

Dry matter

Samples were dried to a constant weight at 105 °C.

Volatile compounds

Volatile compounds were measured by SPME-GC-MS for samples T0, 6 °C and 25 °C under the same conditions as sensory active compounds.

Sensory active compounds

For the evaluation of sensory active compounds, the evaluators were first tested and trained by sniffing sticks (Olfasense GmbH), and the samples T0, 6 °C, and 25 °C were subsequently analyzed by SPME-GC-MS/O.

Testing by assessors

Ten assessors underwent two sets of tests. In the first one, the assessors were asked to match a sniffing stick to an odor written on the list. The second one was to describe the odor of each sniffing stick without using any prompts.
The batch of sniffing sticks included the following standards:

1. (E,E)-nona-2,4-dienal (fatty, rancid odour)
2. non-2-enal (paper, carton)
3. dimethyl disulphide (garlic, sulphur)
4. acetoin (yogurt)
5. methional (boiled potatoes)
6. δ-decalactone (floral, fruit)

Six assessors out of ten who showed low detection limits, low recognition thresholds and were in particular accurate in verbal identification of the unknown aroma of the standard compounds of sniffing sticks were subsequently involved in the olfactometric detection.

SPME-GC-MS/O

1 gram of sample was placed into a 10 mL vial. Determination of the volatile profile and sensory active substances was performed using Agilent GC 7890B, MS

5977A with DB-5 capillary column (30 m x 250 µm x 0.25 µm) and SPME fiber 50/30 µm DVB/CAR/PDMS (Supelco). The injector was operated in split mode 1:1, with He 5.5 flowing at 1.4 mL.min^{-1}. The temperature conditions were as follows: incubation for 60 s at 50 °C, with 1500 s sorption injector temperature was set at 260 °C with 360 s long desorption at 260 °C. GC system was set to 60 °C for 2 min followed by a temperature rise of 10 °C/min to a final temperature of 290 °C. NIST integrated library and its retention indices were used for the identification **(NIST MS Search 2.0)**.

The eluate was split 1:1 between the MS detector (MSD 230 °C, quadrupole 150 °C) and the olfactometer (JAS, 180 °C, capillary diameter 150 µm with the airflow rate 40 mL.min^{-1} of the humidifier) at the outlet of the GC column. Nasal impact frequency (NIF) technique with the posterior evaluation of odor intensity (1 – lowest intensity to 3 – highest intensity) was used. NIF value equals the number of assessors detecting a compound dived by the total number of assessors **(Plutowska and Wardencki, 2008)**.

Statistical analysis

The R Program (R Core team, 2017, version 3.5.2.) for Statistical Computing was used for statistical evaluation namely ANOVA and t-test. Results are presented as mean ±standard deviation

RESULTS AND DISCUSSION

The storage experiment was designed to copy the recommended storage conditions while promoting and accelerating the development of sensory active substances indicative of undesirable changes. For the samples stored at 6 °C for 1 week, there were no significant changes in coliforms, yeast and mold count, dry matter, and pH, as expected, because the declared storage conditions were 4 – 8 °C with a shelf life of 4 days (Figure 1 shows the average values of the 4 measurements). The whey dry matter content did not change significantly (p >0.05) with the storage temperature. At the same time in samples stored at 12 °C and 25 °C, the pH dropped significantly (p <0.001) by 35%. This pH drop was caused by an increased content of organic acids (probably produced by lactic acid or acetic acid bacteria and yeasts) **(Campbell et al., 2011; Sattin et al., 2016)**, which was confirmed by a subsequent chromatographic analysis of the volatile compounds. The number of coliforms and yeasts in the sample stored at 25 °C increased significantly (p <0.05) (coliforms one hundred times, yeasts almost five thousand times). No molds were detected in any samples.

The profile of volatile substances of fresh whey was very poor. Only hexane and octanoic acid had a peak area higher than 10^4. Other peaks were either not identified or were contaminants from the chromatographic system (siloxanes, higher hydrocarbons, etc.). The limited sensitivity of the MS detector is unfortunately due to a compromise of possible simultaneous application of olfactometry (see batch separation conditions and split between detectors).

After the storage experiment at 25 °C, the profile of volatiles changed drastically both in the number of peaks as well as in their area. A number of ketones (acetone, 2,3-butanedione, 2-butanone, acetoin, 2,3-pentandione, 2-heptanone, 2-nonanone), sulphur compounds (dimethyl sulphide dimethyl disulphide, dimethyl trisulphide, 2,4-dithiapentane), carbonyl compounds (heptane, hexane), an aldehyde (nonanal), alcohols (1-butanol 1-hexanol, 1-octanol) and organic acids (acetic acid, hexanoic acid, and octanoic acid) were found. We have not identified as many aldehydes as **Croissant et al. (2009)** but a wider range of compounds more similar to **Leksrisompong, Miracle, and Drake (2010)** and **Liaw et**

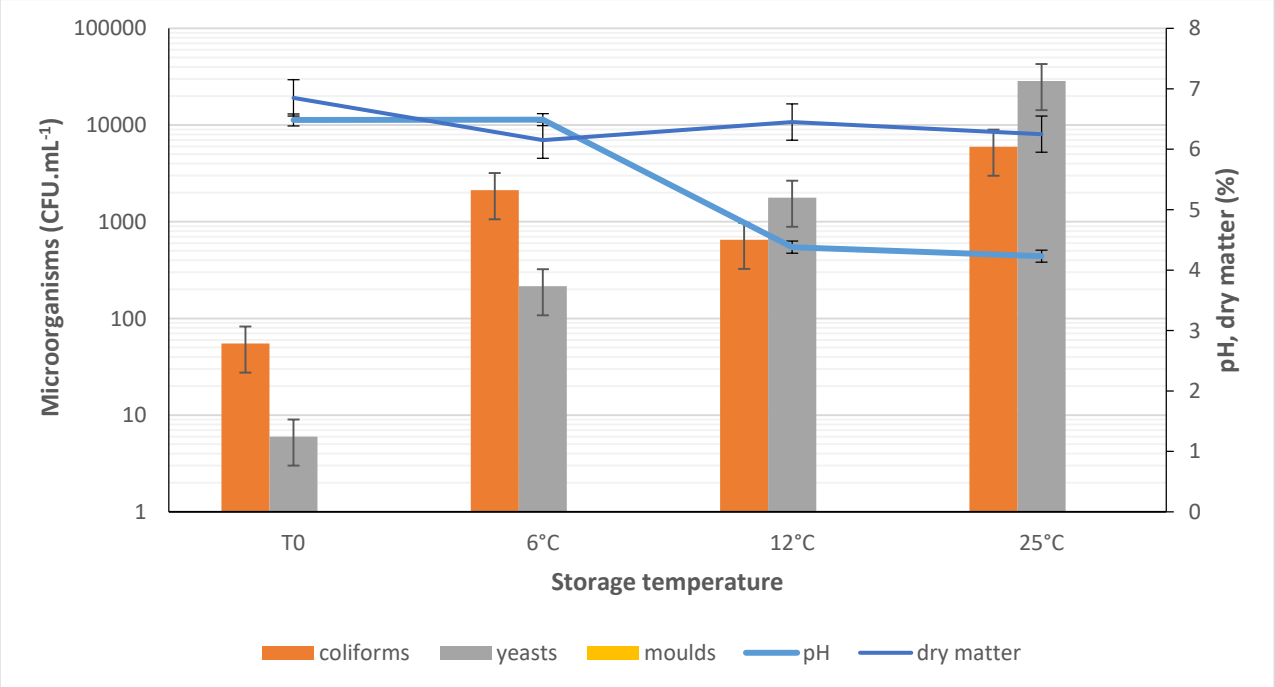

Figure 1 Microbiological, pH and dry matter analysis results obtained from 4 replicates of whey samples analysed at the time of purchase (T0) and after storage in 6, 12 and 25°C for 7 days.

Table 1 Sensory active substances detected by at least 2 assessors out of 6.

Rt	RI (NIST)	Compound	Odour (labelled)	Odour (perceived)	NIF*		
					T0	6 °C	25 °C
1.88	534	Dimethyl sulphide	Cabbage, onion, sulphur	Pungent	-	-	0.50
2.17	593	2,3-butanedione	Butter, caramel, cream, sweet	Butter, sweet, milk	-	-	0.67
5.16	801	Hexanal	Green, fatty, leafy	Fresh, grass, butter	-	-	0.67
7.43		NI		Cabbage, fatty, cheesy	1.00	1.00	1.00
8.52	982	Dimethyl trisulphide	Sulphur, onion, cooked	Cabbage, sulphur, cheese	-	-	0.83
8.71	1000	Hexanoic acid	Cheese, fatty, acid, sweet	Mushroom, fruity	-	-	0.67
11.89	1191	Octanoic acid	Cheese, fatty, sweet, rancid	Milky, musty	0.67	0.67	1.00

Note: *NIF value equals the number of assessors detecting a compound divided by the total number of assessors.

al. (2011) findings, including the not commonly found acetoin (a product of LAB metabolism) **(Nadal et al., 2009)**.

Compared to other dairy products, whey is not very rich in sensory active substances **(Fox et al., 2016; Qian and Reineccius, 2003)**. This finding is in an agreement with our measurements of fresh whey at T0 where only 2 sensory active compounds were detected – not identified (NI) compound and octanoic acid (Table 1). Octanoic acid was found to have a very low odor threshold in air (0.86 $\mu g.kg^{-1}$) **(Cometto-Muñiz and Abraham, 2010)** as opposed to, for example, hexanal (having 0.14 $\mu g.L^{-1}$ therefore 119 $\mu g.kg^{-1}$ in the air at 25 °C **(Ömür-Özbek and Dietrich, 2008)**. This explains why it was detected at T0, along with the fact that hexanal is an oxidation product from linoleic acid, therefore its concentration increases during storage. The other compound that could not be reliably identified by the spectra NIST library (the probability match was less than 50%) had 133 (100), 151 (65), and 13 5 (26) m/z ions as the largest. Detection of such a compound confirms the higher sensitivity of a human nose compared to a mass detector **(Muñoz et al., 2010)**. In total, seven compounds, mostly with an unpleasant odor, were detected by at least two assessors in the sample stored at 25 °C their odor was compared to literature ("The Good Scents Company," n.d.).

Dimethyl sulphide is usually associated with a cabbage-like odor produced by cooking certain vegetables and cereals, formed along with dimethyl trisulphide by bacterial degradation of sulphur amino acids **(Franco-Luesma and Ferreira, 2016; Luo et al., 2018; Nishibori et al., 2014)**. 2,3-butanedione, or diacetyl, is a natural by-product of the fermentation of lactic acid by the oxidative decarboxylation of α-acetolactate **(Hugenholtz et al., 2000)**. It may also be formed as an intermediate in high-temperature treatment with non-enzymatic Maillard browning and may later be involved in Strecker degradation with other free amino acids **(Smit, Smit and Engels, 2005)**. It is responsible together with acetoin for the characteristic taste of butter **(Karagul-Yuceer, Drake and Cadwallader, 2003)**. Hexanal is a lipid oxidation product and has been proposed as a potential quality marker. Free fatty acids (hexanoic and octanoic) are formed by microbial hydrolysis of fats **(Panseri et al., 2011)**.

Based on the assessor's results, dimethyl trisulphide produced the highest intensity odor, even though one assessor did not detect it. There are a number of factors that could have caused it, for example, selective anosmia to sulphur compounds (as dimethyl sulphide was not detected either) or the assessor's fatigue **(Brattoli et al., 2013)**. Dimethyl trisulfide had a peak approximately 20 times smaller than octanoic acid but since the peak area does not correlate with the odor intensity **(Högnadóttir and Rouseff, 2003)**, olfactometry was able to mark it as one of the main compounds responsible for off-odor.

CONCLUSION

When storing whey samples at elevated temperatures (12 °C and 25 °C), there was a significant increase (p <0.001) in the number of coliform bacteria and yeasts which led to an increased amount of organic acids and alcohols, causing undesirable off-odors. However, the scientific hypothesis (Determination of sensory active substances allows for quick and early identification of microbial degradation and lipid oxidation) is only partially confirmed. Since the slight (by 1 – 2 order) increase in the number of pathogenic and spoilage microorganisms at low

storage temperature was not yet reflected in the sufficient production of secondary volatile metabolites (and therefore on the sensory properties of the product) the SPME-GC-MS/O method was not able to detect it.

Thus we conclude that the traditional microbial testing is irreplaceable for a proper setting of storage conditions and shelf life Olfactometers can then play a significant role in detecting the causes of major product odor changes(as we have shown on the sample stored at 25 °C) and therefore spotting specific signs of microbial and chemical degradation.

MEAT PERFORMANCE OF JAPANESE QUAILS AFTER THE APPLICATION OF BEE BREAD POWDER

Adriana Pavelková, Peter Haščík, Marcela Capcarová, Anna Kalafová, Emília Hanusová, Jana Tkáčová, Marek Bobko, Juraj Čuboň, Matej Čech, Miroslava Kačániová

ABSTRACT
The aim of the study was the evaluation of meat performance of Japanese quails after the addition of bee bread powder into their diet. A total of 80 one day-old Japanese quails were randomly divided into 4 groups (n = 20): the control group (C) without additional supplementation, the experimental group E1 supplemented with 2 mg bee bread powder per 1 kg of feed mixture; the experimental group E2 supplemented with 4 mg bee bread powder per 1 kg of feed mixture and the experimental group E3 supplemented with 6 mg bee bread powder per 1 kg of feed mixture. The groups were kept under the same conditions and the quails were slaughtered at 56 days of age. Based on the results, we can conclude that the application of bee bread powder generally has not confirmed a positive effect on the meat performance of Japanese quails, regarding to the quantities of bee bread powder in the experimental groups.

Keywords: Japanese quail; meat performance; bee bread

INTRODUCTION
The poultry industry is considered to be one of the most advanced in the field of food industry and the increase in the production of poultry products has been remarkable. Today, products of different species of poultry, including quail products, are being marketed **(Genchev et al., 2008)**. Japanese quail (*Coturnix coturnix japonica*) is one of the most important species of poultry, which meat and eggs are mostly consumed in Asia, Europe, and America **(Minvielle, 2004; Kayang et al., 2004; Maiorano et al., 2012)**. The Japanese quail is characterized by its rapid growth, enabling quail to be marketed for consumption at 5 weeks of age, early sexual maturity resulting in a short generation interval, high rate of egg-laying and much much lower feed and space requirements than domestic **(Hrnčár et al., 2014)**. The valuable dietetic properties of quail meat are at the background of the increasing interest of consumers in this product. Quails can be used for meat production within a short period (4 – 5 weeks) and mature at an early age of 6 weeks so that female birds are usually in full production at approximately 8 weeks **(Jatoi et al., 2013)**. Japanese quails respond very quickly to the selection for higher body weight. **Anthony, Nestor and Marks (1996)** observed that some selected lines of Japanese quail produced heavier carcasses and more meat. The analysis of efficiency of quail meat production showed that it was the highest if the slaughtering was performed at 35 days of age **(Kajtazov and Genchev, 2004)**. The percentage content of edible meat in Japanese quail is very high: breasts ranging 37.3 – 38.7% of the body, legs 22.7 – 24.6% and the carcass, neck and wings in total 35.9 – 37.8% **(Panda and Singh, 1990; Alkan et al., 2010)**. Boned meat of the valuable parts of the body (breasts and legs) amounts to 36% for the breasts and 15% for the legs **(Vaclovsky and Vejcik, 1999)**.

The major advantage of quail rearing is that it requires minimum space, less capital investments and shorter generation interval. Furthermore, they are characterized by their early sexual maturity, better disease resistance, better feed efficiency and faster growth rate **(Vali, 2008)**. The average weight of a Japanese quail is 250 g and lays 250 eggs per annum. It is the smallest avian species reared for egg and meat purposes. Quail meat possesses low number of calories with high protein content. The average dressed carcass yield is 65 – 70% **(Krishnan, 2019)**.

A huge amount of antibiotics has been used to control diseases and to improve performances in livestock. Antibiotics are microbial metabolites that can inhibit the growth of other microorganisms even in low concentrations **(Nir and Ve-Senkoylu, 2000)**. But by long-term use, may cause some side effects of antibiotics, to occure residues in meat and the development of drug-resistance bacteria and reduction in the ability to cure these bacterial diseases in humans **(Donoghue Dan, 2003)**. To meet consumers' demands, in 2006, the European Union introduced a total ban regarding to usage of feed antibiotics. However, a ban on the use of antibiotics, as growth promoters, has led to a need for finding additives, yet safe for improving production performances without

negative effects on animal health and welfare, the quality of food of an animal origin, human health and the environment **(El-Medany et al., 2017)**. Bee products seem to be an effective natural alternative to antibiotic growth promoters **(Babaei et al., 2016; Haščík et al., 2016a, Haščík et al., 2017)**. Bee bread (ambrosia) is a unique fermented bee product that mainly includes pollen, honey, and secretions of bees' salivary glands **(Vásquez and Olofsson, 2009; Barajas, Cortes-Rodriguez and Rodríguez-Sandoval, 2012)**. It is the result of lactic fermentation of pollen, collected by bees from flowers of melliferous plants and mixed by their digestive enzymes, then they are carried into the hive and kept with a thin layer of honey and bee wax. Bee bread is the main food in the hive, especially for larvae and young bees that produce royal jelly **(Kieliszek et al., 2018)**. Bee bread (BB) represents a richer source of high nutritional and functional compounds for human and honeybees than fresh pollen **(Markiewicz-Żukowska et al., 2013; Podrižnik and Božič, 2015; Denisow and Denisow–Pietrzyk, 2016; Sobral et al., 2017; Kieliszek et al., 2018)**. Compared to fresh pollen, it is characterized by a lower amount of complex polysaccharides, a shift in amino acids, proteins and lipids profiles, and an increase of simple carbohydrates and titratable acidity **(Human and Nicolson, 2006; Anđelković et al., 2012; Lee et al., 2015)**. BB is also characterized by a higher nutritional value, better digestibility, and richer chemical composition than pollen **(Habryka, Kruczek and Drygas, 2016)**. The BB results into a stable food, due to the high concentration of simple sugars (35 – 61% dry weight), low pH (3.8 – 4.3), and the presence of antimicrobial compounds **(Vásquez and Olofsson, 2009; Anderson et al., 2014; Podrižnik and Božič, 2015)**. Bee bread is the source of protein, fats, and vitamins. Although the composition of bee pollen and bee bread are similar, there are some differences. Bee bread contains less protein than bee pollen, but bee bread proteins are easier to digest **(Saa-Otero, Díaz-Losada and Fernández-Gómez, 2000; Bogdanov, 2011)**. **Nagai et al. (2004)** stated that BB contains approximately 20% protein, 3% lipids, 24 – 35% carbohydrates, 3% minerals, and vitamins. Fully balanced proteins contain all of the necessary amino acids, vitamins (C, B_1, B_2, E, K, biotin, nicotinic and folic acid), pantothenic acid, pigments, and other biologically active compounds, such as polyphenols (phenolic acid and flavonoids), carotenoids, sterols. Furthermore, enzymes (saccharase, amylase, phosphatases), are also present. In addition, BB contains more than 25 different micro- and macro- elements, such as Fe, Ca, P, K, Cu, Zn, Se, and Mg. The potential application of bee bread, as food and a nutraceutical supplement, greatly depends on its chemical composition, which varies directly with the flora of the region and the time of collection by the bees **(Markiewicz-Żukowska et al., 2013; Čeksterytė et al., 2016; Sobral et al., 2017)**. The activity of pollen (the number of vitamins and enzymes) decreases after 2 or 3 months of storage. Bee bread keeps its activity longer **(Bogdanov, 2011)**. Biologically active substances present in BB are associated with several medicinal benefits. BB has hepatoprotective, immuno-modulating, antiradiation, and adaptogenic properties **(Berene, Daberte and Siksna, 2014; Bogdanov, 2015)**. BB helps to regulate lipid metabolism and has also a positive effect on the cardiovascular system **(Nagai et al., 2004; Baltrušaitytė, Venskutonis and Čeksterytė, 2007; Tomás et al., 2017)**. BB has shown to possess *in vitro* antibacterial **(Baltrušaitytė, Venskutonis and Čeksterytė, 2007; Zerdani et al., 2011)**, antioxidant **(Zuluaga, Serrato and Quicazan, 2015; Tomás et al., 2017) and antitumor (Markiewicz-Żukowska et al., 2013; Sobral et al., 2017)** proprieties.

The aim was the evaluation of meat performance of Japanese quails after the addition of bee bread powder (perga) into their diet.

Scientific hypothesis

We expect a significant effect of bee bread on the meat performance of Japanese quails, especially on the valuable meat parts such as breast and thigh muscles.

MATERIAL AND METHODOLOGY

Animals and experimental design

Animals and diet

The experiment was carried out in the test poultry station at the Research Institute of Animal Production in Nitra. A total of 80 Japanese quails were included in the experiment. The quails were divided into four groups (10 males and 10 females in each group), as follows: the control group received no additives (C), the experimental group E1 received bee bread powder at a dose of 2 g per 1 kg of feed mixture, experimental group E2 received 4 g of bee bread powder per 1 kg of feed mixture and E3 group 6 g bee bread powder per 1 kg of feed mixture. Bee bread was of Slovak origin (Medula Ltd., Bratislava). The groups were kept under the same conditions. The quails were reared using a cage technology, each cage was equipped with a feed disperser and water intake was ensured ad libitum through a self-feed pump up to 56 days of age.

Table 1 shows the list of the ingredients and nutrient content of the basal diets (HYD-07, HYD-11), formulated to provide the nutrient requirements of quails according to the recommended reference levels. The feed mixture was produced without any antibiotics and coccidiostats.

Slaughter and measurements

At the end of the 56-day feeding period, twenty quails from each group (10 males, 10 females) were weighed and slaughtered at the slaughterhouse of the Slovak University of Agriculture in Nitra. After evisceration, the carcasses were kept at approximately 18 °C for 1 h *post mortem*. After that, the carcasses were weighed and stored at 4 °C until 24 h *post mortem*. All the weighting measurements were performed using the precision balance Kern 440 (Kern & Sohn, Germany) with an accuracy of 0.01 g. The carcass yield was calculated by dividing carcass weight with giblets and abdominal fat weight by live body weight.

Statistical analysis

The data were analyzed using the ANOVA Processed with SAS software (version 9.3, by application Enterprise Guide 4.2). Mean values and standard deviation (SD) are reported in tables. Differences between treatments were tested for significance. The level of significance was established at $p \leq 0.05$.

RESULTS AND DISCUSSION

The results of the meat performance of quails without (control group) and after application of bee bread powder (experimental groups) in their nutrition are shown in Table 2. The main indicator of the quality of poultry meat is the category of a carcass, which is determined by its nutritional status **(Maiorano and Bednarczyk, 2013)**. Generally, in quail boneless meat yields is about 77% of carcass weight, the breast muscle represents 50% of the total carcass meat yield, while leg muscle contributes about 30% **(Shanaway, 1994)**. In the case of broiler chicken, the content of muscle tissue of the carcass varies between 40% and 70% **(Maiorano and Bednarczyk, 2013)**. Generally, due to the economic reasons, broiler quails are slaughtered at approx. 5 – 6 weeks of age **(Genchev et al., 2008)**. Under the good condition of feeding and environmental conditions, the body weight gain of quails increases till the 4th week, then starts decreasing **(Shanaway, 1994; Seker et al., 2007)**.

We can conclude that application of bee bread powder in the diet of Japanese quails without gender difference did not have a significant effect on the achieved live weight except for the experimental group E2 with the addition of 2 $g.kg^{-1}$, where were achieved negative significant differences (- 20.35 g) compared to the control group.

The similar results of live weight were achieved in Japanese quails by sex, where male and female in group E2 achieved significantly the lowest live weight (male 170.32 g and female 185.06 g) among the experimental groups. The carcass yield in Japanese quail ranges from 60 to 70 –75% depending on slaughtering age, line, and sex **(Maiorano et al., 2009; Alkan et al., 2013)**. The effect of sex on slaughtering and carcass characteristics are well known in quail, and was reported as highly significant **(Khaldari et al., 2010; Narinc et al., 2010)**. The tendency of the carcass weight of Japanese quails was similar to that in live weight. Carcass yield, except for the experimental group E3 (68.89%), was at least 70% in all other experimental groups and no significant differences in this indicator were found between groups ($p \geq 0.05$). The highest carcass yield without sex difference was in the E2 group (71.84%). Considering sex, in male the highest carcass yield was in the control group (73.40%) and the lowest in the E3 group (71.70%). In female, the carcass yield was the highest in group E2 (70.73%) and again the lowest in the E3 group (66.08%).

For the sexual dimorphism, females are heavier than males, but the latter are characterized by higher carcass yield **(Marks, 1993)**. Despite that Japanese quail is not a species with a high slaughter yield, the percentage of edible meat is high. It was reported that breasts represent a considerable part of the carcass in Japanese quail **(Vali et al., 2005; Khaldari et al., 2010)** and this is a clear advantage because breast meat is favorable among consumers. The incidence on the carcass of breast muscle is ranging from 25 to 36% and for legs is ranging from 16 to 22% in Japanese quail of different ages **(Genchev et al., 2008; Alkan et al., 2013)**. An important indicator of meat performance is also the weight of valuable parts (breasts, thighs), which was significantly ($p \geq 0.05$) smaller in all experimental groups without sex difference, except for the E1 group with breast weight (52.87) versus the control group (52.57 g).

Table 1 Composition of basal diet and nutrient content of feed mixtures HYD-07 and HYD-11 per kg of diet.

Ingredients (%)	Starter feed mixture (HYD-07) (1st to 21st day)	Finisher feed mixture (HYD-11) (22nd to 56th day)
Wheat	13	15
Maize	34.8	32
Soybean meal (48% CP)	23	19.2
Fish meal (71% CP)	5	3
Malt flower	2	3
Rapeseed meal	5	7
Sunflower meal	5	4.5
Monocalcium phosphate	1	1
Fodder salt	0.2	0.3
Animal fat Bergafat	5	4
Calcium carbonate	5	10
Premix Euromix[1]	1	1
Crude protein	245	200
Fibre	50	60
Ash	140	160
Ca	8	35
P	6.5	5
Na	0.9	1.6
Lysine	14.1	11
Methionine + Cysteine	9.5	7.9
Linolic acid	10	10
ME_N ($MJ.kg^{-1}$)	12.1	11.7

Notes: CP = crude protein; Ca = calcium; P = phosphorus; Na = natrium; ME_N = nitrogen-corrected metabolizable energy; MJ = megajoule; [1]active substances per kilogram of premix: vitamin A 15 000 IU; vitamin E 20 mg; vitamin D3 2 000 IU; riboflavin 6 mg; cobalamin 20 μg; Mn 60 mg; Zn 40 mg; Fe 40 mg; Cu 6 mg; I 1 mg; Se 0.2 mg.

Based on evaluating the weight of the breast muscle regarding to the sex, we can conclude that males gained the highest value in the control group (51.81 g) and the lowest in the group E2 (46.73 g).

On the other hand, females gained the highest value in the E1 group (54.46 g) and lowest in the E2 group (47.42 g). Without sex differences, the highest values of thigh weight of Japanese quail were found in the control group (30.41 g) and the lowest in the E2 group (28.74 g). Regarding to sex, thigh weight was again the highest in the control group (29.92 g) and the lowest in the E2 group (28.49 g). In females, the thigh weight was the highest in E1 group (31.28 g) and the lowest in E2 group (28.98 g).

Based on the overall evaluation of the individual groups of experiments in the achieved meat yield of Japanese quails, the worst was the E2 group with the addition of 4 g bee bread powder per 1 kg of feed mixture.

There are no relevant researches on meat performance characteristics of Japanese quails with the addition of bee bread into their diet. However, this quail is widely used for other researches and therefore other natural supplements were tested in their diet.

Denli et al. (2005) reported a higher carcass weight (+8.2%), without significantly better carcass yield after propolis supplementation. **Canogullari et al. (2009)** reported a better weight gain after an average of 1% propolis supplementation into Japanese quail's diet. They also reported that live weight (246.3 g), carcass weight (181.7 g), carcass yield (73.7 g), liver yield (4.91 g), heart yield (2.18 g) and gizzard yield (5.45 g) were not significantly affected by selected supplementation. **Canogullari et al. (2009)** also observed pollen supplementation into quail´s diet in an amount from 5 to 20 g per kg of feed. In comparison with propolis, they found a similar weight gain, worse live weight (237.5 g) and carcass weight (177.3 g), but better carcass yield. The yield of mentioned three giblets was also higher (5.58 g, 2.31 g and 5.58 g, respectively). **Silici et al. (2007)** reported that propolis had no detrimental effect on the health but did not improve the performance parameters of quail in the first 35 days of age.

In comparison to broiler chickens, **Haščík et al. (2012)** revealed that the use of 400 $mg.kg^{-1}$ of bee pollen as a dietary supplement in broilers led to an increase in the live body weight, carcass weight, giblets weight and carcass yield in males, but it had a negative impact on females, as it decreased the body weight of the hens. **Haščík et al. (2016c)** used 400 mg of propolis extract per 1 kg of feed mixture in broiler chickens' diet. Compared with the control group (control – experimental group), they found higher live weight (2270.20 – 2316.90 g), carcass weight (1629.80 – 1669.10 g), a similar carcass yield (78.54 – 78.31%), a higher giblet weight (152.08 – 155.64 g), a similar weight of liver, gizzard and heart, respectively (40.91 – 40.61; 26.00 – 25.09 and 10.72 – 10.88 g).

Similarly to the present findings, **Haščík et al. (2014)** demonstrated that propolis extract supplementation (200, 300, 400 $mg.kg^{-1}$) increased the body weight of broiler chickens (2354.6 – 2382.9 g) in comparison with 2272.89 g in the control group. Slightly increased ($p \leq 0.05$) when the chickens were fed with the combination of humic acid with garlic powder (E2; 1.97 $g.100g^{-1}$ resp. 1.02 $g.100g^{-1}$) and humic acid plus oregano leaf powder (E3; 2.02 $g.100g^{-1}$, resp. 1.05 $g.100g^{-1}$). The content of mentioned AAs has decreased ($p \leq 0.05$) after the addition of humic acids (E1; 1.81 $g.100g^{-1}$, resp. 0.94 $g.100g^{-1}$) in comparison with the control group.

Except for bee products, other natural supplements were tested in Japanese quails' diet. Dietary supplementation with thyme, in the form of essential oil, did not lead to any significant improvement of carcass weight or carcass yield **(Denli et al., 2004; Sengül et al., 2008),** but on the other hand, the newer research carried out by **Khaksar et al. (2012)** shows a significant improvement in live body weight, carcass yield and even breasts yield**. Chantiratikul et al. (2010)** figured out that duckweed may affect carcass yield (76.7%) of Japanese quail, though not significantly.

Ghazaghi et al. (2014) claimed that peppermint *Mentha spicata* can significantly decrease feed intake without negative effects on carcass, breast and leg yields. But unfortunately, dietary supplementation with peppermint *Mentha piperita* significantly increased feed intake with a decrease of breast and leg yields **(Mehri et al., 2015)**. Green tea is known for its content of bioflavonoids, catechin and epicatechin and was tested by several authors as a dietary supplement in broiler chickens' diet **(Haščík et al., 2016b)**. However, in Japanese quail, it did not improve neither carcass (66.4%), nor giblet yields **(Kara et al., 2016)**. Comparing with our study, a canola-based diet led to a higher carcass weight (133.0 g) similar heart (1.7 g) and lower liver and gizzard weight (4.2 and 3.1 g) **(Mnisi and Mlambo, 2018)**. Both cinnamon essential oil and powder supplementations (100 $mg.kg^{-1}$ and 2 $g.kg^{-1}$ of feed) increased a live weight of Japanese quails **(Mehdipour, Afsharmanesh and Sami, 2013)**. Live body weight and carcass yield were significantly increased after the addition of a chickpea into the Japanese quail diet **(Obregón et al., 2012)**, while in our study this was not observed. Also, earthworm's powder can significantly improve the carcass yield of Japanese quail **(Morón-Fuenmayor et al., 2008; Díaz-Cuellar et al., 2009)**. **Partovi and Seifi (2018)** claimed, that in comparison with the control group, diet supplementation with *E. purpurea* extract at all concentrations decreased total feed intake ($p = 0.0017$) and that there wasn't a significant difference between experimental groups. Diet supplementation with *E. purpurea* extract decreased dressing percentage and the difference was significant between the control group with 0.025% and 0.05% groups. Diet supplementation at 0.2% caused a significant increase in dressing percentage in comparison to 0.025% and 0.05% of *E. purpurea* extract groups, yet the dressing percentage did not reach that of a control group ($p < 0.05$).

Research of **Sahin et al., (2003)** showed that dietary supplementation with vitamin C and folic acid is not suitable for Japanese quails because it led to a decrease of live body weight, carcass weight and carcass yield. Dietary L - carnitine supplementation (30, 40 and 50 $mg.kg^{-1}$) led to a decrease of live body weight (185.83 – 194.44 g) and also carcass weight (119.32 – 121.92 g), but caused an increase of giblets like liver (~2.60 g), heart (~0.92 g) and gizzard (~2.00 g) in comparison to the control group **(Sarica et al., 2005)**.

Table 2 Effect of bee bread powder on meat performance parameters of quails.

Parameter	Sex	C	E1	E2	E3	*p*-value
Live body weight (g)	Male	184.26 ±7.03^{a}	183.58 ±4.80^{a}	170.32 ±4.88^{b}	184.80 ±3.93^{a}	0.0335

Notes: Values are shown as mean ± *SD* (standard deviation); C = control group; E1, E2, E3 = experimental groups; a, b, c = means within a row with different superscripts differ significantly at $p \leq 0.05$, one-way ANOVA.

Raji et al. (2015) observed much lower meat performance characteristics of Japanese quails in comparison with our research. They examined live weight, carcass weight, carcass yields and the weight of the breast and thigh muscle, according to their sex, color type, weight group, and age.

The average live weight was 130.56 g (ranging from 97.19 to 162.67 g); carcass weight of 91.65 g (ranging from 67.60 to 119.54); carcass yield 70.24% (ranging from 68.02 to 72.17); breast muscle weight 27.48 g (ranging from 15.76 to 39.32 g); and thigh muscle weight 19.89 (ranging from 12.61 to 29.30 g).

Some of our results were compared with the results of **Lember and Laan (2012)** who compared male and female carcass characteristics of Estonian, Pharaoh and French White quails. For example, the live body and carcass weight of Estonian quail respectively were similar to our results (comparison of males – females): live body weight 184.4 – 208.6 g and carcass weight 119.1 – 128.8 g. According to the control slaughter, the heaviest quails at the age of 42 days were French white quails (261.2 – 302.4 g), their carcasses were also the biggest (169.8 – 185.8). Females of all quail strains in this study had a bigger live weight at the age of 6 weeks. The lowest weights of the breast and thigh muscle were in Estonian quail male (37.4 and 24.4 g), while the highest in French White (63.0 and 38.5 g). **Nasr et al. (2017)** observed performance, carcass traits, meat quality and amino acid profile of different Japanese quails' strains. There was no significant difference among the quail chicks body weight of different plumages colour at 1 day of age. While at the 6th week of age, the white quail had the highest body weight (205.16 g) and the brown quail had the lowest body weight (174.68 g). The white quail had the highest weight of slaughter and carcass, dressing percentage, carcass yield, weight of liver, gizzard, heart and spleen (197.27 g, 169.27 g, 91%, 82%, 6.63 g, 6.53 g, 2.27 g and 0.40 g, respectively) when compared with the other plumage colours.

CONCLUSION

Based on the results of the experiment, we can conclude that the application of 2, 4 and 6 mg bee bread powderon 1 kg the feed mixture in the nutrition of Japanese quails did not have a positive effect on their achieved meat performance. We propose not to apply this preparation in the amount we tested in their nutrition, respectively to look for other alternative solutions for its application in quails nutrition, alternatively others poultry species.

FACTORS AFFECTING RAW MILK QUALITY OF DAIRY COWS UNDER PRACTICAL CONDITIONS

Vladimír Tančin, Šimon Mikláš, Maroš Čobirka, Michal Uhrinčať, Lucia Mačuhová

ABSTRACT
Under the practical conditions, it is important to evaluate the factors affecting milk performance. Data from test day yield and milk components should be useful for such evaluation. The aim of the experiment was to study the effect of season, udder health (by somatic cell counts SCC), parity, stage of lactation on milk production, milk components, and SCC under the practical conditions. Also, the frequency of incidence of high SCC during the season was observed. The experiment was realized on one dairy farm in dairy practice. The experiment lasted from December 2015 to October 2017. We examined 481 Holstein dairy cows (6910 milk samples). Milk samples were collected once per month – performed by recording test day. Only cows with 9 – 11 test days were evaluated. The effect of season, parity, stage of lactation, and SCC influenced most of the studied traits. The milk yield was highest at 2nd lactation. In the following lactations, the milk yields were decreasing. The SCC significantly increased with advanced parity. The elevated SCC was found in the beginning and in the final part of lactation. SCC as a factor significantly reduced milk yield, lactose content but increased fat and protein content. In conclusion, under practical conditions, the management should use the data from test days and analyze them for a better understanding of the performance efficiency at the farm level and for implementing more sophisticated decision making in farming.

Keywords: dairy cows; data; milk; performance

INTRODUCTION
Raw milk production and its quality at the farm level depends on many factors of external and internal conditions. Most often there are described external factors especially heat stress, season, humidity **(Lambertz, Sanker and Gauly, 2014)**, and internal factors like parity, stage of lactation, udder health, metabolic status **(Tančin, Ipema and Hogewerf, 2007; Tančin et al., 2007; Penev et al., 2014)**. Most of the articles published the results under experimental conditions, but conditions at the farm level are often different due to management practices, even if the breeding conditions are the same. Thus, the effect of above-mentioned factors under practical conditions could be an important source of information for the optimal management of each dairy farm.

One of the most important information coming from the dairy practice is data obtained from milk recording test days (milk yield, milk components, somatic cell count – SCC) performed in a monthly period. After processing, these data could be used for the management of dairy cows. One of the most important information coming from test day is data indicating udder health through SCC **(Tančin, 2013)**. SCC is a gold standard in diagnosing of any forms of mastitis of the udder **(Pyörärlä, 2003; Bobbo et al., 2017)** and it is also negatively related to milk yield and its components **(Barkema et al., 1999, Kull et al., 2019)**, and to technological quality of milk **(Santos, Ma and Barbano, 2003; Leitner et al., 2004, Franzoi et al., 2020)**. SCC data are used in the selection of dairy cows **(Strapakova, Candrak and Strapak, 2016)**. Thus, the economic impact of mastitis should be seriously considered **(Petrovski, Trajcev and Buneski, 2006)** at the farm level. SCC in raw milk is also affected by other internal and external factors like stage of lactation, parity **(Tančin, Ipema and Hogewerf, 2007; Tančin et al., 2007)**, frequency of milking **(Hogeveen et al., 2001)**. However, from the health point of udder, these factors did not increase SCC dramatically as the mastitis do.

Milk production, its components, and udder health (represented by SCC) are data available for dairy farms through regular milk recording test day. However, at the farm level, these data are not processed correctly or even not used. Moreover, critical scientific evaluation of these data could be also important. The aim of the experiment was to study the effect of season, parity, stage of lactation on milk production, its components, and SCC under the practical conditions.

Scientific hypothesis

The season, udder health, parity, stage of lactation significantly influence milk yield, milk components and SCC. SCC reduced milk yield and changed milk components.

MATERIAL AND METHODOLOGY

The experiment was realized in one dairy farm in dairy practice. There were black Holstein cows on the farm with average year milk production 10,500 kg. The experiment lasted from December 2015 till October 2017, during which we examined 481 dairy cows. In total, 739 records of cows were evaluated, as in some cows also 2nd, 3rd, and higher lactations were included. Thus, 36% of evaluated cows were on their first lactation, 26% on their second, 18% on third, 12% on fourth, and 8% on the fifth lactation.

The dairy cows were housed in a free housing system with cubicles. Animals were milked three times a day in 2x10 parallel milking parlour. The parlour was equipped with automatic devices for cluster removal. The milking routine included also udder cleaning with towel and fore-stripping. The cows were fed by a total mix ration two times a day.

Milk samples were collected once per month – on the official recording test day. Only cows with 9 – 11 test days were involved in the statistical examination of data. Some samples were excluded from the evaluation due to insufficient milk collection which was insufficient for analysis of all milk parameters. Thus, in total 6910 samples from the experimental period were included and used for statistical evaluation. The basic milk components (fat, protein, lactose) were determined by MilkoScan FT120 (Foss, Hillerød, Denmark) and somatic cells count were determined using a Fossomatic 90 (Foss Electric, Hillerød, Denmark) after heat samples at 40 °C for 15 min.

Animals on the basis of SCC were divided into four groups: low (SCC $<3x10^5$ cells.mL^{-1}), middle (SCC between $3x10^5$ and $6x10^5$ cells.mL^{-1}), high (SCC between $6x10^5$ and 10^6 cells.mL^{-1}) and the highest (SCC $>10^6$ cells.mL^{-1}). We also created 5 groups of animals according to their parity numbers (first, second, third, fourth, fifth, and subsequent lactation). The stage of lactation was divided into four groups (into intervals of approximately 90 days) – in the first group the cows were on their 52.91 ±21.76 days of lactation, in the second one on 135.01 ±25.96 days, in the third on 224.58 ±26.22 days and the fourth on 296.85 ±16.72 days of lactation. In terms of the season we considered four groups – winter (December, January, February), spring (March, April, June), Summer (June, July, August), Autumn (September, October, November).

Statistical analysis

Obtained data were processed by Microsoft Excel and statistically evaluated by SAS/8.2 (2002). The model was tested by using Fisher's F-test. Differences between the levels of the effects were tested by Scheffe multiple range test for studied traits. Data are presented as LSmeans ± standard error for evaluation of somatic cells the following model was used:

$$y = X\beta + Zu + e$$

Where:

y –was the measurements for somatic cell counts; β – the fixed effects of parity, stage of lactation, season, SCC group; u – random effect of cow, u ~ N (0, I δ2c); e – random error, assuming e ~ N (0, I δ2e); X, Z – incidence matrices for fixed effects and random cow effect, resp.

RESULTS AND DISCUSSION

There is the basic statistics of evaluated data in Table 1. The mean of the daily milk production corresponded to the data obtained from the well managed farm **(Tančin et al., 2006)**. In this herd, the mean of SCC was above the limit for SCC in bulk milk tank **(EU regulation 853/2004)**. On average 76.66% of samples were in the low SCC group and 10.25% of samples were in the highest SCC group of the studied herd. Some seasonal effect was also observed, were in the low SCC group the lowest percentage (70.55%) of samples were in summer 2015 and the highest percentage of samples (81.65 %) were in autumn 2016 (Figure 1).

The effect of season, parity, stage of lactation, and SCC groups influenced most of the studied traits (Table 2). The effect of SCC on fat/protein ratio and parity on protein in milk was not found. The highest LSmeans of milk yield was detected in summer 2015 (32.79 ±0.45 kg) and the lowest in autumn 2016 (27.04 ±0.38 kg, p <0.05). Throughout the study, there were higher milk yields in Spring and Summer with the following decrease in Autumn periods. The highest fat content was found in Winter 2015/2016 (4.41 ±0.03%) and the lowest in Summer 2017 (3.76 ±0.04%, p <0.05). The concentration of protein was the highest in Winter 2016/2017 (3.39 ±0.02%) and the lowest in Summer 2015 (3.11 ±0.02%, p <0.05). The range of lactose LSmeans were from 4.66 ±0.01 % (Autumn 2015) to 4.78 ±0.01% (Winter 2014/15 and Spring 2015). The SCC was lowest in Spring and Summer 2016 (5.12 ±0.03 logPSB.mL^{-1}) and the highest in Spring and Summer 2015 and Summer and Autumn 2017 (5.24 ±0.03 logPSB.mL^{-1}). The significant differences among seasons in SCC were only between summer 2015 and summer 2016 (p <0.05). Though the seasons of the year significantly influenced studied trials in dairy cows, in general, the same seasons did not have a similar effect on studied traits (Table 3). The significant differences of LSMeans at fixed factor „Season" can be found in Table 4.

Most frequently in the science, the season is discussed in relation to SCC. Summer period seems to be a risk factor for udder health in the fact that environmental pathogens caused a higher incidence of mastitis during the summer period **(Smith, Todhunter and Schoenberger, 1985; Penev et al., 2014)** as a possible consequence of suitable living conditions for bacteria **(Mallet et al., 2012)**. This was also confirmed in our previous work in dairy practice **(Tančin 2013)**, where there was a significant increase of SCC during the period of May, June, and July as compared with winter months of the year. But at present work, the summer was not confirmed as the most critical season (Table 3). Another work showed more critical period on mastitis occurrence in the winter season **(Olde Riekerink, Barkema and Stryhn, 2007)**. Under the conditions of healthy mammary glands, the season was pointed out to have no significant influence on SCC **(Malinowski, 2001)**.

In our study, we had summers with the highest, but also the lowest SCC, so other important factors like management and effective mastitis control program might be more important. The climatic, microclimatic conditions and feeding vary from year to year that could diminish or extend the difference among seasons. The stage of lactation is an important factor affecting milk performance. Milk yield and protein content significantly decreased from the first to the fourth stage of lactation (Table 5). Fat content was the highest in the fourth stage and lactose was reduced during the last stages of lactation (third and fourth stage). The SCC significantly changed from the stage to stage of lactation with higher SCC at the first stage, with a reduction in second and again with an increase in the third and the fourth stage of lactation (Table 5). The changes of SCC during lactation showed the most critical period for SCC in the beginning and in the end of lactation. These changes are generally known **(Tančin, 2013)** and again were confirmed at practical conditions. A significant effect of the stage of lactation in dairy cows was also documented by **Laevens et al. (1997)** and **Sebastino, Uribe and Gonzalez (2020)**. From the management point of view, the period early postpartum and before drying are critical for udder health. Therefore, more attention should be focused on the care of cows during both mentioned periods of lactation.

The milk yield and its components and SCC in relation to the parity are shown in Table 5. Milk yield was the highest at second lactation with decreasing in the following lactations. The SCC significantly increased with advanced numbers of lactation. Especially the group of cows on their fifth and subsequent lactations had 5.59 ±0.05 logx.mL^{-1}, compared to primiparous cows with 4.88±0.03 logx.mL^{-1}. There were no significant differences between the first two groups of parities indicating a relatively low increase of health problems during the first two lactations. In our earlier study **(Tančin, Ipema and Hogewerf, 2007)** the multiparous cows had only numerically higher SCC as

Table 1 The basic statistics of evaluated data.

Parameter	N	Minimum	Maximum	Mean	Std Error
Yield, kg	6910	2.50	56.80	33.07	0.11

compared with primiparous cows and this difference is in agreement with other findings **(Laevens et al., 1997)**. Recently **Sebastino, Uribe and Gonzalez (2020)** showed a significant increase of SCC with parity.

SCC as an internal factor significantly reduced milk yield and lactose content on one side and increased the content of fat and protein (Table 5). A similar effect of SCC on milk yield we demonstrated earlier **(Tančin, Ipema and Hogewerf, 2007)**. However, in another study, the lowest fat, SNF, protein, and lactose were determined in milk with SCC >500x10^3 cells.mL^{-1} **(Kull et al., 2019)**. It was further observed that fat % expressed a negative phenotypic correlation with SCC **(Wagay et al., 2018)**. Recently, **Concalves et al. (2018)** also demonstrated the daily milk losses caused by increased SCC. **Bezman et al. (2015)** found out a decrease in milk yield and lactose with increased SCC caused by the presence of mastitis pathogens. In milk with high SCC, the last-mentioned authors also demonstrated an increase or decrease of the protein in milk and a decrease or no changes of fat. These changes were influenced by the presence of different pathogens. In our study, we did not have any information about the presence of pathogens.

Table 5 Least squares means milk yield and its components according estimated factors.

Note: a,b,c,d – means with different letter within column and factor significantly differs at p <0.05.

CONCLUSION

At the studied farm level, the season, parity, and stage of lactation significantly influenced milk performance and SCC. Seasons showed unbalanced milk production, milk components, and also SCC throughout the study period. The SCC significantly increased with parity and was highest at the beginning and at the end of lactation. The SCC significantly reduced milk yield and lactose but increased fat and protein content in milk. Processing the data from the recording test days and their implementation at the farm level could contribute to better managing animal breeding.

INTELLIGENT CONTROL SYSTEM FOR MINCED MEAT PRODUCTION

Boris Kapovsky, Alexander Zakharov, Marina Nikitina

ABSTRACT

This article presents the theoretical aspects of developing a control system for the processing of frozen raw meat by cutters in automatic mode. The method for analytical calculation of the productivity rate of meat cutting by a cutter with a screw tooth provides an accuracy for which relative error does not exceed 6%. The authors show automatic process control in minced meat production using a control system computer (CSC), with the aim of building an automatic control system (ACS) for chopping raw materials frozen in the form of blocks. The task of ACS synthesis was solved: the system structure and its elements were chosen, the topology of their cause-and-effect relationships and an algorithm of control devices were developed, and their parameters were determined. The ACS's control loop scheme for raw material cutting speed was realized, where an assembly of devices was chosen as the object of management (OM): the squirrel cage induction motor (SCIM) of the cutting mechanism drive; the frequency converter (FC) of the supply voltage, which changes the rotation speed of the SCIM (the rotation speed of the milling cutter); and the milling cutter of the chopper. The shaping filter method was used, to predict the size of the meat chips produced, to modulate the perturbation acting on the system from the load side. Based on the single-stage chopping of raw meat, an automatic line is created for producing meat products, with a minced meat quality management system based on artificial intelligence on the principle of 'unmanned technology'.

Keywords: automation of sausage production; innovative approach; minced meat production; machine control

INTRODUCTION

In the technology of meat and meat product processing **(Lisitsyn et al., 2004; Zajác et al., 2015; Herrero et al., 2008)**, it is noted that the structural and mechanical properties are determined largely by the particle size of the chopped raw material, i.e. the degree of chopping. It is also noted that with the help of structural and mechanical properties, it is possible to control the technological parameters of raw materials and minced meat, and the product quality at any stage of the technological process of minced meat preparation, as well as the texture of finished products.

To obtain ready meat products with specified characteristics, first of all, it is necessary to prepare minced meat under rational chopping modes. The duration of chopping (τ_k, s) depends on the type of chopping machine (its geometric and kinematic parameters) and is determined by the following equation **(Kosoj, Malyshev and Yudina, 2005)**:

$$\tau_\kappa = A_1 K_p \left[exp(0.326 K_{vd} + 0.35)\right] \Omega^{-1} \quad (1)$$

Where A_1 is a coefficient equal to 1×10^5 m^3.(kg.s)$^{-1}$; K_p is a coefficient that takes into account additional cutting of the product due to the pressure in the cutting chamber; K_{vd} is the ratio of protein and fat in the meat; and Ω is the generalizing kinematic characteristics of the chopping machine determined by the following dependence:

$$\Omega = f_0 \frac{W_n^2}{W_f}, \quad m^3 / \left(kg \cdot s^2\right) \quad (2)$$

Where: f_0 is the cutting capacity of the machine equal to $f_0 = z n_n F_d / 60 m_f$ m^2/(kg·s) in which z is the number of knives in the cutting tool; n_n is the frequency of blade rotation; F_d is the cross-sectional area of the minced meat layer made with a knife in one revolution, m^2; and m_f is the weight of minced meat, kg. W_n is the circumferential rotation speed of knives at their greatest radius r_n, equal to $W_n = 2\pi r_n n_n / 60$ m.s^{-1}; and W_f is the feed rate of minced meat to the cutting mechanism along the axis of knife rotation, m.s^{-1}.

Machine control of the single-stage chopping mode of initial frozen meat raw materials will allow rational management of the entire technological process on an automatic line developed for sausage production. In this regard, the purpose of automatic control of chopping raw materials by the rotary cutting method can be formulated

as follows: 1) it shall maintain a predetermined degree of chopping of the raw meat under the conditions of raw meat structural heterogeneity and textural features; 2) it shall calculate while chopping the forecast changes in meat particle (meat chip) size by means of an automatic control system (ACS) for the technological process. To achieve these goals, it is necessary to solve the task of ACS synthesis. For this purpose, it is necessary to choose the structure of the system, its elements, and the topology of cause-and-effect relations between them; and to develop algorithms for the control devices and values of their parameters, for example, regulator settings **(Pupkov et al., 2004b; Shaykhutdinov et al., 2016; Yao et al., 2010; Zhou and Wang, 2012; Balejko, Nowak and Balejko, 2012)**.

Frozen meat cut with cutters shows significant differences to that cut with some traditional materials (metals, wood, plastics) – significant heterogeneity of the structural and textural characteristics of frozen meat raw materials affects the quality of chopping **(Kapovsky et al., 2017; Lisitsyn et al., 2016, Lisitsyn et al., 2017; Kapovsky, Zakharov and Nikitina, 2019)**. Different amounts of ice (water) in frozen meat at different storage temperatures and the presence of fat and connective tissues are the structural signs of its heterogeneity. When cutting frozen meat blocks, the quality of chopping is affected by the different orientation of muscle fibres in the mass of the product block in relation to the cutter blades, which is a textural sign of the heterogeneity of the raw material.

The impact of influence factors on the raw materials chopping degree by the rotary cutting method is random due to the above-noted heterogeneity of raw materials. For example, when the cutting blade of the milling cutter is positioned longitudinally to the bundle of fibers in the muscle tissue, the width of the cut layer of meat will be bigger in comparison with the transverse positioning of the same fibers. The orientation of the cutting edge of the chopper working blade during the chopping in reference to individual pieces of meat in the frozen block of raw materials is determined by their random arrangement after molding and freezing in a freezer mold. Taking into account the peculiarities of the meat block topology, it is advisable to analyze statistically the size of meat chips of minced meat obtained in result of chopping experimental blocks of frozen raw materials with cutters of different designs and geometry. The data of statistical analysis will allow defining the regularities of the meat chips size of as a random process, which numerical parameters are determined by the operating parameters of the raw materials chopping (speed of chopping and rate of feed of a block of frozen meat into the chopping zone) and the used chopper blade.

Scientific hypothesis

Let's assume the formation of the chip size as a random process, ACS shall be arranged to calculate the predicted values of the numerical parameters estimates (expected mean and variance) of the statistical distribution of the typical particle size of the chopped meat to determine the parameters of its further processing on an automated line. The specified forecast must correspond to the specified accuracy and reliability, determined by the requirements applied for the manufactured meat products. The calculation by ACS of the predicted value of the typical size of meat chips shall be based on imitating of the mathematical modeling of one-stage chopping of raw frozen meat with a multi-blade chopper tool.

MATERIAL AND METHODOLOGY

To study the single-stage process of frozen meat block cutting by cutters, the following experimental installation IBF-1 (meat block chopper with rotary cutting modification 1) was created. The unit was equipped with cutters of different designs and geometries (Figure 1).

The parameters of the cutting conditions (cutting speed of the rotary cutter and feed rate in the chopping zone) were set by the appropriate settings of the supply voltage frequency converters which work on the electric motor drives of the cutting and feeding systems of the IBF-1 installation. Experimental blocks of frozen meat preliminary cut from industrial-size blocks (second-grade beef and semi-fat pork) were chopped on the experimental installation. In accordance with **GOST R 54704 (2011)** 'Frozen blocks of trimmed meat', the mass fraction of connective and fat tissue in beef was 20% or less; in pork it ranged from 30% to 50%. The temperature of the meat in the centre of the experimental unit before chopping was -12 to -14 °C.

Note: a – cylindrical rotary cutter according to **GOST 29092 (1991)**, type 1 (solid), version 1 (fine tooth), with an external diameter of 100 mm, inner diameter of 40 mm, length of 125 mm, and 18 teeth; b – cylindrical rotary cutter according to **GOST 29092-91**, type 1 (solid), version 2 (with large teeth), with an external diameter of 100 mm, inner diameter of 40 mm, length of 125 mm, and 12 teeth; c – rotary shaft-mounted cutting planer with TM21M EEC carbide inserts (Freud, Italy) with an external diameter of 100 mm, inner diameter of 30 mm, and length off 100 mm.

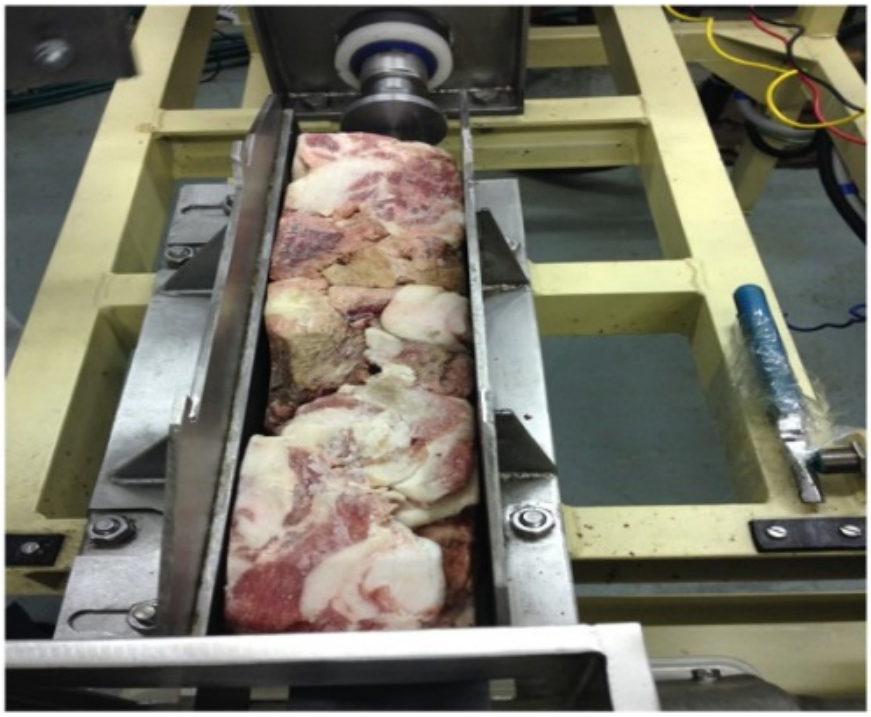

Figure 2 Experimental frozen meat block placed in the guide chute of the IBF–1 chopper.

The placement of the experimental frozen meat block in the guide chute of the IBF-1 chopper is shown below in Figure 2.

The blocks were moved to the rotary cutter by the action of the chopper feeding mechanism's rod, with a preset feed rate along the guide planes. The guiding planes of the IBF-1 working chamber were installed and fixed in accordance with the dimensions of the experimental blocks of frozen meat. The chopped meat was extracted from the collection tank and subjected to microstructural studies carried out in accordance with **GOST 31479 (2012)** 'Meat and meat products.

Method of histological identification of the composition'. Histological preparations were made on a MIKROM HM 525 freezing microtome. The plane sections were studied using an Axio Imager.A1 light microscope (Carl Zeiss, Germany) using computer software for image analysis. The active power consumed by the electric drive of the installation's cutting mechanism in the operation mode was measured and recorded by an AFM-3192 industrial analyzer-recorder.

Statistical analysis

STATISTICA 10.0 software was used in this study for the statistical analyses. The results were calculated as "middle-value ±standard error" (M ±SE). The statistical distribution was equalized with the application of the theoretical (normal) distribution. The equalization was performed by Pearson's criterion **(Book, Velleman and Veaux, 2007; Greenwood and Nikulin, 1996)**. Differences with p-values less than 0.05 were considered as statistically significant.

RESULTS AND DISCUSSION

Figure 3 (a, b, c) shows the microstructure of minced meat chopped by obtained by the chopper IBF-1 with the rotary cutters in which technical characteristics are given above.

The meat chips size obtained from a certain type of rotary cutter and the applied cutting mode of raw materials were statistically analyzed in the following sequence:

1. The data of microstructural analysis of minced meat was grouped into statistical series (Table 1); **(Gaidyshev, 2001; Lagutin, 2007; Protasov, 2005)**.

If the thickness of the meat chips hits between two adjacent ranges, then the number of hits is divided equally between these ranges **(Gaidyshev, 2001)**. The frequency of hits in the range is defined as the quotient between the number of hits in this range and the total number of meat chip thickness measurements. The average value of the meat chips thickness in the range is determined as the arithmetic mean of the measured data for this range.

2. Using the data given in Table 1, the numerical distribution of the meat chips thickness was presented as a histogram according to the selected ranges of the values (Figure 4).

3. By dividing of every frequency of hit into the *i*-th range p_i^* on the stretch of every appropriate range $\Delta_i = a_{i+1} - a_i$, where a_{i+1} and a_i are the selected limits of the range, we get a table of frequency densities f_i^* (refer to the table 2), by which the histogram of the frequency density distribution f_i^* was built according to the range of values of the meat chips thickness (Figure 5); **(Gaidyshev, 2001; Lagutin, 2007; Protasov, 2005)**.

Range 1; 14 – 20	13	0.062	16.92
Range 2; 20 – 26	16.5	0.078	23.58
Range 3; 26 – 30	18.5	0.088	29.56
Range 4; 30 – 35	22	0.104	32.31
Range 5; 35 – 40	28	0.133	37.26
Range 6; 40 – 45	25	0.119	42.34
Range 7; 45 – 50	26	0.123	47.43
Range 8; 50 – 55	15	0.071	52.27
Range 9; 55 – 60	18	0.085	57.40
Range 10; 60 – 66	12	0.057	62.61
Range 11; 66 – 76	8	0.038	70.77
Range 12; 76 – 91	7	0.033	83.50

The presented statistical analysis refers to beef chopping with a fine-tooth rotary cutter at a rotation frequency of 2,289.14 min^{-1} and a rate of meat block feed per cutter = 0.0243 $m.s^{-1}$. The experimental data were used to calculate the estimates of the sample mean values of the thickness and width of meat chips $a^*_{average}$ and $b^*_{average}$, as well as estimates of the standard deviations of the thickness and width of meat chips σ_a^* and σ_b^*.

In the considered case the values of these parameters were as follows: $a^*_{average}$ = 42.28 um and $b^*_{average}$=166.64 um, σ_a^* = 15.86 um, σ_b^* = 90.48 um. In the same way we calculated the same parameters of the experimental distributions obtained when the rotary chopper IBF-1 was equipped with the other types of cutters and the certain cutting mode for raw materials was used. In particular, when equipping the chopper with a large-teeth cutter, the parameter values were: $a^*_{average}$ = 118.99 um and $b^*_{average}$=495.28 um, σ_a^* = 61.15 um, σ_b^* = 245.57 um; the rotary cutter speed = 2,289.14 min^{-1}; rate of the meat (pork) block feed per cutter = 0.0243 $m.s^{-1}$. When equipping the chopper with hard metal plates cutter, the values of the parameters were: speed of the cutter rotation = 2.033.50 min^{-1}; rate of the meat (beef) block feed per cutter = 0.0243 $m.s^{-1}$.

Calculations show that the experimentally obtained statistical distribution of the meat chips thickness is equalized with the help of the theoretical (normal) distribution. The equalization was performed according to Pearson's criterion **(Kobzar, 2006)**. It shall be noted that the mathematical expectation of the distribution of the specified values very well correlates with the supply of raw materials to the cutter tooth. At the same time, the statistical distribution of the meat chips width does not comply with the Gaussian law. This is explained by the prevailing influence of the cutting edge track on the chips width distribution when the rotary cutting edges of the cutter teeth slide on the surface of the meat block **(Book, Velleman and Veaux, 2007; Greenwood and Nikulin, 1996)**. The size of the track varies widely every moment of the chopping process for every tooth of the rotary cutter, while simultaneously taking part in the raw material chopping. This fact is proved by sweeping the lateral surface of a cylindrical rotary cutter with a helical tooth on the cutting surface of the meat block. Thus, to reduce the dispersion of the resulting width of the meat chips, it is necessary to use the rotary cutters with fragmentation of the rotary cutting edges into the equal sized segments (so called "corn-shaped" rotary cutters), which will equalize the width of the meat slices being cut off with all teeth of the rotary simultaneously during the operation.

The moment of resistance to chopping, i.e. the load on the cutter in the operating mode, varies significantly in magnitude. This is caused by the significant heterogeneity

of the initial raw material as noted above. When changing the load on the milling cutter in the operating mode, the frequency of its rotation changes, which leads to additional dispersion of the linear dimensions of the meat chips due to changes in the parameters of the cutting mode (its feed into the rotary cutter tooth and cutting speed of the raw materials). This factor of influence on the degree of meat chopping reduces the homogeneity of the minced meat produced, which leads to a decrease in the quality of the meat products **(Thalhammer, 1998)**.

Given this, it is necessary to ensure the stabilization of the parameters of the meat-cutting mode by means of an ACS for the chopping process in the operating mode of the cutter. The use of automatic control of a single-stage technological process of minced meat production is shown in the example of a line developed for the production of sausages (Figure 6).

When implementing this project, we set the task not only to improve the technological process of cutting frozen meat raw materials through the use of a new method of chopping by the milling method, but also to ensure the production of minced meat of a preset quality on an automatic line.

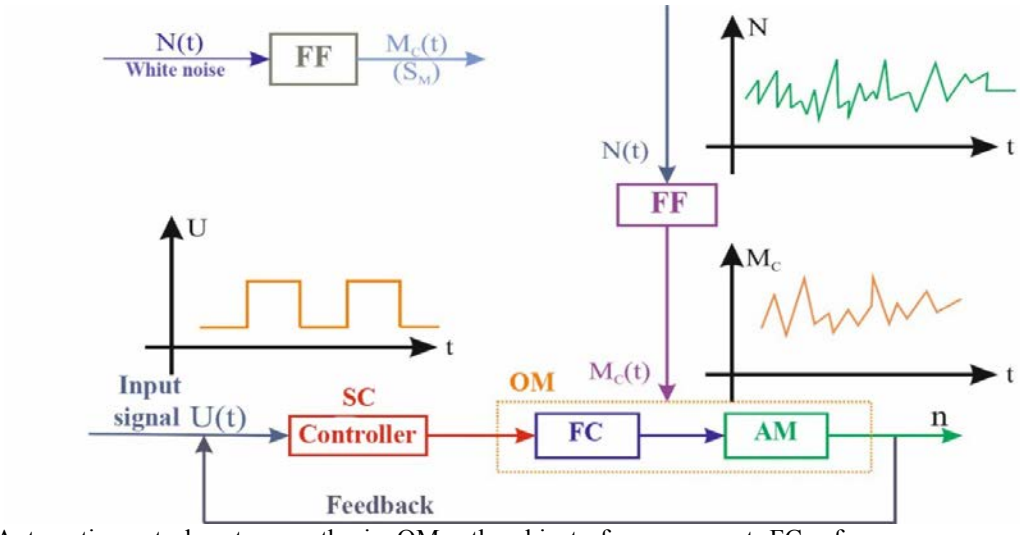

Figure 8 Automatic control system synthesis. OM – the object of management; FC – frequency converter, changing the rotation of the rotary cutter; AM – asynchronous electric motor of the drive on the cutting unit of the chopper; N(t) – white noise; U(t) – input signal (cutting speed setting of the raw material); FF – forming filter; SC – speed controller (frequency) of rotary cutter rotation; Σ – summarizer; n – frequency of the rotary cutter rotation.

To solve this problem, the line is equipped with a storage and dispenser tank, in which the required amount of chopped raw materials of each type (beef, pork, fat) is measured in accordance with the recipe of the finished product. The line also has equipment for monitoring the chemical composition of chopped meat (protein, fat and moisture content) in the production flow in real-time mode. In the process of mixing minced meat in the mixer, its viscosity is controlled by the appropriate sensor and the pH of the minced meat is also measured; water and other components provided by the recipe are dosed and added. The measurement data are sent to the control system computer (CSC – industrial computer), which controls the technological process of producing sausages on the automatic line.

The presented statistical analysis (Figure 7) refers to a beef chopping with a fine teeth rotary cutter at rate of 2.289.14 min^{-1} and a feed rate of a meat block per cutter = 0.0243 $m.s^{-1}$. When constructing the ACS as technological process with the function of stabilization of the operating parameters of one-stage chopping, we can assume that the random process of loading on the cutter is a stationary process with the ergodicity property. This means that any realization of a stationary random process of certain duration represents to a sufficient degree the entire set (ensemble) of realizations of the process considered.

Taking into consideration the normal law of load distribution on the rotary cutter during the chopping process, for mathematical modelling of this disturbance (M_c in Figure 8) it is expedient to use the forming filter (FF) method **(Pupkov et al., 2004c)**.

The FF method is based on the fundamental property of a random stationary process passing through a linear system, which can be expressed as follows **(Gaidyshev, 2001; Kobzar, 2006)**:

$$S_{y(\omega)} = \left|W_{ff(j\omega)}\right|^2 \cdot S_{x(\omega)} \quad (3)$$

where $S_y(\omega)$ is the spectral density of the random process at the system output; $S_x(\omega)$ is the spectral density of the random process at the system input; $|W_{ff}(j\omega)|^2$ is the square of the system transfer function module; and ω is the frequency.

We will consider white noise as a random process at the input. White noise in the theory of stochastic processes (TSP) is understood as the limiting case of a sequence of very short pulses, the amplitude of which is an independent random variable value with a very large dispersion, and the ratio of the dispersion of these pulses to the frequency of their appearance is a constant (finite) value **(Gaidyshev, 2001; Ivashov et al., 2018)**. From the definition of white noise, it follows that the spectral density of the input random process is constant through the entire frequency range and is equal to:

$$S_x(\omega) = S_0 = const$$

If we assume S_0 = 1, then formula (3) will have the following form:

For synthesis of the ACS technological process on the proposed line (in particular solving the task of predicting the size of meat chips in the chopping process), it is necessary to take into account the impact on the rotary cutter from the load side. To do this, it is necessary to develop a mathematical model of the load on the rotary cutter in the process of chopping raw materials. The data obtained during the experiment and processed by methods of mathematical statistics give reason to assume, in the first approximation, the normal law of load distribution on the rotary cutter when chopping industrial-size blocks of raw materials. The experimental statistical distribution of consumption of active power of the cutting mechanism IBF-1 in the chopper drive (Figure 7) is equalized with the help of the theoretical distribution according to the Gaussian law.

$$S_y(\omega) = \left|W_{ff}(j\omega)\right|^2 \cdot S_x(\omega) = \left|W_{ff}(j\omega)\right|^2 \cdot 1 = \left|W_{ff}(j\omega)\right|^2 \quad (4)$$

Thus, in order to realize a random process with a given statistical characteristic, i.e. a given spectral density $S_y(\omega)$, we must send the white noise with a unit spectral density through a linear system with a transfer function $W_{ff}(j\omega)$. Such a linear system in the theory of automatic control is called a shaping filter.

Single-stage chopping control provides automatic maintenance of the set degree of chopping of raw materials while stabilizing the parameters of the cutting mode in real time. The ACS of the technological process on the developed automatic sausage production line has the features of an intelligent control system **(Pupkov et al., 2004a)**: 1) close interaction of the intelligent system's information with the environment when using information communication channels – in the case of control over the single-stage chopping of meat blocks, their temperature, the presence of foreign particles, and the weight of the units are controlled; 2) the availability of forecasts of changes in the external environment and their own behaviour – in this case, the system calculates the forecast amount of meat chips obtained by cutting of the raw materials with a multiblade tool; 3) improving intelligence and improving one's own behaviour – the system is trained in real time, updating the forecast amount of meat chips in the process.

The ACS algorithm (Figure 9) is characterized by the fact that, in addition to the statistical information obtained during chopping of a real block of meat about the change in cutting shaft speed under the influence of the chopping resistance moment, the CSC will have an additional volume of similar statistical information while computer modelling of chopping of 'virtual' blocks of meat.

This allows the CSC to calculate the point and interval estimates of the process under changing rotation speed of the chopper cutting shaft in the chopping process, and on their basis, according to the established analytical dependence, it can determine the same estimates for changing the characteristic size of the resulting meat chips with a preset statistical accuracy and reliability.

The CSC also calculates the variance of these estimates themselves, i.e. determines the degree of 'blurring' of the range limits which include the size of meat chips, which is important in the production of baby food.

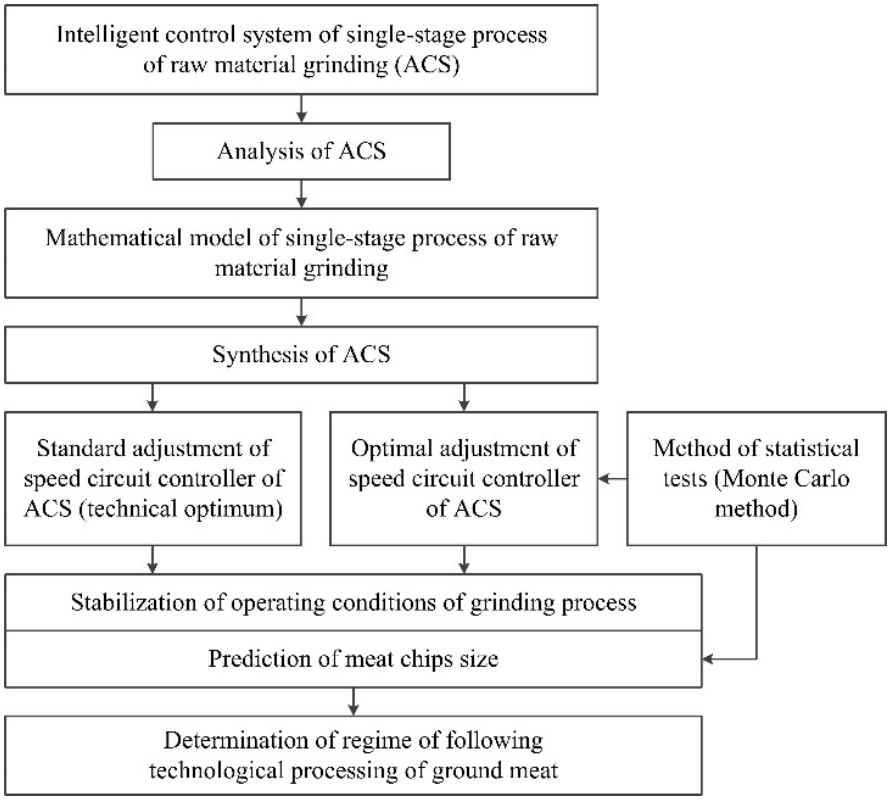

Figure 9 Block diagram of the development of an automatic control system (ACS) for a single-stage process of chopping of frozen meat raw materials.

In the process of real chopping of a block meat, the CSC accumulates and processes statistical information about the chopping process, i.e. the system is trained in the operating mode, improving its prediction of the degree of the raw material chopping. As a result of implementing the above algorithm, the control system will have statistical information about the degree of raw material chopping in an explicit (digital) form. The composition of the ACS may include equipment for rapid analysis of the chemical composition of chopped meat, as well as its temperature after chopping. Then, the further process of minced meat production can be controlled strictly as a function of time, excluding the subjective factor of assessing the degree of the final product readiness. This will allow acquisition of a finished product with a preset high quality.

CONCLUSION

In the proposed project for automatic sausage production lines, the technological chain is reduced in comparison with the traditional solution: instead of three meat-cutting machines: block cutting machine → the top → the cutter, only one is used – the rotary cutter for meat chopping. This significantly reduces the cost of operating meat processing plants engaged in the production of mass market products. Machine control of the minced meat produced for sausages at all stages of its production ensures high quality of the final product. Full automation of the technological process of minced meat production using the proposed control system opens the way to the design of automatic meat processing plants in the future.

THE STUDY OF SELECTED COMPONENTS OF GRAPE AND FRUIT WINES

Marcela Cehula, Mojmir Baron, Tunde Jurikova, Adrian Alumbro, Methusela Perrocha, Ivo Ondrasek, Jiri Mlcek, Anna Adamkova, Jiri Sochor

ABSTRACT

This study aimed to compare chemical properties, in terms of the content of volatile substances, antioxidant compounds, and antioxidant activity (AOA), in samples of fruit and grape wines. For this purpose, the following types of wine were selected, namely fruit wines (apple, strawberry, and elderberry) and grape wines (Müller-Thurgau, St. Lawrence Rosé, and Blue Portugal). Basic analyses of fruit and grape wines were conducted by using the ALPHA method and volatile substances in wines were determined by the GS/MC method. The antioxidant content and AOA were estimated by spectrophotometry, using two types of DPPH method. The results of the experiment showed that the highest values of antioxidant compounds (anthocyanins and flavanols) were found in the samples of Blue Portugal wine and elderberry wine. Significant differences were determined among the wines in antioxidant content, which may have been influenced by the production technology. The results showed that the alcohol content of the wines ranged from 10.99% to 19.49% vol. The highest alcohol content was measured in the elderberry wine samples and the lowest in those of the apple wine. The strawberry wine had the highest titratable acid content, which corresponded to a pH of 3.38. The lowest content was measured in the apple wine samples. Due to the higher acid content of the strawberry wine, a higher residual sugar level of 46.9 $g.L^{-1}$ was obtained. We noted that the red fruit wines contained a higher proportion of valuable bioactive substances than white grape wines. Wines with superior sensory properties did not contain higher levels of antioxidants or higher AOA. The research results can provide a helpful reference for the widespread use of grape and fruit wines in medical, nutritional, and other fields.

Keywords: antioxidant; analytical parameter; fruit wine; grape wine; volatile substance

INTRODUCTION

Wines produced in the Czech Republic have been among the most highly valued in terms of worldwide parameters, as evidenced by several international awards received by winemakers. The success of winemakers is also valued very positively by consumers, who are starting to prefer wines produced in the Czech Republic over foreign wines **(Snopek et al., 2018)**.

The main target of producing quality and premium wines is expressing the connection, through sensory character, to the place where the grapes were cultivated **(Slaghenaufi et al., 2019)**. Similar to other foods, wine has a taste and aroma that significantly affect the interest of the final consumer. These characteristics of the wine are influenced not only by the cultivar used but also by how the wine has been stored during its maturation. The most valuable compounds in wine are volatile organic and bioactive compounds.

The most studied compounds from this group are terpenes **(González-Barreiro et al., 2015)**. Different methods of wine-making technology have affected substance levels **(Baron et al., 2018)**. Polyphenols, especially resveratrol, anthocyanin, and catechins, are the most valued wine antioxidants **(Snopek et al., 2018)**.

The current modern trend has been in plant breeding. One scientific area that has been discussed has concentrated on producing large-fruited cultivars and clones with regular fertility and a higher profile of bioactive substances and AOA. After several years of exploring this issue, crop refinement has only been achieved by selecting the most usable and fastest-growing plants. Eventually, the selection of plants studied has influenced the morphological and quantitative properties of crops all around the world **(Kaczmarska et al., 2015; Cehula et al., 2019)**.

Various polyphenolic compounds are valued for plant cell pigmentation, i.e. anthocyanidins, responsible for red, blue, violet, orange, and purple colors **(Moreno-Montoro et al., 2015; Vallverdu-Queralt et al., 2015; Barba et al., 2016)**.

The aim of this study was the comparison of the different bioactive substance content of grape wines and fruit wines. Three kinds of grape wine (‘Müller-Thurgau’, ‘ St. Lawrence Rosé’ and ‘Blue Portugal’) and three kinds of fruit wine (strawberry, elderberry, and apple wine) were selected. During the study, attention was given to the

evaluation of AOA by the DPPH method, estimation of the total content of anthocyanins, flavanols, acetic, citric, lactic, malic and tartaric acids, alcohol, fructose, glucose, sacharose, and glycerol, of pH, of total acidity, and sugar content.

Scientific hypothesis

H1: The content of antioxidants depends on the type of wine.

H2: Red wines contain higher levels of antioxidant compounds than white wines.

H3: Wines with significant sensory properties contain more antioxidants than other wines.

H4: By monitoring the occurrence of volatile substances, we can show that grape wines will have a higher content than fruit wines.

MATERIAL AND METHODOLOGY

Characteristics of selected wines:

Müller-Thurgau, 2014: Samples were obtained from the Kubík winery (Velké Bílovice, Czech Republic). It is a high quality, fresh, young wine with a typical yellow-green color, spicy taste, and somewhat pleasant smell.

St. Lawrence Rosé, 2014: The samples were obtained from the same winery. It is a quality deep pink wine, with tones of strawberries in aroma and taste.

Blue Portugal, 2014: We obtained the samples of this wine from the Veverka winery (Čejkovice, Czech Republic). The wine is a soft ruby color, with the aroma of flowers. The tannin content provides it with an attractive expression.

Strawberry wine: This is made from the strawberry *Fragaria annanassa*, cultivar ´Karmen´. The fruits were stripped and crushed and were allowed to macerate for 12 hours before the mash was pressed. The juice was drained by sedimentation. Water and sucrose were added to achieve the desired acid reduction. Nitrogenous substances were also treated with nutrient salt. The juice was then inoculated with noble yeast and placed in an appropriate glass container, fitted with a fermentation plug, and allowed to ferment. After fermentation, the wine was removed from the sludge and filtered. Subsequently, the wine was bottled.

Elderberry wine: The wine was made from elderberries (*Sambucus nigra*, L.). The elderberry fruits were stripped and crushed. The mash was heated to 80 °C for 15 minutes, to destroy the sambunigrin, which causes headaches and nausea. Then the mash was macerated for 48 hours and subsequently pressed. The juice was drained by sedimentation. Water and sucrose were added to achieve the desired acid reduction. Nitrogenous substances were also treated with nutrient salt. The juice was then inoculated with noble yeast and placed in an appropriate glass container, fitted with a fermentation plug, and allowed to ferment. After fermentation, the wine was removed from the sludge and filtered, then subsequently bottled.

Apple wine: The wine was made from the cultivar ´Jonagold´. The apples were stripped of stalks and cores, then crushed. The mash was pressed, and the juice was drained by sedimentation. Water and sucrose were added to achieve the desired acid reduction. Nitrogenous substances were also treated with nutrient salt. The juice was then inoculated with noble yeast and placed in an appropriate glass container, fitted with a fermentation plug, and allowed to ferment. After fermentation, the wines were removed from the sludge and filtered, then, subsequently, was bottled.

For our research we used the followed methods:

Determination of antioxidant activity by the DPPH method

For the determination procedure, see the description earlier **(Sochor et al., 2010)**. We mixed 150 µL volume of the reagent (0.095 mM 2,2-diphenyl-1-picrylhydrazyl; $DPPH^{\bullet}$) with 15 µL of wine sample. Each process was repeated twice. All samples were incubated for 10 minutes. After incubation, we measured samples at an absorbance of 505 nm on the spectrometer. The results were expressed as trolox equivalents.

Estimation of anthocyanin content

These measurements were performed using recognized spectrophotometric methods **(Zoecklein et al., 1999)**. The wine sample was placed into a 0.2 cm path-length quartz cuvette, then 200 µL of the sample and 1.8 mL of 1.1 M HCL were added and the resulting solution was thoroughly mixed and kept at room temperature for 180 minutes. A 0.22 M solution of $K_2S_2O_5$ was used as a blank.

The absorbance was read at 520 nm (A_{520}^{HCl}) for anthocyanins. Total concentrations of anthocyanin ($mg.L^{-1}$) were calculated as follows:

$$\text{Total content of anthocyanins } (mg.L^{-1}) = 4 \times \text{dilution} \times [A_{520}^{HCl} - (5/3) \times A_{520}^{SO2}]$$

Estimation of total flavanol content

Total flavanol content was estimated using the *p*-dimethylaminocinnamaldehyde (DMACA) method **(Li, Tanner and Larkin, 1996; Tomášková et al., 2017)**. Compared with the widely used vanillin method, a major advantage of this method is that there is no interference from anthocyanins. Furthermore, it provides higher sensitivity and greater specificity. Wine (20 µL) was poured into a 1.5 mL Eppendorf tube and 980 µL of DMACA solution (0.1 % in 1 M HCl in MeOH) was added. The mixture was vortexed and allowed to react at room temperature for 12 minutes. Absorbance at 640 nm was then read against a blank sample prepared similarly but without DMACA. The total flavanol concentration was then estimated from a calibration curve and constructed by plotting known solutions of catechin (1 − 16 $mg.L^{-1}$) against A_{640} ($r^2 = 0.998$). The results were expressed as $mg.L^{-1}$ of catechin equivalents.

GC-MS determination of individual volatile compounds and sample preparation

The concentration of individual volatile substances in the wine was determined by the previously unpublished method of extraction with methyl t-butyl ether. The following was pipetted into a 25 mL volumetric flask: 20 mL of wine, 50 µL of 2-nonanol solution (500 $mg.L^{-1}$), and cyclopentanone (25 $g.L^{-1}$) in ethanol as the internal standard, and 5 mL of saturated $(NH_4)_2SO_4$ solution.

Table 1 Determination of basic analytical parameters in selected wines.

Type of wine/ parameter	Alcohol (%)	Titr. acids ($g.L^{-1}$)	Red. sugar ($g.L^{-1}$)	pH	Malic acid ($g.L^{-1}$)	Lactic acid ($g.L^{-1}$)	Acetic acid ($g.L^{-1}$)
Müller-Thurgau	12.31	7.07	7.6	3.49	3.76	0.16	0.26

SD	±1.26	±4.16	±1.16	±15.64	±0.03	±0.38	±0.98

Note: Experiment was replicated 3 times.

The flask contents were then thoroughly mixed, and 0.75 mL of extraction solvent added, MTBE with the addition of 1% neohexane. After thorough mixing of samples, and separation phases, the upper organic layer was transferred to a microtube with a portion of the resulting emulsion, centrifuged and the clear organic phase was dried over anhydrous magnesium sulphate. We continued using the treated extract for GC-MS analysis.

Estimation of acetic, citric, lactic, malic and tartaric acids, alcohol, fructose, glucose, sacharose, and glycerol, of pH, of total acidity, and the sugar content

The aforementioned parameters were estimated using the ALPHA apparatus (Bruker, Germany). The ALPHA spectrometer is a compact FTIR analyser based on the principle of ATR sampling. Physical-chemical parameters of wine samples were determined according to the **EEC Official Method by the European Commission (2003)**, which was used in a similar study by **Condurso et al. (2018)**. This method of sampling considerably simplifies the preparation of samples for analysis. This means that samples of clarified wine were analysed directly, (i.e. without any adjustments), while those of musts and fermenting wine were centrifuged at 13 400 rpm for six minutes. Before the measuring of the first sample, the apparatus was thoroughly rinsed with distilled water and the background was measured using deionized water as a blank sample. For analysis, 1 mL of clear wine was sampled with a syringe; of this, one half (0.5 mL) was used for the rinsing of the system, and the remaining half (i.e. also 0.5 mL) was used for the subsequent three measurements. Depending on the method of calibration (musts/fermenting wine/fermented wine), the recorded resulting amounts were automatically evaluated by software.

Separation conditions

Column: DB-WAX 30 m x 0.25 mm; 0.25 μM stationary phase (polyethylene glycol). Sample injection volume: 1 μL split ratio 1:5; carrier gas flow rate He:1 ml/min (linear gas velocity 36 $cm.S^{-1}$); injection chamber temperature: 180 °C. The initial column chamber temperature of 45 °C was maintained for 3.5 minutes, followed by a temperature gradient: up to 90 °C by 12 $°C.min^{-1}$ held for 0.75 minutes, up to 120 °C by 3 $°C.min^{-1}$.

Statistic analysis

For this study, we applied ANOVA, simple descriptive statistical methods, and correlation- regression. Statistical analysis was performed using NCSS 2019 software (ver. 19.0.4.; NCSS, LLC Utah, USA).

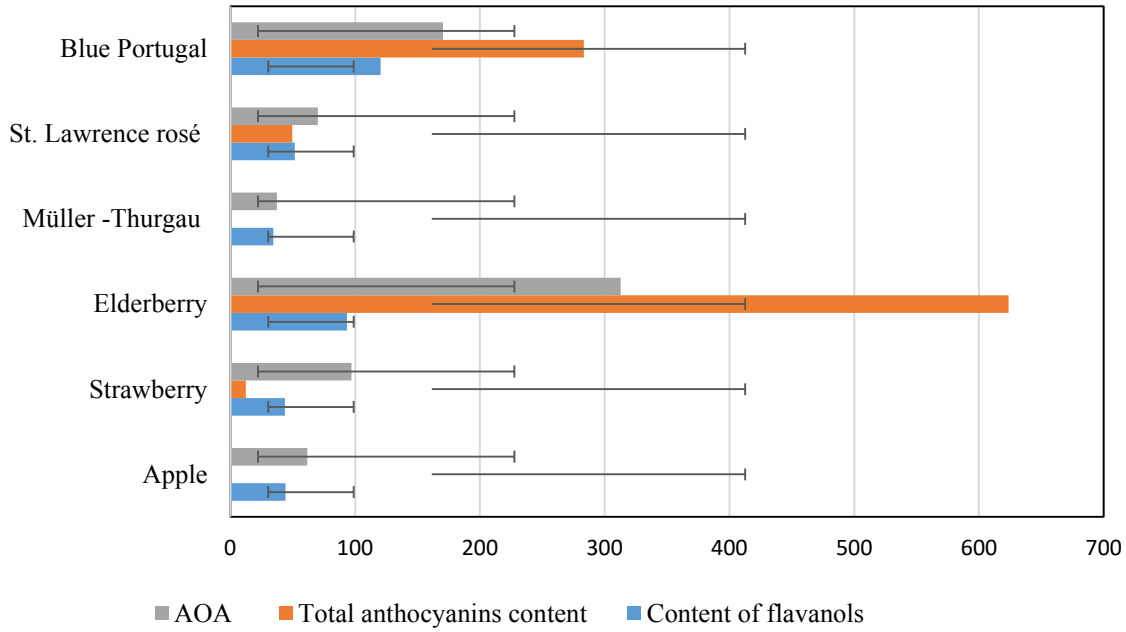

Figure 1 Estimation of Antioxidant activity – AOA (equivalent to TROLOX mg.L^{1}); total anthocyanins content (mg.L^{-1}) and content of flavanols (mg.L^{-1}). Note: Experiment was replicated 3 times.

RESULTS AND DISCUSSION

Determination of basic analytical parameters in selected wines

The results are shown in Table 1. The highest percentage of alcohol was determined in the elderberry wine samples, while the smallest percentage of alcohol was measured in the apple wine samples. The pH range was from 3.25 (apple wine) to 3.98 (elderberry wine). The lowest content of malic acid was determined in the samples of Blue Portugal and the highest content identified in the samples of Müller-Thurgau.

Lactic acid was maximal level in the samples of Blue Portugal, and minimal level in the apple samples. Zero acetic acid content was determined in the case of the apple wine and tartaric acid content in the elderberry wine samples.

On the contrary, the highest values were measured in the Blue Portugal (for acetic acid) and the Müller-Thurgau (for tartaric acid).

We also measured the value of zero in citric acid content, namely in the Müller-Thurgau, very low values in the St. Lawrence rosé and Blue Portugal, and high values in the strawberry wine. We found that the lowest values were of sucrose, of which we measured values close to zero, but we were able to determine higher fructose levels. The values of glucose were from 0.61 to 3.10 g.L^{-1}.

We observed that in the case of the grape wines, the analytical parameters were generally higher than in the case of the fruit wines. Among the grape wines, due to the analytical parameters, we evaluated Blue Portugal as the highest and, among fruit wines, we found that these values were the highest in the elderberry wine.

In the study by **Robles et al. (2019)**, some organic acids were determined and identified in samples of wine. The study mentions that the following organic acids are found in Czech white grape wines: tartaric acid (4.4 – 17.4 mM), malic acid (12.4 – 46.4 mM), acetic acid (1.7 – 27.9 mM), and lactic acid (1.4 – 27.4 mM). The values of tartaric acid measured in our study were in the above range. The content of malic acid in the observed samples was below the levels of those in the above study. Only samples of Blue Portugal corresponded in a range of values of lactic acids. There were no similarities in the other grape wine samples to those in comparable research.

Higginson et al. (2015) demonstrate in their study that single berry samples taken from bunches (grape) showed a large variation in the content of tartaric acid and of malic acid across a single vine. This assayed variation is relevant for studies collecting samples of berries for organic acid analysis. We noted that grape berries (but not fruit) predetermined chemical and sensory properties.

Estimation of antioxidant activity, total anthocyanin content and flavanol content

The next aim of this study was to determine AOA, total anthocyanin content, and flavanol content in all the wine samples. After using statistical analysis methods, we came to the following conclusions:

The highest AOA was measured in the elderberry samples and the lowest content in the Müller-Thurgau samples.

Elderberry wine was the highest-scoring sample regarding total anthocyanin content. Otherwise, low levels were measured in the Müller- Thurgau and apple wine samples. The highest values of flavanol content were found in the Blue Portugal and elderberry wine samples, whereas the lowest values were determined in the Müller-Thurgau. All results are shown in Figure 1. Considering the above-measured parameters, we concluded that elderberry wine and Blue Portugal proved to be the wines with the highest content. Conversely, the lowest levels of

measured parameters were demonstrated in the Müller-Thurgau and apple wine samples. By using the ANOVA statistical method, we showed a statistically significant difference between individual types of wine (grape and fruit wines; $p \leq 0.05$). The correlation and regression method showed that all represented pairs of amounts appeared on a single line and that the function had a rotating character. We found that the coefficient was equivalent to +1, which ultimately means a greater degree of interdependence.

By comparing the various constituents of the wines, we assessed that, in terms of AOA, fruit wines contained higher values than grape wines. Furthermore, in terms of the total anthocyanin content, we evaluated fruit wines as higher than grape wines. However, the flavanol content increased with red wines, elderberry wine, and Blue Portugal, as confirmed by other studies **(Vilas Boas et al., 2019; Lingua et al., 2015)**.

Bruno and Sparapano (2007) mentioned that the content of each substance in grapes was influenced by abiotic factors (e.g. by variety, parent soils, geographic situation, locality, and climatic conditions). We agreed with this statement and we added agricultural and horticultural methods and interventions in vineyards during the growing season. The studies by **Wirth et al. (2010)** and **Baron et al. (2017)** assert that the bioactive substance content and AOA in wine depends on wine-making technology, e. g. by the pressing, maceration, fermentation, filtration, and/or bottling techniques used. They also declare that these contributions have an effect on the sensory properties of wine, the storage time, and other indicators that promote human health.

The study **Čakar et al. (2019)** aimed to determine the potential of the strawberry and drupe (apricot, plum, and sweet cherry) fruits for the production of new fruit wines Improved with phenolic compounds. They found general results that showed that the same fruit wine samples presented high redox potentials, marginally lower than strawberry, and plum wine samples.

The antioxidative potential and total phenolic content were tested in elderberry must and wine in the study **Schmitzer et al. (2010)**. The level of total phenolic content in elderberry must and wine was 2004.13 GAE.L^{-1} and antioxidative potential of elderberry wine was equal to red wine. There was a detected correlation between total phenolic content and antioxidative potential of elderberry wine. Moreover, examinations of elderberry fruits in other studies showed that it contains high biological activity components, primarily polyphenols, mostly anthocyanins, flavonols, phenolic acids, and proanthocyanidins, as well as terpenes and lectins **(Sidor and Gramza-Michałowska, 2015)**.

Mlček et al. (2019) concluded that adequate wine consumption leads to cancer prevention and another health disease. Studies dealing with the content of bioactive substances in beverages made from berries showed that in addition to beneficial effects on human health, these substances have also side effects, e. g. it may cause an allergic reaction for unexplained reasons **(Sedláčková et al., 2018; Nunes et al., 2019; Snopek et al., 2019)**.

Determination of the content of volatile substances in selected samples of fruit and grape wines

Table 2 shows the measured values of individual volatile substances. The fruit wines contained more methanol than the grape wines. The highest level of ethyl acetate was measured in the strawberry wine and other values were similar. Among the terpenes, the most significant that we identified were in the samples of strawberry wine (linalool 100 μg.L^{-1}; α-terpineol 43 μg.L^{-1} and acetoin 9.7 mg.L^{-1}); compared to the strawberry wine, elderberry wine contained more acetoin, and apple wine was higher in methionol content. **Lan et al. (2017)** found that changes in taste properties in wine occur at an early stage of fermentation, i.e. 0 – 4 days. The content of aldehydes, ketones, heterocyclic and aromatic compounds were very reduced by fermentation. The same opinion was presented in studies **Peng et al. (1997); Lubbers, Verret and Voilley (2001)** and **Spence, Velasco and Knoeferle (2014)**.

Comparing the values of volatile substances in grape wines, we found that Blue Portugal and Müller-Thurgau were wines with a relatively high content of linalool. Low total terpene content was demonstrated in samples of St. Lawrence rosé. Geraniol, methionol, and acetoin were measured; Müller-Thurgau differed substantially from Blue Portugal with the highest content of ho-trienol and α-terpineol. The only value of nerol was detected in the Blue Portugal sample. We definitively demonstrated fruit wines as wines with much greater values of volatile substances

Table 2 GC-MS (mg.L^{-1}) determined individual volatile compounds.

	Müller-Thurgau	St. Lawrence rosé	Blue Portugal	Apple wine	Strawberry wine	Elderberry wine	SD
Methanol (mg.L^{-1})	63.70	48.80	100.20	32.60	83.90	221.40	±71.00
2,3-butanediol (mg.L^{-1})	269.00	372.90	1251.30	210.80	2798.10	5087.40	±1883.12

Ethyl acetate (mg.L^{-1})	74.70	73.50	62.80	55.50	191.60	72.40	±57.37
Isoamyl acetate (mg.L^{-1})	4.43	2.49	0.18	3.85	1.11	1.45	±1.72
Linalool (μg.L^{-1})	65.00	10.00	70.00	0.00	100.00	28.00	±39.50
Ho-trienol (μg.L^{-1})	24.00	0.00	8.00	0.00	0.00	0.00	±9.07
α-terpineol (μg.L^{-1})	17.00	0.00	15.00	0.00	43.00	0.00	±16.12
Nerol (μg.L^{-1})	0.00	0.00	3.00	0.00	0.00	0.00	±1.13
Geraniol (μg.L^{-1})	10.00	2.00	12.00	0.00	11.00	8.00	±5.30
Methionol (mg.L^{-1})	1.64	0.57	5.56	10.72	5.32	1.97	±3.78
Acetoin (mg.L^{-1})	0.00	6.40	10.50	1.30	9.70	19.20	±7.05

Note: Experiment was replicated 3 times.

than grape wines. Moreover, we found statistically significant differences between the measured values ($p \leq 0.05$).

Dziadas and Jeleń (2010) measured terpenes in white wines (different cultivars). As an example, we chose Riesling. The results showed that linalool reached a level of 16.6 – 54.4 $\mu g.L^{-1}$. Comparing it with Müller-Thurgau, we noted a higher level of linalool. In contrast, the content of α-terpineol was much lower in our examined samples than those of the results from the comparison study. The nerol content, of which almost none of the examined samples allowed an estimate, had been determined with a decisively higher content in the above research. **Tarko et al. (2008)** declared an opinion that red wines had higher antioxidant potential and total polyphenol content than analyzed white grape and fruit wines. The prevailing volatile compounds of wines were higher alcohols, mainly amyl alcohols and isobutanol. Different conditions of double fermentation were examined in a study **Ubeda et al. (2011)**. There was added SO_2 and pectolytic enzymes which increased the level of methanol and acetaldehyde, especially in strawberry purees. In the study **Kong et al. (2019)** results showed that enzyme treatments improved the contents of volatile substances. The levels of terpenes and higher alcohols increased constantly during alcohol fermentation. **Yang et al. (2020)** and **Bhat (2000)** also mentioned the quality of fruit wines is related to the corrected application of enzymes in the process of winemaking.

Ayestarán et al. (2019) studied the effect of the winemaking process on the volatile composition and aromatic profile of Tempranillo Blanco wines.

The results showed that carbonic macerated wines had a higher level of alcohols and carbonyl compounds. We agreed with this statement.

CONCLUSION

We noted that red fruit wines contained a higher proportion of valuable bioactive substances than white grape wines. Wines with superior sensory properties did not contain more important antioxidants or higher values antioxidant activity. However, we stated that white grape wines contained a higher content of volatile substances, but, especially in the red wine samples (grape and fruit), we measured higher values for the research parameters. Relatively few scientific articles are published on fruit wines. Therefore, it was very interesting to evaluate these wines in terms of basic analytical parameters and make a comparison with grape wines.

DETERMINATION OF VOLATILE ORGANIC COMPOUNDS IN SLOVAK BRYNDZA CHEESE BY THE ELECTRONIC NOSE AND THE HEADSPACE SOLID-PHASE MICROEXTRACTION GAS CHROMATOGRAPHY-MASS SPECTROMETRY

Jana Štefániková, Július Árvay, Michal Miškeje, Miroslava Kačániová

ABSTRACT

The aim of the present study was to describe volatile organic compounds of the traditional Slovak bryndza cheese determined by using an electronic nose (e-nose) and a gas chromatography mass spectrometry (GCMS) with head-space solid phase microextraction (HS-SPME). For the first time, e-nose based on the gas chromatography principle with a flame ionization detector was described to identify and quantify aroma active compounds of bryndza cheese from Slovakia. The e-nose detects aroma compounds of very small concentrations in real-time of a few minutes and identifies them by comparing *Kovats´* retention indices with the NIST library. Bryndza cheese produced from unpasteurized ewe´s milk and from a mixture of raw ewe´s and pasteurized cow´s types of milk were collected from 2 different Slovak farms beginning in May through to September 2019. The flavour and aroma of bryndza cheese are apparently composed of compounds contained in milk and the products of fermentation of the substrate by bacteria and fungi. Regarding volatile organic compounds, 25 compounds were detected and identified by an electronic nose with a discriminant >0.900 with ethyl acetate, isopentyl acetate, 2-butanone, acetic acid, butanoic acid, and butane-2,3-dione confirmed by gas chromatography. We confirm the suitability of the electronic nose to be used for monitoring of bryndza cheese quality.

Keywords: Aroma active compounds; Ewe´s cheese; Slovakia; Electronic nose

INTRODUCTION

One of the traditional ewe´s milk production is bryndza cheese or Oštiepok cheese **(Zajác et al., 2019; Šnirc et al., 2019)**. Slovak bryndza cheese is natural, white, spreadable cheese, manufactured according to the traditional method. It is recognized in the European Union by Protected Geographic Indication (PGI) status as cheese produced in specified mountainous regions of Slovakia **(Commission Regulation (EC) No 676/2008; Šaková et al., 2015; Zeleňáková et al., 2016)** where unpasteurized ewe´s milk is processed to obtain the Slovak bryndza cheese. The mountainous regions of Slovakia differ in altitude, climate, geological, and vegetation profiles and there exists some scientific evidence about the variability of bryndza which is lacking in connection to common characteristics of this Slovak cheese **(Šaková et al., 2015)**. Ewe´s cheese represents a matrix with a specific composition which reflected ewe´s milk and also by different autochthonous lactic acid bacteria (LAB) produce typical aroma profile of ewe´s lump cheese, barreled ewe´s cheese as well as bryndza cheese **(Šaková et al., 2015; Sádecká et al., 2016)**. **Kačániová et al. (2019)** identified 870 isolates from coliforms, enterococci, lactic acid bacteria, and yeasts in Slovak bryndza cheese by MALDI-TOF MS profiling. *Hafnia alvei*, *Klebsiella oxytoca*, *Lactococcus lactis*, and *Lactobacillus paracasei* were the most frequently identified species of bacteria. LAB group was represented by *Lactobacillus*, *Lactococcus,* and *Pediococcus*.

Several volatile organic compounds (VOC) of cheese, including raw milk-based ewe´s cheese, are formed by proteolysis and by the subsequent transformation of amino acids **(Ozturkoglu-Budak et al., 2016)** to α-keto acids **(Čaplová et al., 2018)**. Two different major pathways of amino acid degradation have been identified in *Lactococcus lactis* **(Yvon and Rijnen, 2001)**. The first pathway is initiated by an elimination reaction of methionine catalyzed by amino acid lyases and leads to major sulphur aroma compounds **(Dias and Weimer, 1998a; Dias and Weimer, 1998b)**. The second pathway is initiated by a transamination reaction catalyzed by aminotransferases, and has been observed especially for aromatic amino acids, branched chain amino acids, and methionine **(Rijnen et al., 1999; Bourdat-Deschamps et**

al., 2004). The resulting α-ketoacids are then degraded to aldehydes, alcohols, carboxylic acids, esters, methanethiol, and other sulphur compounds. Most of these compounds are produced by enzymatic degradation but a few ones result from chemical degradation in particular oxidation **(Nierop-Groot and de Bont, 1998, Nierop-Groot and de Bont, 1999)**. VOC are usually analyzed by gas chromatography after the extraction or pre-concentration of the volatile fraction. The most exhaustive methods for this purpose are high vacuum distillation (HVT), solvent-assisted flavour evaporation (SAFE), or solid phase microextraction (SPME) **(Sádecká et al., 2014)** combined with headspace. **Sádecká et al. (2014)** used SPME with gas chromatography-olfactometry (GC-O) for the determination of volatile odorants in May bryndza cheese. Depending on the degree of cheese maturation, from a GC-O point of view, 25 olfactometric responses from groups of alcohols, aldehydes, esters, ketones, fatty acids, and hydrocarbons were recorded.

The aim of this study was to obtain, for the first time, parallel information of principal volatile organic compounds in bryndza cheese determined by an electronic nose and a gas chromatography mass spectrometry with head-space solid phase microextraction sample pretreatment and to confirm the possibility of the use of e-nose for monitoring bryndza cheese quality.

Scientific hypothesis

Hypothesis 1: The impact of the season on bryndza cheese aroma profile determined by e-nose.

Hypothesis 2: The impact of the season on bryndza cheese aroma profile determined by HS-SPME-GC-MS.

Hypothesis 3: The application of the method to monitor bryndza cheese evaluation.

MATERIAL AND METHODOLOGY

Bryndza cheese samples

Samples of bryndza cheese were provided by 2 different producers. The first sample was produced from unpasteurized ewe´s milk by farm dairy. The second one was produced from a mixture of raw ewe´s (min. 50%) and pasteurized cow´s milk by industrial dairy. Samples were collected from May to September 2019. All samples (10) were places in sterile sample containers and transported to the laboratory on ice. Fresh samples were analyzed by head-space solid phase microextraction gas chromatography mass spectrometry (HS-SPME GC-MS) and electronic nose (e-nose) within one day after the delivery.

E-nose analysis

The electronic nose method (e-nose Heracles II, Alpha M.O.S., Toulouse, France) previously described by **Štefániková et al. (2019)** was used for sample analysis. For each analysis, 2.5 g of sample was incubated statically in a 20 mL vial in a thermostat block at 50 °C for 15 min (Autosampler, Alpha M.O.S.) and 5 mL volume of the headspace gaseous compounds was withdrawn using a headspace autosampler syringe and dispensed into the e-nose injector. The identification of compounds was performed by matching the measured peaks with Kovats´ retention indices with the NIST® library (The National Institute of Standards and Technology library) (>50%) by software Alpha Soft V14 (Alpha M.O.S.).

HP-SPME-GC-MS analysis

The head-space solid phase microextraction method was used for a sample extraction according to **Sádecká et al. (2014)** in a modified version. For each analysis, 2.5 g of sample was incubated statically in a 20 mL vial in a thermostat block at 50 °C for 30 min (CombiPal Autosampler 120, CTC Analytics AG, Zwingen, Switzerland), with an SPME fibre (1 cm; DVB/CAR/PDMS) (Supelco, Bellefonte, PA, USA) placed in the CombiPal.

Semi-quantitative composition of samples was determined by gas chromatography coupled with mass spectrometry (GC-MS) using an Agilent 7890B oven coupled with Agilent 5977A mass detector (Agilent Technologies Inc., Palo Alto, CA, USA) equipped with column DB-WAXms (30 m × 0.32 mm × 0.25 μm; Agilent Technologies) operating with a temperature program and MS conditions according to **Sádecká et al. (2014)**.

The identification of compounds was carried out by comparison of mass spectra (over 80% match) with the NIST® 2017 library and retention times of reference standards (ethyl acetate, hexanoic acid, and isopentanol). The semi-quantitative content of determining compounds was calculated by dividing the individual peak area by total area of all peaks. Peaks under 1 % were not counted.

Statistical analysis

Compounds identified by e-nose with a discriminant >0.900 were selected, based on which the semi-qualitative evaluation was performed and PC analysis (Principal Component Analysis) was made by Alpha Soft V14 (Alpha M.O.S.) software. Descriptors were analyzed using single factor analysis of variance and significance was at $p < 0.05$.

The STATGRAPHICS Centurion (© StatPoint Technologies, Inc., USA) and GraphPad Prism 6.01 (GraphPad Software Incorporated, San Diego, California, USA) were used for statistical GC-MS analysis. The ANOVA method complemented by the Test of Tukey´s Multiple Comparison Test with a value of $p < 0.05$ was applied.

RESULTS AND DISCUSSION

In this study, the aromatic profiles of ten bryndza cheese samples by e-nose and HS-SPME GC-MS were evaluated. Bryndza cheese samples were collected from the Slovak dairies. Bryndza cheese is a soft spreadable cheese, made from unpasteurized ewe´s milk or a mixture of ewe´s and cow´s milk. **Kačániová et al. (2019)** previously described the microbiota studies of ewe´s bryndza cheese from the same mountainous regions of Slovakia. LAB, enterococci, and yeasts *Galactomyces candidus* play a key role in flavor development during cheese ripening **(Kačániová et al., 2020; Pangallo et al., 2014; Sádecká et al., 2019)**. The VOC´s are generated by the enzymatic degradation of amino acids in cheese, especially in cheese containing the only LAB.

Table 1 Determination and identification of volatile organic compounds with a discriminant >0.900 in bryndza cheese samples by e-nose.

	Compounds		Compounds
1	ethyl acetate	**14**	benzaldehyde
2	isopropyl acetate	**15**	acetaldehyde
3	isopentyl acetate	**16**	furfural
4	butyl acetate	**17**	2,3-butandione
5	ethyl propanoate	**18**	2-pentanone
6	ethyl butyrate	**19**	2-butanone
7	acetic acid	**20**	benzyl alcohol
8	butanoic acid	**21**	n-butanol
9	propanoic acid	**22**	2-propanol
10	propanal	**23**	1-hexanol
11	butanal	**24**	2-methyl propanol
12	3-methyl butanal	**25**	α-pinene
13	2-methyl propanal		

The amino acid transamination is catalyzed by lactococci aminotransferases and it is the first step in the degradation of aromatic and branches-chain amino acids which are precursors of aroma compounds **(Yvon et al., 1997; Tanous et al., 2005)**. The resulting α-ketoacids are then degraded to aldehydes, alcohols, fatty acids, esters, methanethiol, and other sulphur compounds **(Savijoki, Ingmer and Varmanen, 2006)**.

The identification of the compounds determined by e-nose was performed by matching the measured peaks with *Kovats´* retention indices with the NIST library. Aroma compounds identified in bryndza cheeses by e-nose are shown in Table 1. Total, 25 compounds with a discriminant >0.900 from class alcohols, esters, fatty acids, terpenes ketones, and aldehydes were identified. Ten compounds – 3-methyl butanal, 2-methyl-1-propanol, 2-butanone, 2-pentanone, ethyl acetate, isopentyl acetate, ethyl butyrate, acetic acid, butanoic acid, and butane-2,3-dione were identified in this study by e-nose and by gas chromatography-olfactometry previously described in bryndza cheese from Slovakia by **Sádecká et al. (2014, 2016, 2019)** and **Šaková et al. (2015)**.

Identified compounds by e-nose with a discriminant >0.900 were selected, based on which the semi-qualitative evaluation was performed by the principal component analysis (PCA). Figure 1 displays result processed by the PCA technique of the aroma profile of bryndza cheese samples. The first dimension (PC1 86.927%) allows the separation of July2 and August2 (positive score) from the other samples of cheese (negative score). Among samples May1, July2 and September2 (negative score of the second dimension PC2; 9.402%) and other samples of cheese (positive score PC2) statistically significant differences (p <0.05) were evident in their aroma profiles.

We confirmed differences in aroma profiles between May bryndza and summer or winter bryndza produced from ewe´s milk by the first dairy. On the contrary, more aroma profile differences were in bryndza cheese produced from the mixture of ewe´s and cow´s milk by the second dairy.

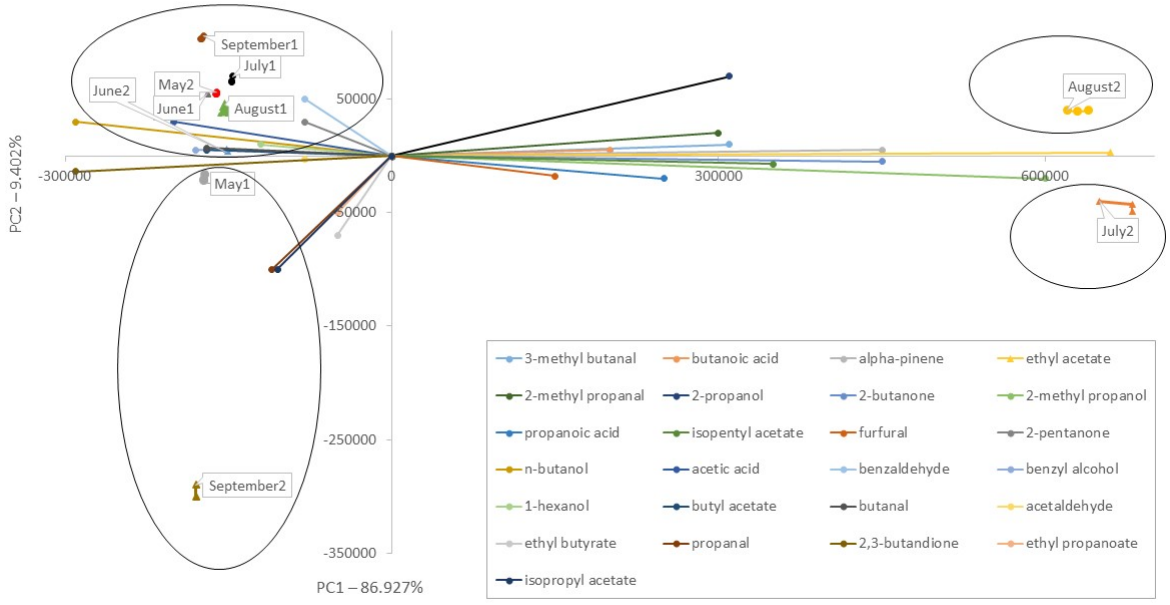

Figure 1 PCA analysis of the aromatic profile of the bryndza cheeses acquired by e-nose.

The samples collected in May and June showed no significant differences in aroma profiles when compared to each other but the aroma profiles were significantly different in comparison with July, August, and September samples and at the same time, the samples collected from July, August, and September showed statistically different (p <0.05) aroma profiles compared to each other.

On the contrary, the position of May2, June2, June1 – September1 samples on the negative score of axis 1 and a positive score of axis 2 could be explained by its higher proportions of acetic acid, benzyl alcohol, butyl acetate, butanal, benzaldehyde, n-butanol, 2-pentanone, and hexanol. The August2 sample is positioned at the opposite on axis 1 due to its higher proportions in butanoic acid, 2-propanol, 2-methyl propanal, 3-methyl butanal, α-pinene, and ethyl acetate. The sample of July2, positioned on the positive score of axis 1 and the negative score of axis 2, contains higher proportions of isopentyl acetate, 2-butanone, 2-methyl propanol, furfural, and propanoic acid and the position of May1 and September2 samples on the negative scores of axes 1 and 2 could be explained by their higher proportions of ethyl butyrate, ethyl propanoate, propanal, 2,3-butandione, and acetaldehyde.

Semi-quantitative content of identified volatile organic compounds in bryndza cheese samples determined by GC-MS is shown in Table 2. In total, 6 higher alcohols, 3 esters, 5 fatty acids, 3 ketones, and methoxy-phenyl-oxime were determined in the samples. Findings showed that principal odorants detected in all samples were acetoin (3.88% – 27.1 %), acetic acid (1.77% – 18.7%), dimethyl-silanediol (1.07% – 6.93%), methoxy-phenyl-oxime (1.78% – 7.01%), and isopentanol (1.72% – 7.44%).

The bryndza cheese from the first dairy contains about 15% of acetoin collected from May and June, and, on the contrary, the next months its content decreased (10.6%, 7.04%, and 10.5% respectively). The content of acetoin in samples from the second dairy was more variable, its amount was decreased (3.88%) in samples collected from July production and increased in samples collected from August production (27.1%).

Table 2 Semi-quantitative content (area %*) of identified volatile organic compounds in bryndza cheeses produced from ewe´s milk (1 – first dairy) and from mixture with cow´s milk (2 – second dairy) collected from May – September determined by GC-MS.

	Compounds	Bryndza cheese samples									
		May1	May2	June1	June2	July1	July2	August1	August2	September1	September2
		Area %									
1	ethyl acetate	1.94	2.62		4.65			10.27			
2	2-phenethyl acetate	0.95	1.08					16.6	0.62		
3	isopentyl acetate							1.76			
4	2-butanone[b]						16.2		16.8		
5	2,3-butanedione (diacetyl)		1.55						2.35	3.55	
6	3-hydroxy-2-butanone (acetoin)	15.2	16.8	15.7	18.5	10.6	3.88	7.04	27.1	10.5	9.73
7	acetic acid[a]	9.00	9.13	11.0	8.55	9.69	13.3	1.77	6.92	18.0	18.7
8	butanoic acid[a]	1.89	1.84	2.21	2.03	1.91	2.11		1.22		
9	pentanoic acid[b]	0.73						1.28			
10	hexanoic acid[a]	3.92	4.07	3.19	2.00	4.10	3.10		2.22		
11	octanoic acid[a]	1.51	1.37			2.42					
12	2-butanol						12.4				
13	2,3-butanediol[a]	3.83	3.67			2.41		1.54		5.42	4.21
14	2,7-dimethyl-4,5-octanediol[a]	1.01	1.06								
15	dimethyl-silanediol[a]	3.99	3.98	2.17	2.3	3.03	2.48	1.07	2.34	6.93	6.16
16	3-methyl-1-butanol (isopentanol)	5.03	4.69	2.06	2.82	3.41	3.21	7.44	1.72	2.41	3.68
17	2-phenyl ethanol	1.05	1.32					12.40	0.61		
18	methoxy-phenyl-oxime[a]	5.13	4.54	7.1	7.01	5.48	5.03	1.87	3.29	2.44	1.78

Note: *listed are the components that represented min. 1% in at least one bryndza cheese sample. Letters in superscript indicates statistically significant difference: a – among samples depending on month of production, b – among samples depending on kind of milk.

The content of acetic acid was in a range of 8.55% – 13.3% in samples produced in May-July, it was decreased in August (1.77% and 6.92%, respectively) and increased in September (18.0% and 18.7%, respectively). While acetoin and acetic acid were the most representative compounds in samples produced in May and June, samples produced in July and August had different profiles. While the samples from the first dairy had a higher content of acetoin and acetic acid (July) and 2-phenethyl acetate and 2-phenyl ethanol (August), the samples from the second dairy had a higher content of 2-butanone and acetic acid (July) and 2-butanone and acetoin (August). Bryndza cheese produced in September had a weaker aroma, but acetic acid and acetoin were identified in the higher amount than in the May and June samples. Statistical analysis by the Test of Tukey´s Multiple Comparison Test confirmed that the amount of eight aromatic compounds (Table 2) was influenced by the month of production. On the other hand, only two aroma substances were notably influenced by the kind of milk.

The compounds identified by the electronic nose with a discriminant >0.900 with ethyl acetate, isopentyl acetate, 2-butanone, acetic and butanoic acids, and butane-2,3-dione were confirmed by GC-MS. Several of the identified compounds (ethyl acetate, 2-phenylethyl acetate, ethyl propanoate, 2-methyl-propanol, 2-phenyl ethanol, 2,3-butanediol, 3-hydroxy-2-butanone (acetoin), 3-methyl butanol, 2,3-butanedione, acetic, butanoic, pentanoic, and octanoic acids) are known to be components of different foreign ewe´s cheese such as the Oscypek, Canestrato Pugliese, Fiore Sardo, Torta del Casar, Terrincho, Roncal, Manchego, and Pecorino Romano **(Barron et al., 2005; Massouras, Pappa and Mallatou, 2006; Majcher et al., 2011; Sádecká et al., 2014; Delgado-Martínez et al., 2019)**.

Other identified compounds, benzaldehyde **(Bourdat-Deschamps et al., 2004)**, 2-pentanone **(Gallegos et al., 2017)**, hexanal **(Gómez-Torres et al., 2016)**, 2,7-dimethyl-4,5-octanediol **(Nájera-Domínguez et al., 2015)** were previously described as secondary metabolites by LAB. **Passerini et al. (2013)** confirmed that strains of *L. lactis* with the *cit*P gene and the *cit*M-G cluster produced a larger amount of aroma-active compounds than the strains without this genetic information. **Bozoudi et al. (2018)** and **Iussig et al. (2015)** reported the quality differences of milk and dairy products from different grazing areas. The terpenoid composition (limonene, myrcene, carvone) of milk and cheese are directly transferred from ingested botanical species and free fatty acids (from acetic to dodecanoic acid) can also be effective to trace animal management and feeding systems **(Moran et al., 2019)**. The free fatty acids are also precursors of methyl ketones, alcohols, lactones, and esters, so they may play an important role in the global aroma development of cheese **(Delgado-Martínez et al., 2019)**. Fatty acids were the most abundant VOCs in the barrelled ewes' types of cheese (intermediate product in the production of winter bryndza) from Slovakia **(Sádecká et al., 2016)** and in the raw ewe´s milk cheese, Feta cheese and Torta del Casar **(Bozoudi et al., 2018; Delgado et al., 2010; Delgado-Martínez et al., 2019)**. The identified 2-methyl propanal **(Griffiths, 2010)** was previously described as milk aromas. The other compounds, n-butanol, dimethyl-silanediol, and methoxy-phenyl-oxime were identified in cheeses produced from pasteurization milk fermented with mixed cultures (*Lactobacillus bulgaricus* and *Streptococcus thermophilus*) and with *Dregea sinensis* Hemsl. protease **(Wang, Wang and Huang, 2017)**.

The e-nose technology in this study can detect the fingerprint of volatile organic compounds present in the headspace of the bryndza sample and parenica cheese previously described **(Štefániková et al., 2019)** by the means of a gas chromatography principle. Several studies used an e-nose method containing 10 metal-oxide semiconductors for characterization of the aroma profile of French cheese types, Danish blue cheese, or Pecorino cheese **(Ghasemi-Varnamkhasti et al., 2019; Trihaas, Vognsen and Nielsen, 2005; Cevoli et al., 2011)**. There was used the e-nose with sensors in the above-mentioned studies, which could not determine or identify concrete volatile organic compounds and therefore there was a need to confirm the results by GC methods.

CONCLUSION

This study has proved for the first time the possibility of bryndza cheese quality evaluation using an e-nose with GC columns and FID detectors. The results were compared with gas chromatography with mass spectrometry. The e-nose method can determine the aroma profile of samples in a short time and the results may be supplemented by aensory evaluation by the assessors. The e-nose may take great advantages over GC-MS in distinguishing the integral aroma profiles, although it cannot identify the explicit volatile compounds of different samples.

INFLUENCE OF INULIN AND OLIGOFRUCTOSE ON THE SENSORY PROPERTIES AND ANTIOXIDANT ACTIVITY OF APPLE JELLY

Mariusz Witczak, Grażyna Jaworska, Teresa Witczak

ABSTRACT
The objective of this study was to analyse the influence of inulin with different degrees of polymerization (DP values) and oligofructose preparation on the sensory properties and antioxidant activity of apple jelly. It has been determined that both the addition of inulin (independently of DP) as well as oligofructose significantly modifies colour and sensory properties and influence antioxidant activity of apple jelly. It has been observed that the manner in which water is bound by the applied preparations may have a significant impact on the analysed properties of jelly. In terms of taste, the highest scores were awarded to the desserts with addition of long-chain inulin and in terms of the overall sensory evaluation those with addition of preparation with medium length chain. The variability of the sensory properties depended on the type and level of the additive, and this impact varied between individual preparation types. The conducted study has enabled the conclusion that inulin may pose an attractive ingredient of desserts with health-promoting properties.

Keywords: apple; inulin, antioxidant; activity; sensory

INTRODUCTION
Inulin is a natural plant biopolymer that belongs to the group of long chain fructans. In plants, inulin acts as a long-term reserve material accumulates mainly in underground parts of plants or short-term in places of active growth. Inulin is stored in largest quantities in the roots and tubers of the *Asteraceae* plant (Jerusalem artichoke, dahlia, artichoke, burdock, asparagus, dandelion) and of the lily (onion, leek, garlic). In smaller amounts inulin occurs in the overground parts of the *Poaceae* plants (rye, wheat, triticale, barley). The most important source of inulin for an industrial scale are Jerusalem artichoke and chicory **(Kiełtyka-Dadasiewicz et al., 2014; Meyer et al., 2011; Nowak et al., 2012; Śliżewska et al., 2013; Trabs, Kasprick and Henle, 2011; Witczak, Jaworska and Witczak, 2020)**.

Due to the fact that inulin has very good technological properties and has an positive health-promoting effect on the human body, it is gaining more and more recognition among both food producers and consumers. Particular attention is paid to the prebiotic and dietary properties of inulin as well as its ability to improve the sensory characteristics of the product. For these reasons inulin is largely used in food production as a texture modifier, substitute of fat and sugar **(Florowska and Krygier, 2007)**.

Inulin properties depend on the source of inulin that affects polymerization degree and the nature of the bonds **(Glibowski, Kulik and Masternak, 2012; Guimarães et al., 2018)**. Physical and chemical properties of inulin (gelation and swelling ability, ability to emulsion formation, thickening, structure stabilization) are widely utilized in the food industry. In the dairy industry, it is used for the production of yoghurts and dairy desserts, in the fruit and vegetable industry for the production of juices, jams, in the fat industry for the production of margarines, in the meat industry for the production of sausages and in the confectionery industry for the production of cookies **(Delgado and Bañón, 2015; Esmaeilnejad Moghadam et al., 2019; Rodriguez Furlán and Campderrós, 2017; Keenan et al., 2014; Rodríguez-García, Sahi and Hernando, 2014; Tárrega, Torres and Costell, 2011; Witczak, Witczak and Ziobro, 2014; Ziobro et al., 2013)**. However, data on the use of inulin in dessert products are limited and they mainly concern milk-based desserts **(Esmaeilnejad Moghadam et al., 2019; Rodriguez Furlán and Campderrós, 2017; Tárrega, Torres and Costell, 2011)**.

The present study aimed at determining the influence of commercial products based on inulin at various polymerization degrees and oligofructose preparation on the antioxidant activity and sensory evaluation of apple jelly.

Scientific hypothesis

Inulin may constitute an attractive alternative for the development of fruit dessert recipes with good sensory and prebiotic properties.

MATERIAL AND METHODOLOGY

Materials

The material used in formulations for jelly preparation consisted of an apple concentrate with the extract content of 69.5% (Apkon Sp. z o.o, Przemyśl, Poland), natural apple flavor (100-fold concentrated), HPX and GR inulin preparations (Beneo, Orafti, Belgium) with different average DP, oligofructose P95 (Beneo, Orafti, Belgium), pectin (Pektowin, Poland). According to the product specification inulin GR contains additionally of a mixture of glucose, fructose and sucrose (8%), HPX 100% of inulin and the P95 preparation contains 95% oligofructose.

Sample preparation

The sample preparation was described in the work of **Witczak, Jaworska and Witczak (2020)**. In brief: the mixture of apple concentrate with water and sugar was boiled, inulin or oligofructose preparation was added, pectin was added, and the mixture was mixed, with citric acid and apple flavour being subsequently added. The solutions were poured hot into jars and were subject to pasteurization at 80 °C ±2 °C for 10 minutes. The obtained samples were cooled down and stored in refrigeration conditions (4 – 6 °C). Analyses were performed on the first day and after 6 weeks of storage. Control jelly was based on the following ingredients (per 1 kg): apple concentrate 152 g, sugar 192 g, pectin 9 g, citric acid 6 g, apple aroma 10 mL, water 631 mL. In samples 3% 30 mL of water was replaced with 30 g, and in 6% 50 mL of water with 60 g of the studied preparations.

Methods

Colour A_{420} was determined via **Burdulu and Karadeniz (2003)** method with own modification for aqueous extracts, prepared via mixing 1 g of jelly with 7 mL of distilled water. The whole mixture was stirred until the jelly dissolved in water entirely. Absorbance measurement was performed on the UV-160A spectrophotometer (Shimadzu, Japan) at 420 nm wavelength.

Total polyphenols and antioxidant activity was determined in methanol extracts. Spectrophotometry with the Folin-Ciocalteu reagent was used for the measurement of the total polyphenol content. Absorbance was measured on the UV-160A Spectrophotometer (Shimadzu, Japan) at wavelength 675 nm against 80% methanol. Polyphenols content was read from the standard curve for (+) – catechin **(Singleton, Orthofer, Lamuela-Raventós, 1999)**.

Antioxidant activity was determined with the use of free radicals 2,2′-azino-bis(3-ethylbenzothiazoline-6-sulfonic acid) ($ABTS^{\bullet+}$) according to the method proposed by **Re et al. (1999)**. Absorbance measurement was performed after 10 minutes, using the UV-160A spectrophotometer (Shimadzu, Japan) at wavelength of 734 nm. Antioxidant activity was expressed as mmol TE per 100 g d.w. (Trolox Equivalent).

Antioxidative activity was determined with the FRAP method according to the **Benzie and Strain (1996)** method. Samples were incubated with acetic buffer, $FeCl_3$ and TPTZ (2,4,6-tri(2-pyridyl)-1,3,5-triazine) solution for 10 minutes and subsequently the absorbance was measured (UV-160A spectrophotometer, SHIMADZU, Japan) at wavelength 595 nm against 80% methanol. The value of antioxidative activity was expressed in μmol Fe^{2+} per g of the edible parts of the jelly.

The sensory evaluation was performed using 5-point scale (5 = excellent, 4 = very good, 3 = good, 2 = bad, 1 = very bad). 8 persons with verified sensory sensitivity participated in the testing. Quality markers such as: surface and clarity, syneresis, colour, consistency, smell and taste. These markers corresponded to importance coefficients, respectively: 2, 2, 4, 4, 4, 4. Selection of importance coefficients was performed based on a discussion conducted within the evaluating panel prior to the evaluation.

Statistical analysis

The data were treated by one-factor analysis of variance (ANOVA), and the averages were compared with the using Duncan test at significance level 0.05. The influence of selected factors was analysed with the use of two- or three- factorial analysis of variance. Additionally the values of Pearson's correlation coefficients between selected parameters characterizing samples properties were calculated. All calculations were performed with statistical software package Statistica 12.0 (StatSoft Inc., USA).

RESULTS AND DISCUSSION

Colour characteristics

Colour measured by means of spectrometry (Table 1) after preparation exhibited the lowest value for samples with 3% P95 addition and the highest for samples with 6% addition of HPX. Samples with addition of inulin with the highest degree of polymerization at lower concentration did not differ from control sample, and at a higher concentration (6%) they were characterized by significantly higher intensity ($p = 0.035$). At the moderate degree of polymerization (GR preparation), samples at both concentrations did not differ significantly from control sample, whereas lower degree of polymerization (P95 oligofructose) resulted in reduced colour intensity with lower concentration, followed by its increase. However, in both cases the obtained values were lower than in control sample. It should be noted that according to the results of the multi-factor variance analysis, all analysed values (time, level and type of additive) had significant impact on the A420 colour. However, as it has been determined, after 6 weeks of storage, in contrast to the first day of storage, no differences could be found between the samples, yet they were also characterized by greater variability. The small variability of the A_{420} parameter obtained in this work coincides with the results obtained earlier **(Morreale, Benavent-Gil, Rosell, 2019; Witczak, Jaworska and Witczak, 2020)**.

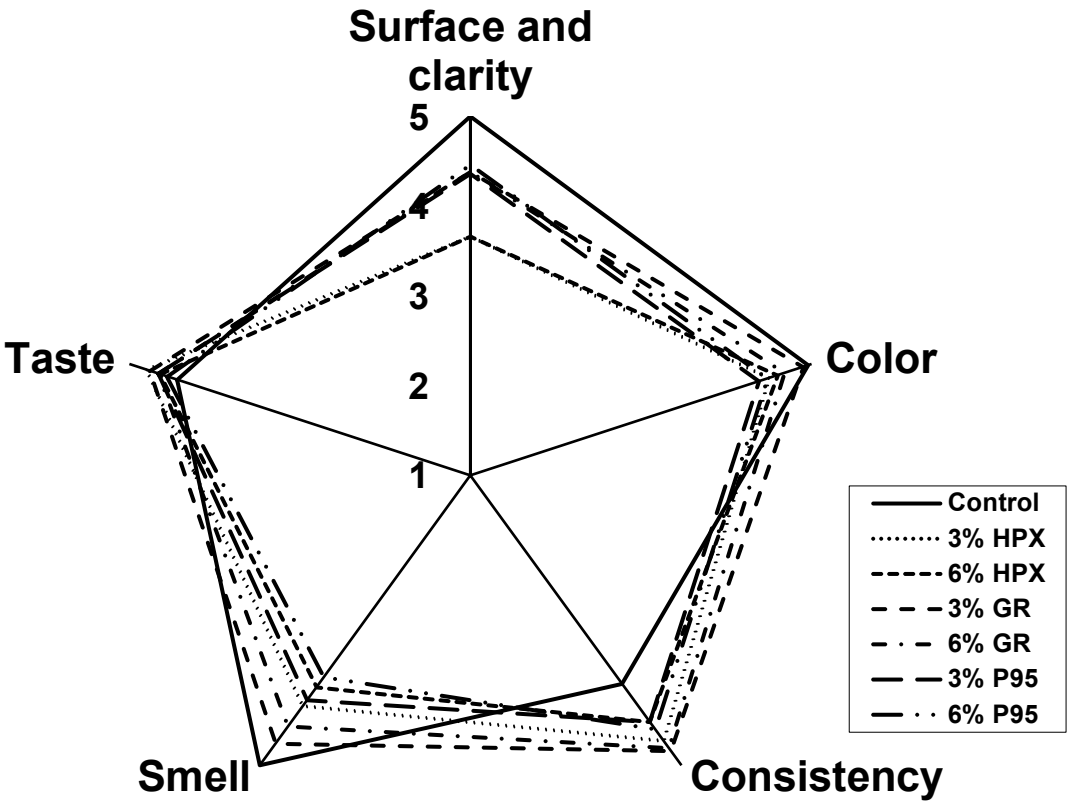

Figure 1 Sensory evaluation of jellies.

Morreale, Benavent-Gil and Rosell (2019) did not find a direct impact of DP on the values characterizing the color of gluten-free bread, but the authors found variability due to yeast type and inulin producer. In turn, **Witczak, Jaworska and Witczak (2020)** found the variability of the L* parameter responsible for the color lightness depending on the type and amount of inulin added. The analysis of the cited works and the results obtained in this work allows us to state that the change in color is conditioned by inulin interactions with the other components of the system, and the variability is not directly related to inulin DP.

Polyphenol content

On the first day of storage only samples with the addition of GR preparation were characterized by lowered content of total polyphenols (Table 1) relative to the control sample, however, also in this case statistically significant differences could not be found. Slightly larger reduction (ca. 10%) in polyphenol content in orange jellie was found after adding trehalose **(Kopjar et al., 2016)**. In turn, **Cano-Lamadrid et al. (2020)** found significant changes in polyphenol content depending on the composition of jelly candies based on pomegranate juice. The authors **(Cano-Lamadrid et al., 2020)** found a decrease in the content of polyphenols with an increase in the addition of gelatin and an increase with the replacement of sugar with honey.

Similarly as after preparation, following the six week storage period, no significant differentiation relative to control sample could be determined. However, in the stored samples, a clearly differentiated impact of individual preparations and concentration levels can be seen. However, a statistically significant change with increased concentration was determined only in the case of the GR preparation (p = 0.006). Similar effect of limiting the decline in polyphenol content during storage was found for orange jellie with the addition of trehalose, what according to the authors is due to the protective effect of the additives used **(Kopjar et al., 2016)**.

Antioxidant activity

An increase of antioxidant activity determined via ABTS method was found (Table 1). The preparation with the longest chain produced a minor increase, while the oligofructose preparation P95 changed the value of ABTS activity to the largest extent. However, statistically significant differences relative to control sample were determined only in the case of 3% addition of this preparation. Similar increase in antioxidant activity determined via ABTS method was found after introducing trehalose into orange jelly and depending on the addition of gelatin for jelly candies based on pomegranate juice **(Cano-Lamadrid et al., 2020; Kopjar et al., 2016)**. After the six week storage period, the samples with addition of GR and P95 preparations were characterized by significantly higher values of ABTS activity than control sample. Samples with addition of the HPX preparation did not differ statistically, although also in this case the values were higher than in control sample. Similar relationship

after storage was obtained for the addition of trehalose to orange jelly **(Kopjar et al., 2016)**. According to **Kopjar et al. (2016)** the change in antioxidant activity may be caused by the degradation of the present antioxidants or their chemical modification.

No statistically significant differentiation of activity determined via FRAP method could be found (Table 1). However, also in this case certain trends can be observed. After preparation, lower values were recorded for samples with HPX addition, in the two remaining cases the values were higher than for control sample. These values differed slightly after storage, where the lowest FRAP activity value was determined for samples with P95 addition. The difference of the behavior of the antioxidant activity depending on the method is due to the fact that each method is specific to only one antioxidant mechanism **(Cano-Lamadrid et al., 2020)**.

Sensory evaluation

Figure 1 and Table 2 presents results of sensory evaluation of the tested jellies. In the case of surface and clarity, no statistically significant difference in one-factor variance analysis could be found. However, a two-factor variance analysis indicated a significant impact of the additive type. This is further indicated by the evaluation results. Control sample was awarded the highest scores, while the lowest to the sample with HPX addition at both levels. The two remaining preparations produced jellies with a similar evaluations, yet significantly lower than control. No differentiation was observed between samples in the case of syneresis (data unpublished). The analysed samples differed significantly in terms of colour (at the level of 0.05). Similarly to surface and clarity, the highest score was awarded to control sample. Similar scores were awarded to the sample with addition of 3% GR, and only slightly lower scores were awarded to samples with 6% addition of HPX and GR preparations – in these cases the differences were statistically insignificant relative to control sample. Worse scores were obtained for the remaining cases. Two-factor variance analysis demonstrated statistically significant impact of the type of preparation used, yet no impact of the addition level. According to the results of one-factor analysis of variance results, the samples differed significantly in terms of consistency and in this case the control sample was awarded the lowest scores. The highest scores were awarded to samples with GR addition (at both levels) and 3% HPX. Slightly lower scores, yet still better than for control sample, were awarded to samples with addition of P95 and 6% HPX. However, it should be noted that according to the results of statistical analyses, no significant differentiation between samples with addition of preparations occurred and only control sample differed significantly from the remaining samples. The greatest differentiation was obtained in the case of smell. In this case, statistical analysis indicates a significant impact of both type and level of additive. The highest score was awarded to control sample and value of the score decreased with the increase of addition level, independently of preparation type. Although samples with P95 addition were awarded the lowest scores, this evaluation was very close to the scores obtained for HPX (statistically insignificant differences). No statistically significant differences were obtained for taste evaluation. However, analysis of the results shows that control sample was awarded the lowest score. The remaining samples were assessed at a very similar level, and the best scores were awarded to samples with addition of 3% inulin products (HPX and GR). The overall evaluation enables the statement that the GR granulated inulin preparation has been evaluated most favourably among the analysed products. The two remaining products obtained overall evaluations at a similar level as control sample. It should be also noted that evaluations for different concentrations were identical or remained at a very similar level. This indicates that a suitably selected recipe stemming from the balance between the amount of preparation and water enables obtaining samples with highly similar sensory traits. Moreover, overall evaluation demonstrates the possibility of utilising all tested preparations as ingredients of jellies based on apple concentrate. These results comply with the results obtained for other products. Values comparable with control in terms of taste, smell and consistency were obtained for kefir with addition of inulin **(Glibowski and Kowalska, 2012)**. On the other hand, **Gramza-Michałowska and Górecka (2009)** obtained increased scores for point evaluations of products with addition of inulin – sponge cake, cake cream, natural yoghurt and ground pork burgers. The study of **Brennan and Tudorica (2008)** analysed the impact of the level and type of dietary fibre on yoghurt properties. No significant differentiation of the overall sensory evaluation was found, although the highest overall evaluation score was awarded to samples with 6% addition of inulin and 6% skimmed milk powder.

CONCLUSION

The obtained results have enabled the statement that addition of inulin and oligofructose significantly modifies the properties of apple jellies. Colour parameter A420 (corresponding to the colour lightness) were subject to a considerable variability. Sensory analysis has demonstrated strong impact of additives only on the smell characteristics. Despite the fact that significant differences have been shown, the variability of the remaining parameters of sensory characteristics was not high. It should be underlined that the highest scores in terms of taste were obtained for the jelly supplemented with HPX preparation, and in terms of overall evaluation with the samples with the addition of GR preparation. A significant impact of additives was observed on the total polyphenols content and antioxidant activity determined via the ABTS method. However, no variability could be found for activity determined via FRAP method. The conducted analyses provide an indication that inulin may constitute an attractive alternative for the development of fruit dessert recipes, which would enable obtaining products with prebiotic properties.

OCCURRENCE OF RESISTANCE TO ANTIBIOTICS THERAPY IN COAGULASE-POSITIVE AND COAGULASE-NEGATIVE STAPHYLOCOCCI ISOLATED FROM SHEEP´S MILK IN HOLDING IN SLOVAKIA

Milan Vasiľ, Zuzana Farkašová, Juraj Elečko, František Zigo

ABSTRACT

The occurrence of bacteria *Staphylococcus* spp. was examined in a total of 3466 individuals and in 12 pool milk samples from 2017 to 2019. The experiment was carried out in two herds of the breed of sheep, Improved Valaska, in the Slovakia region. Eleven species of the genus *Staphylococcus* spp. (n = 431) were isolated and taxonomically identified. From the coagulase-positive staphylococci (CPS), *S. aureus* was isolated during the reporting period, however, most often in the third year (50). The incidence of *S. intermedius* and *S. hyicus* were irregular. The incidence of *S. schleiferi* was highest at the end of the follow-up duration. From the coagulase-negative staphylococci (CNS) (n = 158), were isolated *S. epidermidis* present in 20.4% (88) and *S. chromogenes* 11.4 % (49), *S. caprae, S. xylosus,* and other species rarely occurred. *S. aureus* (n = 133) showed maximum resistance to erythromycin 12.0%, novobiocin 10.5%, and neomycin 9.0%. The incidence of intermedial susceptibility was observed predominantly to a penicillin (16 strains), novobiocin (11 strains), erythromycin (14 strains), oxacillin, and cloxacillin (12 strains), neomycin (11 strains), and lincomycin (9 strains). Observantly, *S. schleiferi* (n = 101) showed the highest resistance to novobiocin (5.9%) and erythromycin (5.0%), however, a high incidence of intermediate susceptibility to erythromycin (9), amoxicillin, novobiocin (8), ampicillin, lincomycin (7), penicillin, methicilin and cefoperazone (5 strains) can be identified as adverse. The incidence of resistant and intermediate sensitive test strains *S. aureus* and *S. schleiferi*, especially for erythromycin, novobiocin, and neomycin, which are often used to treat udder inflammation in sheep, is relatively adverse.

Keywords: Sheep milk; coagulase-positive staphylococci; coagulase-negative staphylococci; antibiotics resistance; mastitis

INTRODUCTION

Mastitis is one of the most common diseases that affects dairy sheep. Mastitis leads to major economic loss, mainly due to discarded milk, reduced milk production, and quality, alteration of cheese-making properties, early culling, and increased health care costs **(Legarra et al., 2007)**.

Over 100 different microorganisms cause mastitis, particularly, coliform bacteria, staphylococci, and streptococci **(Smith and Hogan, 2001)**. In dairy sheep, the most important agents involved in clinical mastitis are bacterial infections, while the most frequently isolated pathogens are coagulase-negative staphylococci (CNS) present on and around the udder skin **(Leitner, Silanikove and Merin, 2008)**, with different pathogenicity causing clinical and subclinical mastitis **(Riggio and Portolano, 2015)**. Mastitis is of both extreme zoonotic and economic importance. It is the cause of multiple hazardous effects on human health and animal production.

Recently, it was recognized that the antimicrobial susceptibility of coagulase-negative staphylococci, which represents the majority of organisms isolated from ovine milk, is important for the early recognition of newly emerging resistant milk-borne bacterial agents **(Onni et al., 2011)**. Furthermore, with reference to specific conditions of ruminants, many authors in their works referred to these as the most frequently isolated: *S. epidermidis, S. chromogenes, S. simulans, S. xylosus, S. haemolyticus, S. warneri,* and *S. sciuri* **(Fthenakis, 1994; Ergün et al., 2009)**.

Although, CNS does not have a comparable range for the virulence factors, such as *S. aureus*, one of the important factors of virulence is the ability to create resistance to an antibiotic, while some were described as multiresistant **(Moniri, Dastegholi, and Akramian, 2007)**. Multidrug resistance is defined as the resistance of three or more classes of antimicrobial agents **(Schwarz et al., 2010)**. The use of antibiotics is the most common treatment for these cases **(Gomes and Henriques, 2015)**, and β-lactams are the most frequently used classes for the treatment of mastitis. Additionally, mastitis therapy is usually started before the results of the antimicrobial susceptibility test of

pathogens **(Hendriksen et al., 2008)**, thus, representing one of the most important reasons for treatment failure. Moreover, this antibacterial strategy has many disadvantages including a low cure rate, increasing the presence of antibiotics residues, and the occurrence of antimicrobial resistance **(Minst et al., 2012)**. Mastitis resistance is a complex and multifactorial trait, and its expression depends on both genetic and environmental factors, including infection pressure **(Tolone et al., 2016)**. In the broadest sense, resistance can be defined as the ability to avoid any infection and/or the quick recovery from an infection **(Rupp and Boichard 2003; Rupp and Foucras, 2010)**. This involves different factors such as preventing the entry of the pathogen into the mammary gland, inducing an immune response capable of limiting pathogen development in the udder and recovery from the infection, as well as controlling the pathogenic effects of the infection, such as tissue damage **(Rupp et al., 2009)**. Resistance to antibiotics may be acquired by spontaneously occurring genetic mutations and, more commonly, by the horizontal transfer of mobile DNA elements from a donor cell to another bacterial species **(Chambers, 2001)**.

Over the years, extensive use of antimicrobials has led to increasingly resistant bacteria at an alarming rate and has become a serious concern worldwide. To ensure suitable antibiotic therapy, bacterial isolation, and evaluation of antibiotic susceptibility are essential. Also, milk produced from animals with subclinical mastitis poses serious veterinary and epidemiology risk since its rich nutrient composition and neutral pH make it a good vehicle for the survival and growth of bacteria. Resistant bacteria may contaminate food products, which could be transmitted to humans through the food chain. This underlines the importance of pathogen surveillance. Consequently, monitoring pathogens and their antimicrobial resistance patterns have become today's necessity **(Ceniti et al., 2017)**.

Scientific hypothesis

This work aimed to determine the occurrence and the most common types of staphylococci. Individual pools and sheep's milk samples were investigated, and a comparison of the incidences of antibiotic resistance of the most numerous tested species *S. aureus* and *S. schleiferi* was conducted.

MATERIALS AND METHODS

Characteristics of experimental breeds of sheep

One of the breeds of sheep with 350 Improved Valaska sheep and another farm with 280 sheep with a program of gradual crossing with the "Lacaune" breed were used for the experiment. Tracking the etiology in mastitis in the findings of the pool samples was carried out during the three seasons of the machine milking in the holdings, compliant with the technological standards of Slovakia. During the three seasons between April and September, a total of 12 complex examinations were repeatedly performed. A significant measure in the course of the experiment was to treat all cases of clinical mastitis solely based on proven susceptibility to a range of selected antibiotics.

Testing and sampling of the herds' sheep's milk

Clinical examination of the udder supplemented by a Californian Mastitis Test individual sheep's milk was conducted at the beginning and the end of each season, alongside a bacteriological examination of samples according to the principles posited by these authors **(Fthenakis, 1994; Vasil, 2004; Mørk et al., 2007)**. Emphasis was placed on aseptic sampling and transport of the mixed pools samples and the individual sheep's milk samples intended for bacteriological examination.

Bacteriological examination

The inoculum of each sample of milk was inoculated on the plates with 5% blood agar, incubated at 37 °C, and after 24 hours of reading. When the growth was more than 7 colonies from one type of colony, it was inoculated and cultured on selective nutrient soils. Identification of *Staphylococcus* spp. bacterial cultures were carried out by assessing the growth of suspected bacteria on nutrient agars (5% of blood Agar, N° 110, Baird-Parker agar, Brilliance UTI Clarity Agar (Oxoid Ltd., Basingstoke, Hants, UK). The pigment formation, hemolysis, catalase positivity, Gram positivity, creation of free or coupled coagulase, and other characters, were determined. The identification of each species was made by STAPHYtest 24 and evaluated by TNW ProAuto 7.0 (Erba-Lachema, Brno, Czech Republic) with a probability of correct designations of the kind above 90%. The functionality of the set was controlled using a strain of *Staphylococcus aureus* CCM 7113 (CCM, Masaryk University, Brno, Czech Republic).

Testing of the sensitivity of antibiotics on the most numerous species of Staphylococcus

Bacteria isolated from various forms of mastitis (n = 432) and pools milk samples (n = 12), were tested *in vitro* by disc method **(EUCAST, 2014)**, by evaluation of the zones of inhibition to grow on Mueller-Hinton agar after 24 h incubation at 37 °C. To test the sensitivity of staphylococci to fourteen antibiotics; ampicillin 10 μg (28 – 29 mm), amoxicillin 25 μg (28 – 29 mm), cefoperazone 30 μg (14 – 18 mm), cefoxitin 30 μg (23 – 29 mm), cloxacilin 5 μg (10 – 13 mm), erythromycin 10 μg (13 – 23 mm), lincomycin 15 μg (9 – 15 mm), neomycin 10 μg (12 – 17 mm), methicillin 10 μg (9 – 14 mm), novobiocin 5 μg (10 – 13 mm), oxacillin 5 μg (10 – 13 mm), penicillin 10U (28 – 29 mm), streptomycin 10 μg (11 – 15 mm), and tetracycline 10 μg (14 – 19 mm) test discs were used (Oxoid Ltd., Basingstoke, Hants, UK). The choice of antibiotics reflects the range contained in several intramammary products available for treating mastitis in Slovakia. The sensitivity or resistance of the bacteria tested was interpreted according to the reference zones in conformity with the instructions of **EUCAST (2014)**. The tribes *S. aureus* CCM 5973 and *S. epidermidis* 4418 were used as a control in the tests. In view of the abundance of the species of the CPS and CNS, it was only possible for the species *S. aureus* and *S. epidermidis* in practical terms, to evaluate resistance as a percentage: a negligible (<0.1%), very low (0.1 – 1%), low (1 – 10%), moderate (10 – 20%), high (20 – 50%) or very high (50 – 70%).

Statistical analyses

Statistical analysis was performed using the Microsoft Excel 2007 software. Chi-square test (χ^2 test) was used to compare the individual proportions **(Kabrt, 2013)**.

The dependence of the individual signs was tested at a significance level $\alpha = 0.05$, with critical value = 5.991.

RESULTS AND DISCUSSION

Table 1 gives an overview of the bacteria *Staphylococcus* spp., which was isolated from sheep's milk, during the three years (2017 – 2019) on holdings in Slovakia. In the reporting period, 273 coagulase-positive staphylococci were isolated of which 48.7% (133) *S. aureus* was isolated in 8.1% (23) *S. intermedius*, 5.9 % (16) *S. hyicus,* and 37.0% (101) *S. schleiferi.*

S. aureus was isolated during the reporting period, although most frequently at the beginning of the reference period (50). *S. intermedius* was isolated in the two last years, most frequently in the second year (12), S. *hyicus* was isolated in the first (12) and second (4) years of the experiment. *S. schleiferi* was isolated during the reporting period, most frequently at the end of the experiment (48).

In the reporting period, 158 coagulase-negative staphylococci were isolated, of which *S. epidermidis* was isolated in 55.7% (88), *S. chromogenes* 31.0% (49), *S. caprae* 3.8% (6), *S. xylosus* 4.4% (7), other species were rarely isolated.

Table 2 shows the reported overview of the occurrence of resistance to 14 antibiotics in four tested species of staphylococci (n = 371), which were most frequently isolated during the experiment.

Although intramammary infections caused by CoNS are usually self-limiting, there are reports of clinical mastitis cases that often require antimicrobial treatment **(Taponen, 2006; Pieterse and Todorov, 2010)**.

Occurrence to resistance to 14 antibiotics in *S. aureus* and *S. schleiferi*, which were isolated from sheep´s milk during the three-year period is reported in Table 3. In the evaluation, the tests of sensitivity of the two most numerous CPS (*S. aureus, S. schleiferi)* were numerically expressed as numbers of (S) – sensitive, (IM) – intermediate, and (R) – resistant as well as the values of the resistance in percentage (%).

Staphylococcus aureus (Table 2 and Table 3) showed the highest resistance to erythromycin 12.0%, novobiocin 10.5%, and neomycin 9.0%. We may consider that there is an adverse incidence of intermediate susceptibility of penicillin (16), novobiocin, and erythromycin (14 strains), to oxacillin and cloxacillin (12 strains), neomycin (11 strains), and lincomycin (9 strains). For other antibiotics, the incidence of resistant strains of *S. aureus* was relatively low.

From all 101 tested strains of *Staphylococcus schleiferi,* it was discovered that 5.9% resistant was to novobiocin, and 5.0% to erythromycin. Intermediate sensitivity was detected to erythromycin (9), amoxicillin and novobiocin (8), ampicillin, and lincomycin (7), and penicillin, methicilin, and cefoperazone (5 strains). Penicillin antimicrobials were reported to be effective against CoNS infections **(Becker, Heilmann and Peters, 2014; Bhattacharyya et al., 2016)**. However, studies declare an increasing prevalence of antimicrobial resistance in CoNS from clinical mastitis cases **(Schmidt, Kock, and Ehlers, 2015; Beuron et al., 2014)**, including resistance to penicillin, tetracycline, lincomycin, and streptomycin **(Taponen et al., 2006)**.

Recent evidence from Europe indicates insignificant problems of resistance to antibiotics commonly used for cases of mastitis in sheep. **Vautor et al**. **(2009)** reported only sporadic resistance in *S. aureus* isolated in France. **Onni et al**. **(2011)**, in Italy, likewise found limited resistance in *S. epidermidis*, except to penicillin for which the resistance rate was 38%. Similar results were observed in Turkey, where in coagulase-negative isolates from subclinical mastitis only resistance to β-lactams was noteworthy (43%), whilst there was a much smaller frequency of resistance to tetracycline (11%) and even less to other agents **(Ergün et al., 2012)**. Moreover, research in Turkey corroborated these findings, the rate of resistance to penicillin was 27% and to tetracycline 8% **(Unal and Çinar, 2012)**. **Martins et al. (2017)** published similar results; 17% of isolates were resistant to penicillin and 11% to tetracycline. Finally, evidence from Greece was consistent with the abovementioned, as the frequency of resistant isolates was 35% of staphylococcal isolates tested **(Vasileiou et al., 2019)**.

The incidence of the following characters (S, IS, R) was compared in two groups, the most numerous of staphylococci *S. aureus* and *S. schleiferi* using a statistical method, the Chi-squared test. On the significance level $\alpha = 0.05$ (5%) was recorded in fourteen antibiotic substances test value ($G < \chi 2$), the statistical independence of tracked characters was confirmed. The antibiotic substance methicillin, penicillin, and oxacillin when applied, $G > \chi 2$, in the test groups of *S. aureus* and *S. schleiferi,* statistical dependence of the observed characters was confirmed, which means that the occurrence of the characters was not random.

Table 1 Bacteria *Staphylococcus* spp. isolated from sheep milk from two herds of sheep during the three-year period in Slovakia.

Bacteria *Staphylococcus* spp.	**2017**	**2018**	**2019**	**Total**	**%**

CONCLUSION

By the bacteriological examination of individual and pool samples of sheep's milk during the three seasons of machine milking was isolated and taxonomically classified 11 species from the total number of 431 bacteria *Staphylococcus* spp. From the coagulation of positive staphylococci (KPS) (n = 273), *S. aureus* was isolated throughout the period considered, but most often in the last year (50). The incidence of *S. intermedius* was highest in the second year (12). *S. hyicus* was isolated in the first and second years of experiment (16) and *S. schleiferi* was most experienced in the last year (48). From the group of coagulase-negative staphylococci (KNS) (n = 158), *S. epidermidis* occurred in 55.7% (88), *S. chromogenes* 31.0% (49), *S. caprae* 3.8% (6), *S. xylosus* 4.4% (7), and other species rarely occurred. *S. aureus* bacteria (n = 133) showed maximum resistance to erythromycin 12.0% and novobiocin 10.5%, and to neomycin 9.0% as well. The incidence of intermediate sensitivity was observed in penicillin (16 strains) of novobiocin, erythromycin (14 strains), oxacillin and cloxacillin (12 strains), neomycin (11 strains), and lincomycin (9 strains). *Staphylococcus schleiferi* bacteria (n = 101) showed the highest resistance to novobiocin (5.9%) and erythromycin (5.0%), however, a high incidence of intermediate susceptibility to erythromycin (9), amoxicillin and novobiocin (8), ampicillin and lincomycin (7), penicillin, methicilin and cefoperazone (5 strains) can be identified as adverse. This work was aimed at testing the most frequent representatives of the genus *Staphylococcus* spp., a relatively adverse development of resistance to the most commonly used antibiotics for the treatment of inflammation of the udder in sheep.

MILK THISTLE FLOUR EFFECT ON DOUGH RHEOLOGICAL PROPERTIES

Tatiana Bojňanská, Alena Vollmannová, Janette Musilová

ABSTRACT
The influence of the addition of partially defatted milk thistle seed flour was studied by analyzing the rheological properties of dough in order to further exploit the functionality of partially defatted milk thistle flour in bakery products. The rheological properties of dough were monitored using Mixolab 2 (Chopin Technologies, France). A rheofermentometer F4 (Chopin Technologies, France) was used to check the dough fermentation, and for the baking trials wheat flour, rye flour, and milk thistle flour were kept in the portion: 50:50:0 (control flour); 50:45:5; 50:40:10 and 50:35:15. The addition of different milk thistle flour in the mixtures resulted in a difference in the viscoelastic properties of the dough. The results showed a weakening of the gluten network in all trial mixtures evaluated. The dough development time values of the control flour were 1.20 min, while an addition of milk thistle flour in portions of 5, 10, and 15% increased these values to 1.30 min, 1.90 min, and 2,80 min, respectively. In addition to higher dough development time values, all trial mixtures exhibited also higher stability (5.07 min; 6.25 min and 8.03 min), when compared to the control flour (4.63 min). The trial mixture with 15% milk thistle flour had different characteristics of gelatinization and retrogradation. The rheofermentometer measured the dough characteristics during proofing, and the trial mixtures with the addition of MTF had a retention volume at approximately the same level as the control flour (WRF). The Volscan profiler was used to determine the bread volume and other parameters. All breads had high volume and specific volume values and can be rated as good, with good porosity and ratio. Mixtures containing 5%, 10% and 15% milk thistle flour added to wheat flour + rye flour maintained rheological parameters within the recommended limits for good technological behavior and, consequently, good quality of bakery products. From all of the above data, it can be stated that, with regard to their baking characteristics, these flour mixtures fall into the category of flours suitable for bakery products.

Keywords: wheat-rye-milk thistle composite; Chopin+ protocol; rheofermentometer; bread quality

INTRODUCTION
Food not only supplies human beings with nutritive components that are indispensable for maintaining a healthy daily life, it also contains many types of biofunctional components that help to maintain good physical and mental health. In the last three decades, a growing interest has occurred in the use of active compounds from natural sources that can contribute to promoting consumer's health and preventing diseases. One opportunity is milk thistle (*Silybum marianum* L. Gaertn); an annual or biennial plant belonging to the family *Asteraceae* and usually growing in dry, sunny areas. The plant native to the Mediterranean area has now spread to other warm and dry regions. It is a plant that has been used in folk medicine for over 2,000 years as a remedy for a variety of medical conditions, especially the liver, kidney, and gallbladder ailments **(Anthony et al., 2013; Eskandari Nasrabadi et al., 2014; Wang et al., 2014; El-haak, Atta and Abd Rabo, 2015; Saad-Allah, Fetouh and Elhaak, 2017; Abenavoli et al., 2018)**.

In Europe, it is cultivated widely for the production of raw materials used in the pharmaceutical industry, especially in Austria, Germany, Hungary, and Poland. Over-the-counter nutritional or dietary supplements are becoming extremely popular in the United States, Europe, and many other countries for liver enhancement and recovery **(Anthony et al., 2013; Jedlinszki et al., 2016; Salomone, Godos and Zelber-Sagi, 2016; Choe et al., 2019; Çeribasi et al., 2020)**.

Milk thistle is a rich source of ingredients, such as amino acids, fatty acids, minerals, and phytochemicals exhibiting nutraceutical effects on human health. The whole plant is used for medicinal purposes. Its seeds (there is confusion about whether milk thistle has fruits or seeds – botanically correct, this plant has a cypselae, which looks like a seed but is technically a fruit.) are rich in proteins, lipids, and total carbohydrates, with concentrations from 19.1 to 30.0%, 20.0 to 30.0%, and 24.2 to 26.3%, respectively. Furthermore, the seed proteins have markedly high amounts of essential amino acids such as lysine, isoleucine, leucine, valine, and threonine, however, they are a poor source of prolin and histidin **(El-haak, Atta and Abd Rabo, 2015; Apostol et al., 2017; Saad-Allah, Fetouh and Elhaak, 2017)**.

In milk thistle seeds linoleic and oleic acids are the predominant fatty acids in its oil **(Tuğba- Çelik and Gürü, 2015)** (Table 1). Milk thistle oil has significant scavenging effects on the DPPH radical. This antioxidant activity reflects the bioactive molecules composition in oil extracted from milk thistle (1.1 ±0.6% of polyphenols on dried material, 13.4 $mg.100g^{-1}$ beta-carotene of carotenoids and 70 – 85% of unsaturated fatty acids) **(Li et al., 2012; Anthony et al., 2013; Rahal et al., 2015; Abenavoli et al., 2018)**.

Silymarin represents 1.5 – 6% of the fruit's dry weight and is an isomeric mixture of unique flavonoid complexes – flavonolignans **(Eskandari Nasrabadi et al., 2014; Bijak, 2017)**. The main representatives of this group presented in silymarin are silybin, isosilybin, silychristin, isosilychristin, silydianin, and silimonin. The chemical composition of milk thistle fruit besides flavonolignans also includes other flavonoids, such as taxifolin, quercetin, dihydrokaempferol, kaempferol, apigenin, naringin, eriodyctiol, and chrysoeriol **(Kvasnička et al., 2003; Bijak, 2017)**. The whole plant is used for medicinal purposes, but the highest content of silymarin is in the seeds. Silybin, a secondary metabolite isolated from the seeds of milk thistle was discovered as the first member of a new family of natural compounds called flavonolignans in 1959 **(Biedermann et al., 2014)**. Since the 1970s, silybin has been regarded in official medicine as a substance with hepatoprotective properties. There is a large body of research that demonstrates silybin's many other healthy properties, but there is still a lack of papers focusing on its molecular structure, chemistry, metabolism, and novel form of administration **(Bijak, 2017)**.

Currently, the most important medicinal application of milk thistle is its use as a hepatoprotective, antioxidant, antiradical, and free radical scavenging food supplement. Silymarin is a natural antioxidant and this action is believed to contribute to the hepatoprotective effects of milk thistle preparations. Cold-pressed milk thistle seed flour was evaluated for its phytochemical composition, and gut microbiota modulating, free radical scavenging, anti-inflammatory, and anti-proliferative capacities **(Surai, 2015)**. The results suggest milk thistle seed flour's potential health benefits in functional foods **(Choe et al., 2019; Menasra and Fahloul, 2019)**, despite its properties observed in experimental studies, the current efficacy of milk thistle preparations in patients with liver diseases is not fully compelling **(Salomone, Godos and Zelber-Sagi, 2016; Abenavoli et al., 2018)**.

Cytotoxic activities of silychristin, silydianin, and silybinin were evaluated against Caco-2 cells (colon cancer cell line) **(Rahal et al., 2015)**, but the anticancer activity of silymarin, as well as silibinin, was demonstrated against various cancer cells such as breast, skin, cervix, ovary, prostate, lung and hepatocellular cancers **(Bosch-Barrera and Menendez, 2015)**.

Most of the existing researches on the milk thistle plant dealt only with pharmacological and medicinal studies due to the production of silymarin and its use for healing some hepatic diseases. However, the defatted milk thistle seed flour which is a by-product, and is typically eliminated as waste, may contain beneficial components such as proteins, carbohydrates (especially crude fibres), minerals, and some phytochemicals and be utilized as a suitable food ingredient in low fibre food **(Li et al. 2012; El-haak, Atta and Abd Rabo, 2015)**. Milk thistle leaves and flowers have been used as a vegetable for salads and a substitute for spinach. On the other hand, milk thistle seeds are roasted for use as a coffee substitute.

The fundamental food in many parts of the world is bread. Wheat flour dough is a viscoelastic system that exhibits an intermediate rheological behavior between a viscous liquid and elastic solid. The viscoelastic protein network plays a predominant role in dough processing as well as in textural characteristics of the finished bread. The gluten network in wheat is constructed from gliadins and glutenins, which are responsible for the dough resistance to extension, thus providing the dough with its unique viscoelastic properties and its ability to retain gases produced during the yeast fermentation process. Therefore, gluten is a fundamental component, which is responsible for the overall quality and structure of bread **(Fendri et al., 2016)**.

The information necessary for the evaluation of the flour quality is obtained on the basis of some indices determined through the chemical, rheological and technological analyses. Rheological characteristics, such as elasticity, viscosity, and extensibility, are important for the milling and bakery industry, used for a prediction of the dough processing parameters and the end product quality **(Jirsa, Hrušková and Švec, 2007; Ziobro et al., 2013; Švec and Hrušková, 2015)**.

Composite flours on the basis of wheat and other cereals and non-grain seeds became popular in the baking technology. The purpose of this research was to identify the percentage of bread flour as well as to find a mixture of flours, the composition of which combines the nutritional value with adequate processing properties in an optimal way. The objective of this work was to characterize mixtures of wheat flour + rye flour, with a replacement of 5, 10, and 15% of milk thistle seed flour, with regard to the technological characteristics of dough (rheological properties) and objective properties of the final product.

Scientific hypothesis

We expect some effect of milk thistle seed flour in addition to baker's flour (wheat flour and rye flour) on the rheological properties of the dough, its ability to retain fermentation gases, and the objective properties of the final product.

MATERIAL AND METHODOLOGY

In this study, commercial blend flours (Miroslav Grznár MLYN ZRNO, Slovak Republic), were used: defatted milk thistle seed flour (8.4% fat) in mixtures with wheat flour (ash 0.65%) and rye flour (ash 0.96%). Three types of mixtures of wheat flour + rye flour and different proportions of partially defatted milk thistle seed flour were obtained, and a control flour without milk thistle flour in the following ratios: 50:45:5, 50:40:10, 50:35:15, and 50:50:0, respectively. Further materials for dough and bread formulation were: salt (K.S. Czech Republic, a. s.), sucrose (Slovenské cukrovary s. r. o.), and dry yeast of the species *Saccharomyces cerevisiae* (Ruf, sušené droždie).

Rheological properties of dough were monitored using Mixolab 2 (Chopin Technologies, France) applying the "Chopin+" protocol. The international standard ICC-Standard Method No. 173, a protocol for complete characterization of flours, was used, and a simplified graphic interpretation of the results was performed. In „Chopin+" protocol Mixolab recorded changes of torque in five defined points as follows: C1 – water absorption; C2 – weakening of the protein-based on mechanical stress at increasing temperature; C3 – the rate of starch gelatinization; C4 – stability of the formed gel; C5 – starch retrogradation during the cooling period.

A Rheofermentometer F4 (Chopin Technologies, France) was used to check the dough fermentation, to measure the dough parameters: the maximum dough height (Hm, mm), the maximum height of the gas release curve (Hm′, mm), the time required to obtain H´m (Tx, hours), total volume (total volume of gas produced in mL), the volume of CO_2 lost (carbon dioxide volume in mL that the dough has lost during proofing), retention volume (carbon dioxide volume in mL still retained in the dough at the end of the test). The dough (315 g) was placed in a movable basket of the gas meter with a 2000 g cylindrical weight, and the cover of the vat was fitted with an optical sensor. The test was conducted at 28.5 °C for 3 h (according to the conditions of the Chopin protocol reported in the rheofermentometer instruction manual). The method conforms to the AACC 89-01 **(AACC, 2000)** standard for the measurement of yeast activity and gas production.

Bread making procedure: for baking trials wheat flour, rye flour, and milk thistle flour (MTF) were kept in the portion: 50:50:0 (control flour WRF); 50:45:5; 50:40:10 and 50:35:15. Other recipe compounds were: water (the level of water used in baking experiments, to obtain the dough suitable for bread baking – the water addition to individual dough mixes ranged between 61 to 64%, 2.0% NaCl, and 1.4% dry yeast. The percentages are based on 100% of the flour mixture. All ingredients were kneaded 3 minutes at lower speed and 4 minutes at higher speed in a spiral kneader type SP 12 D (Diosna Dierks & Söhne GmbH, Osnabrück, Germany). After 40 min fermentation (35 °C) samples were baked for 40 min in mode: 180 °C 7 minutes, 200 °C 20 minutes, and 160 °C 13 minutes, with stream (250 mL) (MIWE Condo). The bread loaves were cooled at room temperature and analyzed by a Volscan Profiler volume analyzer (Stable Mycrosystems, Surrey, UK) one hour after baking (weight of the bread (g), bread volume (mL), specific volume ($mL.g^{-1}$), volume-yield ($mL.100g^{-1}$ flour), the aspect ratio of a middle slice ect.).

Statistical analysis

The results of the technological measurement were statistically analyzed using XLSTAT for Excel (version 2015). The data were subjected to the Z. test at significance level 0.05 to determine differences between samples.

RESULTS AND DISCUSSION

The effect of adding milk thistle flour on the dough properties and bread parameters was investigated.

Bread is widely consumed as a staple food across many cultures and countries worldwide. There are three major stages of bread making: mixing, fermentation (i.e. proofing), and thermal setting (i.e. baking/steaming). The mechanical energy imparted during mixing induces the formation of a viscoelastic dough matrix. Besides the proper development of the gluten network, the initial gas inclusion during mixing and the yeast activity during proofing also greatly affect the bread quality **(Gao et al., 2017)**. Gluten is a major protein component of the same cereals which is responsible for flour processing characteristics in the bakery industry. The reduction of gluten often results in baked bread with a crumbling texture, poor color, and other post-baking quality defects **(Schmiele et al., 2017)**.

In the trial breads prepared with milk thistle, the proportion of gluten gradually decreased with an increasing amount of the addition, which affected the rheological behavior of the dough. The preliminary rheological analysis indicates the influence of applied MTF on the dough properties.

Monitoring the rheological properties of dough is very important for the overall technology to estimate the mechanical properties of dough and to imitate its behavior during its processing or even to anticipate the quality of the final product **(Dapčević-Hadnađev et al., 2014; Torbica, Belović, and Tomić, 2019)**.

The Mixolab measures in real time the torque (expressed in Nm) produced by the passage of the dough between the two kneading arms, thus allowing the study of rheological and enzymatic parameters: dough rheological characteristics (development time, hydration capacity, etc.), protein reduction, enzymatic activity, gelatinization and gelling of starch. Figure 1 exhibits the Mixolab curve (Chopin+ protocol) and parameters of the analyzed sample (WRF 50:50 = control flour). The results confirm that the control flour has a short dough development time (1.2 min) and only average stability (4.63 min), which is due to its composition, especially the high proportion of rye flour which cannot form gluten. During the heating and cooling stages, the control flour showed a high viscosity of starch gelatinization and retrogradation.

The addition of different MTF (5%, 10%, 15%) in the mixtures resulted in a difference in the viscoelastic properties of dough (Figure 2). The results showed a weakening of the gluten network in all trial mixtures evaluated.

Water absorption, amplitude, dough development time, stability, and C1 Mixolab parameters are used to evaluate the gluten network formation, dough development during mixing, and stability at constant mechanical shear. The first stage of the Mixolab curve is related to the farinograph analysis, which allows evaluating the viscoelastic properties of dough including hydration and mixing tolerance index. In Mixolab, the first stage temperature is kept at 30 °C. The mixing process after the first stage may give extra energy to the dough system; therefore, these results should be used with caution because they do not represent the breadmaking process, since the dough can no longer pass through the mixing process after the formation of the gluten network, without weakening the structure during the mixing of the dough **(Schmiele et al., 2017)**.

Table 1 Fatty acid composition milk thistle oil, %.

Note: Means followed by different letters are significantly different (*p* <0.05).

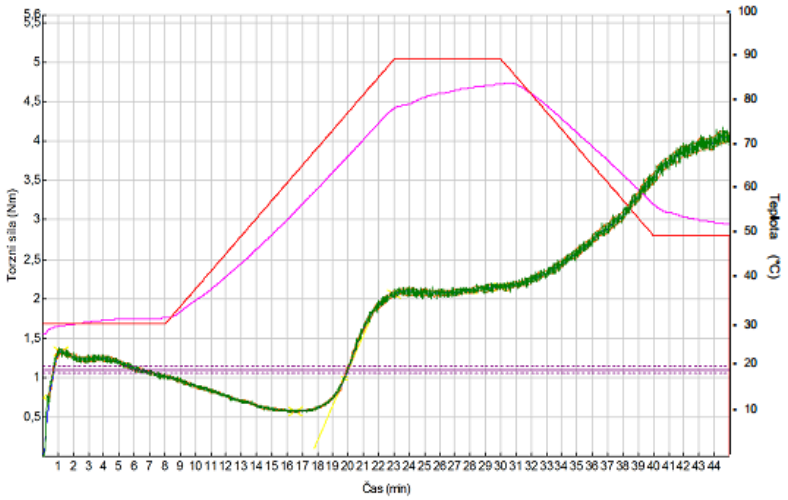

Figure 1 Mixolab curve Chopin+ protocol, control flour (WRF 50:50).

The rheological properties are provided in Figure 3. The dough development time values of the control flour were 1.20 min, while addition milk thistle flour increased these values to 1.30 min, 1.90 min, and 2.80 min, respectively. In addition to higher dough development time values, all trial mixtures exhibited also higher stability (5.07min; 6.25 min and 8.03 min) when compared to the control flour (4.63 min). In general, the increase of the dough development time indicates that higher fibre content slows down the rate of hydration and the development of gluten **(Kohajdova et al., 2011)**. At large, the stability of the dough is attributed to protein poor in sulfhydryl groups, which normally causes dough softening or even degradation. The gluten network is stronger and has higher resistance to shear stress at higher protein content **(Kaur et al., 2016)**. Although milk thistle flour contains a high level of protein, a higher level of fibre may weaken the gluten network **(Shahat Mohamed, Hassein Ahmed and Hady Essam, 2016)**.

The dough development time parameter and stability are very important for bread making because the development of the gluten network should be optimized to ensure loaves with a high volume and soft texture **(Rosell, Collar, and Haros, 2007)**. The enhancing ability of MTF is surprising as this raw material does not bring into the system gluten-forming proteins. Nevertheless, for flours with high rye content, the MTF had, besides its nutritional benefits, also a technological benefit related to a higher mixing tolerance (Figure 2). Similar results were found by other authors **(Apostol et al., 2017; Bortlíková, Kolarič, and Šimko, 2019)**.

The parameters slope-α, C2, and C2-C1 were recorded when the heating reached 52 – 57 °C at the beginning of the second stage. In this phase, starch started to gelatinize, and the proteins changed their quaternary, tertiary, and secondary structures due to protein denaturation. Also, swelling of the starch granules was observed, mainly for the damaged granules, and the changes along the mixing process modified the dough consistency **(Schmiele et al., 2017)**. C2 values, representing the weakening of the protein network, decreased from 1.332 Nm to 0.571 Nm (control flour), or from 1.572 Nm to 0.774 Nm (50:35:15), and then remained at an almost constant value indicating a certain compatibility level of gluten and milk thistle flour proteins during the dough formation.

In the third stage, where the evaluated parameters were slope-β, C3, and C3-C2, the heating step began until reaching 70 °C while the dough remained under constant mixing, stopping protein denaturation and starch gelatinization. Higher C3 values were observed for all trial mixtures when compared to the control flour, but the difference for consecutive samples is rather small.

The fourth stage assessed the parameters slope-γ, C4, and C4-C3, and evaluated the enzymatic activity and heat stability of the starch gel, at temperatures above 80 °C. In this sense, a dependence of the determined values on the dough formulation was sought. A decrease in C4 was observed in the trial mixture 50:35:15 (15% milk thistle flour), and the torque value was significantly lower compared to all other samples during the last stage too.

In the last stage the dough was cooled to 58 – 60 °C, and the parameters C5 and C5-C4 were assessed. The retrogradation stage of starch (C5) for the tested WRF and MTF mixtures demonstrated similar differences as for the starch gel stability. Significant differences in C5 can be seen between the trial mixture 50:35:15 and all other samples.

The trial mixture 50:40:10 (10% MTF) presented the highest C5 values, exhibited the highest retrogradation in the cooling phase, due to the higher degree of starch gelatinization in the heating phase. The differences between this trial mixture, the mixture 50:40:5, and the control flour 50:50:0 were small. This is also documented in Figure 4, because no changes in slope-α and slope γ was observed for the trial mixture 5%, 10%, and 10% MTF, and the control flour. The results from slope-β confirmed that the trial mixture 50:35:15 (15% MTF) has different gelatinization characteristics at a temperature above 52 – 57 °C.

The rheofermentometer analysis of flour and dough enables accurate simulation of the processing conditions during the production of baked goods containing yeast **(Dapčevič-Hadnađev et al., 2011)**. The rheofermentometer measures the characteristics of dough during proofing (the dough development, the production of gas due to yeast action, the porosity of the dough, the tolerance of the dough during proofing), and the analysis determines the total gas production of yeast and dough volume at standard barometric pressure over time. The instrument records two curves during the dough fermentation and rising, one describing the development of the dough and another depicting the production and retention of gas.

Dough development is a function of both yeast gassing power and gluten network integrity. The rheofermentometer analysis allows simultaneous observation of both yeast fermentation and dough growth, which provides direct evidence on the correlation between the two factors. The dough development curves of the control sample (WRF) and trial mixture sample with the addition of MTF 15 % are shown in Figure 5 and Figure 6, respectively. It is evident that the trial mixture dough sample with the addition of milk thistle 15% rose to a greater height (83.5 mm) than the control dough (60.5 mm).

The rising of the control dough can be characterized as insufficient and slow, which is associated with a high proportion of rye in the flour. The results recorded throughout the tests are shown in Table 2, and it can be concluded that the addition of MTF to bread flour (wheat flour and rye flour) influenced all evaluated parameters.

Rheofermentometer curve trial mixtures with MTF 15% showed that the dough after the fermentation completely retained 67.8% of the total CO_2 produced. In comparison, the rheofermentometer curve WRF retained 79.5% of the total CO_2 produced. The maximum dough volume MTF 15% of 1927 mL was reached after 1 hour, 10 minutes, and 30 seconds, in comparison with WRF (1569 mL after 1 hour and 15 minutes).

Figure 7 Bread volume and bread aspect ratio by Volscan profiler.
Note: a – control bread; b – bread with 5% MTF; 7c – bread with 10% MTF; d – bread with 15% MTF.

In general, the trials with the addition of MTF began to release CO_2 too early, probably related to the reduction of gluten, but the total gas produced in these samples was higher than in the control flour (Table 2). During rheofermentometer measurements, the trial mixtures with the addition of MTF have lost significantly higher amounts of CO_2 in comparison with the control flour, which is documented by the retention coefficient lower by 13.1%, 14.3%, and 14.7%, respectively. However, it is important to note that the retention volume at the end of the measurement was at approximately the same level as the control flour (WRF) in all evaluated mixtures, with an MTF addition of 15% even higher than the control flour.

Monitoring the rheological properties of dough is very important for the overall technology to estimate the mechanical properties of dough and to imitate its behavior during its processing or even to anticipate the quality of the final product **(Dapčevič-Hadnađev et al., 2011)**. From all of the above data, it can be stated that, with regard to their baking characteristics, these flour mixtures fall into the category of flours suitable for bakery products.

Bread volume is one of the major quality-determining criteria for bread quality. Bread with a larger volume is

always preferred. A Volscan profiler was used to determine the bread volume, and the result was divided by the sample's weight to obtain its specific volume. The form ratio was also calculated by taking the maximum height divided by the maximum width of the sample, of which the measurements were determined by the Volscan profiler.

As can be seen in Figure 7 (by Volscan) and Table 3, bread volume and specific volume decreased with increased addition of MTF. This could be explained by a better gas retention ability of the gluten matrix in the dough, leading to bread with a larger volume in the control sample. The specific volume of bread decreased when the MTF was added. With 2.12 $mL.g^{-1}$, the specific volume of bread with 5% MTF approaches the value of standard wheat-rye bread (2.64 $mL.g^{-1}$) the most. In comparison, commercial wheat and bread with lower gluten content can only achieve a higher porosity by adding various supplements, which has a negative impact on nutrition and consumer acceptance. According to **Gao et al. (2017)**, the structural and textural attributes of baked bread were significantly correlated with the gluten development and the gas production of the dough. These findings suggest a great dependence on baked bread quality on its gluten network. **Kondakci, Wenjuan-Zhang, and Zhou (2015)** state that the low-, medium- and high-protein bread samples showed lower specific volumes compared to their corresponding control sample.

In general, all breads had high specific volume values and can be evaluated as of good quality, with good porosity and ratio. Even the nutritionally interesting addition of 15% MTF did not cause an important decrease in the quality of the trial bread, giving a good presumption for the application of MTF in baking flour.

The addition of MTF affects the color of the flour as indicated by **Apostol et al. (2017)**, color differences between the control flour and the flour mixtures are noticeable with the human eye. The flour mixtures with the highest percentage of added ingredient showed significantly higher redness values compared to the control flour. As the percentage of added partially defatted milk thistle seed flour increased, the color of the flour mixtures darkened compared to pure wheat flour. The overall acceptability of all experimental breads was evaluated as good.

From a nutritional point of view, in addition to silimarin MTF is a valuable source of minerals, especially calcium, magnesium, iron, and potassium. The mineral contents of the defatted milk thistle seed compared to wheat flour were referred to by **Apostol et al. (2017)**. The authors confirmed that compared to the low mineral content of wheat flour, samples of milk thistle seed flour were having higher levels of minerals. MTF is a good source of proteins, mineral compounds, and fats and therefore it can be used for human nutrition. Moreover, due to the high content of flavonolignans, summarily called silymarin, and their positive effects on the liver, it is also suitable for the production of functional foods **(Bortlíková, Kolarič, and Šimko, 2019; Menasra and Fahloul, 2019)**.

The addition of MTF to bread is in line with the trend of designing food according to consumers' needs, also those with special needs. Food thus becomes an active part of a progressive lifestyle and can help prevent certain diseases.

CONCLUSION

Modern foods are expected to contain nutritive components that are indispensable for maintaining a healthy daily life, but also contain many types of biofunctional components that help to maintain good physical and mental health. One opportunity is milk thistle (*Silybum marianum* L. Gaertn). It is a plant that has been used as a remedy for a variety of medical conditions, especially liver, kidney, and gallbladder ailments. The defatted milk thistle seed flour could be utilized as a suitable ingredient in food production, for example in the composite flours based on wheat and other cereals and non-grain seeds that have become popular in the baking technology.

The analysis of the viscoelastic properties gives information about the influence of the applied ingredients on the rheological behavior of the dough. Preliminary rheological analyses indicated a strong influence of the applied non-wheat flour on the dough properties.

Summarising the results and findings of this study, the following conclusions can be postulated:

-The suitability of WRF replacement with MTF in the range 5, 10, and 15% were studied for the preparation of bread as healthy bakery products,

-During the experiments, the effects of the WRF replacement on the technological properties of the dough were determined using Mixolab characteristics. The results showed that the trial mixture with 5 and 10% MTF had very similar results to the control flour (WRF). The trial mixture with 15% MTF has different characteristics of gelatinization and retrogradation,

-A rheofermentometer measures the dough characteristics during proofing, and the trial mixtures with the addition of MTF have created a large gas volume. During the rheofermentometer measurements, the MTFs lost significantly higher amounts of CO_2 compared to the control flour, but the retention volume at the end of the measurement was approximately the same as with the control flour (WRF) at all evaluated mixtures,

-The rheological analysis to predict the quality of the final product showed that it was possible to make bread with a WRF replacement by these functional ingredients in concentrations that allow maintaining the specific volume similar to the control bread,

-A Volscan profiler was used to determine the bread volume and other parameters and confirmed the predicted properties because all breads had high volume and specific volume values and can be evaluated as of good quality, with good porosity and ratio.

The main conclusion in our study concerning the rheological properties of dough WRF and mixtures of WRF with MTF is that the rheological parameters were maintained within limits that can assure a good technological behavior towards obtaining high-quality bakery products.

From all of the above data, it can be stated that, concerning their baking characteristics, these flour mixtures fall into the category of flours suitable for bakery products. The results suggest that milk thistle seed flours have health benefits potential to be used in functional foods.

THE CONSUMER BEHAVIOR OF SLOVAK MILLENNIALS IN THE SEGMENT OF MILK AND DAIRY PRODUCTS WITHIN PRIVATE LABELS

Ingrida Košičiarová, Zdenka Kádeková, Ľubica Kubicová, Jana Rybanská

ABSTRACT
Despite the fact that the dairy industry has an important position in the food industry (with an 18% share in its total production and sales), dairy businesses are currently struggling with low consumption of milk and dairy products. According to most researchers, the low consumption of milk and dairy products is mainly due to poor eating habits and, last but not least, insufficient promotion of these products. There is also an opportunity for private labels, which are recently on the rise, for which milk and dairy products are the most commonly purchased category of food. This paper aimed to find out how Slovak millennials perceive private labels, in which categories they buy them, what motivates them and on the contrary, discourages them from the purchase, etc. As the main research method, there was chosen the method of anonymous questionnaire survey involving 549 respondents from all over Slovakia; which was subsequently supplemented with a blind test. The submitted results of research declared that our goals were fulfilled and the following conclusions can be stated: Slovak millennials buy private labels in particular in the category of milk and dairy products, perceive private labels as an adequate alternative to their purchase and when purchasing milk and dairy products, they are mostly influenced by recommendations of family and friends and the tasting.

Keywords: private labels; millennials; milk and milk products; blind test

INTRODUCTION
The dairy industry has an important position in the food industry of the Slovak Republic, as it accounts for 18% of its total production and sales. Like production, sales are mostly influenced by the evolution of raw cow's milk prices on both, European and world markets. Prices had a significant impact on the industry in 2009 – 2010, as there were observed sharp fluctuations – while 2009 brought to the dairy sector a profit of 2.8 million €; in 2010, it showed a loss of 7.3 mil. €. The following years did not bring any change and it can be said that the sector is loss-making **(MPRV SR, 2018)**.

The average purchase price of raw cow's milk was the lowest in 2009 when it was around 20.82 €/100 kg. The highest price was reached in 2014, at 33.82 €/100 kg. While the development of average purchase prices of raw cow's milk excluding VAT is in the graphical form shown in Figure 1, Figure 2 shows the production of milk and dairy products in the Slovak Republic.

The raw cow's milk production showed a fluctuating trend over the considered period between 2009 and 2019. The highest production was achieved in 2012 at the level of 959.4 thous. t. On the contrary, the lowest milk production was in 2010, namely 918 thous. t.

Despite the fact that milk and dairy products take an irreplaceable place in everyday food consumption, especially because the milk is a complex food, what is confirmed by its nutritional content, vitamins, magnesium, and iron, which are indispensable in the daily diet **(Nicklas et al., 2009)**. Some ingredients are included in milk in a higher amount, others in a more convenient form to be used by the organism.

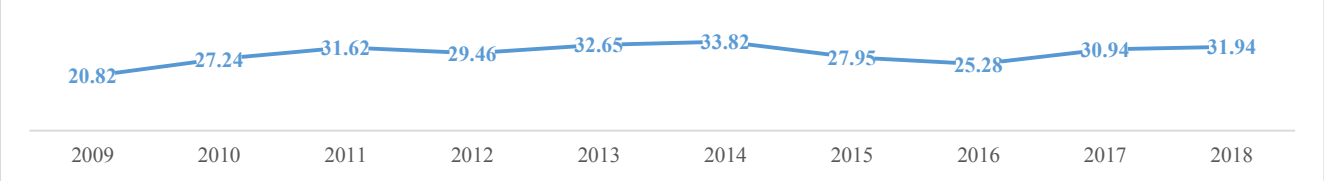

Figure 1 Development of average purchase prices of raw cow 's milk excluding VAT (€/100 kg). Note: Source – **VÚEPP (2019)**.

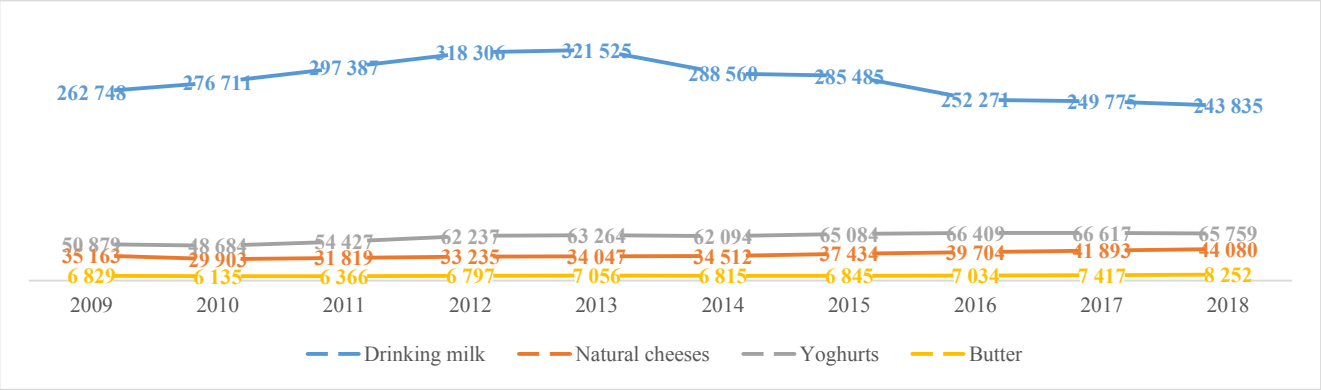

Figure 2 Production of milk and dairy products in Slovakia (t). Note: Source – **VÚEPP (2019)**.

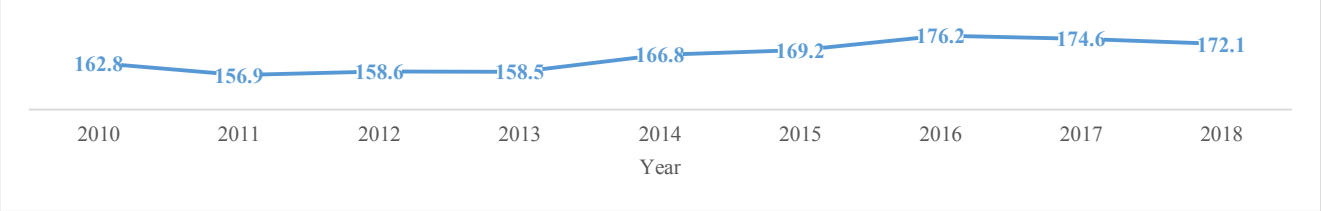

Figure 3 Average milk and dairy consumption per capita (kg/year). Note: Source – **VÚEPP (2019)**.

At the forefront of this, it is calcium that is bound in milk in organic compounds and therefore can be easily used by the growing organism **(The National Dairy Council, 2008)**, nowadays dairy companies are struggling with low milk and dairy consumption – as can be seen from the Figure 3, the consumption of milk and dairy products per capita peaked at 176.2 kg in 2016 and have been rather negative since then.

According to the results of several researches (e.g. **Kubicová and Habánová, 2012; Krivošíková et al., 2019; Kubicová et al., 2019,** etc.), the low consumption of milk and dairy products is caused mainly by poor eating habits of consumers and, last but not least, insufficient promotion of these products. Lower consumption of milk and dairy products adversely affects human health, as they contain many vitamins and minerals that have a beneficial effect on health.

The submitted paper deals with the issue of private labels in the segment of milk and dairy products, where we have focused on a selected group of customers, namely millennials. Our research aims to show how private labels function as an alternative to the purchase and which elements do have an influence in the case of a specific group of customers, so-called millennials.

Millennials, also known as Generation Y or Millennial generation are those born after 1980 and the first generation to come of age in the new millennium **(Polakevičová and Uhríková, 2015)**.

Scientific hypothesis

For a deeper analysis of the research objectives, the following hypotheses were formulated:

Hypothesis 1: We assume that there is a correlation between the purchase of private label products and the respondents´ gender.

Hypothesis 2: We assume that there is a correlation between the frequency of purchase of private labels in the category of milk and dairy products and the respondents´ gender.

Hypothesis 3: We assume that there is a correlation between whether the respondent is the end-user of the purchased private label products and his gender.

Hypothesis 4: We assume that there is a correlation between
what private labels evoke in the respondent and his gender.

Hypothesis 5: We assume that there is a correlation between the decisive factor in the purchase of private labels and the respondents´ gender.

Hypothesis 6: We assume that there is a correlation between what discourages respondents from the purchase of private labels and the respondents´ gender.

Hypothesis 7: We assume that there is a correlation between what would lead the respondents to the purchase of private label products and the respondents´ gender.

MATERIAL AND METHODOLOGY

This paper aimed to find out how Slovak millennials perceive private labels, in which categories they buy them, what motivates them and on the contrary, discourages them from the purchase, etc. An anonymous questionnaire survey was chosen as the main research method, in which a total of 549 respondents from all over Slovakia have participated (the sample of respondents can be considered as representative on the 95% confidence level and 5% error margin as n ≥384).

As it can be seen in Table 1, the majority of our respondents was represented by women (66.3% of respondents), students (67.94% of respondents), respondents with the first degree of higher education (39.2% of respondents), households with net family income over 1.501 € (25.87% of respondents) and city residents (62.84% of respondents).

The questionnaire survey consisted of a total of 16 questions formulated as closed ones with the possibility of one, respectively multiple responses, and four open

questions where respondents were free to express their opinion and six classification questions.

As the second research method, there was used the method of blind test, which was involved by 15 respondents from our focus group. In this test, respondents were offered to taste four samples of parenica – a traditional Slovak cheese as follows: one sample of a traditional brand, two samples of private labels, and one sample produced by a reeve. In this test, our respondents were asked to evaluate on a scale of 1 to 5, with 1 being the best and 5 the worst, the color, flavor, fragrance, and consistency of the given samples. Table 2 provides a more detailed overview of the examined parenica samples.

Table 1 Characteristics of Respondents.

Category of respondents	Number
Female	364
Male	185
Educational Structure of Respondents	**Number**
Primary education	23
Secondary education without A level	17
Secondary education with A level	226
University education- Bachelor degree	245
University education- Masters degree	36
University education- PhD. degree	2
Economic Activity of Respondents	**Number**
Student	373
Employed	147
Unemployed	7
Self-employed	13
Maternity leave	9
Net Money Income of Households per Month	**Number**
Up to 500 EUR	88
501 – 800 EUR	81
801 – 1.100 EUR	136
1.101 – 1.500 EUR	102
More than 1.501 EUR	142
Place of Residence of Respondents	**Number**
City	345
Countryside	204

Table 2 Exmined samples of parenica and their indication.

Indication of the sample	Examined parenica
Sample 1	Parenica produced by a reeve
Sample 2	Private label 1
Sample 3	Private label 2
Sample 4	Traditional brand

Note: Source – results of the research.

Statistical analysis

The results of the questionnaire survey and subsequently of the blind test were verified using statistical verification of formulated dependencies, using mainly the methods of Pearsons' Chi-Square Test, Phi Coefficient, Cramer´s V Coefficient and Friedman's test which were calculated in the statistical programs XL Stat and SAS Enterprise Guide. In hypothesis testing, if the p-value is lower than a significant level, in our case 0.05, the null hypothesis is rejected and its alternative is confirmed.

RESULTS AND DISCUSSION

Nielsen's recent global Consumer Confidence Index reports (2018) proved that there is a new retail revolution underway, and it's going to affect the food industry across the globe over the next five years in ways we have never seen before by the development of private-label products and the new challenges that this will present for brands and manufacturers across the globe, as retailers develop and market their products rather multinational name brands to meet changing consumer needs **(Herstein and Gamliel, 2004; Smith and Bashaw, 2009; Kakkos et al., 2015)**.

Private label brands, also known as "store brands" or "distributor brands", were considered low-price, low-quality products several decades ago; currently, however, they represent a clear alternative to manufacturer brands **(Kapferer, 2008)**. They account for more than 40% of the market in six European countries **(Private Label Manufacturers Association [PLMA], 2015)**. In general, private labels refer to brands owned by the retailer or distributor and sold only in its stores **(Kumar and Steenkamp, 2007)**. Conversely, manufacturer brands are brands owned by manufacturers to commercialize them.

Private labels are not new in the market, as firstly occurred at the end of the 19th century, **(Nagyová and Košičiarová, 2014)**. Nowadays, in a highly competitive environment, the private label products represent a suitable and perfect way of addressing new potential customers **(Polakevičová, 2015; Džupina et al., 2016; Mach et al., 2018; Lorincová et al., 2018; Balcarová et al., 2014**).

Consumers are currently in an increasingly competitive and dynamic market environment **(Mach et al., 2018; Balcarová et al., 2014)**, where the brand itself is either losing its weight or strengthening it. **Koprda (2014)**, **Džupina and Janková (2017)** as well as **Bulanda et al. (2018a)** emphasize that consumer behavior is a complex of behavior that is not influenced by just one factor. It is the combination of different factors and mainly of the price and quality.

Here can be seen the possibility for private labels, which can become a perfect alternative to traditional brands, bringing several benefits not only to the consumer and retailer but also to the supplier himself, especially in increasing his sales volume, lower communication and logistics costs, and options to enter new markets **(Corstjens and Lal, 2000; Collins-Dodd and Lindley, 2003; Richardson et al., 1996)**. While the main advantage for the consumer is the easy identification of private label products, the lower price, respectively the guarantee of authenticity, origin, and standard, as well as of comparable quality **(Tvrdoň and Přibyl, 2004)**, for the retailer it is the strengthening of image **(Liu and Wnag, 2008)**, expanding supply, increasing demand and strengthening customer loyalty **(Cheng et al., 2007; Huang et al., 2007; Kita et al., 2013)** as well as minimizing the risks associated with the introduction of new products **(Baltas, 1997; Sethuraman and Cole, 1999)** and consolidating its position in the retail market **(Lukić, 2011)**.

The mentioned is also true for private labels, and especially those on the Slovak market, whose consumption has been steadily increasing, respectively is slightly fluctuating, as it can be seen from the Figure 4 – purchases of private labels by Slovak consumers have recently increased, respectively they have fluctuated, which in our opinion is largely due not only to the lower price of these products, but also to higher confidence in them, either their ever-increasing quality, which in many cases becomes not only comparable, but also higher than those of traditional brands.

The submitted paper focused on the issue of private labels in the segment of milk and dairy products in a selected segment of customers called millennials, because according to several researches **(Polakevičová and Uhríková, 2015; Šedík et al., 2018a; Šedík et al., 2018b)**, they represent potential customers, with a high potential to become loyal customers.

Submitted paper aimed was to find out how Slovak millennials perceive private labels, in which categories they buy them, what motivates them and on the contrary discourages them from the purchase, while we focused primarily on the segment of milk and dairy products regarding the fact, that many different studies proved that private labels are mainly purchased in the categories of milk and dairy products (e.g. research by **Košičiarová et al. (2014), Retailmagazin.sk (2018), GFK (2018), Košičiarová et al. (2018)** etc.) and the questions focused on the mentioned issue was formulated in the questionnaire survey.

In terms of purchasing private label products, the current situation between potential loyal customers and private label customers in Slovakia among Slovak millennials is favorable, as out of a total number of 549 respondents, 24.41% of respondents buy these products regularly and 57.92% of respondents buy them sporadically, while purchasing them mostly because of good quality, adequate price, good previous experience or recommendations from family and friends, the do not purchase them mainly because of their uninteresting package, low quality, high price as well as their lack of interest to try them. In the case of an exact frequency of purchase, it is possible to say that our respondents purchase private labels mainly once a month (31.06% of respondents), respectively multiple times a week (23.19% of respondents); buy mainly milk and dairy products followed by mineral waters, lemonades, and juices. Products milk and dairy private labels are purchased weekly (40.66% of respondents).

At least are private label products purchased in the

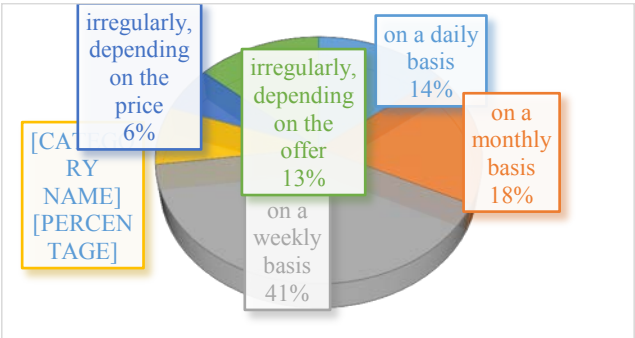

Figure 5 Frequency of purchase of milk and dairy products under the private label (%). Note: Source – results of the research.

Note: Source – results of the research.

categories of frozen semi-finished products, prepared meals, and alcoholic beverages (Table 3 and Table 4).

Our results once again largely correspond to the results of previous researches, e.g. **TNS Slovakia (2015)**, **GFK Slovakia (2010)**, **Nagyová and Košičiarová (2014)**, **Košičiarová et al. (2017)**, etc. which show that Slovak consumers buy private labels primarily several times a week or once a week; they buy them mainly because of their cost-effectiveness, quality and confidence; and that every Slovak household has "favorite brands" in its regular and regular purchases **(TASR, 2010)**.

Because the consumer behavior is changing and nowadays to the forefront is becoming the healthy lifestyle, more people are suffering with special illnesses and specific needs, we have asked our respondents whether they purchase the specific categories of private label products, e.g. gluten-free products, low-fat products, etc. and if so, what are the reasons. The results of research proved, that Slovak millennials start to buy the specific categories of private label products, purchase them mainly sporadically (27.59% of respondents) or regularly (12.93% of respondents) and they do so mainly because of the following reasons: healthy lifestyle, need to try something new, reasonable price or due to the health reasons.

As the consumer is considered to be the end user or the consumer of the given product **(Bulanda et al., 2018b; Pilař et al., 2018)**, the questionnaire survey aimed at finding the answer to whether our respondents are the final users of purchased private label products. It can be confirmed that our respondents are the consumers of private label products, as they have stated that they are the final consumers of purchased private label products (up to 39.06% of the respondents) and therefore it is true that Slovak millennials represent potential loyal customers of private labels. Attracting customers is the primary goal of any business, as the customer creates a demand for goods and services and is very likely to become a loyal consumer who will become loyal to the given business or brand. In doing so, companies compete mainly by promoting and lowering prices to attract the largest customer base **(Kenton, 2018; Světlík and Bulanda, 2019; Kaliji et al., 2019)**.

From this it is necessary to realize what works in the given customer segment, respectively does not work. The results of our research show that while the decisive factor leading to the purchase of private labels is the combination of reasonable price and quality (47.72% of respondents), the decisive factor discouraging from the purchase of private labels is their price, low quality and lack of information about the exact manufacturer (20.04%, 17.12% and 13.84% of respondents). The mentioned results are also confirmed by the researches of e.g. **Kumar and Babu (2014) Paraffin, Zindove, and Chimonyo (2018)** and **Kurajdová et al. (2015)** confirm our results and identify quality and price as the main factors determining the purchase of specific products.

Up to the question, what would influence our respondents to the purchase of private labels, we can say that in the case of Slovak millennials it is mainly the recommendation from their families and friends (40.62% of respondents), resp. tastings (16.21% of respondents), free samples, or more interesting form of promotion (in both cases 15.12% of respondents).

It is very common and it can be said also misconception that the low price is also an indicator of poor quality **(Sproles, 1977; Völckner and Hofmann, 2007; Gabrielsen and Sørgard, 2007; Asker and Cantillon, 2010)**. Private labels are often characterized by a low price, which could mean lower quality. This is why, we have asked our respondents how they perceive private label products, what they suggest about them, what do they think about their quality, respectively whether they prefer them based their purchase and if so, in which product categories this happens.

The results of our research show that Slovak millennials perceive private labels as a suitable alternative to the purchase (58.29% of respondents), private labels evoke in them a sense of adequate quality at a reasonable price (59.74% of respondents), the quality of private labels is up to their opinion comparable with the quality of traditional brands (16.76% of respondents think so exactly and up to 42.08% of respondents think so rather), in the case of milk and dairy products they think that their quality is good or adequate (47.18% of respondents, Figure 6) up to 26.55% of respondents exactly prefer them in their purchase, and this is particularly the case of categories such as milk and dairy products, food in general and cosmetics.

The last questions in our questionnaire survey focused on the issue, whether our respondents would recommend private label products to the other consumers and what they would change on them, if they had that chance. According to our findings, young Slovak consumers would recommend private label products to other consumers (20.95% of respondents has declared the possibility of certainly yes and 46.99% respondents rather yes) and if they had the possibility, they would in particular increase the quality of private label products (28.96% of respondents), they would change their packaging and made it more attractive and lower their price (in both cases 15.49% of respondents).

Evaluation of tested dependencies

Hypothesis 1: We assume that there is a correlation between the purchase of private label products and the respondents´ gender – rejected.

Hypothesis 2: We assume that there is a correlation between the frequency of purchase of private labels in the category of milk and dairy products and the respondents´ gender – rejected.

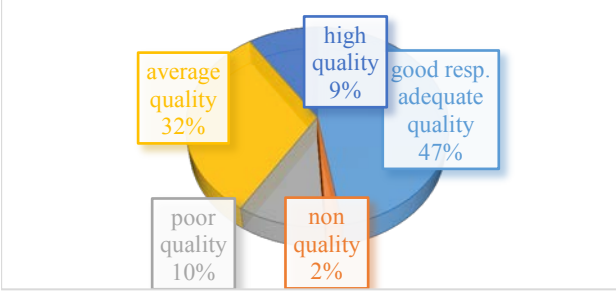

Figure 6 Perceived quality of milk and dairy products under the private label (%). Note: Source – results of the research.

Table 5 Correlation between whether the respondent is the end user of the purchased private label products and his gender.

Statistic	DF	Value	Prob
Chi-Square	3	20.8724	0.0001
Likelihood Ratio Chi-Square	3	21.2857	<.0001
Mantel-Haenszel Chi-Square	1	0.0424	0.8369
Phi Coefficient		0.1950	
Contingency Coefficient		0.1914	
Cramer's V		0.1950	

Note: Source – results of the research.

Table 6 Correlation between evoked stimulus regarding the private labels and the respondents´ gender.

Statistic	DF	Value	Prob
Chi-Square	2	7.7339	0.0209
Likelihood Ratio Chi-Square	2	7.5911	0.0225
Mantel-Haenszel Chi-Square	1	7.0413	0.0080
Phi Coefficient		0.1187	
Contingency Coefficient		0.1179	
Cramer's V		0.1187	

Note: Source – results of the research.

Table 7 Correlation between the decisive factor in the purchase of private labels and the respondents´ gender.

Statistic	DF	Value	Prob
Chi-Square	5	16.6665	0.0052
Likelihood Ratio Chi-Square	5	16.8441	0.0048
Mantel-Haenszel Chi-Square	1	0.8749	0.3496
Phi Coefficient		0.1742	
Contingency Coefficient		0.1716	
Cramer's V		0.1742	

Note: Source – results of the research.

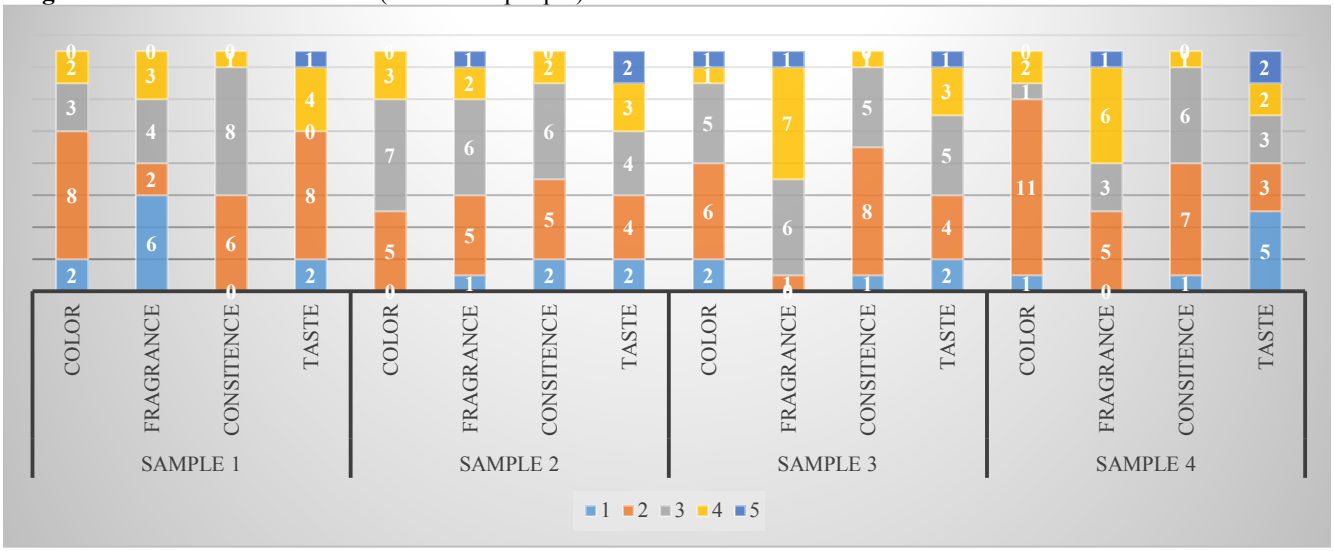
Hypothesis 3: We assume that there is a correlation between whether the respondent is the end-user of the purchased private label products and his gender – confirmed.
Hypothesis 4: We assume that there is a correlation between what private labels evoke in the respondent and his gender – confirmed.
Hypothesis 5: We assume that there is a correlation between the decisive factor in the purchase of private labels and the respondents´ gender – confirmed.
Hypothesis 6: We assume that there is a correlation between what discourages respondents from the purchase of private labels and the respondents´ gender – rejected.
Hypothesis 7: We assume that there is a correlation between what would lead the respondents to the purchase of private label products and the respondents´ gender – rejected.

In addition to the tested dependencies, it can be stated that although the dependencies 3, 4, and 5 were confirmed, they are weak but statistically still significant (Table 5 to 7).

Evaluation of the blind test

As it was mentioned in the part Material and Methodology, in the blind test, there were tested totally four samples of parenica – one sample of a traditional brand, two samples of a private label, and one sample produced by a reeve- on totally 15 respondents from our focus group (Table 2). Our respondents had to taste the mentioned samples without that, that they did not know which kind of parenica it is and they had at a rank from 1 to 5, were 1 is the best and 5 is the worst, evaluate their taste, color, fragrance, and smellAs it can be seen from the Figure 7, our results have proven that the best results are declared – in a case of parenica cheese produced by a reeve (best in the all aspects – in the case of color, consistency, and taste evaluated with the mark 2 and in the case of fragrance mark 1), resp. by a traditional brand (best mark in case of taste), but it must be also mentioned that the difference between the traditional brand and private labels is very small, because all of the tested samples have reached mainly the marks of 2.

Figure 7 Results of the blind test (number of people).



Note: Source – results of the research.

CONCLUSION

Consumer behavior, factors influencing the purchase, the decision-making process of consumers, etc. were of interest to several studies and research works, but very few of them have focused on millennials, not to mention private labels. The submitted paper focused on the issue of private labels but in a specific segment of customers called millennials, who represent potential loyal customers of private labels, and focused on the issue of private labels in the milk and dairy segment, as several researches has shown that private labels are mainly purchased in this category.

An anonymous questionnaire survey was chosen as the main research method, in which participated 549 respondents in the millennials category; which was supplemented by a blind test (15 respondents from the focus group). The results of our research point to many key findings in this issue, where it was proved that our respondents are indeed the end-users of purchased private label products, they buy them mainly in the category of milk and dairy products, their quality is comparable with the quality of traditional brands (also proven by the results of the blind test), that the decisive factor affecting the purchase of private label products is the combination of reasonable price and good quality, the decisive factor discouraging from the purchase of private labels is their price, low quality and lack of information about the exact manufacturer and what can lead our respondents to their purchase are primarily the recommendations of family and friends, and own experience (tastings and free samples).

Zingiber cassumunar roxb. Extract increase the reactive oxidant level and interleukins expression *in vitro*

Nurkhasanah Mahfudh, Nanik Sulistyani, Ghina Adhila

ABSTRACT

Zingiber cassumunar Roxb. (bangle) has a variety of active compounds, including curcumin and phenylbutenoid. Bangle rhizoma reported exhibiting immunomodulatory activities. This research aims to determine the mechanism of bangle extract as an immunomodulator by the secretion of Reactive Oxygen Intermediate (ROI), Nitric Oxide (NO), and interleukin (IL-10 and IL-14) expression level. Bangle extract (*Zingiber cassumunar* Roxb.) was made by the maceration method using 96% ethanol solvent. This research was administered *in vitro* using macrophage cells from male mice with Balb/C strain divided into 2 groups: normal control and treatment group (receiving 25, 50, and 100 ppm of extract). The administration of bangle extract can function as an immunomodulator by an increase of ROI in 25 and 50 ppm of the extract significantly than the control group (p <0.05), the treatment groups decrease NO level (p <0.05), it also was found to increase expression of IL-10 and IL-14 expression levels (p <0.05). *Zingiber cassumunar Roxb.* extract was potentially to be developed as an immunomodulator.

Keywords: Immunomodulator; *Zingiber cassumunar* Roxb.; ROI; NO; IL-10; IL-14

INTRODUCTION

The immune system defends our body against invaders, such as viruses, bacteria, and foreign bodies which are the cause of various diseases. It consists of a natural immune system (innate immunity/non-specific) and an adaptive immune system (adaptive immunity/specific) **(Akrom, 2017; Baratawidjaja and Rengganis, 2014)**. Immunomodulators are pharmacological agents that can modulate a partial immune response that is spurred by an immune response, on the other hand, it inhibits some of the other immune system. Immunomodulators are restoring the imbalance of the disrupted immune system **(Akrom, 2017)**.

Macrophages are professional phagocytes that act as APC and the main effectors in cellular innate and adaptive immune response **(Murphy, 2012)**. In the body's defense mechanism against invaders, macrophages become the leading component of immune blocking. Macrophages express many surface receptors that can catch and swallow (degrade) microbes, in a process called phagocytosis **(Baratawidjaja and Rengganis, 2014)**. Phagocytosis and *reactive oxygen intermediates* (ROI) are the macrophages main mechanism in destroying infected cells **(Akrom et al., 2015)**.

Activate macrophages can stimulate the proliferation and activity of T and B lymphocyte cells. Macrophage cells act as antigen-presenting cells (APC) that will activate Th-0 lymphocytes. Activated CD4 Th-0 lymphocytes will proliferate towards Th-1 or Th-2 depending on the cytokine environment and the location of the antigen. Activated T lymphocytes will release various mediators, differentiation towards Th-1 will produce proinflammatory cytokines while differentiation towards Th-2 produces anti-inflammatory cytokines **(Thiery et al., 2003; Bastos et al., 2004; Akrom and Mustofa, 2017)**.

One of the potential plants in Indonesia is bangle (*Zingiber cassumunar* Roxb.) has been proven to have scientific activity as an immunomodulator. Bangle ethanol extract has been shown to have an immunomodulatory effect, indicated by an increase in the activity of macrophage cell phagocytosis, ROI secretion, and IL-10 expression, decreased NO secretion, and TNF-α production *in vivo* **(Arini et al., 2014; Nurkhasanah et al., 2017; Fitriana et al., 2018)**. *In vitro* research, phenylbutanoid compounds from bangle rhizomes can increase phagocytic activity of macrophage cells, and inhibit NO production **(Chairul et al., 2009; Nakamura et al., 2009; Kaewchoothong et al., 2012)**. Besides, the n-hexane bangle fraction can reduce the phagocytic activity of macrophage cells, and decrease lymphocyte proliferation **(Nurkhasanah et al., 2019b)**. In this study, we want to clarify the activity of bangle ethanol 96% extract as an immunomodulator by analyzing the secretion of ROI, NO, IL-10, and IL-14 by the macrophage.

Scientific hypothesis

Bangle has immunomodulatory activities with a mechanism of increasing ROI and NO secretion level, increasing IL-10 and IL-14 expression level, *in vitro*.

MATERIAL AND METHODOLOGY

Material and subject

Fresh *Z. cassumunar* rhizome purchased from the local market, Yogyakarta, Indonesia. The sample was verified and identified in the Biology Laboratory of Universitas Ahmad Dahlan. Macrophages were obtained from the peritoneal cavity of mice Balb/c strain aged eight weeks old (20 – 30 g) from the Integrated Research Laboratory of Universitas Gadjah Mada (Laboratorium Penelitian dan Pengujian Terpadu, LPPT UGM).

Research Procedure

Preparation of Bangle Extract

Z. cassumunar extraction was carried out using the maceration method and 96% ethanol as the solvent. The maceration was done for 3 x 24 hours. The macerate was filtered, and then evaporated (rotary evaporator) for 2 hours per day in a week, and used a water bath until a thick extract was obtained.

Preparation of Test Animals

The use of test animals in this research had received ethical approval from the Commission for Research Ethics of Universitas Ahmad Dahlan with Number: 011804063. The test animals were male mice Balb/c strain aged eight weeks old.

Isolation of Macrophages

Mice were narcotized with chloroform after being fasted for 10 – 12 hours. Then, mice were placed in the supine position. The mice's abdomen skin cleaned using disinfectant (70% alcohol) and dissected. The peritoneal sheath cleaned with 70% alcohol. Then, 10 mL of cold RPMI injected into the peritoneal cavity and shaken slowly for three minutes. The inner cavity pressed with two fingers and the fluid from the peritoneal cavity (the non-fatty part) drawn using an injection syringe to obtain an aspirate.

The aspirate is centrifuged at 1200 rpm, 4 °C for 10 minutes. The supernatant was removed, and the pellets (macrophages) resuspended with 1,000 µL complete medium. The number of cells counted from 10 µL macrophage suspension in a hemocytometer. The macrophage cell suspension grew in a 6-well microtiter plate (coverslip) with a density of 5 x 10^5 cells/well for the ROI and interleukin assay. And a 6-well microtiter plate with a density of 1 x 10^5 cells/well for the NO assay **(Ulfah et al., 2017; Nurkhasanah et al., 2017)**.

Reactive Oxygen Intermediate (ROI) Secretion Assay

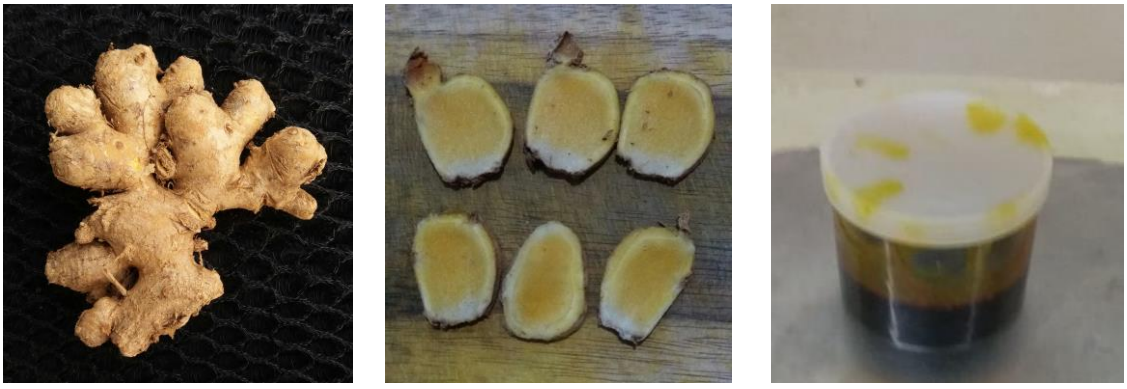
The 100 µL of macrophage cell suspension grew in a 6-well microtiter plate (coverslip) with a density of 5 x 10^5 cells/well. The cells incubated in a 5% CO_2 incubator at 37 °C for 15 minutes. 800 µL of complete RPMI medium added to each well, then microplates incubated overnight. The medium was removed and the sample added each well. The microplates were incubated in a 5% CO_2 incubator at 37 °C overnight.

The 50 – 100 µL of NBT solution and 1 mL of PBS (containing 125 PMA) added to each well, then incubated in 5% CO_2 incubator at 37 °C for 60 minutes. The reagent was removed, dried at room temperature, and fixed with absolute methanol. After dried, applied a 2% neutral red solution to the coverslip. The percentage NBT reduction of macrophage cells, it calculated from 100 cells examined by a binocular microscope (XSZ 107 BN, Novel) and Optilab with 400x magnification **(Nurkhasanah et al., 2017)**.

Nitric Oxide (NO) *Secretion Assay*

Griess Reaction Assay used for NO levels testing. Griess A solution prepared by dissolving 0.1 gram of N-(1-naphthyl) ethylene diamine hydrochloride (Sigma N, 5889) in 100 mL of distilled water. Griess B solution prepared by dissolving 1 gram of sulfanilamide (Sigma N 5589) in 100 mL of 5% orthiohisohoric acid (v/v). Both solutions stored at 0 – 4 °C protected from light. Standard nitrite prepared by dissolving 69.0 mg of sodium nitrite (Merck) in 100 mL of distilled water and stored at 0 – 4 °C protected from light. Stock standard solutions prepared using standard nitrite solutions in concentrations between 1.5625 – 100 µM **(Nurkhasanah et al., 2017)**.

100 µL macrophage cell suspension grew in 96-well microtiter plate-wells with a density of 1 x $10^5.mL^{-1}$. The samples were added to each well, and the microplates were incubated overnight. The standard nitrite was inserted into the blank section of the 96-well microtiter plate, to determine the standard curve. Each well added 50.0 µL



a **b** **c**

Figure 1 *Z. cassumunar* (a. rhizome; b. pieces of rhizome; c. extract).

Griess reagent, allow to stand for 5 – 10 minutes at room temperature and protected from direct light, until the color changes. The absorbance measured using an ELISA reader at a wavelength of 550 nm **(Nurkhasanah and Zulkarmen, 2014; Nurkhasanah et al., 2017)**.

Interleukin-10 and Interleukin-14 Expression Assay

Previously, the preparation of cell culture is the same as in ROI assay. Macrophage cells culture fixed using methanol and then washed with Phosphate Buffer Saline (PBS). The microplates soaked in 300 µL peroxidase blocking solution and washed with distilled water.

Then the microplates added 20 µL protein blocking serum, incubated at humid temperature for 10 – 15 minutes. Added 30 µL Interleukin-10 and Interleukin-14, incubated at room temperature then washed with PBS. Added with 30 µL of biotin, incubated at room temperature then washed with PBS. Added with 30 µL of the enzyme streptavidin-peroxidase, incubated at room temperature then washed with PBS. Added with 30 µL peroxidase substrate solution (DAB), incubated at room temperature, and washed with distilled water. Added with 100.0 µL of Mayer Hematoxylin (counterstain), incubated at room temperature then washed with distilled water. Then the microplates soaked in absolute alcohol, cleaned, and dried. The microplates dipped in xylol and dried. Then the microplates dropped with mounting media and covered using a deckglasser. After dried, observed in a binocular microscope (XSZ 107 BN, Novel) and Optilab with 400x magnification to examine the color of the cells, expression of IL-10 and IL-14 has intense brown **(Javois, 1999; Nurkhasanah et al., 2019a)**.

Statistic analysis

All statistical analyzes performed using the SPSS version 22 program. The normality test and homogeneity test performed about the data ROI levels, NO levels, and the expression of Interleukin-10 and Interleukin-14. Then proceed with the One-way ANOVA and LSD tests (with a significance level of 0.05).

The normality test performed using the Shapiro-Wilk‘s test, with total data of less than 50. The variant homogeneity test performed using the Levene‘s test. If the results of the normality test and homogeneity test are homogeneous variance and normally distributed, then the test continued with the analysis of one way ANOVA variants, and LSD test.

RESULTS AND DISCUSSION

Result of ROI Secretion Assay

The NBT reduction test (tetrazolium nitro blue reduction test, containing PMA (phorbol 12-myristate, 13-acetate)) was used to measure the ability of peritoneal macrophage cells to secrete ROI. NBT (formazan salt) will diffuse into cells, then tetrazolium succinate reductase enzyme will divide into formazan. ROI cause increased respiration and reduction of NBT by forming black formazan deposits **(Leijh et al., 1986)**. It can be seen in Figure 2, macrophage cells are black show secrete ROI due to formazan deposition.

In contrast to macrophage cells that do not secrete ROI, it looks only brown without any formazan deposits.

Table 1 shows the average levels of ROI secretion in the normal control group and the treatment group concentrations of 25, 50, 100 ppm.

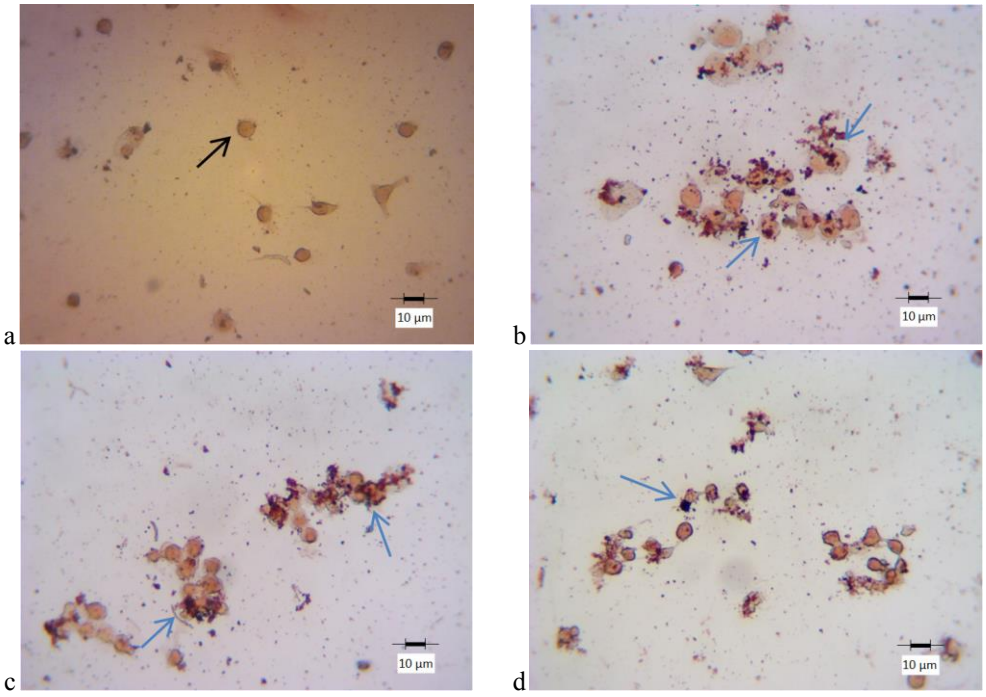


Figure 2 ROI secretion in macrophage cells after treated with bangle (Z. *cassumunar*) extract: a. normal control, b. bangle extract concentration of 25 ppm, c. bangle extract concentration of 50 ppm, d. bangle extract concentration of 100 ppm. (blue arrow: macrophage cells secrete ROI; black arrow: macrophage cells do not secrete ROI). Note: (400x magnification).

Table 1 ROI level by the administration of bangle (Z. *cassumunar*) extract.

Group	ROI secretion level (%) ±*SD*
Normal control	48.68 ±5.76
25 ppm	67.98 ±1.25*
50 ppm	70.38 ±8.35*
100 ppm	49.80 ±8.71[a,b]

Note: *significantly different compared to normal control group (p <0.05); [a]significantly different compared to concentration 25 ppm group (p <0.05); [b]significantly different compared to concentration 50 ppm group (p <0.05).

Table 2 NO level by the administration of bangle (Z. *cassumunar*) extract.

Group	NO secretion level (%) ±*SD*
Normal control	9.262 ±0.360
25 ppm	0.357 ±0.226*
50 ppm	0.762 ±0.840*
100 ppm	0.471 ±0.310*

Note: *significantly different compared to the normal control group (p <0.05).

The normal control group had the lowest ROI secretion (48.68%), not significantly different (p >0.05) with the treatment group concentration of 100 ppm (49.80%). The treatment groups concentrations of 25 and 50 ppm had ROI levels of 67.98% and 70.38%, significantly different (p <0.05) with normal controls, and the treatment group concentrations of 100 ppm.

There was an increase in ROI levels of the treatment group concentrations of 25 ppm and 50 ppm, but a decrease in ROI levels in the treatment group concentration of 100 ppm.

The content of curcumin compounds in bangle extract can cause increased levels of ROI. Curcumin can increase reactive oxygen species (ROS). This is related to macrophage activation and phagocytic activity of macrophages **(Mimche et al., 2011)**. Increased ROS can activate cellular signal pathways to form ROI **(Nathan and Ding, 2010)**. Bangle chloroform extract concentrations of 25, 50, and 100 $\mu g.mL^{-1}$ in vitro showed significantly increased ROI secretion compared to normal controls **(Nurkhasanah et al., 2019b)**. In vivo study, administration of bangle (5 $mg.20g^{-1}$ BW) by seven days duration can increase ROI secretion in mice induced by LPS (0.7 $mg.kg^{-1}$ BW) **(Nurkhasanah et al., 2017)**.

Phenylbutenoid is another component of the bangle extract and has anti-inflammatory activity by inhibiting enzyme cyclooxygenase-2 (COX-2) **(Jeenapongsa et al., 2003; Han et al., 2005; Leelarungrayub et al., 2017)**. The anti-inflammatory mechanism of this compound can be related to the ability of bangle to increase the expression of IL-10 **(Fitriana et al., 2018)**. Increased IL-10 expression will inhibit the production of IL-12, IL-1, and TNF-α. Inhibition of IL-1 and TNF-α production can affect T-cell activation to inhibit the inflammatory reaction. IL-12 has an important role in differentiating CD4 + into Th1 cells, then Th1 cells will secrete IFN-γ to activate macrophage cells to produce ROI. The inhibition of IL-12 production will indirectly inhibit the secretion of IFN-γ in case ROI production will decrease **(Bratawidjaja, 2014)**.

Result of NO Secretion Assay

NO is an effective antibacterial effector in the immune system. NO is a free radical synthesized by the enzyme nitric oxide synthase (NOS) through complex reactions. The main isoform expressed by macrophages is iNOS, this isoform will induce NO expression **(Kil et al., 2012)**. In this study, NO levels were measured using a Griess Reaction Assay (colorimetric method).

The concentration of NO secreted by macrophages will be calculated in the form of nitrites. Sulfanilamide (diazotization reagent) react with nitrite (in alkaline) will form to diazonium salt, then react with N-(1-naphthyl) ethylene diamine hydrochloride (coupling reagent) to be a stable form. The final result is intensive pink color and absorbance can be measured at wavelength 550 nm using Elisa Reader **(Nurkhasanah et al., 2017)**.

In Table 2 the average levels of NO secretion in the treatment group concentrations of 25, 50, and 100 ppm were 0.36; 0.76; and 0.47 μM. This result is significantly different (p <0.05) compared to the average NO level in the normal control group (9.26 μM). The decrease NO levels in the treatment group concentrations of 25, 50, and 100 ppm can be explained because of the results of IL-10 expression parameters. The results of IL-10 expression parameters are the treatment group 25, 50, 100 ppm has higher levels of IL-10 expression, and significantly different (p <0.05) compared to the normal control group.

The decrease NO levels were related to the results of the IL-10 parameter. In this study, the treatment group has a higher IL-10 expression than the normal group. iNOS gene expression is dependent on numerous proinflammatory cytokines in the cellular microenvironment of the macrophage, two of which include interferon-gamma (IFN-γ) and tumor necrosis factor-alpha (TNF-α) **(Salim et al., 2016)**. IL-10 (macrophage inhibitor) acts to inhibit proinflammatory cytokine production included TNF-α, IL-1, and IL-12. IL-12 has a role to stimulate IFN-γ production. Over this explanation, the active component in bangle can act as an immunomodulator by reducing NO levels **(Goodyear-bruch and Pierce, 2002; Akrom, 2017)**.

Table 3 IL-10 expression of mice macrophages by the administration of bangle (*Z. cassumunar*) extract.

Group	IL-10 expression level (%) ±*SD*
Normal control	9.61 ±1.44
25 ppm	69.96 ±3.46*
50 ppm	69.26 ±2.98*
100 ppm	53.29 ±8.39*[a]

Note: *significantly different compared to normal control group (p <0.05); [a]significantly different compared to concentration 25 ppm group (p <0.05).

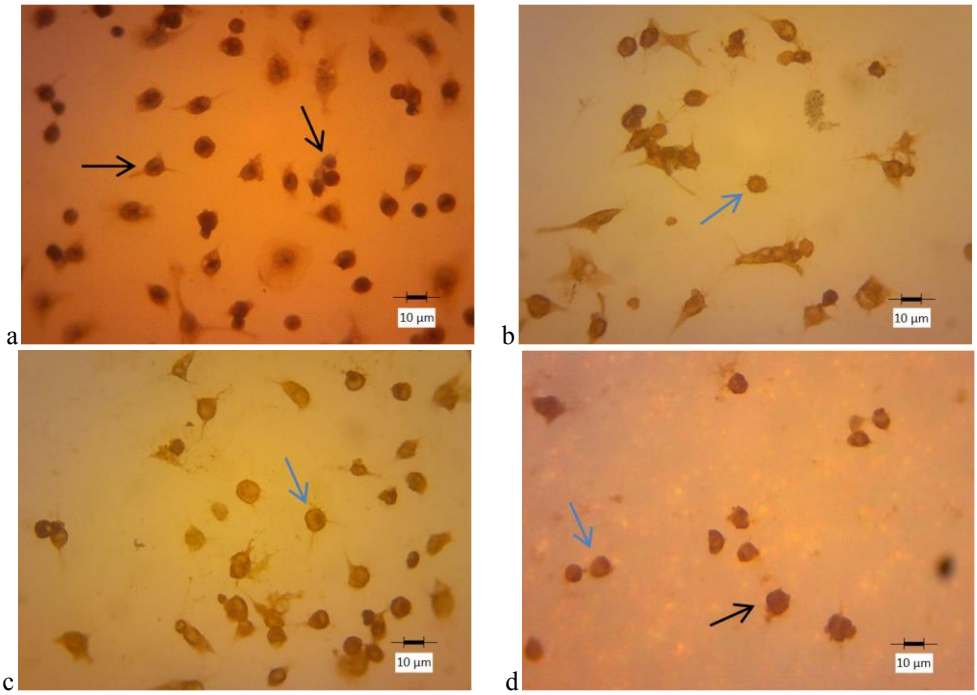

Figure 3 IL-10 expression on macrophage cells after being treated with bangle (*Z. cassumunar*) extract: a. normal control, b. bangle extract concentration of 25 ppm, c. bangle extract concentration of 50 ppm, d. bangle extract concentration of 100 ppm. (blue arrows: macrophage cells express IL-10; black arrows: macrophage cells do not express IL-10). Note: (400x magnification).

Phenylbutanoid was isolated from bangle (*Zingiber cassumunar* Roxb.) has an inhibitory effect of NO production on lipopolysaccharide-induced mouse macrophage cells (LPS) **(Nakamura et al., 2009)**. In other studies, *in vitro*, bangle can reduce NO secretion in murine macrophage RAW 264.7 cell lines **(Kaewchoothong et al., 2012)**. *In vivo* study, administration of bangle (5 mg/20g BW) can significantly reduce NO secretion in mice induced by LPS (0.7 $mg.kg^{-1}$ BW) **(Nurkhasanah et al., 2017)**. LPS causes an increase in NO levels of serum macrophages **(Tunctan et al., 1998)**. NO levels decrease after the administration of bangle extract could be due to the antioxidant content in the extract. Also, curcumin is another active component of bangle reported to inhibit NO production in macrophage activity **(Brouet and Ohshima, 1995)**.

Result of Interleukin Expression Assay

Interleukin-10

Observation of interleukin (IL) expression was carried out by an immunocytochemical method that uses specific antibodies to detect the expression of specific proteins (antigens) in cells. This research uses indirect immunocytochemical methods, the advantage is the results obtained have a more intense color, but it requires more time in the process **(Meshcer, 2017)**. The antigen will be bound indirectly to the primary antibody (IL-10 and IL-14) which has a role to recognize the antigen (first layer), then add a secondary antibody (biotin which binds to the enzyme streptavidin peroxidase) being the second layer.

The addition of secondary antibodies is also followed by the addition of chromogen substrate (DAB or 3,3-diaminobenzidine tetrahydrochloride), this substrate will be changed by enzymes so that it will form color deposits (pigments) in cells. To differentiate cells that are expressed IL-10 will have a brown color by DAB, while cells that are not expressed have a blue or purple color by Mayer hematoxylin (counterstain). Figure 3 shows the expression of IL-10 in macrophage cells treated with extract concentrations of 25, 50, and 100 ppm.

In Table 3 the average levels of IL-10 expression in the treatment group concentrations of 25, 50, and 100 ppm were 69.96%; 69.26%; and 53.29%. This result was higher and significantly different (p <0.05) compared to the average level of IL-10 expression in the normal control group (9.61%). The results obtained are suitable to those reported by other researchers that *Zingiber cassumunar* has the immunomodulatory activities one of activity by increase IL-10. This activity may be attributable to curcumin and phenylbutanoic as an active compound in this extract **(Fitriana et al., 2018; Nurkhasanah et al., 2020)**.

Table 4 IL-14 expression of mice macrophages by the administration of bangle (Z. *cassumunar*) extract.

Group	IL-14 expression level (%) ±SD
Normal control	2.16 ±0.30
25 ppm	87.44 ±7.35*
50 ppm	70.13 ±3.92*[a]
100 ppm	61.15 ±1.52*[ab]

Note: *significantly different compared to normal control group (p <0.05); [a]significantly different compared to concentration 25 ppm group (p <0.05); [b]significantly different compared to concentration 50 ppm group (p <0.05).

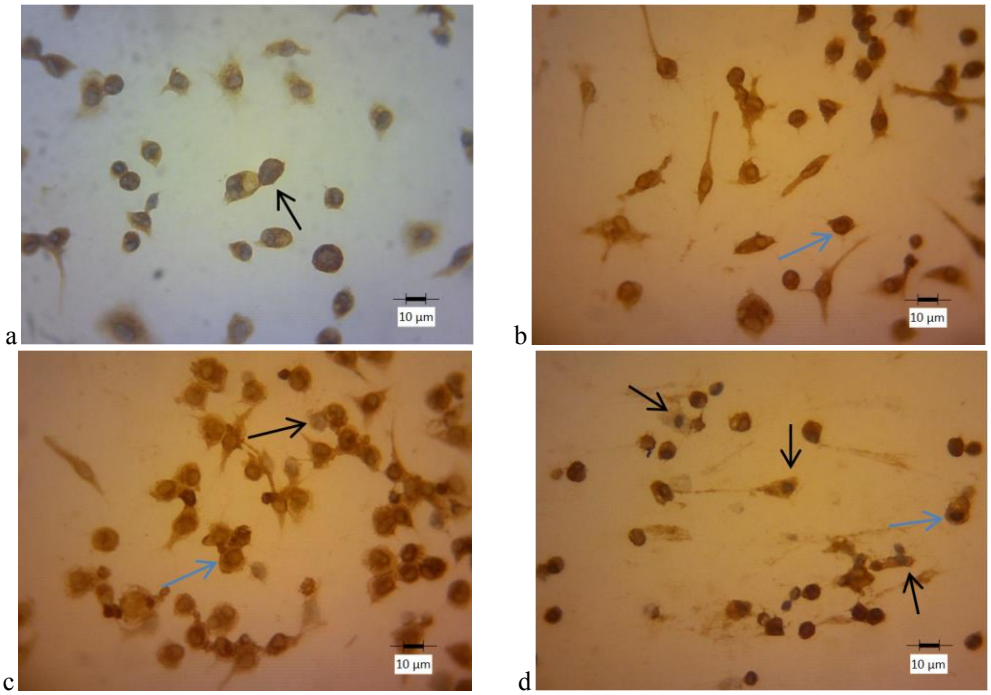

Figure 4 IL-14 expression on macrophage cells after being treated with bangle (Z. *cassumunar*) extract: a. normal control, b. bangle extract concentration of 25 ppm, c. bangle extract concentration of 50 ppm, d. bangle extract concentration of 100 ppm. (blue arrows: macrophage cells express IL-14; black arrows: macrophage cells do not express IL-14). Note: (400x magnification).

The treatment of bangle methanol fraction as a complementary therapy in mice infected with *P. berghei* can increase IL-10 levels **(Fitriana et al., 2018)**. It is known that the administration of bangle ethanol extract can inhibit the production of TNF-α which is a proinflammatory cytokine from Th1 cells, a decrease in TNF-α levels indicates an increase in IL-10 expression, where IL-10 (anti-inflammatory cytokines from Th cells - 2) can inhibit TNF-α production **(Perera et al., 2013; Arini et al., 2014)**. Also, there is a level of *in vivo* research with a length of 21 days and LPS stimulation of E. coli, 2,5 and 5 mg/20g BW of ethanol extract of bangle rhizome in mice can increase the expression of IL-10 **(Nurkhasanah et al., 2020)**.

Increasing the concentration of the test compound does not accord with an increased level of IL-10 expression because IL-10 is produced by active macrophages and Th-2 cells **(Akrom, 2017)**.

The results of the phagocytic activity parameters of macrophages also showed a decrease (%) of active phagocytic cells and phagocytosis index with an increase in the concentration of the test compound **(Adhila et al., 2019)**. The decrease in active macrophages will reduce the expression of IL-10 produced.

Interleukin-14

Similar to IL-10, the way to differentiate between cells expressed IL-14 will have a brown color by DAB, while cells that are not expressed have a blue or purple color by Mayer hematoxylin (counterstain). Figure 4 shows the expression of IL-14 in macrophage cells treated with extract concentrations of 25, 50, and 100 ppm.

In Table 4 the average levels of IL-14 expression in the treatment group concentrations of 25, 50, and 100 ppm were 87.44%; 70.13%; and 61.15%. This result was higher and significantly different (p <0.05) compared to the average level of IL-14 expression in the normal control group (2.16%). The administration of bangle ethanol extract showed the effect was to increase IL-14 expression. Although a decrease in IL-14 levels was seen with the administration the higher concentration of the extract. From this explanation, it can be seen that the active component of the bangle can act as an immunomodulator by improved IL-14 levels.

A previous study highlights that *Zingiber cassumunar* has the immunomodulatory activity which may be caused by curcumin and phenylbutanoic compound **(Chairul et al., 2009; Nurkhasanah et al., 2019b; Nurkhasanah et al., 2020)**. The ethyl acetate fraction of bangle extract concentration of 25, 50 and, 100 µg.mL^{-1} *in vitro* had a

role as an immunomodulator through increased IL-14 expression and the higher extract concentration showed the higher IL-14 expression produced **(Nurkhasanah et al., 2019b)**. Also, there is a level of *in vivo* research with a length of 21 days and LPS stimulation of E. coli, 5 mg.20g^{-1} BW of ethanol extract of bangle rhizome in mice can increase the expression of IL-14 **(Nurkhasanah et al., 2020)**.

CONCLUSION

Bangle ethanol 96% extract decreased NO levels (in all variations of extract concentration), and increased ROI levels compared to normal control groups (at extract concentrations of 25 and 50 ppm) with a significant effect (p <0.05). Also, bangle ethanol 96% extract increased in IL-10 and IL-14 levels compared to the normal control group (in all variations of the extract concentration) with a significant effect (p <0.05). These results indicate that bangle ethanol 96% extract has an immunomodulatory effect *in vitro*.

PREVALENCE OF *CAMPYLOBACTER* SPP. IN A POULTRY AND PORK PROCESSING PLANTS

Yuliya Yushina, Dagmara Bataeva, Anzhelika Makhova, Elena Zayko

ABSTRACT
The study aimed to investigate the prevalence of *Campylobacter* spp. in different stages of poultry and pork processing in the Central region of Russia. A total of 47 *Campylobacter* isolates were obtained from 107 samples from poultry processing plants (40.2%): 87.2% were identified as *Campylobacter jejuni,* whereas 12.8% were identified as *Campylobacter coli*. The prevalence of *Campylobacter* was significantly (p <0.05) higher after evisceration in the poultry processing plant. *Campylobacter* spp.was detected in 62.7% of the equipment and environmental samples. From positive samples of *Campylobacter spp.*, 84.3% of *Campylobacter jejuni,* and 15.7% *Campylobacter coli* were observed. A total of nine *Campylobacter* isolates were obtained from 116 samples from pork processing plants (7.8%): 33.3% of them were identified as *Campylobacter jejuni* whereas 66.7% were identified as *Campylobacter coli*. Splitting and evisceration were also critical in *Campylobacter* contamination. Almost all pork carcasses were *Campylobacter* positive, and all of them were identified as *Campylobacter coli*. The prevalence of positive *Campylobacter* samples in poultry processing plants was significantly (p <0.05) higher than in pork processing plants.

Keywords: *Campylobacter jejuni; Campylobacter coli*; poultry processing; pork processing

INTRODUCTION
Campylobacteriosis is still one of the most important infectious diseases that are likely to challenge global health in the years to come **(Kaakoush et al., 2015)**. According to the World Health Organization (WHO) reports, foodborne diseases, including Campylobacteriosis, are substantial: every year, almost one in 10 people fall ill and 33 million healthy life years are lost. *Campylobacter* is one of the four key global causes of diarrhoeal diseases **(WHO, 2020)**. The Centers for Disease Control and Prevention **(CDC, 2019)** estimates *Campylobacter* infection affects 1.5 million of the U.S. residents every year. Most cases are not part of recognized outbreaks, and more cases occur in summer than in winter **(EFSA and ECDC, 2019)**. The European Food Safety Authority (EFSA) reported that campylobacteriosis is the most common zoonotic disease in the EU. In 2018, member states reported 246,571 cases. The highest occurrence was detected in chicken meat (37.5%) and turkey meat (28.2%) **(EFSA and ECDC, 2019)**. Transmission typically occurs through the consumption of undercooked poultry or handling of raw poultry **(Altekruse et al., 1999; Blaser, 1997)**.

Studies have revealed that about 50% – 70% of human campylobacteriosis can be attributed to the consumption of poultry and poultry products **(Allos, 2001).** Various studies have demonstrated high levels of *Campylobacter* in the broilers, on the broiler carcasses, and retail chickens **(Zhao et al., 2001)**. Researchers have revealed this pathogen was detected in both dirty and clean transport crates, in scalding water, and on the de-feathering machine, and the working table at the end of the working day, but not at the beginning. After defeathering, *Campylobacter* spp. was detected in all of the sampled carcasses **(Perez-Arnedo and Gonzalez-Fandos, 2019)**. During slaughter, the main critical points for carcass contamination were identified as plucking, gutting, and final washing **(Facciolà et al., 2017)**. It was established that at low positive temperatures, *Campylobacter jejuni NCTC*11168 could remain viable in minced meat for at least seven days **(Bataeva and Sokolova, 2018)**.

However, in a study of goat and ovine milk in the Czech Republic, no *Campylobacter* bacteria were detected **(Bogdanovičová et al., 2015)**.

Campylobacter spp. survival was also investigated in the poultry industry before and after cleaning and disinfection. The fat removal machine, a gutting machine, a floor, a sink, a conveyor belt, shackles, and broiler meat were analyzed, and *C. jejuni* and *C. coli* were isolated. The results showed that the prevalence of *C. jejuni* and *C. coli* was 94.5% and 5.5%, respectively **(Sánchez et al., 2017)**. In one study, the detection of *Campylobacter* on carcasses was higher than that on cloacal swabs, which could

indicate cross-contamination during the slaughtering process **(Borges et al., 2020)**.

In some European countries, flock colonization of chickens with *Campylobacter* has a clear seasonal pattern, with the highest rates seen in the summer or autumn **(EFSA, 2010)**. The reasons for the seasonal variation are not fully understood but are likely to involve the frequency and nature of exposure of the flocks to *Campylobacter* spp. There is further evidence that climatic factors, such as temperature, correlate with both broiler flock and human infections **(Jorgensen et al., 2011)**.

Also, it has been reported that *Campylobacter* exhibits a cyclical pattern of contamination, where the level of contamination consistently increases and decreases depending on the season **(Hinton et al., 2004)**. Despite poultry are an important reservoir and source of human campylobacteriosis **(Hayama et al., 2011)**, the contribution of other sources, reservoirs, and transmission warrants further research. The predominant species in poultry is *C. jejuni*, whereas the predominant species of *Campylobacter* in pigs is *C. coli* **(Fosse et al., 2009; Horrocks et al., 2009; Varela et al., 2007)**. Authors also reported that control of this microorganism must rely on careful food processing and storage of pork, rather than an on-farm approach **(Varela et al., 2007)**.

Most human infections in the U.S. are associated with *C. jejuni*, whereas in Europe, a high incidence of human infection with *C. coli* is reported.

The authors reported that the sampling points with the greatest contamination rates were after evisceration, and contamination significantly decreased after chilling and washing **(Lee, et al., 2017)**.

Studies have shown that all processing plants sampled indicated a reduction in the *Campylobacter* populations along the processing line. Also, it was shown that proper cleaning of the equipment as well as a regular influx of freshwater, and using antimicrobials at the points of intervention during processing is crucial to preventing higher contamination **(Wideman et al., 2015; Berrang and Dickens, 2000)**.

Scientific hypothesis

This study was focused on the isolation of *Campylobacter* spp. from swabs of poultry and pork carcasses, and environmental swab samples from poultry and pork processing plants. The study aimed to investigate the prevalence of *Campylobacter* spp. in the processing of poultry and pork in Russian processing plants and to compare it with the European baseline data on Campylobacter prevalence.

MATERIAL AND METHODOLOGY

Poultry and pork processing plants in the Central region of Russia were selected. Swabs from poultry and pork carcasses and environmental swab samples from processing plants were selected as objects of the study. The following sampling points on the poultry processing line were selected: evisceration, processing and preparation, and packaging. The following sampling points on the pork processing line were selected: splitting and evisceration, removal of skin, deboning, and cutting.

Sampling

Environmental samples were taken using sterile sponges (3M TM, Saint Paul, 110 Minnesota, USA). Samples were transported at 4 °C to the laboratory and processed within 24 h.

Detection of *Campylobacter* spp.

The isolation of *Campylobacter* spp. was performed according to **ISO 10272-1 (2017)**. Environmental samples were performed according to **ISO 18593 (2018)**. They were taken using sterile sponges from 100 cm^2 and homogenized in 100 mL of Bolton broth (Merck, Germany). Swabs of poultry and pork carcasses were homogenized for 20 s with 225 mL of Bolton broth. The samples were incubated at 41.5 °C for 44 h under a microaerobic atmosphere. *Campylobacter* isolation was done on modified charcoal cefoperazone deoxycholate agar (mCCDA) (Merck, Germany) and selective agar Preston under microaerobic conditions at 41.5 °C for 44 h. Confirmation of presumptive colonies was performed according to the **ISO 10272-1 (2017)** principles – typical colonies were seeded on blood agar (Oxoid, UK) and incubated at 41.5 °C for 24 h and then confirmed using biochemical tests (Oxoid, UK).

Statistical analysis

StatPlus 6.2.2.0 Software (AnalystSoft) was used. Tukey's test for the comparison of means was performed using the same program. The significance level was defined at $p < 0.05$.

RESULTS AND DISCUSSION

Presence of Campylobacter spp. in environmental samples and poultry carcasses at various stages of poultry processing.

A total of 47 *Campylobacter* isolates were obtained from 107 environmental samples and poultry carcasses (40.2%): 87.2% were identified as *C. jejuni* whereas 12.8% were identified as *C. coli* (Figure 1).

Table 1 shows the presence of *Campylobacter* at different stages of poultry processing. After evisceration, *Campylobacter* spp. was detected in 62.7% of the equipment and environmental samples. From positive samples of *Campylobacter* spp. 84.3% of *C. jejuni* and 15.7% *C. coli* was observed. The predominance of *C. jejuni* over *C. coli* has been shown by other authors **(Sánchez et al., 2017)**. In that study, the abundances of *C. jejuni* and *C. coli* were 94.5% and 5.5%, respectively. These results confirmed those reported by **Lee et al. (2017)** that the greatest contamination rates were after evisceration. According to **Facciolà et al. (2017)** during slaughter, the main critical points for poultry carcass contamination were identified by plucking, gutting, and final washing. Other authors described slaughtering and evisceration as critical points of *Campylobacter* contamination **(Gruntar et al., 2015; Sasaki et al., 2013)**.

Campylobacter spp. was not detected after deboning and cutting, but it was found after packaging. The *Campylobacter* spp. isolated during packaging was identified as *C. jejuni*.

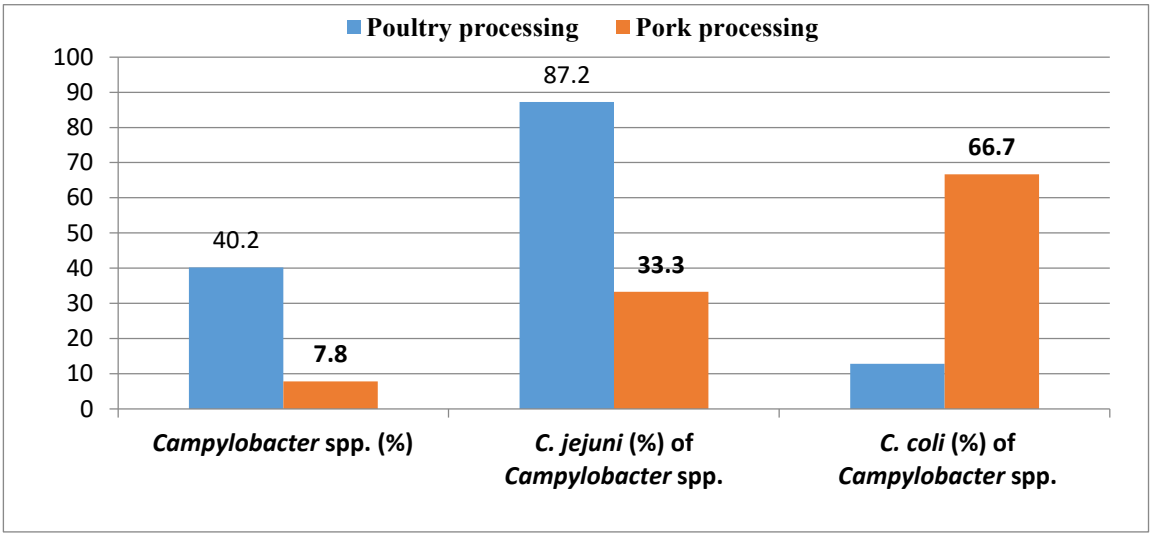

Figure 1 Prevalence of Campylobacter in poultry and pork processing plants.

Table 1 Presence of *Campylobacter spp.* in environmental samples and poultry carcasses at various stages of poultry processing.

Sampling location/Sample	*Campylobacter*/Total (%)	*C. jejuni*/Total positives (%)	*C. coli*/Total positives (%)
Evisceration	32/51 (62.7)	27/32 (84.3)	5/32 (15.7)
Bonning and cutting	0/9 (0.0)	0/0 (0.0)	0/0 (0.0)
Packaging	1/9 (11.0)	1/1 (100.0)	0/1 (0.0)
Poultry carcasses (total):	14/38 (36.8)	13/14 (93.0)	1/14 (7.0)
-cloaca	6/12 (50.0)	6/6 (100.0)	0/6 (0.0)
-legs	3/12 (25.0)	2/3 (67.0)	1/3 (33.0)
-carcasses	4/12 (33.0)	4/4 (100.0)	0/4 (0.0)
-neck	1/12 (8.3)	1/1 (100.0)	0/1 (0.0)

It is also an important contamination point due to the possible intestinal ruptures that can occur during the mechanical removal of the intestines **(Perez-Arnedo and Gonzalez-Fandos, 2019)**. Moreover, 50% of the investigated cloacal swabs samples were *Campylobacter* positive. These two stages can be related to each other and can cause cross-contamination of carcasses. Also, 5 mg of caecal content can increase the number of Campylobacter on eviscerated broiler carcasses **(Berrang et al., 2004)**. These findings support the idea of cross-contamination from contaminated equipment and work surfaces to carcass. Studies are confirming the genetic identity of the strains contaminating slaughterhouse equipment and meat products **(Elvers et al., 2011; Prachantasena et al., 2016)**.

Thirty-three percent of the investigated carcasses were *Campylobacter* positive. All *Campylobacte*r positive samples from cloacal swabs, carcasses, and necks were identified as *C. jejuni*.

However, in our research, the prevalence of *Campylobacter* was significantly (p <0.05) higher after evisceration than in carcasses. It is very important to decrease *Campylobacter* prevalence in poultry meat, because although *Campylobacter* spp. do not replicate in food **(Corry and Atabay, 2001)**, a low dose can cause an infection **(Vidal et al., 2014)**.

C. coli was detected in five environmental samples after evisceration and in the leg of one poultry sample.

Presence of Campylobacter spp. in environmental samples and pork carcasses at various stages of pork processing.

A total of nine *Campylobacter* isolates were obtained from 116 environmental samples and pork carcasses (7.8%): 33.3% of them were identified as *C. jejuni* whereas 66.7% were identified as *C. coli* (Figure 1). As reported in previous studies, *C. jejuni* prevailed in the poultry farm compared to the lower presence of *C. coli* **(Pepe et al., 2009; Peyrat et al., 2008; Wieczorek et al., 2015)**.

Table 2 shows the presence of *Campylobacter* at different stages of pork processing. After splitting and evisceration, *Campylobacter* spp. was detected in 7.4% of the equipment and environmental samples. A significant difference (p <0.05) in positive *Campylobacter* samples was found between poultry and pork evisceration. The prevalence of positive *Campylobacter* samples in poultry processing was significantly (p <0.05) higher than in pork processing. From two positive samples of *Campylobacter* spp, *C. jejuni* was observed. Environmental and equipment samples after removal of skin, deboning, and cutting were investigated. One of them was identified as *C. jejuni*, another one as *C. coli.*

Pork carcasses (neck, leg, belly, skin) were also investigated for the prevalence of *Campylobacter* spp. Almost all pork carcasses were *Campylobacter* positive, and all of them were identified as *C. coli*.

Table 2 Presence of Campylobacter spp. in environmental samples and pork carcasses at various stages of pork processing.

Sampling location/Sample	*Campylobacter*/Total (%)	*C. jejuni*/Total positives (%)	*C. coli*/Total positives (%)
Splitting and evisceration	2/27 (7.4)	2/2 (100)	0/2 (0.0)
Removal of skin	1/32 (3.1)	1/1 (100.0)	0/1 (0.0)
Bonning and cutting	1/21 (4.8)	0/1 (0.0)	1/1 (100.0)
Pork carcasses (total):	5/36 (13.9)	0/5 (0.0)	5/5 (100.0)
-neck	2/9 (22.2)	0/2 (0.0)	2/2 (100.0)
-leg	0/9 (0.0)	0/0 (0.0)	0/0 (0.0)
-belly	2/9 (22.2)	0/2 (0.0)	2/2 (100.0)
-skin	1/9 (11.1)	0/1 (0.0)	1/1 (100.0)

Our results confirm those reported by others, who found the predominant species of *Campylobacter* in pigs was *C. coli* **(Fosse et al., 2009, Horrocks et al., 2009; Varela et al., 2007)**. While the reservoirs of *Campylobacter* are recognised as both poultry and pigs **(Quintana-Hayashi and Thakur, 2012)**, *C. coli* is the main species found in pigs **(Avrain et al., 2004)**. Authors also reported that control of this microorganism must rely on careful food processing and storage of pork **(Varela et al., 2007)**. A factor that is associated with an increased risk of *Campylobacter* in pork is a high level of contamination in farms. Bacteriological study results showed that 77% of the piglets and 100% of the fattening pigs were infected with high levels of contamination, but *Campylobacter* was not detected after deboning **(Minvielle et al. 2007)**. The authors also note the importance of animal selection, transportation to the slaughterhouse, and time spent in the slaughterhouse **(Hald, Sommer and Skovgård ,2007)**.

The application of strict biosecurity measure proved to be effective in preventing the *Campylobacter spp.* contamination. There are: cleaning and disinfection of the plant equipment; a control of the entry of persons, birds, rodents or other animals; an insect control; water control; waste control **(Hansson et al., 2007; Guerin et al., 2007; Nesbit et al., 2001)**.

It was previously reported that survival during storage and under stress factors, such as microaerophilic conditions, *Campylobacter* in food products could be aerotolerant. Interestingly, a greater prevalence of aerotolerant strains (80%) was found among *C. coli* isolates as compared to *C. jejuni* isolates (6%); these strains were previously isolated from retail chicken meat, chicken livers, chicken gizzards, turkey, pork, and beef liver samples **(Karki et al., 2018)**.

Many studies describe the antibiotic resistance of *Campylobacter* strains **(Noormohamed and Fakhr, 2014)**. The increasing trend of antimicrobial resistance among *Campylobacter* strains indicates a high risk of new outbreaks **(Geissler et al., 2017)**.

Further studies are needed to investigate the antimicrobial resistance profile and aerotolerance of isolated *Campylobacter* strains. Potential approaches for the control of *Campylobacter* in processing poultry and pork plants are also necessary.

CONCLUSION

Campylobacter prevalence was estimated at poultry and pork processing plants in the Central Region of Russia. A total of 47 Campylobacter isolates were obtained from 107 samples of poultry processing (40.2%): 87.2% were identified as *C. jejuni,* whereas 12.8 % were identified as *C. coli*. The prevalence of *Campylobacter* was significantly (p <0.05) higher after evisceration in poultry processing plants: *Campylobacter spp.* was detected in 62.7% of the equipment and environmental samples. Of the positive samples of *Campylobacter* spp., 84.3% of *C. jejuni* and 15.7% *C. coli* were observed. A total of nine *Campylobacter* isolates were obtained from 116 samples of pork processing (7.8%): 33.3% of them were identified as *C. jejuni,* whereas 66.7% were identified as *C. coli*. Splitting and evisceration were a critical point of *Campylobacter* contamination. Almost all pork carcasses were *Campylobacter* positive, and all of them were identified as *C. coli*. The prevalence of positive *Campylobacter* samples in poultry processing was significantly (p <0.05) higher than in pork processing. The prevalence of *Campylobacter* was significantly (p <0.05) higher after evisceration in poultry processing plants: *Campylobacter spp.* was detected in 62.7% of the equipment and environmental samples. Among the positive samples of *Campylobacter* spp., 84.3% of *C. jejuni* and 15.7% *C. coli* was observed.

Further studies are needed to investigate the antimicrobial resistance profile and aerotolerance of isolated *Campylobacter* strains. Potential approaches for the control of *Campylobacter* in processing poultry and pork plants are also necessary.

THE DONOR PROPERTIES OF RESOURCES RESISTANCE AGAINST THE EXCITER OF WHEAT RUST WHEAT

Hanna Kovalyshyna, Yuliia Dmytrenko, Oleksandr Makarchuk, Natalia Slobodyanyuk, Mikhailo Mushtruk

ABSTRACT

A collection of soft winter wheat specimens investigated on the artificial infectious background of the leaf rust pathogen and selected resistance among them. The genetics of resistance sign in varieties and specimens were determined by hybridological analysis of F_2: Lovrin 32, KM 1485-6-8, VR 89 Bo 22, Beres, Tobarzo, 0-74-8-2, MIKM 1851-80, 4347-4, NS 326-99, 5517 A-5-5 Yr, Florida 302, VR 87 Bo 15, Matyo, NS 1308, 200-830, Polka, NS 2630/1, NS 18-30, HBE 0140-119, HBE 208-120, HBE 0303 156, HBE 0425-156, Tx91v4511, Tx92v4511, Plyska, Zernogradskaya 31, Volshebnitsa, Myronivska 40, Myronivska ostysta, Myronivska 28, Estet, Volynska napivintensivna, Kyivska 8, Expromt, Mironivska 29, Remeslivna, Garant, Selyanka, Erythrospermum 15761, Erythrospermum 12557, Erythrospermum 12735, Vympel odeskyiy during 1990–2018. The gene non-identity of the investigated donors was determined. In a variety of VR 89 Bo 22, 2 resistance genes, one of them *Lr19*, was investigated. The results of investigations of the composition of the leaf rust pathogen population by a series of isogenic lines and varieties of carriers of known effective resistance genes are presented. The high resistance against the leaf rust pathogen in the forest-steppe of Ukraine provide the genes *Lr9*, *Lr19*, *Lr37*, *Lr42* + *Lr24*, *Lr43* (*Lr21* + *Lr39*) + *Lr24*, *Lr9* + *Lr26*, *Lr10* + *Lr24*.

Keywords: wheat; gene pool; donor; infectious background; resistance genes

INTRODUCTION

Soft wheat is the leading grain crop by value in the world **(El-Khoury, 2009)**. The yield potential of this crop is not fully realized due to the damage to crops by phytopathogens. The diseases significantly reduce the yield and quality of the grain winter wheat. The gross collection losses are up to 20% annually, and in the epiphytotic years – 50% **(Novohatka, 1979)**. Breeding disease-resistant varieties are the most effective method in the struggle against wheat diseases **(Palamarchuk et al., 2019)**.

The creation of resistant varieties largely depends on the correct selection of initial material, determination of genetic factors of resistant control. However, the sources of resistance, the genetic nature sign of resistance to disease, is known identified not enough **(Dinh et al., 2020)** Therefore, the search and investigation of the immunological features of effective donors of resistance is the main problem in the creation of new competitive winter wheat varieties. Breeders need characteristic the varieties, not only by their phenotypic expression but also by their genetic characteristics recommended for hybridization **(Vyerchenko et al., 2019)**.

The leaf rust, the exciter of which is the fungus *Puccinia recondita* f. sp. *tritici*, is one of the most common diseases of wheat in Ukraine and the world. Breeding efficiency for leaf rust resistance can be improved by using different *Lr* resistance genes. More than 90 *Lr* genes are registered in the International Catalog Gene Symbol Directory, half of which are alien to date **(McIntosh, et al., 2003; McIntosh, et al., 2007; McIntosh, et al., 2008; McIntosh, et al., 2009; McIntosh, et al., 2010; McIntosh, et al., 2011; McIntosh, et al., 2012; McIntosh, et al., 2014; McIntosh, et al., 2016; McIntosh, et al., 2017; McIntosh, et al., 2018; McIntosh, et al., 2019)**. It is a great interest to investigate the resistance of wild relatives and endemic wheat species, identifying among them new immune forms and new effective resistance genes.

The immunity of *Triticum durum* and *T. dicoccum* must be widely used in the breeding of soft wheat for resistance to leaf rust **(Leonova et al., 2013)**. There are no reliable sources of resistance against this pathogen in the culture. But breeders are most interested in resistant varieties found among soft and durum wheat. World collections provide the possibility to use the achievements of breeding in different countries **(Kovalyshyna and Dmytrenko, 2017)**.

The investigation resistance against the disease of the gene pool of wheat is an important task, which can best be a solution from the attitude of the theory of co-evolution of

the plant and pathogen **(Mushtruk et al., 2020)**. Only based on such testimony can the right approach be made to the choice of sources of stability and the most effective method of breeding.

Scientific hypothesis

The scientific hypothesis is founded on identifying nature inheritance and manifest resistance genes to exciter of leaf rust. It is attaining by investigation of composition population exciter of disease and identifies resistance genes at collectible samples soft wheat. It is making it possible to increase the resistance gene pool and creating new heterogeneous varieties of soft wheat.

MATERIAL AND METHODOLOGY

The research material was winter wheat the collection specimens received from the World Collection Federal Center for Plant Genetic Resources, All-Russian Institute of Plant Genetic Resources, The Plant Production Institute named after V. Ya. Yuryev of NAAS and varieties of winter wheat from research institutions in Ukraine were materials for investigation.

The investigations were conducted under the conditions of artificial inoculation by the agent of leaf rust in the field infectious nursery of the Mironivka wheat institute named after V.M. Remeslo. A local and synthetic population of the pathogen obtained from the Institute of Plant Protection of the National Academy of Sciences of Ukraine was used for creating an artificial infectious background. The wheat plants contaminated with leaf rust spores in the field in the phase of plant exit into the tube according to the method of **(Bober et al., 2020)**. The variety of Mironivska 10 susceptible to this pathogen is used as an accumulator of infection in experiments. The resistance of plants against the disease was determined on a scale resistance of plants against the disease was determined on a scale **(Strahov, 1951)**, according to which the affection is expressed in relative percentages of leaf area covered with pustules of the pathogen **(Geshele, 1971)**.

Experiments on the evaluation of varieties and collections samples of wheat for disease resistance using artificial inoculation were laid out according to the schemes used in the system of state variety testing of crops **(Tkachyk, 2014)**, using the method developed by us to evaluate the resistance of wheat varieties against pathogens of major diseases **(Trybel et al., 2010)**.

The method of intraspecific hybridization, which was carried out by the "twell method" following the method used for creating the hybrid material of winter wheat **(Merezhko et al., 1973)**.

To identify resistance genes and the nature of the inheritance of the trait of resistance to the agent of leaf rust, using the method of hybridological analysis **(Radchenko and Odintsova, 2008)**. All samples were crossed with tester lines - carriers of known effective resistance genes MC Nair 2203 (*Lr9*), Flex (*Lr19*), Osage (*Lr24*) to identify effective resistance genes. Samples were crossed with each other according to an incomplete diallel scheme to determine the allelic ratio of genes.

Statistical analysis

To obtain information on the number and interaction of resistance genes, the obtained ratios of classes of resistant and susceptible plants (actual) were compared with one of the theoretically expected cleavages using the chi-square (χ^2) correspondence criterion.

The assumption that the difference between the actually obtained and theoretically expected splits is random was rejected if $\chi^2_{fact.}$ exceeded the critical $\chi^2_{st.}$ ($\chi^2_{0.05} = 3.84$). The error of results in statistical analysis $p = 0.05$. Statistical processing was performed in Microsoft Excel 2016 in combination with XLSTAT. Values were estimated using mean and standard deviations.

RESULTS AND DISCUSSION

The greatest immunological diversity of forms can be detected in the centers of co-origin of the host plant and the pathogen according to the coevolution theory of the host plant and the pathogen **(Leary et al., 2018)**. The center of origin of wheat is located in the Trans-Asian Center, which includes the Caucasus, which plays a leading role in it **(Dorofee, 1972)**. There is also a center for leaf rust formation **(Leppik, 1970)**.

In the work of scientists discovered the pattern in the distribution of immune forms among wheat species for the first time. He considered where there is a species or racial specialization of the pathogen, immune forms and varieties can be found. The Caucasus is the center of origin of many endemic, rust-resistant forms, and should occupy the first place in the globe in terms of the abundance of genetic and physiological types of wheat pointed **(Khaneghah et al., 2018)**. The *Triticum timopheevii* with complex resistance against all types of rust, powdery mildew, and soot was found in the Caucasus.

10 highly resistant endemic species of wheat and its relatives with the highest immunity to rust, in particular: *Triticum monococcum*, *T. timopheevii*, *T. militinae*, *T. Zhykovski*, *T. fungicidum*, *Haynatriticum*, *Aegilops umbellulata* are distinguished **(Varella et al., 2017)**.

In the work **(Casey et al., 2016)** found forms immune to rust, powdery mildew, and soot among *Triticum dicoccum*.

The principles of researching gene pool of wheat resistance against leaf rust, based on **(Flor, 1971)** theory of "gene-for-gene", developed **(Lodgering, Johnston and Hendricks, 1974; Berlyand-Kozhevnikov et al., 1985)**.

The majority number of leaf rust resistance genes identified in cultivated wheat varieties are derived from its wild relatives and endemic wheat species. The almost half of the known *Lr* genes are alien and transferred to *Triticum aestivum* from different types of wheat, egilops, couch grass, elimus according to the information given in the gene symbol catalogs **(McIntosh et al., 2003; McIntosh et al., 2007; McIntosh et al., 2008; McIntosh et al., 2009; McIntosh et al., 2010; McIntosh et al., 2011; McIntosh et al., 2012; McIntosh et al., 2014; McIntosh et al., 2016; McIntosh et al., 2017; McIntosh et al., 2018; McIntosh et al., 2019)**. The effective sources of resistance genes against the causative agent of leaf rust are *aegilops speltoides* – genes *Lr28, Lr35, Lr36, Lr47, Lr51, Lr66; Aegilops tauschii – Lr4, Lr21, Lr22a, Lr32, Lr39, Lr42; Aegilops umbellulata – Lr9, Lr76; Aegilops triuncialis – Lr58, LrTr; Aegilops ventricosa – Lr37; Aegilops kotschyi – Lr54; Aegilops sharonensis – Lr 56;*

Aegilops peregrine – Lr59; Aegilops neglecta – Lr62; Aegilops geniculate – Lr57; Elymus trachycaulis – Lr55; Secale cereale – Lr25, Lr26, Lr45; Thinopyrum elongatum – Lr19, Lr29, Lr24; Triticum timopheevii – Lr18, Lr50; Triticum spelta – Lr44, Lr65, Lr71; Triticum dicoccoides – Lr53, Lr64; Triticum timopheevii spp. *viticulosum – LrTt1; Triticum turgidum – Lr61;Triticum monococcum – Lr63.* All found effective resistance genes except *Lr10* and *Lr23* are alien.

The new highly efficient resistance genes against the local leaf rust population: *LrAc1*, *LrAc2* – from *Aegilops cylindrical*, *LrTe1*, *LrTe2* – from *Triticum erebuni* and *LrAd1*, *LrAd2* – from amphidiploid Ad4 (*Triticum dicoccoides* x *Triticum tauschii*) are identified by **Babaiants (2011)**. The collection samples obtained from the National Center for Plant Genetic Resources of Ukraine, varieties of different breeding establishments of Ukraine, and Mironivka Institute of Wheat named after V. M. Remeslo were investigated to select sources of resistance to leaf rust under conditions infectious background of the pathogen on a specially assigned phytoplot.

The effective resistance genes for the Forest Steppe zone of Ukraine leaves: *Lr9*, *Lr19*, *Lr24*, *Lr25*, *Lr37*, *Lr42* + *Lr24*, *Lr43* (*Lr21* + *Lr39*) + *Lr24*. It was installed as result investigations of the composition population leaf rust on a series of isogenic lines of Thatcher variety and varieties of carriers of known effective resistance genes (Table 1-2).

There was a slight lesion of *Lr19* gene carrier, indicating that clones were virulent against it. In some years, there was a slight lesion of the pathogen and on varieties protected by the *Lr9* gene. The varieties protected by the *Lr24* gene lose their stability. The *Lr37*, *Lr42* + *Lr24*, *Lr43* (*Lr21* + *Lr39*) + *Lr24*, *Lr9* + *Lr26*, *Lr10* + *Lr24*, *Lr19* + *Lr25* genes have shown high efficiency in recent years.

Genes show the high efficiency against the local population of the brown rust pathogen in the Forest-steppe of Ukraine: *Lr9*, *Lr19*, *Lr37*, *Lr42* + *Lr24*, *Lr43* (*Lr21* + *Lr39*) + *Lr24*, *Lr9* + *Lr26*, *Lr10* + *Lr24* **(Kovalyshyna, 2013)**, *Lr24*, *Lr25*, *Lr28*, *Lr34*, *Lr36*, *Lr41*, *Lr42* are determined by results of investigations domestic researchers **(Lisova, 2012)**. The virulence genes against *Lr9*, *Lr19*, *LrAc1*, *LrAc2*, *LrTe1*, *LrTe2*, *LrAd1*, *LrAd2* are rarely found in the Steppe of Ukraine **(Babaiants, 2011)**.

The genetics of the trait resistance of these samples was able to determine by hybrid analysis of F_2 (Table 3). The resistance of variety the Lovrin 32, KM 1485-6-8, VR 89 Bo 22, Beres, Tobarzo, Mironivska 40, Mironivska ostysta, Estet, Mironivskay 28, Volynska napivintensivna, Kyivska 8 is controlled by two dominant genes (15 : 1) (confidence probability p = 0.95). The resistance to the agent of leaf rust is controlled by two genes, one of which is dominant and one is recessive (13 : 3) in varieties 0-74-8-2, MIKM 1851-80, 4347-4, NS 326-99, Pliska, 5517 A-5-5 Yr, Florida 302, VR 87 Bo 15, Matyo, HBE 0140-119, HBE 208-120, Expromt, Mironivska 29, Remeslivna, Garant, Selyanka (confidence probability p = 0.95). Two complementary genes (9 : 7) control resistance in samples NS 1308, 200-830, Polka, Zernogradskaya 31, Volshebnitsa, Vympel odeskyiy, Erythrospermum 15761 (confidence probability p = 0.95). Two duplicate recessive resistance genes (7 : 9) identified in samples NS 2630/1,

Table 3 Genetic characteristics of leaf rust resistance donors (Mironivskyiy Institute of Wheat named after V. M. Remeslo, NAAS, 1990 – 2018).

Resistance donors	Cleavege by phetype (resistant: susceptible)	The nature of interaction genes
Lovrin 32, Myronivska 40, Myronivska ostysta, KM 1485-6-8, VR 89 Bo 22, Myronivska 28, Estet, Volynska napivintensyvna, Kyiivska 8, Beres, Tobarzo 0-74-8-2, MIKM 1851-80, 4347-4, Plyska, NS 326-99, 5517 A-5-5 Yp, Florida 302, VR 87 Bo 15, Expromt, Myronivska 29, Remeslivna, Garant, Selyanka, Matyo, HBE 0140-119, HBE 208-120	15: 1 9 *A-B-* : 3 *A-bb* :3 *aaB-* : 1 *aabb*	Genes *A* and *B* are manifesting equally. Resistance dominates in both cases (two duplicates dominance genes)
	13: 3 9 *A-B-* : 3 *A-bb* : 3 *aaB-*: 1 *aabb*	Genes *A* and *B* are manifesting equally. Resistance dominates in case *AA* and recessive *bb* (two duplicates genes, one dominance and one recessive)
NS 1308, Erytrospermum 15761, 200-830, Vympel odeskyii, Zernogradskaya 31, Volshebnitsa, Polka	9: 7 9 *A-B-* :3 *A-bb* : 3 *aaB-* : 1 *aabb*	Genes *A* and *B* are interacting complementary. The presence of *A* or *B* alone is not sufficient to demonstrate the resistance of the phenotype (complementation of two dominant genes)
Erytrospermum 12557, Erytrospermum 12735, NS 2630/1, NS 18-30, Tx 91 v 4511	7: 9 9 *A-B-* : 3 *A-bb* : 3 *aaB-* : 1 *aabb*	Genes *a* and *b* are manifested equally. Recessive resistance in both cases (two duplicate recessive genes)
HBE 0303 156, HBE 0425-156	3: 1 1 *A* : 2 *Aa* : 1 *aa*	One dominant gene
Tx 92 v 4511	1 : 3 1 AA : 2 Aa : 1 aa	One recessive gene

NS 18-30, Tx 91v4511, Erythrospermum 12557, Erythrospermum 12735 (confidence probability $p = 0.95$). One dominant resistance gene (3 : 1) contains samples HBE 0303 156, HBE 0425-156, and the collection sample Tx 92v4511 contains one recessive resistance gene against leaf rust (1 : 3) (confidence probability $p = 0.95$).

The splitting observed, by crossing sources of resistance among themselves in all combinations of F_2, which confirms the non-identity of genes in these donors. The crossing of resistance donors with testers of known efficient genes *Lr9*, *Lr19*, *Lr24* observed splitting into resistance and unresistance except for the combination of VR 89 Bo 22 x Flex (*Lr19*). In ones, splitting into resistance and unresistance phenotypes was not detected. This indicates that VR 89 Bo 22 contains the *Lr19* genes (confidence probability $p = 0.95$).

The genetic control of the resistance sign in 42 donors was investigated. The variety VR 89 Bo 22 contains the

Lr19 genes. Other donors of this sign have resistance genes independent of the known effective ones, which makes it possible to replenish the leaf rust resistance gene bank and create new heterogeneous winter wheat varieties on this basis.

Successful breeding requires a clear understanding of the evolution of the pathogen and host-pathogen interactions, of the types of resistance, methods of material evaluation, resistance genes, and the nature of inheritance of this trait and its relationship to other economic and biological traits. It is only based on such testimony that the right approach to the choice of sources of resistance and the most effective method of breeding work can be worked out.

CONCLUSION

The more than 200 collections samples and varieties of winter wheat of different ecological and geographical origins were evaluated for resistance to leaf rust on the artificial infectious background of its pathogen during 1990 – 2018. 42 samples were identified that examined the genetics of resistance to the disease among them. The samples: Lovrin 32, KM 1485-6-8, VR 89 Bo 22, Beres, Tobarzo, 0-74-8-2, MIKM 1851-80, 4347-4, NS 326-99, 5517 A-5-5Yr, Florida 302, VR87Bo15, Matyo, NS 1308, 200-830, Polka, NS 2630/1, NS 18-30, HBE 0140-119, HBE 208-120, HBE 0303 156, HBE 0425-156, Tx91v4511, Tx92v4511, Plyska, Zernogradskaya 31, Volshebnitsa, Myronivska 40, Myronivska ostysta, Myronivska 28, Estet, Volynska napivintensivna, Kyivska 8, Expromt, Myronivska 29, Remrslivna, Garant, Selyaynka, Erythrospermum 15761, Erythrospermum 12557, Erythrospermum 12735, Vympel odeskyiy contain resistance genes are independent of each other and known to be effective (confidence probability $p = 0.95$). In the variety VR 89 Bo 22 one of the genes *Lr19*. This makes it possible to replenish the leaf rust resistance gene bank and create new heterogeneous varieties of winter wheat.

As a result of studying the composition of the leaf rust population on a series of isogenic lines of Thatcher variety and varieties of carriers of known effective resistance genes, we determined that the resistance genes of the forest-steppe zone of Ukraine remain: *Lr9*, *Lr19*, *Lr24*, *Lr25*, *Lr37*, *Lr42+Lr24*, *Lr43* (*Lr21* + *Lr39*) + *Lr24*.

As a result of research, it was found that the wheat variety Myronivska Ukrainian selection is quite productive in comparison with other varieties and resistant to pathogens of various diseases, especially to the pathogen (brown rust).

EFFECTS OF MEAT AND PROCESSED MEAT CONSUMPTION ON THE LIPID PROFILE IN THE POPULATION WITH CARDIOVASCULAR DISEASES

Jana Kopčeková, Jana Mrázová, Martina Gažarová, Marta Habánová

ABSTRACT

Meat represents an important source of high-quality dietary protein for a large proportion of the global population. Also, red meat, in particular, significantly contributes to the intake of a wide range of micronutrients, including iron, zinc, selenium, vitamin D, and vitamin B12. Excessive consumption of meat and meat products is often associated with overconsumption of energy and fat, resulting in excess weight, obesity, and an increased risk of chronic diseases, such as cardiovascular disease and type 2 diabetes. This study aims to evaluate the relationship between meat and processed meat consumption frequencies and lipid profile in a group of 800 randomly selected patients hospitalized in the Cardiocentre Nitra. Patients were 20 – 101 years, (men, the average age was 61.13 ±10.47 years). The data necessary for the detection of dietary habits were obtained by a questionnaire method. Statistical comparisons between groups were made utilizing a one-way analysis of variance (one-way ANOVA) followed by Tukey's post hoc test. Our results show, that most respondents consume meat 1 – 2 times per week, while we did not notice a significant effect (p >0.05) of the type of meat on the lipid profile. The highest T-C, LDL-C, and TG values were seen in men who consume pork 3 – 4 times per week. Statistically significant was only the effect of pork meat on total cholesterol and triglycerides (p <0.05). In the consumption of beef and poultry, there was a non-significant effect on biochemical parameters of blood (p >0.05). We recorded a significant effect (p <0.05) of the consumption of frankfurters between consumption 1 – 2 times per week and 3 – 4 times per week. Up to 40.2% of respondents consume salami 3 – 4 times per week, and we recorded a significant effect on LDL levels between consumption 1 – 2 times per week and sometimes (p <0.05). Respondents who consume sausage, headcheese, and others products 1 – 2 times a week have non-significant higher T-C, LDL, TG, and lower HDL compared to less frequent consumption. High consumption of meat, mainly pork and processed meat seems to be associated with higher levels of total cholesterol, LDL cholesterol, and triglycerides.

Keywords: meat; processed meat; cardiovascular disease; lipid profile; dietary habits

INTRODUCTION

The incidence of cardiovascular diseases (CVD) is rapidly increasing worldwide and is currently considered to be the leading cause of death in both developing and developed countries **(Gaziano et al., 2010; Mittal and Singh, 2010)**.

Nutrition is widely recognized as a crucial driver of chronic disease **(Mozaffarian, 2016)**. Dietary habits influence many risk factors for cardiometabolic health, leading to type 2 diabetes, stroke, and heart disease, which are among the leading causes of death globally. Collectively, these risk factors associated with poor quality diet pose substantial health and economic burdens, and studies have shown that dietary factors are one of the main causes of the global burden of disease (measured as disability-adjusted life years) **(GBD 2016 Risk Factors Collaborators, 2016)**.

Most people all over the world eat meat, and meat is central to Western diets **(Pfeiler and Egloff, 2018)**. Consumption of red meats (meats of mammalian origin including beef, pork, and lamb) and processed meats (meats transformed through salting, curing, fermentation, smoking, or other processes to enhance flavor or improve preservation) has been increasing rapidly worldwide **(Godfray et al., 2018; Willett et al., 2019)**.

The epidemiologic literature usually classifies the meat consumed as ”red”, ”white”, and processed meat. Although it does not exist a clear classification of meat and subtypes, in general, all meats obtained from mammals are red meats because they contain more myoglobin than white meat (obtained from chicken or fish) **(Clonan, Roberts and Holdsworth, 2016)**. Processed meat refers to any meat that has been transformed through one or several of the following processes: salting, curing, fermentation, smoking, or other processes to enhance flavor or improve preservation. Most processed meats are made from pork or beef, but may also include other red meats, poultry, offal, or meat by-products such as blood. It is also important to

distinguish between industrial processing and household preparations. As there is a huge variety of processed meat products, it is difficult to sort them into categories **(Santarelli et al., 2008)**.

Although consumption of red meat is valuable for the source of protein, iron, vitamin B12, and other vitamins B in the human diet **(Pereira and Vicente, 2013; Salter, 2018)**, however, evidence from epidemiological studies suggests that higher consumption of red meat and processed meat is associated with a higher risk of developing type 2 diabetes mellitus **(Micha, Michas and Mozaffarian, 2012; Pan et al., 2013)** cardiovascular disease (CVD), **(Micha and Mozaffarian**, **2010)** and certain cancers **(Lippi, Mattiuzzi and Cervellin, 2016; Klurfeld, 2015; Wu et al., 2016)**.

Thus, a recent meta-analysis indicates that higher consumption of red meat and processed meat is associated with an increased risk of total, cardiovascular, and cancer mortality **(Wang et al., 2016)**. Several hypotheses have been formulated to explain the potential association of meat intake (mainly processed meat) with the risk of CVD. For instance, the addition of salt or preservatives to meat for conservation purposes may increase the sodium and nitrate content of meat (processed meats could contain about 400% more sodium and 50% more nitrates per g, although this depends strongly on the type of meat and the methods used) **(Linseisen et al., 2006)**.

Nevertheless, findings from randomized controlled trials assessing the effect of red meat intake on CVD risk factors are inconsistent **(Maki et al., 2012; O'Connor et al., 2017)**. Increased cardiovascular risk related to high consumption of red and processed meat has been linked to their high content of saturated fatty acids (SFA) and cholesterol **(Mozaffarian et al., 2010; Rohrmann and Linseisen, 2016; Clonan, Roberts and Holdsworth, 2016)**. Although the recommendation about dietary cholesterol has become obsolete and the role of saturated fatty acids is currently being reconsidered **(Fernandez, 2012; Lawrence, 2013; Mozaffarian and Ludwig, 2015)**, few consumers are up to date regarding these topics.

Scientific hypothesis

This study aims to evaluate the relationship between meat and processed meat consumption frequencies and lipid profile in a group of randomly selected patients with cardiovascular diseases. We assume that a high-frequency consumption of meat and especially processed meat will be associated with higher levels of total cholesterol (T-C), LDL cholesterol (LDL-C), and triglycerides (TG).

MATERIAL AND METHODOLOGY

We evaluated the relationship between meat and meat products consumption frequencies and lipoproteins concentration in a group of randomly selected patients hospitalized in the Cardiocentre Nitra. This study was conducted according to the guidelines of the Declaration of Helsinki and approved by the Cardiocentre Nitra and the Ethics Committee of the Specialized Hospital St. Zoerardus Zobor, protocol number 10.6.2014. Patients were 20 – 101 years, (men, the average age was 61.13 ±10.47 years). Selected respondents have either overcome the *myocardial infarction* or were diagnosed with *angina pectoris* and hospitalized after a procedure so-called catheterization. The data necessary for the detection of dietary habits were obtained by a questionnaire method. The questionnaire was applied individually by a single interviewer. The questionnaire was anonymous, its completion was voluntary with only one response to be circled for each question. The questionnaire contained two parts. The first part included questions concerning the socio-demographic situation of the subjects, body height and weight, physical activity, use of tobacco, and to any changes that took place in the participant's. Based on the data on body height and weight, the Body Mass Index (BMI) was calculated for each of the participants by a standard formula. The second part of the questionnaire concerning the analysis of selected dietary habits: number of the consumed meals, their regularity, snacking between the meals, kinds of the consumed snacks, and eating frequency of selected groups of food products. Data collection was carried out simultaneously with a somatometric and biochemical examination of the respondents ensured by the Cardiocentre Nitra. The lipid profile in blood serum was measured by automatic biochemical analyzer BioMajesty® JCA-BM6010/C (DiaSys Diagnostic System GmbH). The following parameters were evaluated: total cholesterol (T-C), LDL cholesterol (LDL-C), HDL cholesterol (HDL-C) and triacylglycerols (TG) because these parameters are considered to be one of the major risk factors for cardiovascular diseases.

Statistical analysis

Data were expressed in figures as mean ± standard deviation (SD) and statistical comparisons between groups were made utilizing one-way analysis of variance (one-way ANOVA) followed by Tukey's post hoc test. Significance was accepted when $p < 0.05$. The program STATISTICA Cz version 10 (TIBCO Software Inc., Palo Alto, California, USA**)** belonging to the available statistical programs and MS Excel 2007 (Microsoft Corporation, Redmond, Washington, USA) was used.

RESULTS AND DISCUSSION

Table 1 and Table 2 describes the basic and demographic statistical characteristics of the study population.

Meat consumption

A well-balanced diet is an important element for health and wellbeing through the whole life span **(Gille, 2010; Löser, 2014)**. It is still widely acknowledged that lean red meat is an important complete protein source, in addition to contributing to essential micronutrient requirements, particularly iron, zinc, and B vitamins **(Biesalski, 2005; McAfee et al., 2010; Webster-Gandy et al., 2012; Pereira and Vicente, 2013)**.

Most participants consumed meat regularly. Only 1 man indicated they were vegetarian. Figure 1 shows the consumption frequency of different kinds of meat as stated by the participants of the study. Table 3 shows the effect of the frequency of consumption of meat on the lipid profile. Pork and poultry were consumed most often: 70.7% (pork) and 63.9% (poultry) of the participants indicated that they consumed these meats 1 – 2 times per week.

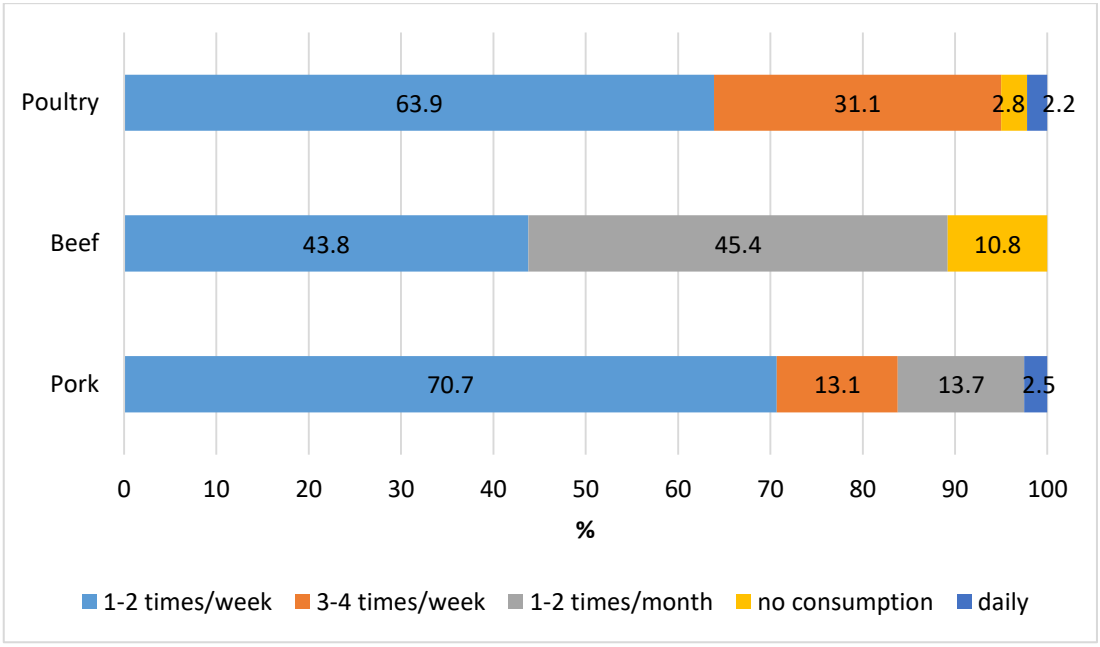

Figure 1 Percentages of consumption frequencies of meat of all respondents (n = 800).

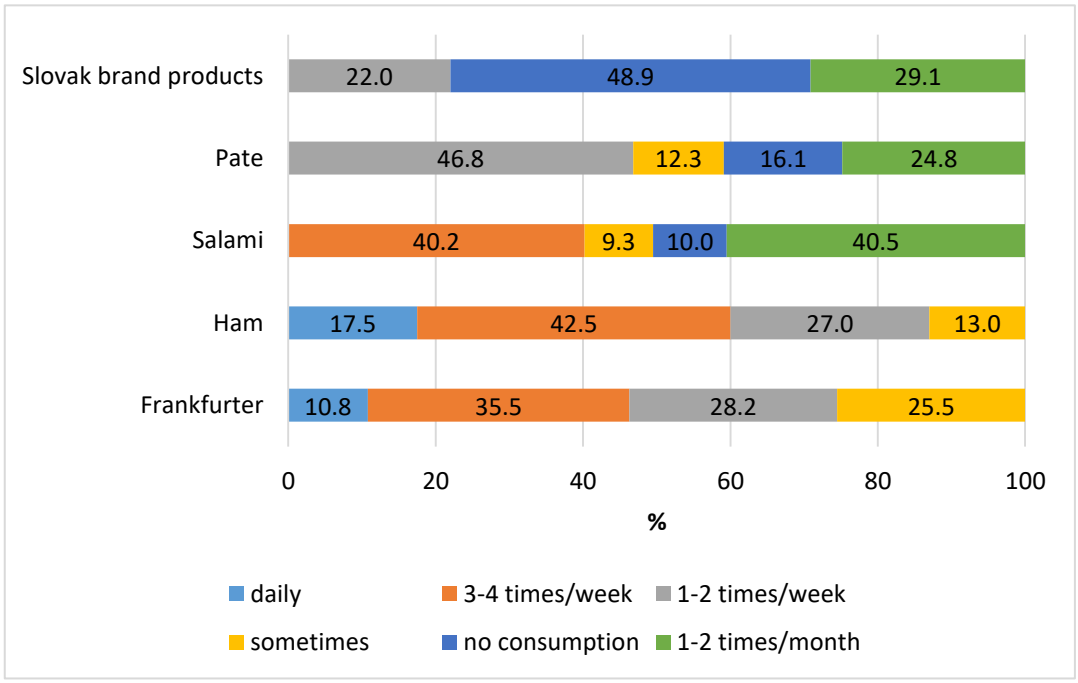

Figure 2 Percentages of consumption frequencies of meat products of all respondents (n = 800).

Table 1 Basic characteristics of study participants (n = 800).

Characteristic	Average ±SD	Min	Max
Age (yrs)	61.13 ±10.47	20.00	101.00
Height (m)	1.75 ±0.07	1.57	1.94
Weight (kg)	90.67 ±15.23	58.00	178.00

1 – 2 times per week	4.55 ±0.07	2.57 ±0.43	1.19 ±0.03	1.74 ±0.05
p – value	>0.05	>0.05	>0.05	>0.05

Note: TC – total cholesterol; (LDL-C) – LDL cholesterol; (HDL-C) – HDL cholesterol; TG – triglycerides; [a]Significant difference between between 1 – 2 times per week and 3 – 4 times per week; [b]Significant difference between between 1 – 2 times per week and 1 – 2 times per month.

Similarly, **Schmid et al. (2017)** found out that, the consumption frequency of beef, pork, and poultry of elderly Swiss population is the highest, with ≥50% of the participants consuming these types of meats at least once a week. **Kopčeková et al. (2015)** in 204 patients with cardiovascular diseases have recorded consumption of meat more than four times per week in 60.28% of men, while more than 30% of men eat meat daily. Respondents indicated poultry and pork as the most commonly consumed meat. **Escriba-Perez et al. (2017)** monitored the consumption of meat in 800 respondents aged 25 to 75 years. Most commonly consumed was chicken, which consumed up to 90.87% of respondents at least once a week. The second most frequently consumed was beef (63.62%), and the third was pork (52.62%).

High concentrations of total cholesterol, LDL cholesterol, and triacylglycerols indicate that the individual is at risk for the onset of cardiovascular disease **(Wooton and Lynne, 2017)**. Elevated serum LDL-C is a long-established risk factor for the development of heart disease; however, the relationship between serum concentrations of LDL-C and dietary cholesterol is not clear **(Zachary et al., 2017)**. Reducing high blood cholesterol is thus important for CVD prevention **(Grundy et al., 1990; Cohen et al., 2006)**. LDL-C is a measure of the total cholesterol content of LDL particles, reflecting both the number of LDL particles and their cholesterol content. Most current guidelines include LDL-C as a primary target for initiating and adjusting lipid-lowering interventions **(Stone et al., 2014; Jacobson et al., 2014)**.

Table 4 Effect of the frequency of consumption of selected processed meat on lipid profile.

Note: SD – standard deviation; Min – minimum value; Max – maximum value; TC – total cholesterol; (LDL-C) – LDL cholesterol; (HDL-C) – HDL cholesterol; TG – triglycerides; [a]Significant difference between 1 times per week and 2 – 3 times per week; [b]Significant difference between 1 times per week and daily; [c]Significant difference between 2 – 3 times per week and sometimes; [d]Significant difference between 1 – 2 times per week and sometimes.

Red meat intake is commonly considered a risk factor for CVD because of its saturated fat and cholesterol contents **(Rohrmann and Linseisen, 2016)**.

Our results show, that most respondents consume meat 1 – 2 times per week, while we did not notice a significant effect (p >0.05) of the type of meat on the lipid profile.

The highest T-C, LDL-C, and TG values were seen in men who consume pork 3 – 4 times per week. Statistically, significant was the only effect of pork meat on total cholesterol and triglycerides (p <0.05). In the consumption of beef and poultry, there was a non-significant effect on biochemical parameters of blood (p >0.05). **Kopčeková et al. (2015)** in 204 patients with cardiovascular diseases found in both men and women in significantly higher values of HDL for the less frequent consumption, while the values of triglycerides and LDL cholesterol were higher for more frequent consumption. **Kontogianni et al. (2008)** found that a high intake of red meat (more than 8 servings/month) was associated with an increased risk of acute coronary syndrome, but low income (less than four servings/month) showed no association. A recent meta-analysis of 24 randomized controlled trials assessing the effects of red meat intake on CVD risk factors concluded that ≥0.5 serving/day of red meat did not influence blood lipids, lipoproteins, or blood pressure in comparison with <0.5 serving per day **(O'Connor et al., 2017)**. According to **Guasch-Ferré et al. (2019)** findings from the present systematic review and meta-analysis showed that total red meat intake did not differentially influence blood lipids and apolipoproteins, except triglycerides, when all comparison diets were analyzed together.

Processed meat consumption

Processed meat includes meat products that have been modified to change the taste or extend shelf life through curing, smoking, salting, or adding preservatives. Frequently consumed examples are: ham, sausages, salami, bacon, hot dogs, corned beef, beef jerky, ham, canned meat, and meat-based sauces **(Rohrmann et al., 2013; Clonan, Roberts and Holdsworth, 2016)**. Accumulating evidence links excessive consumption of processed meat, and to a lesser extent unprocessed red meat, to an increased risk of obesity, diabetes, cardiovascular diseases, and some cancers **(Micha and Mozaffarian, 2010; Zeng et al., 2019)**.

Figure 2 shows the consumption frequency of different kinds of processed meat as stated by the participants of the study. Table 4 shows the effect of the frequency of

consumption of selected processed meat on the lipid profile.

Most respondents consume frankfurters (hot dogs) 3 – 4 times per week (35.5%) or 1 – 2 times per week (28.2%). Approximately 11% of respondents consume frankfurters daily, which is associated with non-significant higher LDL and lower HDL levels (p >0.05). We recorded a significant effect (p <0.05) of the consumption of frankfurters on the lipid profile. Almost half of the respondents consume meat pate 1 – 2 times per week and 24.8% only 1 – 2 times per month. Most respondents consume ham 3 – 4 times per week (42.5%), daily consumption of ham was recorded in 17.5% of patients. Different frequency of ham and meat pate consumption show non-significant changes for the lipid profile (p >0.05). Up to 40.2% of respondents consume salami 3 – 4 times/week, and we recorded a significant effect on LDL levels between consumption 1 – 2 times/week and sometimes (p <0.05). We also monitored the consumption of traditional Slovak brand products (sausage, headcheese, and others). Processed meats such as sausages have a higher content of saturated fatty acids and cholesterol than fresh red meat; reaching the proportion of fat in sausages more than 50% of weight **(Lajous et al., 2014)**. Almost half of the respondents (48.9%) state that they do not consume sausage, headcheese, and others at all. 29.1% of patients consume this product 1 – 2 times per month and 22.0% 1 – 2 times per week. Respondents who consume sausage, headcheese, and other products 1 – 2 times a week have non-significant higher T-C, LDL, TG, and lower HDL compared to less frequent consumption.

Micha and Mozaffarian (2010) in their meta-analysis of 20 studies (17 prospective cohorts and 3 cases control studies) that included 1218380 individuals concluded that intake of processed, but not red, meat was associated with an increased incidence of coronary heart disease and the authors speculate that the higher sodium and nitrate content of processed meat might contribute to their impact on CVD. This investigation in EPIC, including nearly half a million participants across 10 European countries and more than 5000 cardiovascular events, confirms that consumption of processed meat is strongly associated with CVD risk, and that consumption of unprocessed red meat has little to no association **(Rohrmann et al., 2013)**. **Watson and Preedy (2013)** report the results of research that focused on the effect of regular consumption of processed red meat (25, 75 grams or more per day) in 37035 healthy people. Probands who consumed 75 or more grams of meat products per day were 28% more likely to have heart failure than those who consumed less than 25 grams of meat products per day. Probands who consumed the most meat products had at least twice the risk of dying from CVD compared to those who consumed them.

CONCLUSION

In our study, we observed the associations between consumption of meat and meat products and lipid profile in a group of randomly selected patients with cardiovascular disease. Most participants consumed meat and meat products regularly. High consumption of meat, mainly pork and processed meat seems to be associated with higher levels of total cholesterol, LDL cholesterol, and triglycerides. This study offers support to the perception that food consumption is an important determinant in cardiovascular disease and its risk factors. As diet is a modifiable CVD risk factor, health promotion activities should consider specific advice on lowering processed meat consumption and, to a lesser extent, red meat consumption. Results like ours strongly suggest that to accurately investigate this relationship in the future, both red and processed meat must be analyzed separately. Further studies are needed to examine the role of meat and meat products in the prevention and management of cardiovascular diseases. A healthy lifestyle, including a healthy diet is the best strategy for the prevention of cardiovascular disease and other diseases.

DIETARY SUPPLEMENTATION WITH MAGNESIUM CITRATE MAY IMPROVE PANCREATIC METABOLIC INDICES IN AN ALLOXAN-INDUCED DIABETES RAT MODEL

Olena Shatynska, Oleksandr Tokarskyy, Petro Lykhatskyi, Olha Yaremchuk, Iryna Bandas, Andrii Mashtalir

ABSTRACT

The purpose of the current study was to evaluate the protective properties of dietary magnesium supplementation on pancreatic tissue of rats with alloxan-induced *diabetes mellitus*. Twenty-five male Wistar rats were split into five groups (control, diabetes, diabetes with 100 mg Mg daily, diabetes with 250 mg Mg daily, diabetes with 500 mg Mg daily) with feeding supplementation starting on day 1, diabetes induction on day 21, and animal sacrifice on day 30. Fasting glucose in blood serum was measured on days 21, 25, 27, and day 30. Glucose metabolism enzymes, namely, lactate dehydrogenase and glucose-6-phosphate dehydrogenase, were measured in pancreatic tissue upon the sacrifice, as well as lipid peroxidation, antioxidant system protective enzymes (catalase and superoxide dismutase), and glutathione system components (glutathione reductase, glutathione peroxidase, and glutathione reduced). Pearson correlation coefficients showed strong negative correlation between serum glucose (control and diabetic animals) and glucose metabolism enzymes, catalase, superoxide dismutase, glutathione peroxidase in pancreatic tissue ($r > -0.9$, $p < 0.05$), moderate negative correlation with reduced glutathione ($r = -0.79$, $p < 0.05$), moderate positive correlation with lipid peroxidation index ($r = +0.67$, $p < 0.05$), weak correlation with glutathione reductase ($r = -0.57$, $p < 0.05$). Magnesium supplementation slowed down diabetes onset considering fasting glucose levels in rats ($p < 0.05$), as well as partially restored investigated dehydrogenase levels in the pancreas of rats comparing to diabetes group ($p < 0.05$). The lipid peroxidation index varied between treatments showing the dose-dependent influence of Mg^{2+}. Magnesium supplementation partially restored catalase and superoxide dismutase activities in pancreatic tissue, as well as glutathione peroxidase and reduced glutathione levels ($p < 0.05$), while glutathione reductase levels remained unaffected ($p > 0.05$). The obtained results suggested a model, where magnesium ions may have a possible protective effect on pancreatic tissue against the negative influence of alloxan inside β cells of the pancreas.

Keywords: alloxan; diabetes; rat model; magnesium oral supplementation; pancreas

INTRODUCTION

Diabetes mellitus is a major health-related problem worldwide, with the number of people with diabetes increasing from 108 million in 1980 to 422 million in 2014, according to the WHO **(WHO, 2018)**. Dietary habits, together with a genetic predisposition, may influence *diabetes mellitus* development in healthy individuals. Magnesium is a macroelement involved in virtually all biochemical pathways in cells **(de Baaij, Hoenderop and Bindels, 2015)**. Considering its importance, the serum Mg^{2+} levels are maintained between 0.7 and 1.05 mM level in blood serum **(de Baaij, Hoenderop and Bindels, 2015)**. Low serum Mg^{2+} levels could be attributed to either dietary restriction, impaired intestinal absorption, or increased renal wasting. Hypomagnesemia has been long reported as a risk factor for type 2 *diabetes mellitus* development, as a contributing reason for **(Dong et al., 2011)**, as well as a consequence of insulin resistance **(Pham et al., 2007; Chaudhary, Sharma and Bansal, 2010)**. "A vicious cycle" of hypomagnesemia described by **Gommers et al. (2016)** implies the necessity of Mg^{2+} for insulin receptor autophosphorylation and therefore preventing insulin resistance from one side, while circulating excess of insulin being able to activate renal Mg^{2+} channel transient receptor potential melastatin type 6, which stimulates the secretion of Mg^{2+} with urine. Magnesium influences glucose metabolism and insulin action in several ways. Firstly, it is involved in the autophosphorylation of β-subunits of insulin receptor through tyrosine kinase activity binding to ATP. Rats with hypomagnesemia had reduced levels of the phosphorylated insulin receptor, mimicking insulin resistance **(Paxton and Ye, 2005; Suárez et al., 1995)**. Secondly, recent studies showed that

oral Mg^{2+} supplementation increased GLUT1 and GLUT4 expression in muscles of STZ-induced diabetic rats and mice, resulting in lowering serum glucose levels and its uptake by muscle tissue **(Biddinger and Kahn, 2006; Solaimani et al., 2014)**. Thirdly, Mg^{2+} is an important anti-inflammatory mediator, and hypomagnesemia increased production of proinflammatory interleukin 1, tumor necrosis factor-α by adipocytes, causing the production of reactive oxygen species that may lead to chronic inflammation, insulin resistance, and reduced GLUT4 activity **(Rodriguez-Moran and Guerrero-Romero, 2004; Weglicki et al., 1992)**. And finally, Mg^{2+} affects insulin production in pancreatic β cells. Under normal physiological conditions, increased blood glucose levels stimulate the influx of glucose into β-cell via GLUT2 transporter, followed by its conversion to glucose-6-phosphate (G6P) by glucokinase, which is a " glucose sensor" for insulin secretion. G6P is further metabolized through glycolysis and Krebs cycle, producing ATP, excess of which directly induces closure of K_{ATP} channel Kir6.2. Closure of this channel causes depolarization of plasma membrane, the opening of a voltage-dependent influx of Ca^{2+} ions, which causes exocytosis of insulin into the bloodstream. From one side, Mg^{2+} directly positively influences glucokinase activity by acting as a cofactor of adenine nucleotides, though it may be happening even at sub-physiological levels. Conversely, Mg^{2+} initiates K_{ATP} channel opening through MgATP, negatively affecting L-type Ca^{2+} channels, an influx of Ca^{2+} into β cells, and restraining insulin release. However, those are short-time negative consequences, while in a long run Mg^{2+} may improve β cells functionality, similar to cardiomyocytes, where low Mg^{2+} level was shown to decrease expression of L-type Ca^{2+} channels **(Gommers et al., 2016)**. It was shown that in humans without diabetes decreased serum Mg^{2+} was associated with decreased insulin secretion **(Rodríguez-Morán and Guerrero-Romero, 2011)**. Similarly, supplementation of individuals without diabetes with $MgCl_2$ significantly improved β-cell function and insulin secretion **(Guerrero-Romero and Rodríguez-Morán, 2011)**.

Alloxan is a cytotoxic glucose analog, which selectively binds to GLUT2 receptors of pancreatic β cells and enters them, causing necrotic cell death, thus modeling type 1 diabetes **(Lenzen, 2008)**. Alloxan is highly unstable in solutions with neutral pH and bloodstream and decomposes to alloxanic acid within minutes **(Szkudelski, 2001)**. A single intraperitoneal injection of 150 $mg.kg^{-1}$ of live weight is sufficient to cause alloxan-induced diabetes in fasting rats, causing permanent hyperglycemia between 24 to 48 hours post-injection **(Ighodaro, Adeosun and Akinloye, 2017)**. Being a thiol reagent, alloxan inhibits glucokinase ("glucose sensor"), and, therefore, glucose phosphorylation in β cells, initially causing rapid ATP increase followed by rapid insulin secretion and severe hypoglycemia, followed by halting and inhibition of insulin secretion **(Szkudelski, 2001; Lenzen, 2008; Ighodaro, Adeosun and Akinloye, 2017)**. More importantly, alloxan enters redox cyclic reaction coupled with its oxidized form, dialuronic acid, which spontaneously autooxidizes to generate toxic superoxide radicals and hydrogen peroxide, commonly known as reactive oxygen species (ROS) **(Munday, 1988; Winterbourn and Munday, 1989; Lenzen, 2008)**. Thiol groups, specifically, but not limited, to reduced glutathione are required for dialuronic acid production **(Szkudelski, 2001)**. A temporary compound of alloxan-glutathione, namely, "compound 305", is formed during each cycle, resulting in decreased GSH/GSSG ratio and depletion of reduced glutathione **(Munday, 1988; Szkudelski, 2001)**. The ultimate damage is caused by another ROS, hydroxyl radicals, which acts together with superoxide radicals and hydrogen peroxide, causing massive cellular damage, and ultimately apoptosis. Interestingly, few reviews noted massive Ca^{2+} influx in β cells and subsequent disruption of intracellular calcium homeostasis as one of the major reasons for β cell necrosis as well **(Szkudelski, 2001; Ankur and Shahjad, 2012)**. Antioxidant enzymes, namely, superoxide dismutase (transforming superoxide radical into hydrogen peroxide), and catalase (transforming hydrogen peroxide into water and oxygen), protect cells against ROS produced by alloxan **(Grankvist et al., 1979; Winterbourn and Munday, 1989)**. Glutathione peroxidase also detoxifies cells from hydrogen peroxide, though it requires reduced glutathione as a substrate. Cell debris, produced by necrotic dying β cells, are quickly scavenged by macrophages.

The purpose of the current study was to evaluate the influence of magnesium dietary supplementation on the duration and late progression of alloxan-induced diabetes related to pancreatic metabolic indices, including enzymes of glucose metabolism (lactate dehydrogenase, LDH, and glucose-6-phosphate dehydrogenase, G6PD), state of lipid oxidation (lipid hydroperoxide, LOOH), antioxidant enzymes (catalase, CAT, and superoxide dismutase, SOD), and glutathione system (glutathione peroxidase, G-Per, glutathione reductase, G-Red, and reduced glutathione, GSH). To the best of our knowledge, this study relative to pancreatic health state after late progression of alloxan-induced diabetes, with or without oral magnesium supplementation, was not performed yet. Additionally, we measured fasting serum glucose levels in rats with alloxan-induced diabetes, with or without dietary magnesium supplementation, as a time-dependent variable influenced by diabetes onset and progression.

Scientific hypothesis

We hypothesize that magnesium supplementation will not prevent, but may reduce the toxic effects of alloxan on pancreatic β cells. This may include the restoration of pancreatic glucose metabolism enzyme function back to the levels of the healthy control rats; decrease in LOOH comparing to alloxan-treated rats, reducing their levels back to the levels found in healthy control rats; activation of CAT and SOD, as protectors against ROS; increase in levels of G-SH and glutathione system enzymes, namely, G-Red and G-Per. Additionally, we hypothesize that magnesium supplementation may reduce fasting blood glucose levels in alloxan-induced diabetic rats due to the improved pancreatic function.

MATERIALS AND METHODOLOGY

The alloxan-induced diabetes rat model

Twenty-five white Wistar rats (ca. 140 g each, same age) were used for the experiments. The animals were kept in cages under standard conditions (20 – 25 °C, 40 – 45% air relative humidity) with free access to compound feed, while water was strictly supplemented (20 mL daily). Compound feed composition remained unknown. All procedures with animals were carried out according to the "European Convention for the Protection of Vertebrate Animals for Experimental and Other Scientific Purposes" (Strasbourg, France, Council of Europe, March 18, 1986) and were approved by the local institutional ethical committee.

The rats were divided into five groups, 5 rats per group: intact control (group 1, C); induced diabetes (group 2, D); magnesium supplementation (100 mg Mg^{2+} kg^{1} weight, daily dose) with diabetes (group 3, Mg100-D); magnesium (250 $mg.kg^{-1}$) with diabetes (group 4, Mg250-D); magnesium (500 $mg.kg^{-1}$) with diabetes (group 5, Mg500-D). Day 0 was the date of dietary supplementation start, while alloxan induction of diabetes was performed on day 21, and all animals were sacrificed on day 30. Magnesium citrate ($C_6H_6O_7Mg$) was dissolved in tap water in the amount of 6.17, 15.44, and 30.88 mg per mL corresponding to 14, 35, or 70 mg Mg^{2+} in 20 mL water per animal, which relates to 100, 250, and 500 mg Mg^{2+} per kg of live weight. A single intraperitoneal injection of alloxan monohydrate ("Sinbias", Ukraine) in 0.85% physiological saline was performed on each rat from groups 2, 3, 4, and 5 (150 $mg.kg^{-1}$ of body weight) after 24-hours fasting on the 21st day from the start of the experiment. All animals were sacrificed under ether anesthesia by decapitation on day 30, followed by removal of the pancreas within 2 minutes after the death. The removed pancreas was kept on ice for 5 to 6 minutes followed by bleeding through repeated perfusion with physiological saline (0.85% NaCl, 4 °C). The pancreas was chopped coarsely by scissors. One gram of chopped tissue was homogenized with 9.0 mL of 5 mM Tris-HCl buffer (1:10 dilution), pH 7.4, for 50 seconds at 0 °C (MRTU-421505-63, Ukraine). The homogenate was filtered through two layers of cheesecloth into a centrifuge tube followed by centrifugation (3,000 g, 10 minutes, 0 °C). The supernatant was used immediately for biochemical markers quantification and called "tissue sample" throughout the research paper.

All reagents used for the experiments, if not specified, were of laboratory grade or better.

Fasting blood serum glucose determination

Glucose determination was done on venous blood drawn from rat tails using glucose oxidase method (Gamma TM mini glucometer) after at least 6-hours fasting on days 21, 23, 25, 27, and day 30 (sacrifice day). The principle of the method is based on the reaction catalyzed by glucose oxidase:

$$\text{Glucose} + O_2 \rightarrow \text{Glucolactone} + H_2O_2 \quad (1)$$

using test strips and calibration strips supplied by the manufacturer.

Lipid hydroperoxide (LOOH) determination

LOOH determination is based on the interaction of ethanol extracts of lipid hydroperoxides with ammonium thiocyanate after precipitation of proteins with trichloroacetic acid (TCA). The original method developed by **Wagner, Clever and Peters (1947)**, and later updated and modified by **Mihaljević, Katušin-Ražem and Ražem (1996)**, was adapted. Briefly, 0.2 mL of tissue sample was placed in a centrifuge tube with 2.8 mL of ethanol (95%) and 0.05 mL of 50% TCA at 4 °C. The tube was tightly closed and shaken for 5 minutes, followed by centrifugation, resulting in protein precipitation (3,000 g, 10 minutes, 4 °C). 1.5 mL of the resulting supernatant was mixed with 1.2 mL of ethanol, 0.02 mL of concentrated HCl, and 0.03 mL of 1% Mohr's salt, $Fe(NH_4)_2(SO_4)_2$, in 3% HCl. The mixture was shaken, followed by addition of 0.2 mL of 20% NH_4SCN. Optical absorbance (A_{480}) was measured after 10 minutes of incubation time (spectrophotometer UNICO S1205, λ = 480 nm). The control sample was prepared by tissue sample replacement with 0.2 mL of deionized water. LOOH in samples was calculated using the following equation:

$$\Delta A_{480}\ \text{LOOH}.g^{-1} = DF \times (A_{480\ exp} - A_{480control}) \quad (2)$$

The obtained results were expressed as the difference in optical absorbance between experimental and control samples (λ = 480 nm), adjusted to 1 g of pancreatic tissue (ΔA480 $LOOH.g^{-1}$) by dilution factor DF.

All reagents used for the experiments, if not specified, were of laboratory grade or better.

Total protein determination

Protein concentration in the tissue sample was determined by the Lowry method using standardized kits (SIMCO Ltd, Ukraine) according to the manufacturer's instructions. The method is based on the formation of non-ferrous products of the interaction of aromatic amino acids with the Folin-Ciocalteu reagent in combination with the biuret reaction to peptide bonds of the protein **(Lowry et al., 1951)**. The results were expressed in mg of protein per mL of the tissue sample using spectrophotometer UNICO S1205 for absorbance measurements. The protein concentration of tissue samples from the pancreas of each rat was used to estimate enzyme activity per mg of protein in the subsequent analysis of SOD, CAT, G-Per, G-Red, G6PD, and LDH enzymatic activities in tissue samples.

Superoxide dismutase (SOD) determination

The principle of the method for superoxide dismutase (EC 1.15.1.1) activity determination is based on the ability of the enzyme to compete with nitroblue tetrazolium for the superoxide anion radicals, which are formed as a result of aerobic interaction of NADH and phenazine methosulfate **(Ponti et al., 1978)**. As a result of this reaction, nitroblue tetrazolium is reduced to formazan dye. In the presence of SOD, the percentage of nitroblue tetrazolium reduction is reduced. Enzyme activity was determined by the percentage of blockage of formazan dye formation **(Durak et al., 1993)**. Briefly, 1.5 mL of incubation mixture (containing 37 mg EDTA-Na_2, 330 mg nitrotetrazolium blue, 55 mg phenazine methosulfate, and

0.3 mL 0.15 M phosphate buffer, pH 7.8) was mixed with 0.1 mL of a tissue sample and 0.1 mL of 1 mM NADH in Tris-EDTA buffer (pH 8.0) followed by 10 minutes incubation at room temperature. Optical absorbance was measured against water (UNICO S1205, $\lambda = 540$ nm). The control sample was prepared using distilled instead of a tissue sample. The enzyme activity was determined with the following equation:

$$\% \text{ blockage} = 100 \times (A_c - A_t)/A_c \quad (3)$$

where A_c – optical absorbance of the control sample; A_t – optical absorbance of the test sample. Superoxide dismutase activity was expressed in relative units per 1 mg of protein (1 relative unit = 50% blocking).

Catalase (CAT) determination

The principle of the method for catalase (EC 1.11.1.6) activity determination is based on the ability of H_2O_2 to form a stable colored complex with molybdenum salts. According to **Góth (1991)**, the color intensity of molybdenum peroxide compounds depends on the amount of H_2O_2 in solution; and therefore, on the activity of catalase in the sample. The catalase reaction was started by mixing 0.1 mL of a tissue sample with 1 mL of 0.05 M Tris-HCl buffer (pH 7.8) and 2 mL of 0.03% H_2O_2. Blank included 1 mL of 4% $(NH_4)_2MoO_4$ in 0.025 N H_2SO_4 and 2.0 mL H_2O_2. The reaction in the test sample was stopped after 10 minutes by adding 1 mL of 0.25 N H_2SO_4 and 1 mL of 4% $(NH_4)_2MoO_4$. To complete the blank, 1 mL of 0.25 N H_2SO_4 and 0.1 mL of tissue sample was added to the blank.

Samples were centrifuged for 5 minutes at 3,000 g. Optical absorbance was determined spectrophotometrically (UNICO S1205, $\lambda = 410$ nm). The catalase activity in $\mu mol.min^{-1}.mg^{-1}$ was calculated using the following equation:

$$E_a = (\Delta A \times DF)/(\varepsilon \times t \times C \times l) \quad (4)$$

Where: ΔA – difference between the optical absorbance of blank and test samples; DF – dilution factor of the original tissue sample; ε – molar extinction coefficient of the H_2O_2 complex with ammonium molybdate at $\lambda = 410$ nm, equal to 22200 $M^{-1}.cm^{-1}$; C – tissue sample protein concentration, $mg.mL^{-1}$; t – reaction time, 10 minutes, l – optical path, 1 cm.

All reagents used for the experiments, if not specified, were of laboratory grade or better.

Glutathione peroxidase (G-Per) determination

The activity of glutathione peroxidase (EC 1.11.1.9) was measured through the oxidation rate of reduced glutathione in the presence of tertiary butyl hydroperoxide **(Moin, 1996)**. Change in absorbance is due to the interaction between SH-groups and Ellman's reagent (0.01 M solution of 5,5'-dithiobis-2-nitrobenzoic acid (DTNB) in methanol) with the formation of a colored product, 5'-thio-2-nitrobenzoic acid. The amount of the latter is directly proportional to the number of -SH groups that reacted with Ellman's reagent. Briefly, 0.83 mL of 4.8 mM reduced glutathione in 0.1 M Tris-HCl buffer (pH 8.5), containing 6 mM EDTA and 12 mM NaN_3, was added to 0.2 mL of the tissue sample. The mixture was incubated at 37 °C for 10 minutes. Following incubation, 0.07 mL of 20 mM tertiary butyl hydroperoxide was added and the mixture was incubated for an additional 5 minutes. The reaction was stopped by adding 0.2 mL of 20% trichloroacetic acid at 4 °C. A blank sample was prepared identically, but with distilled water instead of the tissue sample. The samples were centrifuged for 10 minutes at 3000 g. The supernatant (0.02 mL) was mixed with 2 mL of 0.1 M Tris-HCl buffer (pH 8.5) and 0.02 mL of Elman's reagent. After 5 minutes incubation, the samples were analyzed spectrophotometrically (UNICO S1205, $\lambda = 412$ nm). The G-Per result was expressed in $\mu mol.min^{-1}.mg^{-1}$ protein and calculated using the following equation:

$$E_a = (\Delta A \times DF \times C_s)/(A_s \times t \times C) \quad (5)$$

Where: ΔA – the difference between optical absorbance of the control and experimental samples; DF – dilution factor of the original tissue sample; A_s – absorbance of the standard G-SH solution; C_s – concentration of the standard G-SH solution; C – protein concentration in the tissue sample, $mg.mL^{-1}$; t – reaction time, 5 minutes.

Glutathione reductase (G-Red) determination

The activity of glutathione reductase (EC 1.8.1.7) was determined spectrophotometrically as the rate of glutathione reduction in the presence of NADPH as suggested by **Carlberg and Mannervik (1985)**. The reaction mixture contained 2 mL of 0.15 M phosphate buffer, pH 7.4; 0.2 mL of 10 mM EDTA**;** 0.5 mL of 7.5 mM oxidized glutathione, 0.1 mL of 2 mM NADPH; and 0.2 mL of the test sample. The enzyme activity was determined by measuring the reduction in NADPH content within 10 minutes at 37 °C (UNICO S1205, $\lambda = 340$ nm). The activity of G-Red was expressed in $\mu mol(NADPH).min^{-1}.mg^{-1}$ protein and calculated using equation 4, where ΔA – absorbance difference between the start and end time of the reaction; DF – dilution factor of the tissue sample; ε – molar extinction coefficient for NADPH, $\varepsilon = 6220\ M^{-1}.cm^{-1}$; t – reaction time, 10 minutes.

Reduced glutathione (G-SH) determination

The content of reduced glutathione (G-SH) was determined by the level of 5'-thio-2-nitrobenzoic acid formation as a result of the interaction of the glutathione – SH groups with 5,5'-dithiobis-2-nitrobenzoic acid (DTNB) at $\lambda = 412$ nm as per method developed by **Beutler, Duron and Kelly (1963)**. The following reagents were used: a precipitating reagent (glacial metaphosphoric acid – 6.68 g; EDTA – 0.80 g; sodium chloride – 120.0 g; distilled water to 400 mL); 0.3 M Na_2HPO_4 solution in distilled water; Elman's reagent (0.04% solution of 5.5-dithiobis-2-nitrobenzoic acid in 1% solution of trisodium citrate) **(Rahman, Kode and Biswas, 2006)**.

Stage I. Sample: tissue sample – 2 mL, precipitating reagent – 3 mL; control: distilled water – 2 mL, precipitating reagent – 3 mL. The mixtures were kept at room temperature for 5 minutes followed by centrifugation

at 3,500g, through which protein-free supernatant was obtained.

Stage II. Sample: supernatant from stage I – 2 mL, 0.3 M Na_2HPO_4 – 8 mL, Elman's reagent – 0.1 mL; Control: control supernatant from stage I – 2 mL; 0.3 M Na_2HPO_4 – 8 mL, Elman reagent– 0.1 mL. After 5 minutes of incubation, the absorbance measurement of the sample against control was performed (UNICO S1205, $\lambda = 412$ nm). The calculation of the amount of G-SH in the pancreas in mmoles per gram of tissue was estimated against G-SH standard solution with known concentration C_s using equation 6:

$$N_{GSH} = (\Delta A_{412} \text{ x } DF \text{ x } C_s)/A_{412s} \quad (6)$$

All reagents used for the experiments, if not specified, were of laboratory grade or better.

Lactate dehydrogenase (LDH) and glucose-6P-dehydrogenase (G6PD) determination

LDH and G6PD enzymatic activity were determined using spectrophotometric methods based on the coupled oxidation/reduction systems of nicotinamide coenzymes (UNICO S1205, 37 °C, NADH and NADPH molar extinction coefficient $\varepsilon = 6220$ at $\lambda = 340$ nm, t = 5 minutes of enzymatic reaction). The reaction was carried in 0.2 M tris-HCl buffer (pH 7.5) with a total volume of 3 mL, including 0.2 mL of the tissue sample. The final concentrations of the reaction components were as follows:

LDH – 1×10^{-3} M sodium pyruvate, 5×10^{-5} NADH, 3×10^{-3} M $MgCl_2$ **(Sevela and Tovarek, 1959)**.

G6PD – 1×10^{-3} M glucose-6-phosphate, 5×10^{-3} M $MgCl_2$; 0.5×10^{-4} M $NADP^+$ **(Evans, 2009)**.

The enzymatic activity was expressed in $nmole.min^{-1}.mg^1$ protein and calculated using equation 4.

All reagents used for the experiments, if not specified, were of laboratory grade or better.

Statistical analysis

Two-factorial ANOVA was used to analyze the influence of treatment (D, Mg100-D, Mg250-D, Mg500-D) and time of experiment onset (day 21, day 25, day 27, and day 30), as well as their interaction (treatment x time), on the fasting glucose levels in rats. If the influence of factors or their interaction was significant ($p < 0.05$), means were separated using the Fisher LSD procedure.

Pearson correlation coefficients were calculated between paired serum glucose levels of the control (C) and diabetes-induced rats (D) on day 30 and LOOH, SOD, CAT, G-Per, G-Red, G-SH, G6PD, and LDH levels in pancreas after animal sacrifice.

One-way ANOVA was used to analyze the influence of treatment (C, D, Mg100-D, Mg250-D, Mg500-D) on carbs metabolism enzyme activity, namely, G6PD and LDH; on lipid oxidative damage index, namely, LOOH level; on antioxidant enzymes activity, namely, SOD and CAT; and on glutathione system, namely, G-Per and G-Red activities and G-SH levels, in pancreatic tissue. If the influence of the factor was significant ($p < 0.05$), means were separated using the Fisher LSD procedure.

RESULTS AND DISCUSSION

As expected, oral magnesium supplementation did not prevent alloxan induction of diabetes, though somewhat significantly slowed its progression (Figure 1, $p < 0.05$). There was a significant influence of both factors, treatment (D, Mg100-D, Mg250-D, Mg500-D) and time of experiment onset (day 21, day 25, day 27, and day 30), on fasting serum glucose concentration ($p < 0.05$, Figure 1), though their interaction (treatment x time) did not affect ($p > 0.05$). Glucose levels increased gradually with the time of the experiment onset (Figure 3), while 250 $mg.kg^{-1}$ magnesium-dose had the most profound effect on the fasting glucose reduction (Figure 2). Similarly, **Abayomi et al. (2011)** showed that a single intraperitoneal injection of magnesium (100 and 150 $mg.kg^{-1}$ live weight) one hour before alloxan-induced diabetes (120 $mg.kg^{-1}$ live weight) in rats improved fasting glucose levels on days 2, 5, 7, and 10 compared to diabetes alone, but still was significantly higher comparing to control. Additionally, **Ige et al. (2010)** showed a similar effect of a single intraperitoneal injection of magnesium (100 $mg.kg^{-1}$) one hour before diabetes induction in rats even at a higher level of alloxan dose (150 $mg.kg^{-1}$ live weight).

The Pearson correlation coefficients between serum glucose levels (C and D groups) and investigated indices are shown in Table 1. The increased glucose levels, as a result of alloxan-induced diabetes, had strong negative correlations with LDH and G6PD enzymes, possibly indicating cellular damage and reduced metabolic activity of pancreatic cells; strong negative correlations with CAT, SOD, G-Per, possible indicating damage of antioxidative enzyme system as a result of confronting ROS produced by alloxan; medium negative correlations with G-SH, indicating G-SH consumption and possible impairment during alloxan redox cycling with dialuronic acid. A weak negative correlation was observed with G-Red, and moderate positive correlation with LOOH, indicating residual oxidative damage to the lipids of the cell membranes. These weak positive correlations could be because alloxan-induced diabetes was already established and necrotic β cells already removed by macrophages before the day of animal sacrifice (day 30).

Polyunsaturated fatty acids (PUFAs), which in their esterified state are present in membrane or storage lipids, are prone to ROS-induced peroxidation, resulting in the damage to the biomembranes. Final products of lipid peroxidation (LOOH) are reactive aldehydes, which are relatively stable, can diffuse far from the location of oxidative injury, and may act as second messengers or free radicals **(Gasparovic et al., 2013)**. Levels of LOOH were significantly different between treatments as shown in Table 2 ($p < 0.05$). LOOH increased non-significantly in the diabetes group, and was significantly decreased compared to diabetes in Mg250-D group ($p < 0.05$). Paradoxically, the highest LOOH levels were observed at high Mg^{2+} supplementation (500 $mg.kg^{-1}$), possibly showing that at such levels influence of Mg^{2+} may be negative, which is also confirmed by increased fasting serum glucose in this group (Figure 2). Though the major effect of targeted alloxan cytotoxic action on β cells is massive production of ROS, such as superoxide radical, hydrogen peroxide, and hydroxyl radical **(Munday, 1988; Winterbourn and Munday, 1989)**, the result is apoptosis

of β cells followed by cell debris removal. The determination of LOOH was done long after alloxan major damage and after its degradation in rat body (day 10 after the onset of diabetes), and presumably all damaged cells were either removed or repaired back to normal. Therefore, LOOH values could be non-informative.

Another possibility is the lack of the precision in determination of these values due to the low number of observations, causing an absence of significant differences between treatments.

Evaluation of enzyme activity, due to their protein nature, and sensitivity to various processing conditions, as well as pathological processes, is widely used in industry, life science, and medical research **(Tokarskyy et al., 2009; Yaremchuk and Posokhova, 2011; Lykhatskyi et al., 2019)**.

Table 1 Pearson correlation coefficients (p <0.05) between fasting serum glucose levels in control (C) and diabetic (D) groups vs. investigated indices (LOOH, SOD, CAT, G-Per, G-Red, G-SH, LDH, G6PD).

	LOOH	SOD	CAT	G-per	G-red	G-SH	LDH	G6PD

Note: * Same letters within the same lane mean non-significant difference (p >0.05).

Results of CAT and SOD determination are shown in Figure 4 and Figure 5, respectively. Treatment had a significant influence on both enzymes (p <0.05). Alloxan-induced diabetes caused a significant decrease in activities of both enzymes, while magnesium supplementation restored those values, causing even over-production of catalase. Both enzymes are important in detoxifying ROS produced by alloxan, with SOD reducing superoxide radicals to hydrogen peroxide and molecular oxygen, and catalase breaking down hydrogen peroxide into water and oxygen **(Lenzen, 2008)**. These reactions force Fenton reaction, and therefore, production of hydroxyl radical, the major damaging ROS related to β cell death, to halt **(Lenzen, 2008; Munday, 1988; Winterbourn and Munday, 1989)**. It was shown that excess of catalase production in liver hepatocytes, also possessing GLUT2 transporter and suitable for alloxan selective absorption, halted toxic effects of alloxan related to ROS production to the minimum **(Grankvist et al., 1979; Tiedge et al., 1997)**.

Data for G-SH and G-Per are shown in Table 3, with treatment having a significant influence on their values (p <0.05). The results for G-Red were non-significant (p >0.05, Table 3). Reduced glutathione is an important thiol-containing molecule, the presence of which causes alloxan- dialuronic acid cycling, resulting in the eventual production of ROS **(Lenzen, 2008)**. Alloxan-induced diabetes reduces levels of G-SH, and therefore, decreases reduced glutathione/oxidized glutathione ratio (G-SH/GSSG). However, increased levels of G-SH in β cells have a protective effect for glucokinase ("glucose sensor") inhibition by alloxan, as alloxan is kept in its oxidized form, dialuronic acid, incapable of reacting with thiol groups of glucokinase and deactivating it **(Ighodaro, Adeosun and Akinloye, 2017)**. Secondly, increased levels of G-SH cause activation of glutathione peroxidase, one of the enzymes capable of hydrogen peroxide deactivation. Progressed and established alloxan-induced diabetes reduced residual levels of G-SH in pancreatic tissue, though magnesium supplementation partially restored) G-SH levels to the value found in control animals (Table 3). A similar effect was observed with G-Per (Table 3), which also decomposes hydrogen peroxide. Glutathione reductase, which restores reduced glutathione levels through the reduction of its oxidized form, GSSG, using NADPH as reducing power, remained unchanged between treatments (Table 3).

Results for LDH and G6PD activity in pancreatic tissue after late established alloxan-induced diabetes are shown in Figure 6 and Figure 7. Treatment had a significant influence on both enzymes (p <0.05), with a significant decrease in their activities during late established diabetes (group D), and partial restoration in the case of magnesium supplementation after the onset of the disease in late progression. G6PD is a rate-limiting, first enzyme involved in the pentose phosphate pathway, which was shown to be inhibited during diabetes in the kidney cortex **(Xu, Osborne and Stanton, 2005)**. Pentose phosphate pathway generates extra reducing power in the form of NADPH, which can serve a substrate for glutathione reductase, which transforms oxidized GSSG into reduced G-SH, improving antioxidative "health" of the cells **(Xu, Osborne and Stanton, 2005)**. The LDH is the final enzyme in anaerobic oxidation of glucose, transforming pyruvate into lactate, and vice versa. Enzymatic activities of both LDH and G6PD in control untreated samples may serve as overall cell health state evaluation, and reduction in their activities may indicate impaired cellular health.

Several mechanisms may cause Mg^{2+} oral supplementation positive influence on pancreatic tissue, and specifically β cells, during experimentally induced diabetes. Magnesium complex with ATP activates glucokinase, an enzyme that serves as a "glucose sensor" as an initial step in cascade reactions of insulin release **(Gommers et al., 2016)**. Though it may happen even at a low sub-physiological level, some specific association between Mg-ATP and glucokinase may still exist **(Molnes et al., 2011)**, possibly decreasing alloxan inhibition of glucokinase. Intracellular magnesium concentrations inhibit L-type Ca^{2+} opening, avoiding massive Ca^{2+} influx inside cells, and "preserving" immediate insulin release and initial severe hypoglycemia caused by alloxan. Massive Ca^{2+} influx could also be one of the reasons for β cells death, besides ROS production **(Szkudelski, 2001)**. Magnesium serves as an antagonist of calcium, and more importantly, the ratio between Ca and Mg, not concentration levels themselves, causes insulin vesicle exocytosis **(Atwater et al., 1983)**. Additionally, magnesium dietary deficiency decreased antioxidant enzyme activities, namely, superoxide dismutase and catalase, in rat cardiac tissue, causing oxidative injury and explaining the pathogenesis of cardiac lesions in Mg-deficient rats **(Kumar and Shivakumar, 1997)**. A similar protective mechanism may be applied to magnesium influence on antioxidant enzymes in the pancreas. Contrary, although magnesium-deficient diet in rats caused decreased reduced glutathione levels in erythrocytes, implying its role in the maintenance of G-SH concentration to protect against oxidative damage in the erythrocyte membrane, the magnesium-deficient diet caused increased reduced glutathione levels in liver and kidneys, with no influence on other soft tissues **(Hsu, Rubenstein and Paleker, 1982)**. **Chaudhary, Boparai and Bansal (2007)** also showed an individual effect of low magnesium diet, as well as a combined effect of low magnesium with high sucrose diet on the development of oxidative stress in rats, namely, increase in plasma and liver lipid hydroperoxide levels, decrease in plasma reduced glutathione, decrease in liver superoxide dismutase, glutathione-S-transferase, and catalase enzyme activity.

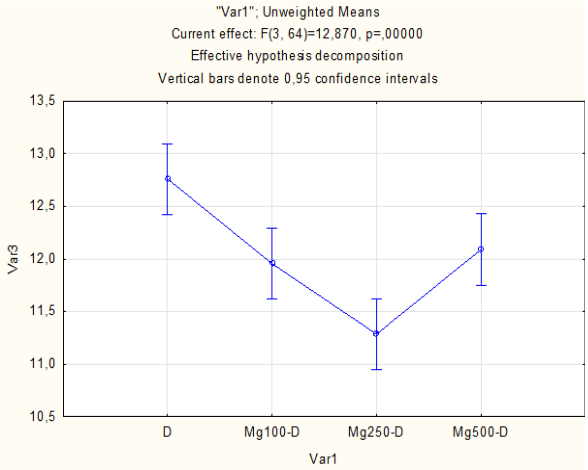

Figure 2 Influence of treatment (D, Mg100-D, Mg250-D, Mg500-D) on the mean value of fasting blood serum glucose levels on different days (day 21, 25, 27, 30). Error bars reflect standard error of mean. Adapted from Statistica ver 10.0.

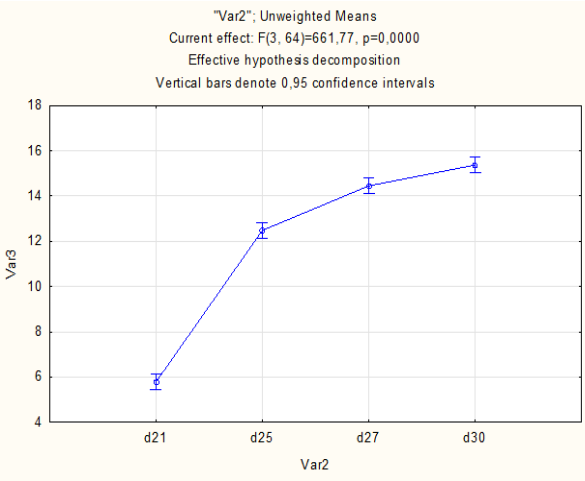

Figure 3 Influence of time factor (day 21, 25, 27, 30) on the mean value of fasting blood serum glucose levels in diabetic (D), magnesium supplemented diabetic rats (Mg100-D, Mg250-D, Mg500-D). Error bars reflect standard error of mean. Adapted from Statistica ver 10.0.

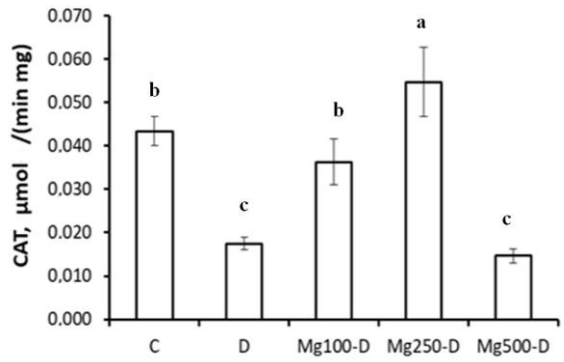

Figure 4 Mean values of pancreatic catalase (CAT) activity in control (C), diabetic (D), magnesium supplemented diabetic rats (Mg100-D, Mg250-D, Mg500-D) as measured on day 30 (sacrifice day). Error bars reflect standard deviations. Means with the same letters are not significantly different (p >0.05).

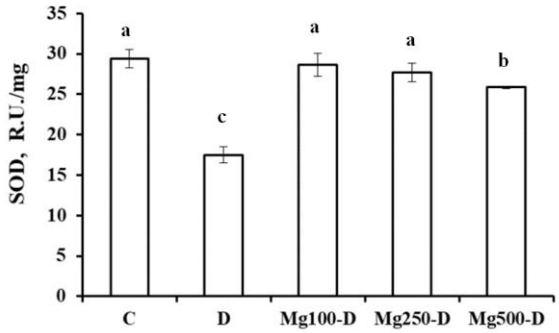

Figure 5 Mean values of pancreatic superoxide dismutase (SOD) activity in control (C), diabetic (D), magnesium supplemented diabetic rats (Mg100-D, Mg250-D, Mg500-D) as measured on day 30 (sacrifice day). Error bars reflect standard deviations. Means with the same letters are not significantly different (p >0.05).

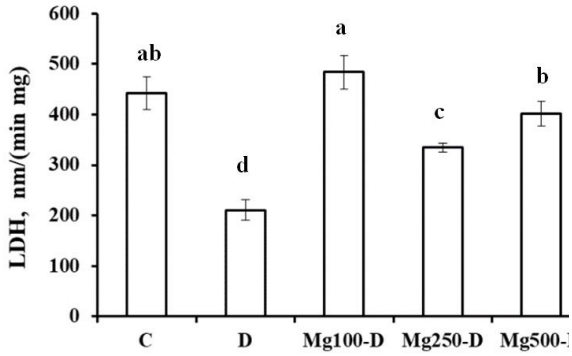

Figure 6 Mean values of pancreatic lactate dehydrogenase (LDH) activity in control (C), diabetic (D), magnesium supplemented diabetic rats (Mg100-D, Mg250-D, Mg500-D) as measured on day 30 (sacrifice day). Error bars reflect standard deviations. Means with the same letters are not significantly different (p >0.05).

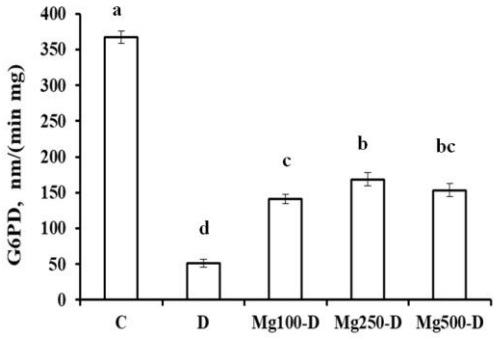

Figure 7 Mean values of pancreatic glucose-6-phosphate dehydrogenase (G6PD) activity in control (C), diabetic (D), magnesium supplemented diabetic rats (Mg-100D, Mg250-D, Mg500-D) as measured on day 30 (sacrifice day). Error bars reflect standard deviations. Means with the same letters are not significantly different (p >0.05).

CONCLUSION

To summarize, daily oral magnesium supplementation at a dose of 250 $mg.kg^{-1}$ live weight in advance before alloxan-induced diabetes and within 10 days of the diabetic state improved fasting glucose levels in rats, though did not prevent the onset of diabetes. Oral supplementation with magnesium restored glucose metabolism enzymes levels, such as LDH and G6PD, in diabetic rat pancreas, compared to alloxan-induced diabetes alone, which suppressed their activity. Additionally, antioxidant system enzymes, namely, catalase, superoxide dismutase, glutathione peroxidase, and reduced glutathione levels, all improved in pancreatic tissue after magnesium administration in late-stage diabetic rats. Inconclusive results were obtained regarding lipid hydroperoxide, either due to technical issues or lack of influence of magnesium on the pancreas due to very late testing after the development of diabetes.

THE EVALUATION OF EXTRACTION OF SOME NUT OILS USING SCREW PRESSING

Vladimír Mašán, Lukáš Vaštík, Patrik Burg, Radek Sotolář, Miroslav Macák

ABSTRACT

Today's consumers prefer low-sugar, low-calorie, natural, and so-called safe products. These trends are also reflected in nuts products and groceries. Globally, the European Union is the largest importing market of edible nuts. Considering the increasing demand for new sources of food, the importance becomes the efficiency of production. This study evaluates the influence of rotation speed in the extraction of almond nut, walnut, hazelnut, cashew nut, and peanut oils using screw pressing. In tested samples, the oil content was on average between 69.14 ±0.79% (walnut) and 46.7 ±1.45% (peanut). From the pressing of oils, it is seen that the oil yield decreased when pressing speed increased (from 30 rpm to 90 rpm, for example in walnut from 0.36 kg to 0.16 kg.h^{-1}) and that the oil sediment yield increased when speed increased (for example in hazelnut nut from 8.51% to 17.37%). The highest amount of oil yields had hazelnut with 3.03 ±0.05 kg.h^{-1}, then walnut with 2.05 ±0.02 kg.h^{-1}, almond nut with 2.34 ±0.05 kg.h^{-1}, peanut with 2.15 ±0.01 kg.h^{-1}, and finally cashew nut with 2.07 ±0.03 kg.h^{-1}.

Keywords: pressing time; oil yield; sediment yield; Soxhlet extraction; cake oil residue

INTRODUCTION

The European Union can produce only little amount of nuts within its area and therefore the EU is the largest importing market for edible nuts in the world, representing more than 40% of the total world imports **(CBI, 2018)**. Import in the year 2016 was 86,450 tons and volume is steadily increasing, but export was just 36,764 tons **(FAOSTAT, 2018)**.

Nuts are well known due to their high polyunsaturated fatty acids (PUFA) content and overly are very beneficial for health **(Christopoulos and Tsantili, 2015; Gharibzahedi et al., 2013; Kendall et al., 2011)**.

Consumers currently prefer low-sugar, low-calorie, natural, and so-called safe products which are the same for nuts groceries and products. The intentions of the food and confectionery industry are to exploit the full potential of nuts. Not only by adding them directly to products, but by making the most of their potential, for example by pressing oil and making use of cakes.

Oil from walnut kernel can be obtained in three ways, which are mechanical extraction (pressed oil), chemical or solvent extraction, and supercritical CO2 extraction **(Bhuiya et al., 2020; Zanqui et al., 2020; Alves et al., 2019; Singh and Bargale, 2000)**. The extraction by mechanical screw presses is one of the methods that are presently used and is typical for a lower proportion of collected oil **(Chapuis et al., 2014; Karaj and Müller, 2011)**. But benefits of screw pressing are to produce high-quality oil containing bioactive compounds, the possibility of using the cake residue, has relatively low initial and operation cost **(Al Juhaimi et al., 2018; Rabadán et al., 2018; Roncero et al., 2016; Alonge and Olaniyan, 2006; Alonge et al., 2003)**. The amount and quality of pressed oil are dependent on factors such as press time, temperature, the particular size of nuts, etc. **(Jokić et al., 2016; Gong and Pegg, 2015; Labuckas, Maestri and Lamarque, 2014; Teh and Birch, 2013)**.

The main objective of this study is to verify oil production from the imported seeds of hazelnut, walnut, almond nut, peanut, cashew nut and to compare its yield parameters.

Scientific hypothesis

The values of the pressing process for example yield, amount of sediment, or oil temperature of nut oils depend on the pressing speed.

MATERIAL AND METHODOLOGY

Nuts and kernels

Nuts and kernels (Figure 2), that were subject to this study, were vacuum-packed and purchased in the wholesale market. Before pressing, the water content in the nuts and kernels was assessed. They were ground in a stainless-steel mill with a pro-homogenization sample to

the fraction of size from 0 mm to 6 mm. Then, the material was pressed (Figure 1).

Determination of water content of nuts and kernels

The water content of nuts and kernels was determined by dehydration at 103 °C in a drying oven according to the **CSN EN ISO 665 (461025) (2001)**. The analysis was made on 5 g of grinded sample, weighted with an accuracy of 0.1 mg. Results are expressed as the ratio of water loss per gram of dried sample.

Screw press

The screw press type UNO FM 3F made by the Farmet Company in the Czech Republic was used for experimental measurements. The press allows precise adjustment of rpm from 0 to 200. The pressing device components are a matrix, 220 mm screw, head, heating mantle, nozzle holder, and nozzles of different in diameter (6, 8, and 10 mm). From the pre-test, the 8 mm nozzle was chosen as optimal. After the pressing process was the sediment separated and yield parameters of oils were determined. The oil temperature was measured directly on the press head every second by Testo 176 T4 – Temperature data logger (Testo SE & Co. KGaA, Germany) with stainless steel food probe.

Determination of the total fat content in the nuts, kernels, and cakes through extraction

To determine the total fat content, we used the Soxhlet extractor with hexane as a solvent. Crushing the walnut kernels always took place immediately before the oil extraction and from the pressed cakes directly after the pressing. For this purpose, the IKA MF 10 basic (IKA-Werke GmbH & Co. KG) on the sieve with an average of 3 mm was used. Precise cleaning of the grinder to avoid distorting results was always emphasized. The temperature of the extraction mixture was kept by the heating mantle closely around the boiling point of hexane (70 °C). Extraction was always carried out for 8 hours. Subsequently, the hexane was evaporated on the vacuum evaporator, type IKA RV 10 (IKA-Werke GmbH & Co. KG) control at the pressure of 200 kilopascals until the hexane was evaporated. After that, the pressure was lowered down to 60 kilopascals for another 2 hours at a constant temperature of 40 °C. The weight of total fat was then measured on the scales type KERN EG 2200-2NM (KERN & SOHN GmbH).

Statistical analysis

Analytical determinations were done in triplicate and data were reported as means ± standard deviation. Tukey's honestly significant difference (HSD) tests were conducted to determine the differences among which means that the statistical significance was declared at $p \leq 0.05$. The differences were analyzed only within the specific sample, not between the different samples. These statistical evaluation methods were applied using the computer software package "Statistica 12.0" (StatSoft Inc., USA).

RESULTS AND DISCUSSION

Table 1 and Table 2 shows the values of the main parameters. The average water content was at 3.95 ±1.21%, while the maximum content has hazelnut 5.8%, which corresponds to the values recommended for storage **(Poggetti et al. 2018; WCO HS 0802, 2017; Gong and Pegg, 2015; Christopoulos and Tsantili 2015)**. A most important parameter in the production of cold-pressed oils is oil content in nuts and kernels and the yield of producing oil. In samples, the oil content was on average between 46.7 ±1.45% until 69.14 ±0.79%.

From Table 1 and Table 2, it can be seen that the oil yield decreased when pressing speed increased **(Savoire, Lanoisellé and Vorobiev, 2013)**. This results confirmed Table 3 as a significant negative correlation between speed and yield of oil. The sediment is made by the imperfect separation of oil from the pressed material and represents an undesirable residual during the pressing process. It is also a signal that the press is not optimally set. Table 3 shows the significant correlation between speed and sediment in oils in Hazelnut, Walnut, and Almond nut, but not in Peanut and Cashew nut.

The results in Table 3 significantly proved that the amount of oil in pressed cakes and the efficiency of the press depends on the extraction parameters **(Rabadán et al., 2018; Jokić et al., 2016; Rombaut et al., 2015; Labuckas, Maestri and Lamarque, 2014; Teh and Birch, 2013)**, in our case on the rotation speed. Hourly performance increased with increasing speed, but not directly proportionally. At higher speeds, the efficiency of the press was lower due to the greater amount of sediment produced in the oil and the imperfect extraction of oil from the material. Therefore, the oil content in cakes increased. Oil temperature decreased in most of the cases while the speed was increasing. The evolution of the temperature of nut oils using screw pressing during oil extraction corresponds to the results of **Rabadán et al. (2018)**.

Many authors state, that in the pressed cakes, the leftover is between 5 – 31% of oil **(Gong and Pegg, 2015; Labuckas, Maestri and Lamarque, 2014; Acheheb, Aliouane and Ferradji, 2012)** and the value of sediment in pressed oil range from 7.95 to 17.57%.

The optimum speed for maximum oil yields for all samples was 30 rpm. But the higher speeds of the press increase the press capacity (yield of oil per hour), which is important for producers of oils. This is the reason why the setting of the pressing process is important according to the needs of each producer.

Hazelnut

Many authors reported that oil content in hazelnut ranged from 51 to 75% **(Kornsteiner-Krenn, Wanger and Elmadfa, 2013; Xu, Hanna and Josiah, 2007; Ebrahem et al. 1994)**. Our sample has a total fat content of 60.31 ±0.62%. The screw press makes it possible to achieve yield 50% **(Jokić et al., 2016)**, which was confirmed by this experiment and the total maximum weight of pressed oil was 51%, with 8.51% of sediment.

Table 1 The values of oil yield depended on speed.

Sample	Water content (%)	Total oil content (%)	Speed (rpm)	Weight of pressed oil (kg)	Weight of oil without sediment (kg)	Oil temperature (°C)
Hazelnut	5.8 ±0.57	60.31 ±0.62	30	0.51^{a} ±0.01	0.47^{c} ±0.02	49.2
			50	0.48^{a} ±0.01	0.41^{a} ±0.01	48.3
			70	0.45^{b} ±0.01	0.41^{a} ±0.00	43.7
			90	0.44^{b} ±0.02	0.36^{b} ±0.01	42.6
Walnut	4.2 ±0.66	69.14 ±0.79	30	0.42^{d} ±0.01	0.36^{a} ±0.01	47.6
			50	0.35^{c} ±0.01	0.33^{a} ±0.01	51.3
			70	0.29^{b} ±0.01	0.24^{c} ±0.03	42.1
			90	0.22^{a} ±0.01	0.16^{b} ±0.02	39.6

			90	0.36^{a} ±0.01	0.32^{a} ±0.02	39.4

Note: Alphabetical superscripts indicate significant differences (p <0.05) among values in columns for each sample.

Walnut

Many studies report, that walnut kernels have high oil content which varies from 52 to 72%. The fat content in tested raw material was determined at 69.14 ±0.73%, which is a rather higher percentage in comparison with other authors **(Kornsteiner-Krenn, Wagner and Elmadfa, 2013; Labuckas, Maestri and Lamarque, 2014)** and was the highest of tested samples. By pressing, the production of oil yield was 42%, with 12.94% of sediment. The results match with the results of **Gharibzahedi et al. (2013)** who indicates the highest yield crude pressed oil 34.9% and **Labuckas, Maestri and Lamarque (2014)** who states oil extraction in between 41.0 – 44.4% and a little lower than stated by **Sena-Moreno et al. (2016)** 57 ±3%.

Almond nut

Almond oil is extracted mainly from sweet almonds, which contain around 50% **(Fernandes et al., 2017)**, or 54.3% of oil **(Kornsteiner-Krenn, Wagner and Elmadfa, 2013)**. **Tungmunnithum et al. (2020), Prats (2000) and Roy, Mukherjee and Jana (2019)**, obtained yields of oil at 40 – 45%, which matches with our results 43% (with 6.98% of sediment) and **Sena-Moreno et al. (2016)** declare higher yield, almost 53 ±2%. This particular difference might be caused for example by the specific sample. To compare, our sample had total oil content 52.23%.

Peanut

Peanut seeds have oil content at 45 – 50% **(Kornsteiner-Krenn, Wagner and Elmadfa, 2013; Grosso et al., 1997)**. **Nader, Afif and Louka (2016)** state the yield production at 70% (when using the hydraulic press). At our experiment, we achieved the total maximum yield production of 45%, with 8.83% of sediment.

Cashew nut

The total oil content is on average between 45.2% **(Kornsteiner-Krenn, Wagner and Elmadfa., 2013)** to 52.08% **(Acheheb, Aliouane and Ferradji, 2012)**, with the highest oil yield 44.17% when the moisture content was 3.97%. The total maximum oil yield in this experiment was 45%, with 9.68% of sediment.

Table 2 The values of residues depended on speed.

Sample	Speed (rpm)	Amount of sediment in oil (%)	Weight of pressed cakes with oil (kg)	Weight of oil in pressed cakes (kg)	Amount of oil in pressed cakes (%)	Press capacity of oil ($kg.h^{-1}$)
Hazelnut	30	8.51^{a} ±1.29	0.43^{a} ±0.01	0.14^{b} ±0.02	31.59^{b} ±2.79	1.04^{b} ±0.04

CONCLUSION

The food and confectionery industry intend to exploit the full potential of nuts, for example by pressing oil and making use of cakes. The extraction by mechanical screw presses is one of the methods that is used for the production of cold-pressed oils.

In tested samples was oil content on average between 46.7 ±1.45% (peanut) until 69.14 ±0.79% (walnut). From the experiment, it is seen that the oil yield decreased when pressing speed increased (from 30 rpm to 90 rpm, for example in walnut from 0.42 kg to 0.22 $kg.kg^{-1}$) and that the oil sediment yield increased when speed increased (for example in almond nut from 5.56% to 19.54%).

BIOLOGICALLY ACTIVE COMPOUNDS CONTAINED IN GRAPE POMACE

Klára Vojáčková, Jiří Mlček, Soňa Škrovánková, Anna Adámková, Martin Adámek, Jana Orsavová, Martina Bučková, Vlastimil Fic, Lenka Kouřimská, Martin Búran

ABSTRACT

A healthy lifestyle and gastronomic trends based on traditional and local foods accompanied by waste-free technologies are currently in the primary focus. One of the raw materials with properties in alignment with such requirements is grape pomace. This paper evaluates the antioxidant activity of grape pomace (which is homogenized into a brown powder) and selected commonly available commercial flours – wheat bread, rye plain, and rye whole grain flour – using DPPH (2,2-diphenyl-1-picryl-hydrazyl-hydrate) and total polyphenol content method, where was used Folin-Ciocalteaure agent and then it was determined by spectrophotometric method (the measure of absorbance). The total amount of polyphenols in grape pomace was measured of 47.94 mg GAE.g^{-1}, but the value 0.27 mg GAE.g^{-1} was measured in wheat bread flour. Grape pomace performed the antioxidant activity of 57.45 mg AAE.g^{-1}, whereas wheat bread flour of only 0.21 mg AAE.g^{-1} Compared to selected commercial flours, the total amount of polyphenols in grape pomace was up to 150 times higher and the ratio of antioxidant activity between grape pomace and wheat bread flour was even more than 280 times higher. This makes it possible to fortify commercial, commonly available flours with different amount of grape pomace so that products with a higher amount of biologically active substances can be prepared. Another benefit could be a reduction in health risks and a contribution to improving consumer health.

Keywords: grape pomace; polyphenolic compounds; antioxidant activity; flour

INTRODUCTION

The interest in healthy and balanced nutrition has been increasing. The society is striving to find suitable food beneficial to the human body – a diet rich in vitamins and minerals. The WHO recommends 600 g of fruit and vegetable, including cooked vegetables, as a daily intake **(WHO, 2013)**. The ratio between fruit and vegetable should be 1:2 **(The Czech Society for Nutrition, 2012)**. Unfortunately, in many European countries, their income is lower. However, fruit and vegetable are rich in biologically active substances **(Juriková et al., 2016)**. These include antioxidants, such as vitamins C, E, provitamin A, minerals with antioxidant properties, polyphenols, tannins, and other groups of substances that can reduce health risks and contribute to health enhancement **(Salter, Wiseman and Tucker, 2012; Tomás-Barberán and Gil, 2008)**. One source of these substances may be grapevine and products from it **(Katalinić et al., 2010; Kim et al., 2011; Liang et al., 2014; Stockham et al., 2013)**.

Grapevine is one of the best known and most widespread fruits in the world **(Yang et al., 2009; Yang, Martinson and Liu, 2009; Soto, Brown and Ross, 2012)** and includes four species: the European type (*Vitis vinifera* L.), American grape type (*Vitis labrusca* L.), Muscadine type (*Vitis rotundifolia* Michx.) and Amurensis (*Vitis amurensis*). Out of these, the European type has spread worldwide and accounts for 71% of total grape production in the wine industry **(Yang, Martinson and Liu, 2009)**. An example of producing of grapes can be mentioned in Brazil, where the production was approximately 534 million kg in the year 2009. This number increased by 24%, which means that the number was 709 million kg two years later (in the year 2011). Logically, when the production of grapes increased, automatically the amount of grape pomace increased as well **(Casagrande et al., 2019)**. Grapes serve as a suitable source of phenolic compounds with antioxidant effects, such as anthocyanins, flavonoids, and resveratrol **(Yang, Martinson and Liu, 2009; Hernández-Salinas et al., 2015)**.

It is a fruit consumed all over the world. It can be eaten in a form of fresh table fruit and also in a form of diverse processed products including wine, juice **(Kim et al., 2017)**, grape flour, or grape pomace. Grape pomace, dried and homogenized grape seeds and skin, is a by-product of wine production applied for further processing. It can be used as a substrate to produce alcoholic beverages due to sufficient sugar content. The most famous liquor prepared

from grape pomace is Italian Grappa. In France, brandy originated from grape pomace is known as Marc, in Spain it is named De orujo and in Portugal Bagaceira **(Piras, 2008; Gasnier, 2005)**. Furthermore, the inedible components such as seeds and skins can be used as a food additive, feed, fertilizer, seed source for oil production, or fuel. Therefore, grape pomace is considered to be a favorable alternative product allowing waste-free management. Grape pomace is rich in polyphenols, especially flavonoids such as gallic acid, catechin, and epicatechin **(Özvural and Vural, 2014)**.

Polyphenolic compounds are plant secondary metabolites present in plant foods and they can affect human health **(Ziauddeen et al., 2019; Pinto and Santos, 2017; Zehiroglu and Sarikaya, 2019)**. It is a complex group of phytochemical compounds ranging from simple phenols and phenolic acids to high molecular weight polymer structures (e.g. hydrolyzed and condensed tannins) **(Ziauddeen et al., 2019; Zamora-Ros et al., 2016)**. From a chemical point of view, it is a diverse and heterogeneous group of organic compounds **(Llobera and Cañellas, 2007)**. Their distribution in different parts of plants is diverse. Commonly, they are present in outer layers of fibrous plant material; insoluble substances in the cell walls, and soluble in vacuoles **(Pandey and Rizvi, 2009)**. The number of phenolics which has been found in plants is over 8000. The particular profile of polyphenols depends also on specific cultivar within a species. An example can be given grape varieties where the composition can depend on factors, such as geographical region, soil composition, or terroir. This is the reason why are different polyphenolic compositions but also the success of growing specific species of wine **(Bakota et al., 2015)**.

As a by-product, grape pomace is an inexpensive source of polyphenolic antioxidants **(Bakota et al., 2015)** attracting growing interest as it offers a wide range of usable products in the food, cosmetic and pharmaceutical industries **(Milella et al., 2019)**. Several phenolic compounds have a role in preventing lifestyle diseases, such as cardiovascular diseases, diabetes mellitus type 2, neurodegeneration, and certain types of cancer **(Bončíková et al., 2012; Ziauddeen et al., 2019)**.

The process of obtaining polyphenols from fruit or vegetable is usually extraction. It can be for example Soxhlet extraction, maceration, or hydrostillation. Nowadays there are also new non-conventional methods, due to the effort to use a method that is environmentally friendly to compare to the classical method. An example can be ultrasound, microwave, and pressure-assisted extractions (it can be applied alone or together with various solvents for the sake of reducing solvent requirements and the energy) **(Milella et al., 2019)**.

Furthermore, apart from phenolic compounds with antioxidant effects, grape pomace contains other antioxidants neutralizing free radicals. In the human body, free radicals may harm compounds altering cell membranes, cause cell damage and cell inflammation, promote abnormal cell growth including certain types of cancer and even cause cell death. Free radicals are formed in the body in natural metabolic processes. In their formation, exogenous factors, including ultraviolet light, radiation, fumes, and air pollution, play an important role **(Krishnaswamy et al., 2013)**. Antioxidants, comprising phenolic compounds, flavonoids, and carotenoids, can reduce the risk of oxidative damage by converting free radicals into inactive molecules **(Štípek et al., 2000)**.

These beneficial properties of grape pomace are in accordance with current nutritional trends emphasizing the application of traditional, local and organic food in compliance with waste-free management **(Burg, Masan and Ludin, 2017; Makris et al., 2008)**.

Due to the fear of the unfavorable effects and the safety of synthetic antioxidants, the studies started to be more interested in studies that were focused on natural products. Namely, it was for example herbs, vegetables, fruits, or agro-industrial waste. The reason for attention on these products is because they are rich in polyphenols and they can be used instead of synthetic antioxidants that are used in the pharmaceutical, food, or cosmetic industry **(Casagrande et al., 2019)**.

It is assumed that polyphenol content is about 60 – 70% in grape seeds, 30% in the skin, and merely 6% in the flesh **(Kim et al., 2017)**.

Homogenized grape pomace has reached the market and allows fortification of common commercial flours or their complete replacement. The purpose of fortification is to increase the content of biologically active substances. First, it is necessary to identify the original content of biologically active substances in the individual basic materials.

This paper aims to compare polyphenolic substances in grape pomace and their antioxidant effects with commercial, commonly available flours on the market.

Scientific hypothesis

Hypothesis No. 1: The total content of polyphenolic substances and antioxidants in grape pomace is higher than in the commercial flours.

MATERIAL AND METHODOLOGY

Material for analysis

The analysis employed material samples from grape pomace (Figure 1), wheat bread flour, rye flour, and rye wholemeal flour. A presented grape pomace sample came from viticulture Ludwig, vineyard track ”Zbavce”, village Němčičky, region Velkopavlovická, area Moravia. It was homogenized from grapes of the Riesling variety which was manually harvested in October 2018. Next, the grapes were processed using a time-driven horizontal press. Drying and grinding were performed at 70 °C. The grinding was performed until the grape pomace reached similar size as the flours which were bought for the analysis.

The flours were bought in a supermarket as a commonly available commercial material:

– wheat bread flour – wheat flour “Babiččina volba”, GoodMills Česko inc., Prague, the Czech Republic, with the following nutritional values per 100 g: energy 1461 kJ/345 kcal, fats 1.7 g, of which saturated fatty acids 0.2 g, carbohydrates 69 g, of which sugar 2.0 g, fiber 3.1 g, proteins 12 g, salt <0.01 g;

Figure 1 The grape pomace sample.

– rye plain flour – rye plain dark flour "Babiččina volba" GoodMills Česko inc., Prague, the Czech Republic, with the following nutritional values per 100 g: energy 1435 kJ/339 kcal, fats 1.0 g of which saturated fatty acids 0.2 g, carbohydrates 70 g, of which sugars 6.0 g, fiber 9.0 g, proteins 8.0 g, salt <0.01 g;
– rye wholemeal flour – "Pernerka" rye wholemeal fine flour, Mlýn Perner, Svijany, the Czech Republic, with the following nutritional values per 100 g: energy value 1449 kJ/342 kcal, fats 1.3 g of which saturated fatty acids 0.13 g, carbohydrates 72.1 g, of which sugars 1.8 g, proteins 6.1 g, salt 0 g.

An extract (5 g of sample extracted in 50 mL of methanol (MERCI, s.r.o., Brno, the Czech Republic)) was prepared from all flour samples and used for further determination.

Total phenolic content analysis

To determine the total phenolic content (TPC) Folin-Ciocalteaure agent (Sigma Aldrich, the Czech Republic) was used. The extract of the amount of 0.1 mL was mixed with water in a 10 mL volumetric flask. Then, 0.5 mL of Folin-Ciocalteaure agent and 1.5 mL of 20% solution of Na_2CO_3 (Sigma Aldrich, the Czech Republic) were added to the solution. Specord 50 Plus (Analytik Jena, Jena, Germany) was used to measure absorbance at a wavelength of 765 nm. Pure water was used as a reference **(Thaipong et al., 2006)**. To express the results, unit milligrams of Gallic acid (GAE) per grams of fresh mass (FM) were used. TPC was measured four times.

Total antioxidant capacity analysis

Total antioxidant capacity (TAC) was established applying DPPH (2,2-diphenyl-1-picryl-hydrazyl-hydrate) (Sigma Aldrich, the Czech Republic) assay in accordance with the study by **Brand-Williams, Cuvelier, and Berset (1995)**.

The stock solution was prepared by the solution of 24 mg of DPPH in 100 mL of methanol (MERCI, s.r.o., Brno, the Czech Republic) which was stored at -20 °C until it was needed. The absorbance of DPPH radical without any added extract was recorded and corrected every day. The sample solution used for measuring was prepared by mixing 10 mL of the stock solution with 45 mL of methanol to obtain the absorbance of 1.1 ±0.02 units at 515 nm using spectrophotometer Specord 50 Plus (Analytik Jena, Jena, Germany). The extract (210 μL) was allowed to react with a 4 mL DPPH solution for 1 hour in the dark. Then, the absorbance was recorded at a wavelength of 515 nm. TAC was measured three times.

For the calculation of antioxidant capacity, a decrease of the absorbance value was used following the formula:

Antioxidant capacity (%) = $(A_0 - A_i/A_0) \times 100$,

where A_0 is the absorbance of a blank without the sample and A_i is the absorbance of the mixture containing the sample. The calculated antioxidant capacity was converted using a calibration curve of the standard and expressed in ascorbic acid equivalents (AAE) **(Vasantha Rupasinghe, Jayasankar and Lay, 2006)**.

Statistical analysis

Excel 2013 (Microsoft Corporation, USA) and STATISTICA CZ version 12 (StatSoft, Inc., USA) were used for data analysis. The results were expressed by mean ± standard deviation. The comparison of TPC and total antioxidant activity (TAA) of grape pomace with those of flour samples were calculated by non-parametric tests – Kruskal-Walllis test Wald-Wolfowitz test, Kolmogorov-Smirnov test and Mann-Whitney U Test ($\alpha = 0.05$).

RESULTS AND DISCUSSION

The comparison of total polyphenol content of grape pomace and selected commercial, commonly available flours are shown in Table 1. The lowest value of polyphenols was established in wheat bread flour with a value of 0.27 $mg.g^{-1}$. Rye flour showed a slightly higher value in both plain and whole grain flour. The total amount of polyphenols in grape pomace was measured to be 150 times higher, namely 47.94 $mg.g^{-1}$. This indicates a statistically significant difference between grape pomace and commercial flours.

Due to the non-compliance with the prerequisites for the ANOVA type statistical evaluation, the Kruskal-Walllis test based only on the order of the individual samples had to be applied to compare obtained data as can be seen in Table 2. For this reason, a statistically significant difference was observed only between grape pomace and wheat bread flour, although the measured values indicated a statistically significant difference between grape pomace and all the commercial flours. In case that only two individual samples are compared, there was a statistically significant difference ($p < 0.05$) between all flour samples both using non-parametric tests (Wald-Wolfowitz test, Kolmogorov-Smirnov test, Mann-Whitney U Test) and using the parametric Welch t-test. However, the homogeneity condition is not met in this test.

Published studies devoted to the issue of this study have revealed a wide range of values. For instance, **Costa et al. (2019)** declared the value of 4.7 ±0.0 mg $GAE.g^{-1}$ for grape pomace of red wine from Brazil. In contrast, **Theagarajan et al. (2019)** established the total content of polyphenols in dry compacts from ripe red grapes of the Muscat variety grown in India at the amount of 280.6 ±3 mg $GAE.g^{-1}$. **Chamorro et al. (2012)** determined the total content of extractable polyphenols in grape seeds

from France of 296 ±9 mg GAE.g^{-1} in dry material and 23.6 ±0.8 mg GAE.g^{-1} in grape pomace originated from Spain. Similar values of total polyphenol content as found in this study are documented in the article by **Casagrande et al. (2019)** in the range of 17.91 to 35.10 mg GAE.g^{-1}. Considering grape seeds from different cultivars, **Sung and Lee (2010)** reported polyphenol levels varying from 7.92 mg GAE.g^{-1} to 43.69 mg GAE.g^{-1}. **Rockenbach et al. (2011)** measured the total phenolic content in various wines and the measured range is 32.62 – 74.75 mg GAE.g^{-1}.

In a comparison of different types of flour, **Li et al. (2015)** measured different coloured wheat, where the values were in the range of 0.51 to 0.66 mg GAE.g^{-1}. **Ragaee, Abdel-Aal and Noaman (2006)** state that in wheat flours and whole grain cereals is the range of 0.50 to 4.22 mg GAE.g^{-1}, which is similar to the value of wheat flour which was measured in this paper, and again lower than the values for grape pomace.

For gluten-free flours, in the paper **Rocchetti et al. (2019)** the values were similar too – the total polyphenolic content was in the range 0.52 to 5.00 mg GAE.g^{-1}. **Alvarez-Jubete et al. (2010)** measured the polyphenols of seeds of amaranth, quinoa, buckwheat, and wheat in the range 0.21 – 3.23 mg GAE.g^{-1} dry-weight basis.

Interesting results for comparing were also analyzed in **Ky and Teissedre (2015)** where was measured total phenol content in grape pomace seed and skin extracts. The measured amount was 128.22 – 215.93 mg GAE g^{-1} of dry weight in grape seed pomace extract and 71.88 – 196.71 mg GAE g^{-1} of dry weight in grape pomace skin extracts when for the measuring was used the extraction method which is appropriate for the preparation of edible extracts.

For comparison, there are some studies where were measured the amounts of polyphenols in wines, where the unit was in mg GAE.L^{-1}. In the study **Boussenna et al. (2016)** three different grape pomace extracts were used. The amount of polyphenols was in the range of 140 to 400 mg GAE g^{-1} grape pomace extract. **Snopek et al. (2018)** were analyzing wine where the values for white wine were 203.06 – 678.78 mg GAE.L^{-1} and for red wine 905.21 – 1349.12 mg GAE.L^{-1}. The average amount of measured wine in **Bajčan et al. (2016)** was 2,424 mg GAE.L^{-1}. **Bajčan, Čéryová and Tomáš (2012)** measured range 1579 – 2734 mg GAE.L^{-1} in Blaufränkisch. The range of wine from various Slovak vineyard areas which was measured by **Bajčan et al. (2015)** was 2064 – 4274 mg GAE.L^{-1}. In the study **Lapčíková, Lapčík and Hupková (2017)** was measured the range 549.44 to 2832.78 mg GAE.L^{-1} for a variety of wines. The higher values were measured by **Garaguso and Nardini (2015)**, where the mean was 4417 mg GAE.L^{-1} for organic wines and 4225 mg GAE.L^{-1} for conventional wines. **Faitová et al. (2004)** measured the amount of total polyphenolic content in twelve bottles of Traminer, and the values were in the range 257.7 – 282.5 mg GAE.L^{-1}. The study **Ivanova-Petropulos et al. (2015)** is showing that the differences can be seen in the same country (Macedonia) but different regions, where the values were measured in the range of 1394 to 3097 mg.L^{-1}. The wide range is shown in **Fanzone et al. (2012)** where were used thirty red wines from the 2010 vintage, the values were 1585.6 – 4203.2 mg.L^{-1}.

Kondrashov et al. (2009) measured different varieties of Merlot and Cabernet wine, and the total phenolic content was in the range from 1447 to 2414 mg GAE.L^{-1}. **Burin et al. (2010)** measured Cabernet as well and the results of their measurings are in the range of 1750.9 – 2424.1 mg GAE.L^{-1}. **Yoo et al. (2011)** reported wide range, namely 1417.14 – 3588.57 mg GAE.L^{-1} for Cabernet Sauvignon and 1181.43 – 3288.57 mg GAE.L^{-1}

Table 1 Total Polyphenol Content in individual samples.

Flour	Total Polyphenol Content	
	M **(mg GAE.g^{-1})**	***SD*** **(mg GAE.g^{-1})**
wheat bread	0.27	0.01
rye plain	0.40	0.01
rye wholemeal	0.51	0.01
grape pomace	47.94	0.11

Note: *M* – mean, *SD* – standard deviation.

Table 2 Total phenolic content (TPC) in individual analysed samples – Multiple comparison of *p* values.

Flour	wheat bread	rye plain	rye wholemeal	grape pomace
wheat bread		*p* >0.05	*p* >0.05	***p* <0.05**
rye plain	*p* >0.05		*p* >0.05	*p* >0.05
rye wholemeal	*p* >0.05	*p* >0.05		*p* >0.05
grape pomace	***p* <0.05**	*p* >0.05	*p* >0.05
