Table 3 Total antioxidant activity (TAA) in individual analysed samples.

Flour	Total antioxidant activity	
	M **(mg AAE.g^{-1})**	***SD*** **(mg AAE.g^{-1})**
wheat bread	0.21	0.06
rye plain	0.41	0.06
rye wholemeal	0.63	0.03
grape pomace	57.45	0.42

Note: *M* – mean, *SD* – standard deviation.

Table 4 Total antioxidant activity (TAC) in individual samples – Multiple comparison of *p* values.

Flour	wheat bread	rye plain	rye wholemeal	grape pomace
wheat bread		*p* >0.05	*p* >0.05	***p* <0.05**
rye plain	*p* >0.05		*p* >0.05	*p* >0.05
rye wholemeal	*p* >0.05	*p* >0.05		*p* >0.05
grape pomace	***p* <0.05**	*p* >0.05	*p* >0.05	

for Shiraz wines. **Paixão et al. (2007)** compared five red wines, one rosé wine and five white wines and the result was in the range 282 – 1936 mg GAE.L^{-1}. As can be seen, there are differences between wine (the liquid product of grapes) as well, which shows the variety of polyphenols which can be seen in the different types of grapes, that were grown in the different conditions.

The amount of TPC is affected by a number of factors, so the results presented in this article may be different compared to the others. The content of polyphenols can be affected by environmental factors such as soil type, sunlight, climate, etc., TPC is further affected by storage, during which polyphenols oxidize easily. Concentrations of phenolic acids generally decrease during maturation, while concentrations of anthocyanins increase. Another parameter that affects the content of polyphenols is culinary treatment – grinding of plant tissues degrades polyphenols and maceration can increase the content of polyphenols due to diffusion in the juice **(Manach et al., 2004; Pandey and Rizvi, 2009)**.

Table 3 summarizes antioxidant activities which were up to 280 times higher in grape pomace than in other commercial flours. Grape pomace performed the antioxidant activity of 57.45 AAE $mg.g^{-1}$, whereas wheat bread flour of only 0.21 AAE $mg.g^{-1}$. Samples of rye flour differed from wheat bread flour by only 0.20 AAE $mg.g^{-1}$, which is a negligible difference if compared to grape pomace.

Similarly to the determination of the total amount of polyphenols, it was not possible to apply the ANOVA test. Therefore, a comparison of the obtained data was performed using the Kruskal-Walllis test as displayed in Table 4. The results follow the same trend as for total polyphenols content. As with the TPC determination, non-parametric tests (Wald-Wolfowitz test, Kolmogorov-Smirnov test, Mann-Whitney U test) and parametric Welch t-test between individual pairs of samples were performed again. There was a statistically significant difference (p <0.05) between all pairs in all tests.

Concerning grape seeds from different cultivars, **Sung and Lee (2010)** reported antioxidant activity ranging from 28.2 ("Agawam") to 121.2 ("Cabernet Sauvignon") µmol Trolox.g^{-1}. **Costa et al. (2019)** documented 160.9 ±22.3 µmol Trolox.g^{-1} in unprocessed grape seeds and 105.5 ±2.0 µmol Trolox.g^{-1} in defatted grape seeds. Grapes pomace samples of Château Roslane (Meknes, Morocco) were employed in the study by **Aziz et al. (2019)** publishing the values ranging from 0.12 ±0.0 to 0.23 ±0.0 mmol Trolox.g^{-1} dry weight.

Even though more studies are examining this issue, data comparison is very problematic as different methodologies and their modifications, different grape varieties, and sample processing techniques of TPC and TAA determination were applied. It is essential to consider specifics of biological material that may be influenced by the ambient conditions (climate, temperature, sunshine), cultivation technologies (soil fertilization, harvest time, harvesting method), and by post-harvest processing and storage.

For future practical applications, it would be appropriate to monitor TAA and TPC in the mixtures of common commercial meals and grape pomace in various ratios to enable fortification of traditional flour with a small percentage of grape flour. Furthermore, it is necessary to identify specific characteristics of such mixtures, including sensory properties and leavening, and subsequently, to examine properties in baked goods, such as shelf life, to distinguish their mutual influences.

CONCLUSION

This research has examined the content of antioxidants and polyphenolic substances in grape pomace which were gained from the local farmer and it was thoroughly compared with three different commercials, commonly available flours, where two of them were from one company and the last one was from the different one for more valuable comparison. It evaluates differences in existing products and products containing non-traditional alternatives to commercial ones. The results indicate that grape pomace performed magnitude higher values of both polyphenolic contents and antioxidant properties than commercial flours.

As this study has revealed, grape pomace provides a diverse array of applications in the food industry; it plays a role as a food additive improving sensory and technological properties and works as a dietary supplement reducing the risk of civilization diseases including cardiovascular diseases, diabetes mellitus, and obesity. Newly, further advantageous attributes still required to investigate more is the possibility to employ grape pomace in gluten-free and lactose-free products.

DEVELOPMENT OF AN INTEGRATED FOOD QUALITY MANAGEMENT SYSTEM

Mykola Nikolaenko, Larysa Bal-Prylypko

ABSTRACT
The high-speed growth in the global population has resulted in a deficit of foods, which has stimulated the development of technologies for planting agricultural products and fattening domestic animals. However, these processes are supplemented in many cases by worsening of the quality of foods and their pollution by foreign substances. To guarantee the proper quality and safety of foodstuffs for health, the International Organization for Standardization developed the standards ISO 9001:2015 and ISO 22000:2018. At the same time, businesses fabricating foods, especially meat-based ones, have to observe the norms of the international standard ISO 14001:2015. Finally, because treatments of raw materials and ingredients used in food products contain in many cases substances harmful for health, enterprises must introduce the norms of standard ISO 45001:2018. To simplify management processes, enterprises introduce so-called 'integrated management systems'. This study proposes one variant of such a system recommended for use in food-producing organizations including those that treat raw meat and produce products based on its use.

Keywords: quality management system; integrated management system; quality; safety; food; food safety; quality standard

INTRODUCTION
The world population is currently 7.7 billion people and continues to increase. The United Nations Population Division estimates that it will be about 9 billion in 2042 and may rise to 16 billion by 2100.

As a consequence of such fast growth, the problem of ensuring humankind has an adequate quantity of foodstuffs originated as early as the 1940s. This phenomenon prompted the beginning of the so-called 'green revolution' in agriculture, i.e. the dramatic change in technologies of planting and of fattening domestic animals **(Hazell, 2009)**. The principal steps in such evolution were the introduction of the practice of irrigation and the use of pesticides and chemical fertilizers which permitted a doubling of cereal productivity to 1985. However, solely increasing output is not sufficient to solve the problem of supplying foodstuffs because it is not the only task of the food industry. Enterprises must also produce products safe for the health of consumers. They must also observe the norms of the technologies of farming and reprocessing of crops, protection of the environment, and guaranteeing safe labour conditions for production personnel.

The current problem in the food industry is that intensification of farming practice has resulted in decreasing water availability, infringement of water intake schedules, and salification and desertification of considerable areas of fertile soils. The result of wide-ranging use of mineral fertilizers and chemical means of protecting plants (aromatic heterocyclic compounds of chlorine and phosphorus) is worsening human health and is the origin of problems of ecological character. Hence the World Health Organization (WHO) adopted a resolution that recognizes the problem of food safety as crucial in protecting human health because food pollutants of chemical and radiological character, bacteria, viruses, and vermin provoke the origin of more sicknesses **(WHO, 2014)**. It has been shown that consumption of poor-quality food and water results in the death of up to 2 million people worldwide each year **(Brijnath, Butler and McMichael, 2014)**.

To decrease the rate of accidental deaths, the WHO recommends the introduction of the following principles of alimentary hygiene: a) consumption of only safe water and raw materials in the fabrication of foods, b) protection of raw materials and ingredients against contact with insects, rodents and vermin, c) prevention of contamination of products by harmful substances and pathogens transferred by people, domestic animals, and vermin, d) placing raw products and finished ones in separate places to prevent their cross-contamination, e) cooking of foods at scheduled temperatures and for a time sufficient to annihilate harmful microorganisms, f) storage of finished foods at the scheduled temperature **(WHO, 2018)**.

Thus, the issue of food safety and quality control is an important area of research in Ukraine and across the world. A similar issue has been raised and studied in Russia **(Tsaregorodtseva et al., 2020)**. The authors argue for the use of the best practices of EU countries in Russia, to improve its own regulatory and legislative framework to empower the elimination of threats to the safety of food raw materials and food products. This will allow the reduction to an acceptable level of the risks of contaminating food products at all stages from production to sales, thereby guaranteeing the end-user safety of food products.

Scientific hypothesis

As a result of a systematic analysis of theoretical research, we will have formulated and implemented the principles of a systematic approach to the development of an integrated management system for product quality and safety of meat processing enterprises in Ukraine. This approach will provide an opportunity to develop a risk and critical control point (HACCP) plan for meat processing plants, following the example of the world's best practices. Based on a comprehensive approach to the systematization of international standards, an integrated system of product quality management and the safety of meat processing enterprises operating in conditions of minimal environmental damage will be developed. Thanks to the introduction of an integrated quality system, the overall level of food safety in Ukraine will be increased.

MATERIAL AND METHODOLOGY

Theoretical research methods were used in the work: a comprehensive study of the provisions of legislative, regulatory, and normative documents on the criteria for compliance of food industry enterprises with the norms of product quality and safety, the proper state of the environment, and safe working conditions for staff.

Theoretical methods of research

Methods of literary source and document analysis, induction and deduction, analysis and synthesis **(Hennink, Hutter and Bailey, 2020)** were used, which made it possible to determine the principles of a systematic approach to the development of an integrated management system for product quality and safety of meat processing enterprises in Ukraine.

International documents as a subject of analysis:

1) HACCP meat processing plant; good practices of hygiene (GHP), manufacture (GMP), and distribution (GDP).

2) **ISO 45001:2018 (2018)**, **ISO 9001:2015 (2015)**, **ISO 14001:2015 (2015)**, **ISO 22000:2018 (2018)**, **ISO 22004:2014 (2014),** and the national standards of different countries.

Normative documents on the problems of industrial sanitation and safety of work on production lines, as a subject of analysis:

Fire safety rules according to **GOST (1992)**; air quality standards of the working area according to **GOST (1989)**; vibration safety standards according to **DSTU GOST (2009a)**; norms of fire and explosion safety of static electricity according to **GOST (1993)**; safety standards for handling technological equipment according to **GOST (1991)**; norms of safe arrangement of workplaces according to **DSTU GOST (2009b)**; safety standards for technological processes according to **GOST (2014)**; norms of arrangement of supply and exhaust ventilation systems according to **DSTU (2010)**; norms of industrial noise according to the state sanitary norms of **LTO (1999a)**; vibration norms in the organization of production activities according to the state sanitary norms **LTO (1999b)**; microclimate parameters in production facilities according to the state sanitary norms of **LTO (1999c)**; parameters of heating, ventilation and conditioning according to sanitary norms and rules of **SNiP 2.04.05-91 *U (1997)**; the procedure for washing and disinfection of industrial and domestic premises according to the instructions **I 123-5/990-11-84 (1984)**; fire safety rules according to the norms of the document **NAPB (2004)**; lighting standards according to the requirements of the state building code **DBN (2006)**; norms of providing personnel with special clothes, special shoes and personal protective equipment according to the norms of the document **NPAOP (2008)**; the procedure for training and retraining of staff according to the requirements of the document **NPAOP (2005)**; rules of work on electrical installations according to the requirements of the document **NPAOP (1998)**.

Statistical analysis

The classic methods of Deming and Juran were used, which were developed during the whole period of formation of quality management and which have remained relevant today. Their essence is to study the development of methods of quality planning and statistical analysis **(Anderson et al., 1995)**.

RESULTS AND DISCUSSION

The first step in realizing a system of management for the safety of foodstuffs was the introduction by businesspeople of the principles of the HACCP system **(Hulebak and Schlosser, 2002; Lozova, 2019)** and GHP, GMP and GDP, as well as sanitary norms for maintaining equipment, buildings, and installations normalized by the international standard of food safety **ISO 22000:2018 (2018)**. This document normalizes the order of work by identifying risks and verifying the conformity of the index quality of production and its ingredients with their regulated norms (Table 1).

Table 1 Foodstuff quality control procedures.

Stage of work	Procedure	Result
Inspection	Control of conformity of procedures of work with the recommended norms	Working group reaches specified result
Control	Evaluation of results of work and/or comparing quality indices of samples in development with the basic norms	Quality control indices of new products reach their normalized values
Confirmation	Attestation of facilities by manufacture of new products	Production is safe and its quality conforms with the needs of specific groups of the population (children, adults with specified needs, etc.)

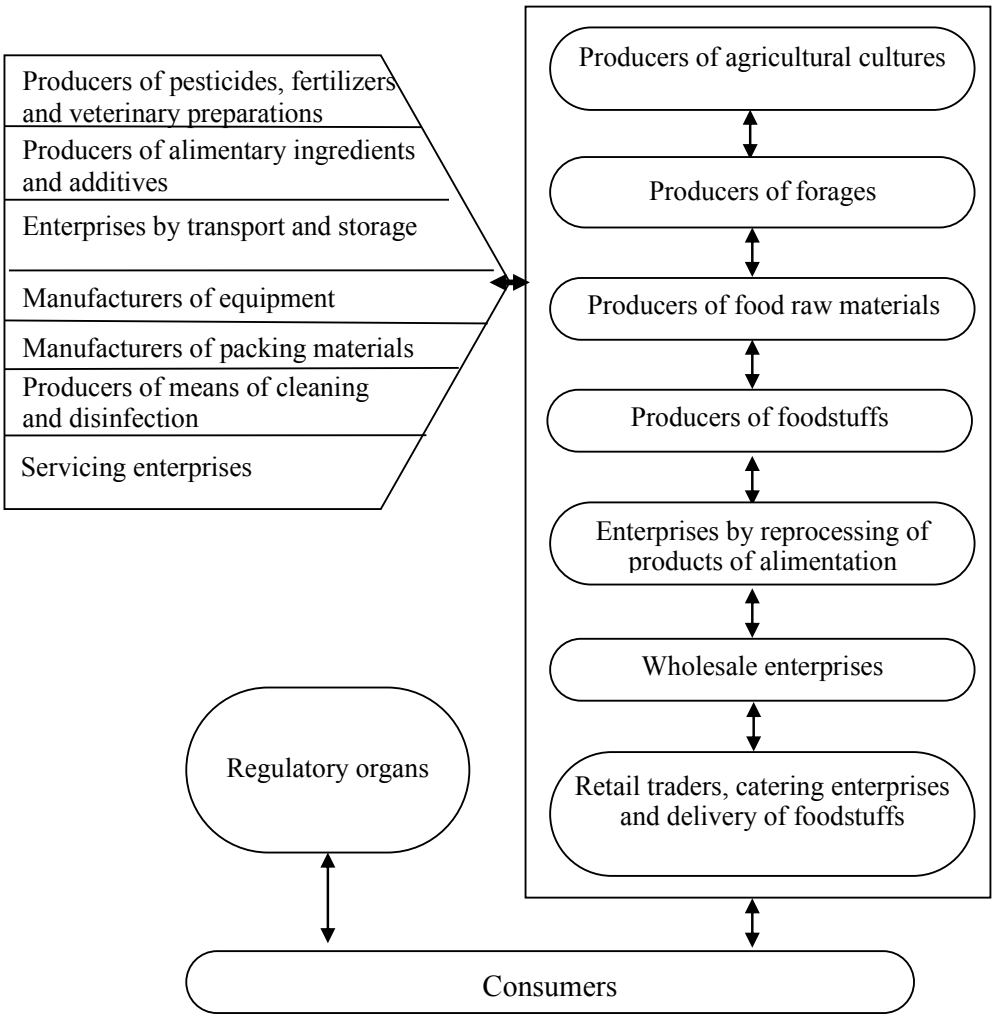

Figure 1 Order of information exchange for raw food.

The auxiliary standard **ISO 22004:2014 (2014)** identifies the objects of control as follows: a) ingredients of foodstuffs, alimentary additives, drinking water, etc., b) processes of treating water, c) state of equipment, condition of working surfaces, packing and other materials, d) compliance with the established requirements of qualification of testing and measuring laboratories and their work procedures, e) observance of norms of personal hygiene and industrial sanitation, f) procedures for storage, transport and distribution of produced foods.

To guarantee observance of the norms established by this document, European persons of the economy have developed several documents regulating the procedures of work for producing safe foods, e.g. the national standards **DS 3027 (2002)** (Denmark standard), **Netherlands specification (2002)**, **BRC (2019)** and **IFC (2019)**.

However, achieving the safety of a certain foodstuff only is not enough in modern conditions because the raw materials and ingredients used are potential sources of hazards, for example, pollution by bacteria, the existence of admixtures of pesticides and heavy metals, and so on. Therefore, the obligatory norm of standard **ISO 22000:2018 (2018)** is the continuous informing of all persons in the food chain (Figure 1).

The typical order of work in assuring the proper quality of manufacture normalizes the international standard **ISO 9001:2015 (2015)**. The ideas at the core of such a document may be classified into four groups: a) planning of quality: establishing the purposes and indices of quality, as well as norms of use of the management system, b) quality management: identification and observance of established norms of work, quality control and correction of non-proper actions, c) assuring quality: works convincing interested parties in the correspondence of objects of control to established norms, d) control and bettering of quality: carrying out work to increase the effectiveness of the enterprise's operation.

At the same time, the quantity of waste formed in the world annually has reached 1.3 billion tons and is estimated to increase to 2.2 billion tons in 2025 **(WHO, 2018)**, so optimizing the procedures of this activity will not solve the problem of assuring healthy conditions of life. Hence here becomes more insistent on the problem of utilization of harmful waste and emissions in the atmosphere, rivers, and seas, because wind, animals, and birds do not know state borders. So, there arose the crucial problem of minimizing the quantity of waste and eliminating sequences of negative human influence on the state of the environment, critical for guaranteeing the health of living and future generations.

We have identified the basic principles of a system of ecological management as a constituent part of a general system of management. They are successfully used in the training of quality management specialists **(Bal-Prylypko et al., 2017)**: a) principle of stable progress: satisfying the needs of humankind realized without the threat of limiting the capability of future generations to use natural resources, b) principle of raising the environmental purity of the enterprise: introduction of measures that assist in decreasing of the level of the negative influence of the person of the economy on the state of the surrounding nature (air, water, and soils) in conditions of the simultaneous raising of the economic and social effects of manufacture.

Karamanos (2001) and **Mitchell (2003)** believed that the components of an environmental management system are: a) consciousness that humankind is an inseparable part of nature and the state of its being depends completely on the state of the environment, b) consciousness of the possibility of health being conditional on the adequate state of natural systems only, c) consciousness of the scantiness of the natural and resource potential of the planet, d) the voluntary limitation of using natural resources up to a level that would not lead to irreversible changes in the state of nature, e) replacing existing goods manufacturing technologies with ecologically compatible ones, f) limitation (if possible) of the global population and the negative influence of its activities on the state of the environment at local, regional and global levels.

People's anxiety about the crucial worsening of global environmental conditions has also found its reflection in the norms of numerous documents and legal instruments devoted to problems of protecting the state of nature in Ukraine **(Law of Ukraine, 1991)**. The result is the development of international standard 14001:2015 'Environmental management systems – Requirements with guidance for use' **(ISO 14001:2015, 2015)**, which establishes the norms for the protection of surrounding nature.

The basic principles of action to reduce environmental damage from industrial waste can be presented in the form of a pyramid **(Kumar and Kumar, 2018)** (Figure 2).

Finally, the staff of food-producing enterprises is live people who are in continual contact with materials, semi-finished products, and finished foodstuffs that contain compounds and substances potentially harmful for their health. At the same time, all work in manufacturing, packing, storage, transporting and distribution involve contact of products with people, which may lead to product contamination and risks to the future health of consumers if hygiene norms are not observed by the personnel of the enterprise. Therefore, a crucial requirement is the observance of the norms of GHP and the creation of healthy and safe working conditions for personnel engaged in manufacture. The norms for organizing such work are found in the international standard **ISO 45001:2018 (2018)**.

Therefore, an enterprise engaged in work with foods must observe at all times the norms of some documents of regulative character, and control of their observance has to be done by specialized departments in its structure. However, the control functions of different kinds of work double in many cases so, to optimize the organizational structure, top management of enterprises has introduced integrated systems of management that comprise all the norms of documents of an administrative character.

We reckon that at a minimum they have to include the norms of four basic international standards, namely **ISO 9001:2015 (2015)**, **ISO 14001:2015 (2015)**, **ISO 22000:2018 (2018),** and **ISO 45001:2018 (2018)**. The layout of the organization of work in the development of such a system is represented in Figure 3 **(Nikolaenko, 2019)**.

Table 2a Succession of work and characteristics of basic norms of standards **ISO 9001:2015**, **ISO 14001:2015**, **ISO 22000:2018** and **ISO 45001: 2018**, used in the development of integrated management system (block 1).

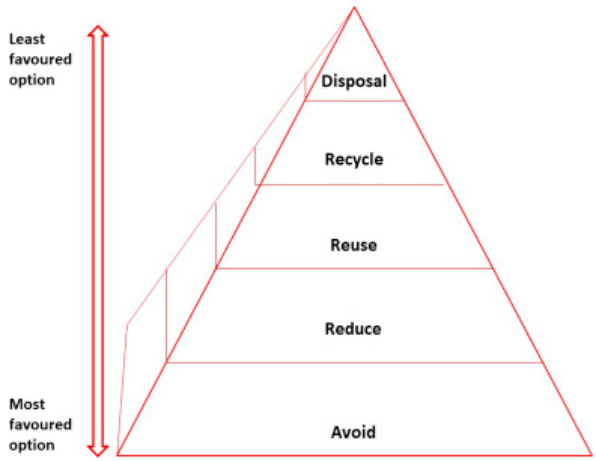

Figure 2 Waste management practice.

This system is also used in the educational process of our university.

The universality of methodology and most of the norms of ISO 9001 were used as a basis for developing system permits to simplify the task of integrating the activities of meat processing enterprises into one management system by the addition of the above standards.

The system offered by us successfully works in the advanced enterprises of Ukraine. We plan to patent it in the future. The succession of works in the development of integrated management systems is shown in Table 2a and Table 2b (blocks 1 and 2) **(Nikolaenko, 2019)**.

The posting shown in Table 2a and Table 2b may be recommended as a typical one in the development of complex integrated quality management systems in meat processing enterprises. The distinctive feature of its chapters is that those have to be taken in the order given in the table.

In Ukraine, the basic document in this area of meat production is the Law of Ukraine 'On Basic Principles and Requirements for Food Safety and Quality' **(Law of Ukraine, 1998)**. However, the norms for production organization established by it have a fragmentary character and cannot be recommended as a basis on which the corresponding products can be designed and put into operation **(Kyryliuk and Kyryliuk, 2017)**. In our opinion, the main reasons are the failure to take into account the provisions of good practices – production, hygiene, distribution, laboratory activities, etc. We eliminate all this in the proposed integrated system (Table 2a and Table 2b). In the proposed variant, the production of meat products is organized in such a way that the probability of occurrence of undesirable situations and a negative impact on the environment is minimized. Today, food legislation in Ukraine is also evolving. The new **Law of Ukraine (2018)** has come into force.

The development was based on the provisions of the Codex Alimentarius Commission, the HACCP principles, and the document **SQF (1995)**. Of greatest practical interest in Ukraine for producers of meat and meat products is Module 11: Food Safety Fundamentals – Good Manufacturing Practices for Processing of Food Products – GFSI El, Ell, Elll, ElV, and L **(SQF, 2017)**. This is especially important for products of animal origin and their processing with a short shelf life and sale.

There is continuous improvement of food production technologies **(Medina et al., 2019)** and the introduction of new product recipes, including those using non-traditional raw materials **(Tavdidishvili et al., 2020)**. All this also requires a comprehensive approach to risk management in the field of meat production.

Microstructural studies of ready-to-cook chopped meat products allow identification of their components, the establishment of the different properties of various tissue and cellular structures, and control of the manufactured articles **(Paska et al., 2019)**. Minced beef as the object of research was modified, with 5%, 10%, or 15% of the meat part replaced with lupin flour and 0.5% with elecampane root powder added as an aromatic raw material. It has been shown that histological studies, with the PAS reaction used, help determine the meat and plant content in the ready-to-cook meat developed, and that hematoxylin and eosin can help determine the functional ingredient content. With this in mind, we conclude that the traceability of meat products is important at all stages, which will ensure an integrated quality system.

Regardless of the size and scope of the enterprise, when developing an integrated management system (IMS) in accordance to the requirements of two or more standards it should be developed a single comprehensive documentation, policy, documented information (procedures, forms of records), processes and management assessment that would create a universal management system for individual objects (quality, food safety, ecology, occupation health and safety, etc.) guided by the general approach of ISO standards to management systems.

Guided by Table 2a and Table 2b, we developed an algorithm for the implementation of IMS, taking into account the requirements of the four standards for management systems in the meat processing plant, presented in Figure 3.

To develop and implement the IMS, a team of specialists from each field (business process management, food safety, ecology, and labour protection) should be established, and a person will be appointed to manage and coordinate the team's activities and be responsible for the development and operation of the overall management system. That is, the IMS managing group should consist of 4 – 5 people. Usually, selected individuals must have appropriate qualifications in their field, understand the processes and manage them, and have sufficient knowledge of the requirements of individual standards. The IMS team leader must have the competence, knowledge, and ability to apply general approaches and requirements to management systems according to selected standards and rules and conditions of integration of management systems, as well as have leadership qualities for overall management and coordination of the IMS group. In the future, it is the IMS group and its head who are responsible for implementing the algorithm for implementing IMS in production.

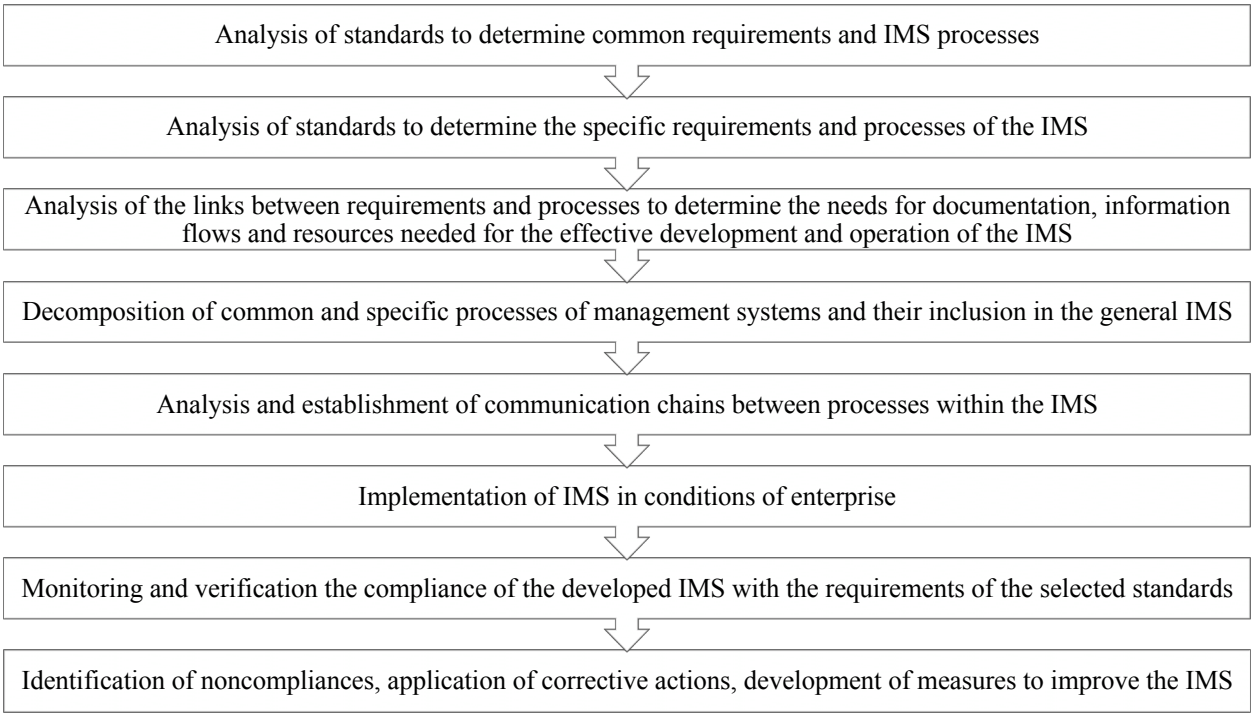

Figure 3 Algorithm of the introduction of IMS in the conditions of the meat-processing enterprises.

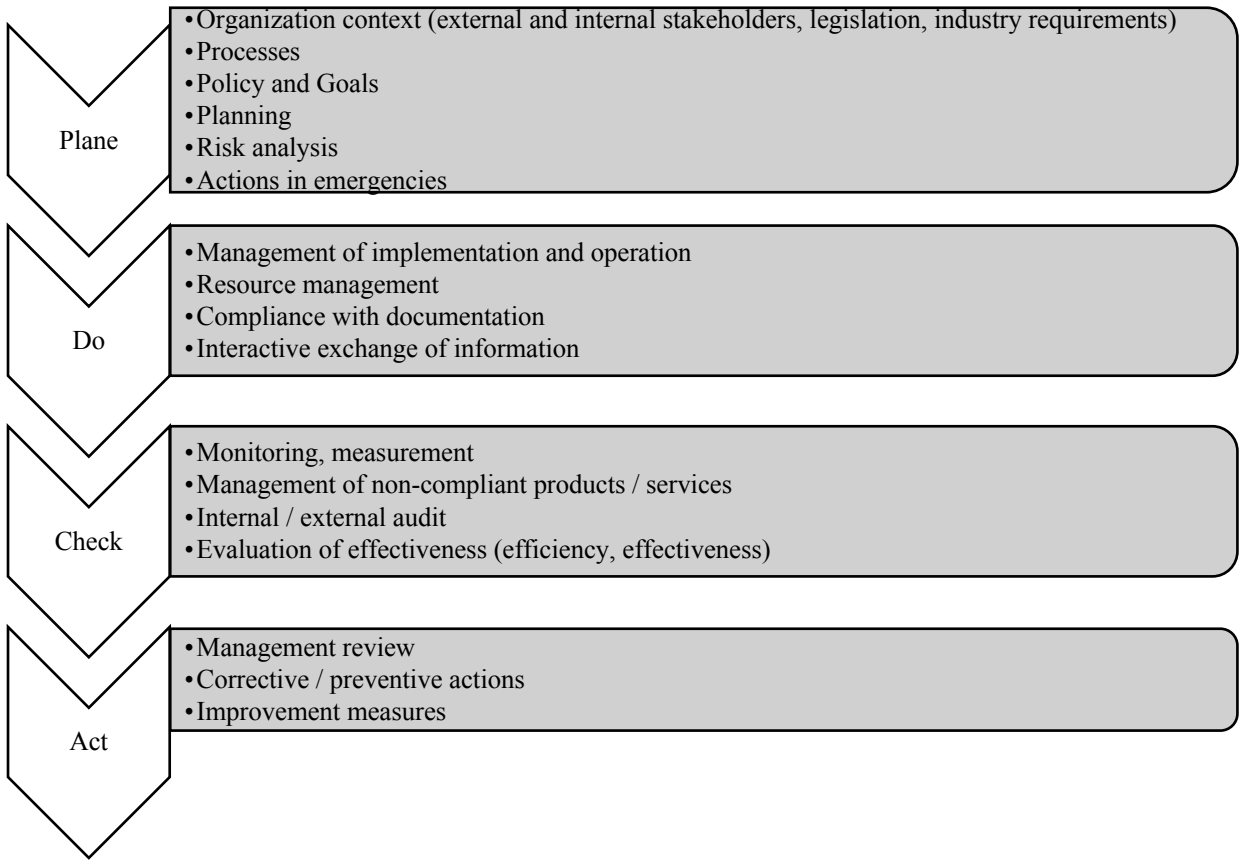

Figure 4 General requirements for IMS, taking into account the cycle Plan-Do-Check-Act.

Applying **PAC 99 Integrated Management (2016)** we have identified common elements of the IMS, taking into account the structure and requirements of the standards **ISO 9001:2015 (2015)**, **ISO 14001:2015 (2015)**, **ISO 22000:2018 (2018)**, **ISO 45001:2018 (2018)**, and the cycle Plan-Do-Check-Act (Figure 4).

Among the common requirements is the requirement to establish the context of the organization, i. e. to identify internal and external stakeholders in the activities of the organization, which either affect the organization or are affected by its activities. Where necessary, the limits of the application of the IMS are agreed with the stakeholders, unless otherwise specified in the contractual obligations or the legislation of the country.

The IMS should not only include external standards and specifications but should also be guided by industry or internal instructions and documentation, provided they are available and acceptable.

Next, the scope of the IMS should be defined, which includes standards, structural units of the enterprise, production sites, products/services, etc.

After defining the scope of the IMS, the management, core, and support processes required for the development, implementation, and operation of the IMS should be identified and the necessary processes should be available in the organization. When determining the processes involved in the IMS, it should be borne in mind that all processes necessary for the proper functioning of the system should be involved, including accounting, marketing, personnel management, etc., because without the inclusion of these processes it is impossible to produce/sell products, services.

In addition to determining the necessary processes, it is necessary to establish their sequence, interaction, and relationship, to establish the criteria and methods necessary to ensure the effectiveness of processes within the IMS.

For each process, it is necessary to develop maps of processes, the main purpose of which is to illustrate the technology of the process and reflect the movement of flows from inputs to outputs between departments and structural units of the enterprise. Exits from one process should be entirely inputs to other processes, and the reflection of inputs and outputs of all involved processes in the enterprise should reflect the relationship and responsibility for the compliance of the final product and activities to the requirements of stakeholders. Process maps should reflect the process with the degree of detail that is necessary to obtain reliable, reproducible, and acceptable process results. The process map is visualized in any form, but there are a number of mandatory elements that should be displayed, among them: name of the process; process operations; resources necessary for the proper course of the process (material, technical, human, information, etc.); competence and qualification of staff; special conditions or parameters of the process; documentation containing requirements for the process product; methods of process monitoring; reporting documentation on the implementation of the process; methods of checking the effectiveness of the process.

As a rule, the graphic and text form of process maps is most often used, which combines a block diagram of the process and a text description of it.

In the future, guided by the requirements of the selected standards for IMS and process maps, the structure of IMS documentation is created. If you define the general documentation that should be within the IMS, it is: IMS policy; objectives taking into account the scope of management of IMS standards; general organizational rules of the enterprise taking into account the requirements of the legislation, stakeholders and the accepted corporate culture; rules of daily routine and remuneration; IMS Guide, which describes the guidelines, processes, and documentation structure of the management system; procedures and documented information as required by relevant standards, specifications used and included in the IMS; documentation required for proper planning, operation, and monitoring of the effectiveness of IMS processes.

The company's policy should include all standards of management systems involved in the IMS, as well as clearly reflect the scope of the system. Objectives should be measurable, achievable, relevant, and include all aspects of management: quality, food safety, environmental and occupational health, and safety. In addition, the goals in different aspects of the IMS should not contradict each other and be clearly understood.

The main document of the IMS, which describes the established management system, is the IMS Guide.

The indicative structure of the IMS Guide is presented below:

1 Integrated management system
- 1.1 Terms
- 1.2 Scope
- 1.3 The organizational structure of IMS
- 1.4 Description of process interaction

2 Regulatory references

3 Terms and definitions

4 Requirements for documented information
- 4.1 General regulations
- 4.2 IMS Guide
- 4.3 Document management
- Records management

5.1 The context of the organization
- 5.1 Defining the context of the organization
- 5.2 Identifying the needs of stakeholders

6 Leadership
- 6.1 Leadership and commitment and leadership responsibilities
- 6.2 Consumer orientation
- 6.3 IMS policy formation
- 6.4 Responsibility and authority

7 Planning
- 7.1 Quality management system
  - 7.1.1 Risks and opportunities
  - 7.1.2 Management measures
- 7.2 Environmental management system
  - 7.2.1 Environmental aspects
  - 7.2.2 Management measures
- 7.3 Food safety management system
  - 7.3.1 Programs are prerequisites
  - 7.3.2 Dangerous factors
  - 7.3.3 Prerequisite programs
  - 7.3.4 Critical control points
  - 7.3.5 Management measures

7.4 Occupational safety and health management system
7.4.1 Hazard identification and risk assessment
7.4.2 Management measures
8 Provision
8.1 Provision of resources
8.2 Human resources, competence and awareness
8.3 Infrastructure
8.4 Functional process environment
8.5 Resources for monitoring and measurement
8.5.1 General regulations
8.5.2 Traceability of measurements
8.6 Knowledge management
8.7 Interactive information exchange
9 Production activity
9.1 Production process planning
9.2 Requirements for products and services
9.3 Definition, analysis and changes in requirements for products and services
9.4 Design and development of new products and services
9.5 Management of processes, products and services supplied by external suppliers
9.5.1 Type and degree of control
9.5.2 Informing suppliers
9.6 Production
9.6.1 Production control
9.6.2 Identification and traceability
9.6.3 Property owned by consumers or external suppliers
9.6.4 Storage
9.7 Supply of products and services
9.8 Change management in production
9.9 Management of inappropriate products and services
9.10 Planning and management of IMS work
9.11 Readiness for emergency stock
10 Evaluation of performance
10.1 General regulations
10.2 Satisfying the needs of consumers
10.3 Analysis and evaluation
10.4 Investigation of events / complaints
10.5 Internal audits
10.6 Management analysis
11 Improvements
11.1 General regulations
11.2 Corrections and corrective actions

After the implementation of the IMS, process monitoring procedures should be provided to obtain objective evidence of the effectiveness of the management system taking into account the established and defined requirements, as well as validation and verification of processes, documentation and overall IMS to assess the effectiveness of the IMS and policy compliance standards and stakeholders.

As a rule, conformity assessment is based on the results of internal and external audits. The overall evaluation of the IMS and the development of measures to improve the management system is based on the results of management analysis. After the analysis, the management updates the policy, goals, resource planning, and the next cycle of the IMS.

CONCLUSION

The principles of a systematic approach to the development of an integrated management system for quality and product safety of meat processing enterprises in Ukraine were formulated and put into practice. This made it possible to develop a plan for risk control and critical control for meat processing plants in Ukraine, taking into account best practices across the world. An integrated system for managing product quality and safety for meat processing enterprises operating in conditions of minimal environmental damage has been developed.

In conclusion, it should be noted that the introduction of IMS in food enterprises in general and meat processing, in particular, will provide a number of advantages:

1 prevent conflicts between management systems that are already in place or planned to be implemented;

2 reduce the level of duplication of documentation, powers, responsibilities and the general level of bureaucratization of the company's management;

3 due to the coherence of the IMS processes, the efficiency and effectiveness of the company's activities are increased and the general coherence of the actions of all structural subdivisions, both production, and non-production, are achieved;

4 a company that implements IMS receives a number of benefits that are aimed at optimizing the external and internal environment (context), and therefore focus on customer and stakeholder satisfaction while meeting the requirements of international standards and best international practices.

THE INFLUENCE OF HONEY ENRICHMENT WITH BEE POLLEN OR BEE BREAD ON THE CONTENT OF SELECTED MINERAL COMPONENTS IN MULTIFLORAL HONEY

Celina Habryka, Robert Socha, Lesław Juszczak

ABSTRACT
Bee products, such as honey, pollen, and bee bread, are an excellent source of bioactive ingredients, including minerals, having a health-supporting effect. However, due to the specific sensory properties of bee pollen and bee bread, the best way to include them in a diet is to add them to honey. Therefore, the aim of this paper was to evaluate the influence of the added bee pollen or bee bread on selected minerals content in multifloral honey. The mineral content was analyzed using absorption atomic spectrometry (FAAS) with prior dry mineralization. On the basis of obtained results, it was found that the addition of bee pollen or bee bread to honey significantly influences the content of selected macro- and microelements, excluding sodium. The greatest increase in mineral content was observed for magnesium, iron, and zinc. Enrichment of honey with the highest dose of bee pollen or bee bread resulted in an over 20-fold increase in the Mg and Fe content, and an over 14-fold increase in the Zn content. Honey enriched with the maximum addition of bee pollen was characterized by a higher content of K, Ca, Mg, Fe, and Cu compared to honey with bee bread. Due to a fact that both bee pollen and bee bread are good sources of minerals, their addition to honey significantly increases its ability to cover daily demand for macro- and microelements.

Keywords: honey; bee pollen; bee bread; mineral composition

INTRODUCTION
Honey is a naturally sweet substance produced by honey bees *Apis mellifera* from plant nectar, secretions of live parts of plants or insect excretions. Honey has been valued for centuries, in different countries and cultures, due to a diversified range of its preventive and health-supporting properties **(Bogdanov et al., 2008; Socha, Habryka and Juszczak, 2016; Socha, Habryka and Juszczak, 2018)**. Consumption of natural honey contributes to improved immunity and enriches diet in many valuable nutrients and bioactive substances. It is an excellent form of easily digestible sugars, vitamins, organic acids, and many other biologically active substances **(Bogdanov et al., 2008; Wesołowska and Dżugan, 2017)**. Due to its highly diversified chemical composition, it is used as a treatment supporting agent **(Bogdanov et al., 2008)**. Apart from direct consumption, it is used to sweeten food and drinks, baking, preserving food, and preparing of mead **(Dżugan, Ruszel and Tomczyk, 2018)**.

Honey contains mineral ingredients deriving mainly from plant juice creating nectar, or from honeydew. The mineral ingredients content in honey depends on its variety and environmental conditions **(Kačániová et al., 2009; Grembecka and Szefer, 2013)**. Differences in contents of bioelements between varieties, or even within the same variety of honey result from their varying content in obtained plant material **(Pohl, Sergiel and Stecka, 2009; Kędzierska-Matysek et al., 2013; Dżugan et al., 2017)**. Levels of these compounds are the lowest in light nectar honey, while they are the highest in honeydew honey **(Gonzalez-Miret et al., 2005)**. Potassium is the main mineral ingredient found in honey, and its content corresponds to half of the total mineral content. Magnesium is found at a relatively stable level in honey, while the calcium content can vary significantly, depending on the honey origin **(Dżugan et al., 2017)**. Phosphorus, iron, manganese, silicon, nickel, and sulfur are found in smaller quantities, while trace elements include copper, barium, cobalt, zinc, tin, palladium, aluminum, tungsten, chromium, titanium, molybdenum, vanadium, cadmium, and others **(Solayman et al., 2016)**. Differences in macro- and microelements contents within the same honey variety results from the biodiversity of material, which contributes to a significant diversification of its mineral composition **(Gonzalez-Miret et al., 2005; Kędzierska-Matysek et al., 2013)**. The number of mineral ingredients found in honey is correlated with species of plants from which the material is harvested. The botanical origin, in turn, is closely correlated with the location of an apiary, because soil composition and climatic conditions also determine the presence of metals in

melliferous plants. Environmental pollution and other anthropogenic processes should also be considered as an additional source of metals in honey, including Cu, Fe, and Zn **(Kačániová et al., 2009; Pohl, Sergiel and Stecka, 2009; Roman and Popiela, 2011; Solayman et al., 2016)**.

Apart from honey, bee products also include pollen, bee bread, propolis, royal jelly, bee venom, and wax. Pollen, depending on plants visited by bees, forms pollen loads of a color characteristic for a given plant species. Its composition is varied and depends on the origin and on weather conditions prevailing during anther forming and maturing **(Gabriele et al., 2015; Kędzia and Hołderna-Kędzia, 2016)**. Bee pollen is a diversified plant product rich in biologically active ingredients. Over 200 active substances were found in it **(Gabriele et al., 2015; Kieliszek et al., 2018)**. Bee pollen is also rich in valuable bioelements essential for human health. They include macroelements such as phosphorus, potassium, magnesium, and calcium, microelements such as iron, manganese, zinc, and trace elements like copper, cobalt, and nickel **(Kędzia and Hołderna-Kędzia, 2016)**.

The bee bread is formed from plant pollen preserved by bees. Bees place flower pollen loads in honeycomb cells, wetting it with the secretion of their salivary glands and honey. Then bees pack it tightly in the cells to secure it against the access of air **(Kieliszek et al., 2018; Bakour et al., 2019)**. In anaerobic conditions, this mixture of pollen, honey, and bee saliva is fermented by *Lactobacillus* bacteria, which contribute to the formation of antibacterial peptides, hydrogen peroxide, and organic acids. Enzymes found in bee saliva and bacteria themselves contribute to differences in the chemical composition of fresh pollen loads and bee bread **(Kieliszek et al., 2018; Bakour et al., 2019)**. When compared to pollen, bee bread is characterized by higher nutritional value, better digestibility, and richer chemical composition **(Socha, Habryka and Juszczak, 2016)**.

The literature review indicates that bee products such as bee pollen and bee bread are an excellent source of bioactive ingredients, and their addition to the diet may significantly enrich it with bioactive substances, including minerals, having health-supporting effects. Due to the specific sensory properties of bee pollen and bee bread, apparently, the best way to include them in a diet is to add them to honey **(Kňazovická et al., 2011; Juszczak et al., 2015)**.

Therefore, the aim of this paper was to evaluate the influence of the added bee pollen or bee bread on selected minerals content in multifloral honey.

Scientific hypothesis

Enrichment of honey with bee pollen or propolis at a sensoric acceptable level causes a significant increase in the content of mineral components.

MATERIAL AND METHODOLOGY

Materials

The multiflower honey (District Beekeeping Cooperative "Pszczelarz", Krakow, Poland) and the bee pollen and bee bread (Biopharmaceutical Laboratory „Aria", Krakow, Poland) were used as experimental materials. Based on the preliminary sensory assessment, honey was enriched with bee pollen or bee bread in a quantity ranging from 5% to 25%. The use of the maximum pollen addition to honey, at a level of 25%, was supported by conducted preliminary sensory evaluation. The increasing levels of pollen or bee bread in honey changed the perception of its color, smell, texture, and palatability.

Methods

Determination of the chosen mineral components content was made by atomic absorption spectrometry (ASA) in accordance with the requirements of the Polish Standard **(PN-EN 14082, 2004)**. Mineralization of the tested sample was carried out at 600 °C in a muffle furnace (SNOL 8.2/1100, Lithuania) for 12 h. After mineralization, the ash content was calculated. The mineralized samples were dissolved in hot 6.0M hydrochloric acid and then in 0.5 M nitric acid. The chosen mineral components in honey were determined with an Avanta Sigma atomic absorption spectrometer (GBC, Australia), flame technique (FAAS), using acetylene/air or, for calcium, acetylene/nitrogen monoxide). The levels of macroelements including calcium, magnesium, sodium, and potassium as well as microelements: iron, zinc, copper, and manganese were determined. The quantitative analysis was carried out on a base of calibration curves made for standard solutions (Merck, Germany). The work parameters of the spectrometer are given in Table 1.

Table 1 Spectrometer parameters used in the mineral composition analysis.

Element	Wavelength (nm)	Working range (μg.ml^{-1})	Equation of the calibration graph	R^2
K	769.9	2.0 – 12.0	y = 8.947x + 0.017	0.9998
Na	589.6	0.2 – 1.5	y = 6.320x - 0.023	0.9983
Ca	422.7	1.0 – 4.0	y = 42.421x - 0.343	0.9905
Mg	202.6	0.5 – 1.5	y = 0.799x + 0.025	0.9872
Fe	248.3	0.2 – 0.4	y = 23.894x – 0.422	0.9948
Zn	213.9	1.0 – 0.8	y = 3.925x + 0.071	0.9981
Cu	324.7	0.1 – 1.5	y = 12.368x + 0.066	0.9995
Mn	279.8	0.2 – 0.4	y = 8.988x + 0.028	0.9973

Statistical analysis

The analyses were made in triplicate, and the results were expressed as mean values ± standard deviations. In order to determine the significant differences between the means, the data were treated by one-way analysis of variance, and the Fisher test at a significance level α = 0.05 was calculated.

In order to assess the impact of both the type and amount of additive level (i.e., bee pollen or bee bread) to honey a two-way analysis of variance was performed. The values of Pearson's linear correlation coefficients between ash content and the content of individual mineral components were calculated, and their significance was verified by the Student's t-test at the significance level of 0.05. Calculations were performed with statistical software package Statistica 11.0 (StatSoft Inc., USA).

RESULTS AND DISCUSSION

The physical and chemical properties and nutritional value of honey are significantly influenced by its ash content, which also reflects the content of total and individual minerals. The ash content is a parameter depending on botanical origin, and it is also correlated with honey color **(Gonzalez-Miret et al., 2005; Pohl, Sergiel and Stecka, 2009)**. The ash content in the studied multifloral honey and in honey enriched with bee pollen or bee bread is shown in Figure 1. The determined ash content was 0.19 g per 100 g of pure multifloral honey.

The obtained results are within the extensive range specified for Polish multifloral nectar honeys **(Kędzierska-Matysek et al., 2013)**. The increasing addition of pollen or bee bread contributed to a significant (p <0.05) proportional increase in the honey ash content.

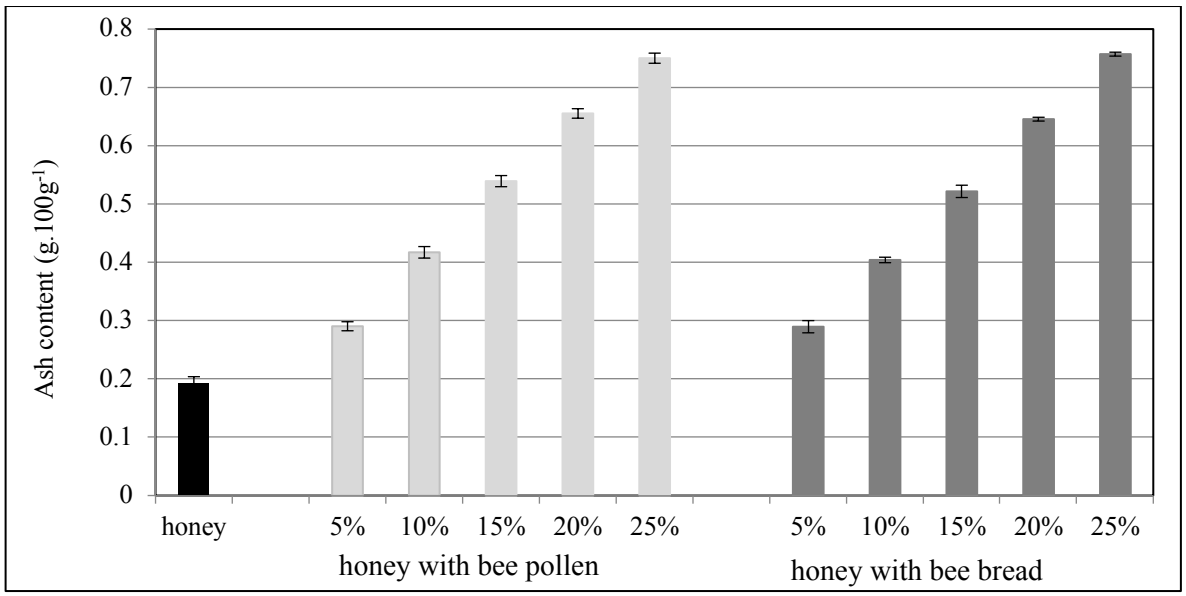

Figure 1 Ash content of multifloral honey and samples enriched with pollen or bee bread.

Table 1 list average contents of macroelements in multifloral honey and in honeys enriched with bee pollen or bee bread. In the plain multifloral honey, potassium was an element found at the highest level, and its content corresponded to over 90% of the total minerals determined. Its average content amounted to 271.4 mg per 100 g (Table 1), and this confirms earlier results for multifloral honeys **(Grembecka and Szefer, 2013; Kędzierska-Matysek et al., 2013; Juszczak et al., 2018)**. The addition of pollen to honey significantly (p <0.05) increased its potassium levels. The greatest increase in potassium content, to 639.3 mg.100g^{-1} was noted for 25% concentration of bee pollen in honey.

This observation confirms results obtained by **Juszczak et al. (2018)** for the commercial samples of honey with pollen added, who determined its potassium content at a level of 494 mg to 651 mg per 100 g. A significant (p <0.05) increase in potassium levels in honey enriched with pollen results from the high content of that ingredient in pollen. According to **Kędzia and Hołderna-Kędzia (2016)**, potassium content in pollen ranges from 284.3 mg to 2000 mg per 100 g. The potassium content in honey enriched with bee bread increases in a similar way, where a 5% addition already increased the content of that element to 350.8 mg.100g^{-1} and a 25% addition increases that content to the level of 617.8 mg.100g^{-1} (Table 1). Much higher average potassium content in commercial samples of honey enriched with bee bread was observed by **Juszczak et al. (2018)**, and this resulted from a significantly higher addition of bee bread. The conducted two-way analysis of variance has shown that the potassium content in enriched honey significantly (p <0.05) depends both on the type and the level of the added ingredient. Furthermore, a significant positive linear correlation (r = 0.9823) was found between ash and potassium content. A significant increase in potassium content following the addition of bee products to honey significantly influences its nutritional value. While 100 g of multifloral honey covers ca. 13% of the daily potassium demand, products enriched with pollen or bee bread cover over 39% of that demand.

The sodium content in the analyzed multifloral honey amounted to 8.1 mg.100g^{-1}, representing ca. 2.7% of the total determined mineral ingredients (Table 1), and this confirms previous observations for Polish multifloral honey **(Kędzierska-Matysek et al., 2013)**. The addition of bee products did not result in a significant (p >0.05) change in contents of this element, and this observation was confirmed by the two-way analysis of variance (Table 1). Studies conducted by **Grembecka and Szefer (2013)** show that the bee pollen sodium content amounts to 5.86 mg.100g^{-1}, while **Bakour et al. (2019)** determined the sodium content in bee bread at a level of 14.2 mg.100g^{-1}.

Thus, the literature data indicates that the sodium content of bee pollen and bee bread is similar to its content in honey, therefore, their addition does not significantly (p >0.05) influence the content of that macroelement.

The calcium content in the analyzed multifloral honey amounted to 13.9 mg.100g^{-1}, representing ca. 4.7% of the total determined mineral ingredients (Table 1), and is within an extensive range reported for Polish multifloral honey **(Grembecka and Szefer, 2013, Kędzierska-Matysek et al., 2013, Juszczak et al., 2018)**.

Increasing addition of bee pollen to honey increased the calcium content from 23.9 mg to 67.8 mg per 100 g of the product, while enrichment with bee bread increased the content of this element from 21.5 mg to 50.1 mg.100g^{-1} (Table 1). The literature data indicate that the calcium content in pollen is much higher than in multifloral honey **(Grembecka and Szefer, 2013)**, hence its significant (p <0.05) increase after the enrichment. The conducted two-way analysis of variance has shown that the calcium content in enriched honey significantly (p <0.05) depends both on the type and the level of the added substance. Furthermore, a significant positive linear correlation (r = 0.9625) was found between ash and calcium content. Although honey is not a good source of calcium because at the determined content per 100 g (Table 1) it covers less than 2% of daily demand for this element, yet when honey is enriched with pollen or bee bread, the coverage of the daily calcium demand rises to ca. 6% to 8% per 100 g of the product.

Table 2 Microelements content in multifloral honey and samples enriched with pollen or bee bread.

Type of ingredient	Amount of ingredient (%)	Fe (mg.100g^{-1} ±SD)	Zn (mg.100g^{-1} ±SD)	Cu (mg.100g^{-1} ±SD)	Mn (mg.100g^{-1} ±SD)
honey	0	0.34 ±0.03^{k}	0.19 ±0.00^{i}	0.10 ±0.00^{i}	1.20 ±0.01^{k}

	10	3.73 ±0.03^{g}	1.50 ±0.00^{e}	0.18 ±0.01^{f}	2.89 ±0.02^{d}
	15	3.38 ±0.03^{h}	2.27 ±0.05^{c}	0.26 ±0.02^{e}	3.61 ±0.02^{c}
	20	5.01 ±0.24^{d}	2.74 ±0.01^{b}	0.30 ±0.02^{d}	4.21 ±0.01^{b}
	25	7.26 ±0.19^{b}	3.75 ±0.02^{a}	0.46 ±0.01^{b}	4.92 ±0.04^{a}
Two-way ANOVA – p					
Factor I (Type)		p <0.05	p <0.05	p <0.05	p <0.05
Factor II (Amount)		p <0.05	p <0.05	p <0.05	p <0.05
Factor I x Factor II		p <0.05	p <0.05	p <0.05	p <0.05

Note: Mean values assigned with the same letters in particular columns are non-significant at the 0.05 level of confidence.

In the analyzed multifloral honey, magnesium was at the level of 2.3 mg.100g^{-1} (Table 1), and this corresponds to over 0.74% of the total mineral ingredients determined. The determined magnesium content was within the extensive range reported for Polish multifloral honeys **(Grembecka and Szefer, 2013; Kędzierska-Matysek et al., 2013; Juszczak et al., 2018)**. The addition of bee pollen or bee bread significantly (p <0.05) influences an increase in the magnesium content, and this observation was confirmed by the results of the two-way analysis of variance (Table 1).

As reported by **Grembecka and Szefer (2013)**, floral pollen is richer in magnesium than honey, therefore, its addition contributed to a significant (p <0.05) increase in contents of that element to a level of 50.7 mg.100g^{-1} in the enriched honey. In honey enriched with bee bread content of that element was not much lower (Table 1). Although honey is not a good source of magnesium because at the determined content per 100 g (Table 1) it covers only about 0.6% of daily demand for this element, yet when honey is enriched with pollen or bee bread, the coverage of the daily magnesium demand rises to ca. 12% to 13% per 100 g of the product.

Determinations also included contents of iron, zinc, copper, and manganese in multifloral and enriched honey. The average contents of these microelements are presented in Table 2. Iron is an element that in the studied honey represented 0.11% of all determined mineral compounds, and its content amounts to 0.34 mg.100g^{-1} (Table 2). The obtained result was within the extensive range reported for Polish multifloral honey **(Grembecka and Szefer, 2013, Kędzierska-Matysek et al. 2013)**. The addition of bee pollen to honey at a level of 25% contributed to the significantly (p <0.05) increase in the iron content to the level of 9.67 mg.100g^{-1}, while the addition of the bee bread increased the iron content to the value of 7.26 mg.100g^{-1}. Slightly lower values for the iron content in samples of commercial honey enriched with pollen or bee bread were reported by **Juszczak et al. (2018)**. According to **Grembecka and Szefer (2013)**, bee pollen is a rich source of iron, and its content ranges from 3.26 to 3.96 mg.100g^{-1}. For this reason, honey enrichment with these bee products significantly (p <0.05) contributes to the increase in the level of that microelement. The conducted two-way analysis of variance has shown that the iron content in enriched honey significantly depends both on the type and the level of the added substance. Furthermore, a significant positive linear correlation (r = 0.9471) was found between ash and iron content. A significant increase in iron content following the addition of bee products to honey significantly influences its nutritional value. While 100 g of multifloral honey covers ca. 2.5% of the daily iron demand, enriched honey cover as much as 69% of that demand for bee pollen and ca. 52% for bee bread.

In the analyzed honey, the zinc content was at the level of 0.19 mg.100g^{-1} (Table 2), and this corresponds to over 0.06% of the total mineral ingredients determined. The obtained values are consistent with data reported by **Grembecka and Szefer (2013)** for Polish honey, and by **Kačániová et al. (2009)** for Slovak honey. Other report indicate a slightly higher Zn content in Polish multifloral honey **(Kędzierska-Matysek et al., 2013; Juszczak et al., 2018)**. With the rising addition of bee pollen, the Zn content in tested samples also significantly (p <0.05) increased, and for the addition of 25% it reached 2.73 mg.100g^{-1} (Table 2). The zinc content at the maximum bee bread concentration was 3.75 mg.100g^{-1} (Table 2). The similar zinc content in commercial samples of honey enriched with pollen was reported by **Grembecka and Szefer (2013)** and **Juszczak et al. (2018)**. According to **Grembecka and Szefer (2013)**, bee pollen is a rich source of zinc, and its content in this substance amounts to 2.9 mg.100g^{-1}. For the bee bread used as a honey ingredient, the increase of the zinc content was higher than in the case of pollen, and with the maximum supplementation, the content of that microelement reached 3.75 mg.100g^{-1}. As the two-way analysis of variance demonstrated, both the type and the level of the additive have a significant (p <0.05) influence on zinc content in enriched honey. Furthermore, a strong positive linear correlation (r = 0.9690) was found between ash and zinc content. An increase in zinc content following enrichment of honey with bee products significantly influences its nutritional value. While 100 g of multifloral honey covers ca. 2% of the daily zinc demand, enriched honey cover that demand in ca. 27% for pollen and ca. 37% for bee bread.

The copper content in both multifloral honey and honey enriched with bee products was the lowest of all mineral ingredients. In the multifloral honey, the copper content amounted to 0.10 mg.100g^{-1} (Table 2), and this corresponds to just 0.03% of all elements determined. The obtained results are similar to values reported by **Kędzierska-Matysek et al. (2013)** for Polish honey, and by **Kačániová et al. (2009)** for Slovak honey. As the conducted two-way analysis of variance has shown, both the type and the level of the additive have a significant (p <0.05) influence on the copper content in enriched honey (Table 2) and the addition of pollen or bee bread increases the content of the discussed element about five times. Furthermore, a strong positive linear correlation (r = 0.9603) was found, indicating a relationship between ash and copper content. The average reference human demand for copper is low and amounts to 1 mg. While 100 g of multifloral honey covers ca. 10% of the daily copper demand, enriched honey cover that demand in ca. 57% for pollen and ca. 46% for bee bread.

In the analyzed honey, the manganese content was at the level of 1.2 mg.100g^{-1} (Table 2), and this corresponds to 0.40% of the total mineral ingredients determined **(Grembecka and Szefer, 2013; Kędzierska-Matysek et al., 2013; Juszczak et al., 2018)**. The determined value is within the extensive range reported for Polish multifloral honey. An addition of bee pollen or bee bread to honey caused a significant (p <0.05) increase in the manganese content. For bee pollen, the manganese content increased about two times, while for bee bread it increased four times. The conducted two-way analysis of variance has shown that the manganese content in enriched honey significantly (p <0.05) depends both on the type and the level of the bee product added. Honey can be considered a very good source of manganese, as at the determined level of this ingredient, 100 g of honey covers 60% of the daily demand. Honey enrichment with bee products, which increased the manganese content, also caused honey's ability to cover the daily demand for that element to a level of 117% for pollen and as much as 246% for bee bread.

CONCLUSION

Based on obtained results it was found that the addition of pollen or bee bread to honey significantly influences the content of ash and selected macro- and microelements, excluding sodium. Significant positive linear correlations between the ash content and the content of some elements were observed. The greatest increase in mineral content was observed for magnesium, iron, and zinc. Enrichment of honey with the highest dose of bee pollen or bee bread resulted in an over 20-fold increase in the Mg and Fe content, and an over 14-fold increase in the Zn content. Honey enriched with the maximum addition of bee pollen was characterized by a higher content of K, Ca, Mg, Fe, and Cu compared to honey with bee bread. In turn, honey enriched with bee bread was characterized by a higher content of Zn and Mn. Due to a fact that both bee pollen and bee bread are good sources of minerals, their addition to honey significantly increases its ability to cover daily demand for macro- and microelements.

SIMULTANEOUS DETERMINATION OF SWEETENERS AND PRESERVATIVES IN BEVERAGES BY HPLC-DAD-ELSD

Pavel Diviš, Zuzana Jurečková, Milena Vespalcová, Jaromír Pořízka, Lenka Punčochářová

ABSTRACT

People suffering from diabetes or being overweight must severely reduce their sugar use, often seeking food with sweeteners. Often, sugar is replaced by non-nutritious sweeteners in beverages, which also contain several other substances like vitamins, caffeine, amino acids, phenolic compounds and thus increasing the shelf life of the beverages is additionally treated with the addition of preservatives. As the concentration of additives in food (including beverages) is determined by the legislation in force, it is necessary to have an appropriate analytical method for food control. Since artificial sweeteners and preservatives are very different substances, they are determined separately using different HPLC methods. In this work HPLC method combining the advantages of specific (diode array detector, DAD) and universal (evaporative light scattering detector, ELSD) detector was validated and used for simultaneous determination of benzoic acid, sorbic acid, aspartame, acesulfame K, saccharin, sucralose and steviol glycosides in sugar-free beverages. The proposed analytical method showed good linearity, precision, and accuracy. Measured limits of detection (0.6 – 11.8 mg.dm^{-3} depending on the analyte) were sufficient to analyze 5-times diluted beverage samples. The validated method has been successfully used for the simultaneous analysis of artificial sweeteners and preservatives in beverage samples (energy drinks, ice teas, carbonated drinks). Except for steviol glycosides, the concentration of monitored substances in beverages did not exceed the maximum permitted concentrations given in the valid legislation.

Keywords: sweeteners; preservatives; beverage; chromatography; DAD ELSD detectors

INTRODUCTION

Carbohydrates are the most important and quickest source of energy, accounting for more than half the energy value of our food. In addition to the natural carbohydrate content, foods are further sweetened with sugars and various sweeteners that give the products a pleasant sweet taste. Sweeteners are divided into intensive (non-nutritious) and bulk (nutritional) sweeteners **(Basoli and Merlini, 2003)**. Intensive sweeteners include both synthetic and natural sweeteners. The most commonly used are saccharin, sucralose, acesulfame K, stevioside, and rebaudioside A. The most popular bulk sweeteners are erythritol, sorbitol, xylitol, maltitol, isomalt, lactitol, and mannitol **(Mortensen, 2006)**. An increase in the number of autoimmune diseases, an ageing population, and above all, an unhealthy lifestyle is increasing the proportion of people suffering from diabetes. People with diabetes cannot use their blood glucose. This leads to a rise in blood sugar (hyperglycaemia) and other serious consequences **(Bartnik, Norhammar and Rydén, 2007)**. In addition to diabetes, excessive intake of refined sugars also poses a problem in terms of obesity and tooth decay **(Kamal, O´Toole and Bernabé, 2019)**. The use of sugar substitutes and intense sweeteners makes it possible to produce sweet foods for people suffering from diabetes while reducing the caloric value of the food at the same time it reduces the risk of obesity. The use of sweeteners in food products is governed by applicable national legislation. The list of permitted sweeteners in the Czech Republic is given in the Decree No. 122/2011.

Preservatives ensure the quality and safety of the product and prevent the adverse reactions that are responsible for food spoilage. At the same time, they inhibit the growth of undesirable microorganisms (bacteria, fungi, yeasts) and thereby prolong the shelf life of food during distribution and storage. Preservatives can be divided into natural, synthetic, and antibiotic **(Silva and Lidon, 2016)**. Preservatives used in the food industry must meet certain criteria. Preservatives and their metabolites must not be toxic or harmful. They should be readily soluble in water and have sufficient stability, even at higher temperatures. It must have antimicrobial properties within the pH range of a particular foodstuff. Preservatives should not affect the sensory properties of products and react with other food ingredients. The most common synthetic preservatives used in the food industry are benzoic acid, sorbic acid, or salts thereof.

Since the concentration of sweeteners and preservatives used in food production is limited by the laws in force it is necessary to monitor these substances in food and to have

the necessary analytical methods for this purpose. The most commonly used method for analysis of sweeteners and preservatives is high-performance liquid chromatography with UV or DAD detector **(Sik, 2012; Ha et al., 2013; Javanmardi et al., 2015; de Queiroz Pane et al., 2015)**. Since some substances absorb a small amount of radiation in the 200 – 700 nm range, universal detectors such as MS **(Yang and Chen, 2009; Di Donna et al., 2017)** or ELSD **(Wasik, McCourt and Buchgraber, 2007)** are also used. Due to the different nature of the substances, sweeteners and preservatives are usually determined using different HPLC methods separately. In this work HPLC method combining the advantages of specific and universal detectors was validated and used for simultaneous determination of benzoic acid, sorbic acid, aspartame, acesulfame K, saccharin, sucralose, and steviol glycosides in beverages.

Scientific hypothesis

By combining two detectors (DAD and ELSD) and by using HPLC it is possible to determine selected sweeteners together with preservatives in beverages using one method and one injection.

The concentration of sweeteners and preservatives used in sugar-free drinks complies with the limits set out in the applicable legislation.

MATERIAL AND METHODOLOGY

The individual standards of sweeteners and preservatives as well as formic acid, ammonium acetate, and triethylamine were purchased from Sigma-Aldrich (Germany). The purity of all standards and chemicals except stevioside and rebaudioside A was at least 99 %. The purity of stevioside was >95 % and purity of rebaudioside A was >96 %. Methanol, acetonitrile, and acetone (HPLC grade) were purchased from VWR (France). Ultrapure water with resistivity > 18 MΩcm was obtained from ELGA Purelab Classic UV (Veolia, France).

An Agilent 1260 liquid chromatograph with Poroshell 120 EC-C18 (4.6 x 150 mm, 2.7 μm) column, equipped with 1260 Infinity diode array detector (DAD) and 1260 Infinity evaporative light scattering detector (ELSD) was used in this study. The injection volume was 5 μL. The flow of the mobile phase was 0.5 $mL.min^{-1}$. The temperature in the column thermostat was 30 °C. The signal from the DAD detector was monitored at 210 nm. For ELSD detector nitrogen flow of 2 $dm^{-3}.min^{-1}$, nebulization temperature of 90 °C and evaporating temperature of 95 °C has been set.

Samples of sugar-free beverages were purchased from the supermarket located in Brno, Czech Republic. Four samples of energy drinks (S1 – S4), 2 samples of carbonated drinks (S5 – S6), and 2 samples of iced teas (S7 – S8) were purchased.

Statistical analysis

For each sample data analysis and statistical evaluation were performed in Microsoft Excel (Microsoft, USA) and XL-stat (Addinsoft, France, version 2014.5.03). Before the main data analysis, results were tested for outliners using the Grubbs test at significance level α=0.05).

RESULTS AND DISCUSSION

First, a suitable column was selected for the HPLC method to be tested. Non-polar C18 columns are most commonly used in the literature for the type of analysis required **(Grembecka et al., 2014; de Queiroz Pane et al., 2015; Sik, 2012)**. Thus, the end-capped Poroshell 120 EC-C18 column, which is packed with solid-core surface-porous microparticles and a porous silica gel outer layer, to which a non-polar dimethyl-n-octadecyl silane monolayer is bound, was chosen for the method being investigated.

The next step was to select the appropriate mobile phase. In the literature, mobile phases containing phosphate buffers are often mentioned for the analysis of sweeteners and preservatives **(Dossi et al., 2006; de Queiroz Pane et al., 2015; Zygler, Wasik and Namieśnik, 2009)**, however, the phosphate buffer is not compatible with the ELSD detector, and therefore a mobile phase with a different composition had to be chosen. Thus, the use of a mobile phase containing methanol, acetonitrile and 0.01 $mol.dm^{-3}$ ammonium acetate (mobile phase 1) and a mobile phase containing methanol (A), acetone (B) and a mixture of 0.02 $mol.dm^{-3}$ formic acid and 0.02 $mol.dm^{-3}$ triethylamine (C) (mobile phase 2) was investigated. Using Mobile Phase 1, separation of all analytes was not possible even by gradient adjustment. By using mobile phase 2, on the contrary, by optimizing the gradient, optimal separation of all analytes (except stevioside and rebaudioside A) was achieved. Stevioside and rebaudioside were mixed to one standard and quantified together as steviol glycosides (Figure 1 and Figure 2). The final gradient setting was: time 0 – 4 min 85% v/v C, 10% v/v A, 5% v/v B; time 4 – 10min 70% v/v C, 25% v/v A, 5% v/v B; time 10 – 15 min 60% v/v C, 35% v/v A, 5% v/v B; time 15 – 30 min 35% v/v C, 60% v/v A, 5% v/v B; time 30 – 40 min 85% v/v C, 10% v/v A, 5% v/v B.

In the following step, the linearity was verified. Calibration plots were constructed using mixed standards of 10, 25, 50, 100, 250, and 500 $mg.dm^{-3}$ (the 10 $mg.dm^{-3}$ standards were omitted for sucralose and steviol glycosides). Because the response function of the ELSD detector is known to be nonlinear, a logarithmic conversion for both concentration and peak area was performed. For all constructed calibration curves coefficients r^2 were >0.99 showing very good linearity in the concentration range tested.

The precision of the investigated method was verified by repeatability test during which a mixed standard of 10 $mg.dm^{-3}$ of the analytes of interest was repeatedly injected onto the column (steviol glycosides and sucralose concentration was 25 $mg.dm^{-3}$). Results from this test are presented in Table 1. The RSD values of the retention time were found to be <1%, the RSD of area and height of each analyte peak was found to be <2%.

Limits of detection and quantification were determined from calibration lines after repeated injection of a mixed standard of 10 mg.dm^{-3} of the analytes of interest (steviol glycosides and sucralose concentration was 25 mg.dm^{-3}) according to the method described by **Shirivastava and Gupta (2011)**. The limit of detection was determined to be 0.9 mg.dm^{-3} for acesulfame K, 0.6 mg.dm^{-3} for saccharin, 1.6 mg.dm^{-3} for aspartame, 10.4 mg.dm^{-3} for sucralose, 5.5 mg.dm^{-3} for benzoic acid, 4.4 mg.dm^{-3} for sorbic acid and 11.8 mg.dm^{-3} for steviol glycosides. Limit of quantification was determined to be 2.7 mg.dm^{-3} for acesulfame K, 1.9 mg.dm^{-3} for saccharin, 4.9 mg.dm^{-3} for aspartame, 31.4 mg.dm^{-3} for sucralose, 16.5 mg.dm^{-3} for benzoic acid, 13.3 mg.dm^{-3} for sorbic acid and 35.4 mg.dm^{-3} for steviol glycosides.

The accuracy of an analytical method was determined by performing a recovery test. The background concentration of analytes of interest in the sample used for the recovery test was 278 mg.dm^{-3} (acesulfame K), 75 mg.dm^{-3} (sucralose),
222 mg.dm^{-3} (steviol glycosides), 147 mg.dm^{-3} (benzoic acid) and 125 mg.dm^{-3} (sorbic acid). The sample was further spiked with all analytes at a concentration of 50 mg.dm^{-3} and then analysed again. The concentration of analytes in the sample after spiking was 319 mg.dm^{-3} (acesulfame K), 45 mg.dm^{-3} (saccharin), 48 mg.dm^{-3} (aspartame), 115 mg.dm^{-3} (sucralose), 278 mg.dm^{-3} (steviol glycosides), 245 mg.dm^{-3} (benzoic acid) and 171 mg.dm^{-3} (sorbic acid) which corresponds to recovery between 90 and 98%. Based on the measured results, it can be stated that the proposed method has very good accuracy.

After validation of the HPLC-DAD-ELSD method, this method was applied to the analysis of real samples. Results from the analysis are presented in Table 2 and Table 3 and the chromatogram obtained from the analysis of a real sample is shown in Figure 3 and Figure 4. Saccharin was detected only in one sample at the concentration of 94 ±5 mg.dm^{-3}. The most common sweetener in the beverages analyzed was acesulfame K, whose concentration ranged from 186 to 278 mg.dm^{-3}. The use of other sweeteners varied depending on the type of sample analyzed and their concentration in beverages was around 200 mg.dm^{-3}. Measured results are consistent with data published by other authors. **Sik (2012)** analyzed 56 soft drinks and only in 10 samples he detected the use of saccharin (27 – 78 mg.dm^{-3}). The concentration of acesulfame K in soft beverages is given in the literature in the range of 3 – 258 mg.dm^{-3}, the concentration of aspartame in the range of 27 – 559 mg.dm^{-3}, sucralose in the range of 13 – 152 mg.dm^{-3} and steviol glycosides in the range of 3 – 83 mg.dm^{-3}. **(Sik, 2012; Ha et al., 2013; Grembecka et al., 2014; de Queiroz Pane et al., 2015; Yongsun Lee et al. 2017; Di Donna et al., 2017)**. Not all samples contained preservatives. The measured concentration of benzoic acid in beverages was about 150 mg.dm^{-3}. Sorbic acid was found at a higher concentration. The concentration ranged from 104 to 223 mg.dm^{-3}. The measured concentrations are comparable with those published by other authors **(Grembecka et al., 2014)**, however, in some cases extremely high concentrations of monitored preservatives in beverages can be found **(Javanmardi et al., 2015)**. The sweeteners and preservatives identified in all samples examined corresponded to the composition on the product packaging. Except for steviol glycosides, the concentration of monitored substances in beverages did not exceed the maximum permitted concentrations given in the valid legislation. The maximum permitted concentration of steviol glycosides in beverages is 80 mg.dm^{-3}. This limit was exceeded by about three times in two samples.

CONCLUSION

The scientific hypothesis that by the combination of two detectors (DAD and ELSD) with HPLC it will be possible to determine sweeteners and preservatives in beverages using one method and one sample injection was confirmed. Using non-polar C18 stationary phase, mobile phase containing methanol, acetone, and a mixture of 0.02 mol.dm^{-3} formic acid and 0.02 mol.dm^{-3} trimethylamine were found as the most suitable. The proposed analytical method showed good linearity, precision, and accuracy. Measured limits of detection were sufficient to analyze 5-times diluted beverage samples. The concentration of monitored additives in beverages was following valid legislation. Only the amount of steviol glycosides in two samples was exceeded by about three times the maximum allowed content in beverages.

MONITORING THE STABILITY OF FORTIFIED COLD-PRESSED SUNFLOWER OIL UNDER DIFFERENT STORAGE CONDITIONS

Dani Dordevic, Simona Jancikova, Alexandra Lankovova, Bohuslava Tremlova

ABSTRACT

The aim of the study was to evaluate the stability of cold-pressed sunflower oil mixed with different seeds and herb. The seeds and herb were added at 1% and 5% concentrations; samples were divided into 2 groups: stored in the dark and light. The primary products of oxidation and chlorophyll content were monitored during 3 months of storage. The results showed very low oxidation stability of experimentally produced cold-pressed oil mixtures/dressings, especially during storage on the light. The samples with 5% of hemp herb addition showed the best stability since they have peroxide value under 20 mekv $O_2.kg^{-1}$, both in the dark and on the light. Other samples, both stored in the dark and on light, were declared as not for human consumption due to high oxidative product development. The research represents an important storability evaluation of products that can be found on the market and that can be found very attractive for consumers.

Keywords: sesame; chia; hemp; oil dressings; storability

INTRODUCTION

The production of cold-pressed edible plant oils includes only pressing and occasional filtering of plant material rich in oil. Many consumers found this production attractive and this food commodity is becoming more popular. Especially because in this kind of edible oil production, organic solvents are prohibited. The advantage of cold-pressed oil is that natural beneficial components, that are present in the raw material, are preserved **(Febrianto and Yang, 2011; Parker et al., 2003)**.

Sunflower has good tolerance to drought and different soil typology. These properties have made sunflowers to be one of the most important oilseeds in the world, both in developed and developing countries. The production of cold-pressed oil has been increasing due to the chance for smaller farmers to produce it, while the demand for it is increasing too **(Foppa Pedretti et al., 2019)**. On the other hand, edible plant cold-pressed oil has low oxidative stability. The fortification of this food commodity should lead to longer shelf life and consequently the better oxidative stability **(Mazaheri et al., 2019)**.

Cold-pressed oils, including sunflower cold-pressed oil, are a good source of polyphenols, chlorophylls, and carotenoids. These compounds have beneficial properties for humans since they have anti-inflammatory, anticancer properties, same as antioxidant and antibacterial activities **(Song et al., 2019; Wu et al., 2019)**. The total area in the Czech Republic used for the planting of oilseeds is 412 060 ha **(Zehnalek, 2019)**.

Food fortification has been gaining in popularity recently. Chia seeds are often called "superfoods" due to the high nutritional value for humans. Chia, hemp, and sesame seeds can be used for the fortification of cold-pressed plant oils since they have a beneficial nutritional composition **(Urbizo-Reyes et al., 2019; Bartkiene et al., 2019; Kermani et al., 2019)**.

On the other side, the quality and stability of these seeds fortified cold-pressed oils are questionable. The study aimed to monitor oxidative-hydrolytic stability and nutritional profile of cold-pressed sunflower oil fortified with o chia, sesame, and hemp seeds, as well as hemp herb.

Scientific hypothesis

The fortification influence on the stability of cold-pressed sunflower oil. Since chlorophylls can act as antioxidants and prooxidants independence on storage conditions we are expecting different stability properties of experimentally produced oil mixtures/dressings.

MATERIAL AND METHODOLOGY

The Velox cultivar of sunflower (*Helianthus annuus*) was cultivated in the Czech Republic and was obtained from the company Olejářství z Horňácka, Uherské Hradiště. Sunflower seeds were harvested and stored in a dry cellar until pressing. After milling the oil was stored in the dark until mixing with seeds and herb (15 days).

Table 1 The samples description.

Samples	Sample description
1% SS1	1% sesame seeds
5% SS5	5% sesame seeds
1% SKS1	1% hemp seeds
5% SKS5	5% hemp seeds
1% SCH1	1% chia seeds
5% SCH5	5% chia seeds
1% SKC1	1% hemp tea
5% SKC5	5% hemp tea
SK	without addition of seeds/tea

Table 2 The measured parameters in sunflower samples at the beginning of the experiment.

	Peroxide value (mekv $O_2.kg^{-1}$)	Free fatty acids mg $KOH.g^{-1}$	Total phenol content $mg.mL^{-1}$	Chlorophyll content ppm
Sunflower oil	8.20 ±0.87	0.07 ±0.01	0.23 ±0.01	2.78 ±0.19

The sesame seeds (*Sesamum indicum* L.), hemp seeds (*Cannabis sativa* L.), and chia seeds (*Salvia hispanica* L.) were obtained from the retail shop "Zdraví z přírody" in Brno, the Czech Republic. The hemp herb was obtained from the retail shop "Sativa-Medical" in Brno, the Czech Republic.

The sesame/chia/hemp seed and hemp herb were added to the sunflower cold-pressed oil in the following concentrations: 1% and 5%. The samples were stored in glass bottles and divided into two groups, one group was covered with aluminum foil and stored in the dark; another group was exposed to the daylight, without aluminum covering. Samples were stored at 25 °C at the Department of Vegetable Foodstuffs Hygiene and Technology, Faculty of Veterinary Hygiene and Ecology, the University of Veterinary and Pharmaceutical Sciences Brno, Czech Republic (GPS: 49°12'59.2"N 16°35'41.0"E). The control samples were without seed/herb addition. The samples were analyzed at the beginning of the experiment and after 1 and 3 months of storage. The description of the samples is given in Table 1.

The peroxide value (PV) was determined according to **ISO 3960 (2017)** standard. 5 g of the sample was mixed with 30 ml of a mixture of chloroform and glacial acetic acid (2:3 ratio). The mixture was shaken for 1 minute, then 30 mL of distilled water and 5 mL of 1% starch solution were added. The sample was titrated with 0.01M $Na_2S_2O_3$. The blank sample was prepared in the same way with the addition of water instead of the sample.

The determination of chlorophylls was performed by the spectrophotometric method according to **Kraljić et al. (2013)**. The absorbance of chlorophylls in oil was measured at 670, 630, and 710 nm against cyclohexane (blank sample) by spectrophotometer (CE7210 DIET-QUEST, Cambridge, England).

Statistical analysis

Statistical significance at $p < 0.05$ was evaluated by one-way ANOVA analysis of variance, and parametric Tukey post hoc test (in the case when Levene's test showed equal variances $p > 0.05$) and nonparametric Games–Howel post hoc test (in the case when Levene's test showed unequal variances $p < 0.05$) for finding differences within groups. Overall differences among samples were checked by principal component analysis (PCA) using SPSS 20 statistical software (IBM Corporation, Armonk, USA).

RESULTS AND DISCUSSION

Table 2 is showing the results of the samples (cold-pressed sunflower oil samples without seeds and herb) at the beginning of the experiment.

The amount of primary products of oxidation, represented as peroxide values (mekv $O_2.kg^{-1}$), in the samples of sunflower oil (mixtures, same as without seeds/herb addition) after one month of storage can be seen from Table 3. The results are clearly indicating the high influence of storage conditions on the formation of hydroperoxides. After one month of storage, both on light and in the dark, only SKC5 (5% of hemp herb addition) samples showed better oxidation stability than control samples (SK).

3 months of storage showed an even higher oxidation ratio. Significant ($p < 0.05$) changes occurred in almost all oil mixture. The significant differences between samples stored in the dark and in light can be also seen from the principal component analysis (Figure 1). Out of all investigated samples only sample SKC5, stored in the dark, had a lower peroxide value than 20 mekv $O_2.kg^{-1}$. All other samples had peroxide value over 20 mekv $O_2.kg^{-1}$. This finding is making these samples be declared as not for human consumption.

The peroxide value, as the method for the determination of primary oxidation products, can be significantly influenced by the presence of antioxidants, such as phenols and chlorophylls. Chlorophylls have been proven to be good antioxidants in cold-pressed olive oil, but only during the storage in the dark. When cold pressed oil is stored on light, chlorophylls were found to act as prooxidants and they even make food matrix to oxidize more rapidly.

Table 3 Determination of peroxide value (mekv $O_2.kg^{-1}$).

Samples	Storage in dark		Storage on light

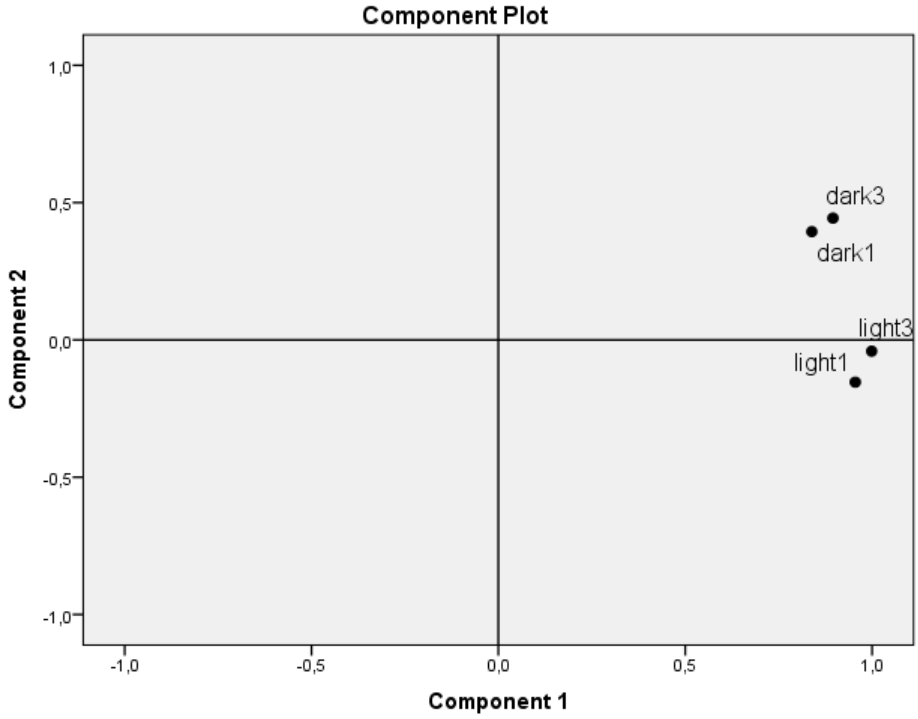

Figure 3 Principal component analysis (PCA) of overal differences between samples stored in the dark and on light dark1 – the samples stored 1 month in the dark; dark3 – the samples stored 3 months in the dark; light1 – the samples stored 1 month on light; light3 – the samples stored 3 months on light.

That is the main reason for the better oxidation stability of refined edible plant oils, since polyphenol, carotenoid and chlorophyll compounds are removed during the production **(Choe and Min, 2006)**. The results are emphasizing that cold-pressed sunflower oil has a very short shelf life since the majority of the investigated samples developed rancid taste. Rancidity is developed when peroxide value is over 20 mekv $O_2.kg^{-1}$ **(Ekwenye, 2006)**. Oxidation stability is the main property of edible plant oil and our results indicated very low stability of cold-pressed sunflower oil. The fortification/addition of different seeds and herb did not affect positively oxidation stability. Oppositely, the fortification resulted in higher oxidation degradation, especially after 3 months of storage on light (Table 3). Photooxidation, which influences the oxidation processes of samples stored on light, is producing singlet oxygen that is more reactive than triple oxygen (produced by auto-oxidation) and leads to faster oxidation. Sunflower can be declared worldwide as the most consumable edible oil. Though, the disadvantage of sunflower oil, especially cold-pressed, is its low oxidative stability **(Caponio et al., 2005)**.

Table 4 is showing the ratio of chlorophyll content in sunflower oil, both fortified and not fortified, during 3 months of storage on light and in the dark. It can be seen the amount of chlorophyll degradation during the storage period. The samples stored on light had significantly (p <0.05) lower chlorophyll content than samples stored in the dark. The degree of chlorophyll degradation is also clearly visible from the principal component analysis, where the sample stored one month in the dark formed one group and differ from the rest samples (Figure 2). The distinguish between samples stored in the dark and on the light during 3 months of storage are also visually observable from Figure 3. The results of the samples stored in the dark and in light, analyzed by principal component analysis, formed separate groups. A certain amount of chlorophylls occurs in cold-pressed vegetable oil, while these contents are removed in refined oils by a refining process **(Szydłowska-Czerniak et al., 2019)**. Chlorophyll contents decrease during longer storage periods and with higher storage temperatures **(Rasul and İnanc, 2014; Islam et al., 2019)**. Under light chlorophylls degrade more rapidly than in the dark **(Lee et al., 2014)**. Chlorophylls are affecting the beneficially nutritional profile of oils and also oil color. The auto-oxidation is triggered when pigments are exposed to light or heat. Chlorophylls are capable to transform electromagnetic radiation energy to triplet oxygen and produce highly oxidative singlet oxygen. Consequently, unsaturated fatty acids react with these free radicals. In this way, the quality of the oil is degraded **(Diaz et al., 2019)**. During auto-oxidation primary products of oxidation, hydroperoxides are triggering free radical formation reaction and off-flavor products. These off-flavor products are formed by the release of short-chain fatty acids during oxidation **(Kiritsakis and Markakis 1984; Kiritsakis, 1995)**.

Chlorophylls are strong antioxidants, but when oil is stored in the dark since on light they have acted as prooxidants **(Choe and Min, 2006)**. That is the reason for the following requirement: edible plant refined oil should have chlorophyll content under 1 $mg.kg^{-1}$ **(Szydłowska-Czerniak et al., 2019)**. The same trend of lowering chlorophyll content during 2 months of storage, under light, was noticed with cold-pressed olive oil **(Caponio et al., 2005)**.

CONCLUSION

The study emphasized cold-pressed edible plant oils storage issues, such as sunflower oil. The study unambiguously indicates that the storability/stability of cold-pressed sunflower oil is highly questionable. Fortification with seeds and herb did not affect significantly (p <0.05) experimentally produced oil mixtures/dressings since oxidation even in fortified samples were over the consumption limit. Certain, slightly better oxidation stability was noticed in fortified samples during 3 months storage in the dark. The only samples with peroxide value below 20 mekv $O_2.kg^{-1}$ (the palatable limit) were samples prepared with 5% of the hemp herb. The study showed very low oxidation stability of cold-pressed sunflower oil; the fortification was reasonable only in the samples with the addition of 5% hemp tea, only these samples stayed significantly more stable in comparison with other experimentally produced samples. The study emphasized the rapid degradation nature of chlorophylls during storage under the light. Since these kinds of products can be already found on the market and can be found attractive for consumers, our study represents valuable information for producers and consumers.

RESEARCH OF SELECTED PHYSICAL INDICATORS OF TABLE EGGS IN THE SMALL-SCALE BREEDINGS FROM THE ASPECT OF HEALTH SAFETY

Mária Angelovičová, Michal Angelovič, Lucia Zeleňaková

ABSTRACT

The purpose of this study was to investigate selected indicators of the table eggs in small-scale breedings, focusing mainly on the eggshell and its contamination and damage. Our object of study was eggs, shell, damage, and contamination of table eggs. Four small-scale breedings were randomly selected in Slovakia. These breeds were alternatively with an outdoor free-range. Laying hens Dominant was bred under conditions small-scale breeds No.1, No. 2 and No. 3 in the 1st laying cycle, and No. 4 in the 2nd laying cycle. Egg weight was balanced in three small-scale breedings. Egg weight was significantly higher in the fourth small-scale breeding, statistically significant (p <0.05) compared to egg weight in the studied 3 small-scale breedings. Shell weight and shell thickness in the equatorial plane of the egg were balanced in three small-scale breedings and in the fourth small-scale breedings were significantly higher, statistically significant (p <0.05). The higher egg weight per breeding is related to the higher laying hens age that was in the 2nd laying cycle compared to laying hens 3 small-scale breedings in the 1st laying cycle. Higher eggshell weight in three farms may be related to improved conditions in breeding hygiene, as confirmed by the results of investigations into contamination and damage to table eggs. These differences may also be related to nutrition.

Keywords: small-scale breeding; egg; eggshell; contamination; damage

INTRODUCTION

Improved animal welfare is the sum of physical and mental well-being. Many factors affect the welfare of laying hens. The results obtained from research into improved living conditions may be contradictory. In this context, experts agree that a suitable approach to assessing the welfare of laying hens is to integrate the information across disciplines, using several different methodologies **(Scientific Panel on Animal Health and Welfare, 2005)**.

The assessment of the indicators of egg external quality raised laying hens in the system of alternative environments, such as on litter, is fundamental for the promotion of this rearing system. To determine the effects of the rearing environment on the performance and welfare of hen laying, the analysis of productive parameters and egg quality and safety are examples of some measures adopted **(Alves, Silva and Piedade, 2007)**.

According to the knowledge previously published, it is known that laying hens kept in domestic conditions (small-scale breeding) they largely preserve kinds of natural behavior, generally according to their wild ancestor **(Fraser and Broom, 1990)**.

Laying hens have been bred for several thousand years in some properties. Domestication and selection took place. Some types of behavior originate in genetics and persist in the environment, that it requires to prepare conditions for satisfying hen laying needs. This type of behavior is known as instinct. Ethologists (scientists who specialize in animal behavior studies) explain that, in terms of motivation and ethological needs, strongly motivated behavior is largely controlled by internal factors (such as changes in hormone levels), which are available regardless of the type of outdoor environment **(Duncan, 1998)**.

Behavior identified as important for improved welfare laying hens includes nesting, examination, perch, raking and nutritional behavior, dusting, engaging in comfortable behavior (such as over lighting, etc.) **(Petherick and Rushen, 1997)**.

Laying hens are biologically able to adapt to environmental conditions when the environment is appealing to them. At that time, they increase interest in

such an environment, which in turn increases the quality of their living conditions. The environment is engaging, increases interest, and adds to the quality of animal life.

A rich and diverse environment stimulates exploratory behavior and allows pecking and raking **(Knierim, 2006)**.

According to **Baer (1998)**, an enriched environment has a positive impact on the physical, mental, and social well-being of animals, including laying hens and can improve their health. European Food Safety Authority, Panel on Animal Health and Welfare (AHAW), an independent an advisory body providing the scientific basis for European policy and legislation, based on the processing of scientific literature, it has come to the following conclusion: stabling systems differ in the possibilities for laying hens to show species-specific behavior, such as raking, dusting, exploring and selecting a suitable nest. Sufficient space must be provided for laying hens, to carry out the above-mentioned natural activities. A free-range breeding system in nature can pose a risk of laying hens and endanger their health. Layers in outdoor free-range may be exposed to wild birds, insects, and other potentially infectious agents **(Scientific Panel on Animal Health and Welfare, 2005)**.

The laying hens may come into contact with bacteria and intestinal parasites and coccidia **(McDougald, 2003; Scientific Panel on Animal Health and Welfare, 2005)**.

The object of social interest in the context of the welfare of laying hens, it is largely focused on farm conditions, most for breeding systems, conditions for natural behavior, and limited conditions associated with stress and mutilation. However, the impact of genetics on the welfare of laying hens is clear, with strong genetic effects on traits including immune function **(Bridle et al., 2006)**, bone strength **(Stratmann et al., 2016; Candelotto et al., 2017)**, feather pecking, feather condition and associated mortality **(Su et al., 2005; Brinker et al., 2014; Muir et al., 2014)** and fear **(Uitdehaag et al., 2008; de Haas et al., 2014)**.

Bacteria belong to the main cause of human foodborne diseases v worldwide and infected poultry flocks are the most common cause of human infection through the storage of foods.

Human salmonellosis is more often associated with the consumption of poultry and poultry products, including eggs, than with the consumption of food from other animals. All producers of table eggs, regardless of the type of breeding system, are subject to strict safety requirements **(Gast, 2003)**.

De Reu et al. (2006) note that the high risk of transmission of infection to table eggs is the higher the microbial contamination in the environment, such as in *Salmonella enteritidis*.

De Knegt et al. (2015) reported that in a laying hen flock, it was caused by human Salmonella as the main source of infections. They attributed approximately 40% of all Salmonella cases to *Salmonella enterica* serovar Enteritidis.

The incidence of human *S. enteritidis* infections is related to the prevalence of this pathogen in commercial flock eggs **(Arnold et al., 2014)**.

For extensive implementation, comprehensive risk reduction programs and testing of laying hens in flocks intended for the production of table eggs are attributed to a reduction in the incidence of human *S. enteritidis* infections **(Wright et al., 2016)**.

Verhallen-Verhoef and Rijs (2003) reported that hygiene in breeding conditions is one of the most important factors for laying hens. If there is a large number of laying hens in a small area, it is a great problem to maintain hygiene and then the hens are exposed to a lot of stress.

Otter (2015) notes that in the conditions of the small-scale breedings there is common breeding with a free-range system, which has proved its worth. In the breeding area, it is very appropriate to provide the facilities necessary for carrying out the natural activities of the laying hens, e.g. such as perch for rest, litter material for raking, and others. Hygiene and cleanliness in the breeding environment are the basis for the good health of laying hens, but also for the laying of non-harmful eggs concerning the consumer. The application of welfare aspects is also important for laying hens under small-scale conditions. These aspects support the healthy development of laying hens and the production of quality and health-safe table eggs.

In the **Council of the European Union (2006)** it was noted that table eggs are sold worldwide. On the European Union market, eggs are classified in quality class A or quality class B. Quality class A is classified for direct human consumption. On the contrary, class B eggs are marked as technical and are not intended for direct human consumption. Laying hen nutrition and post-laying egg handling are factors that play a very important role in determining the safety and quality of table eggs. The eggshell is characterized by being a natural external packing table of laying hens, the task of which is to prevent the penetration of contaminants into the internal egg content. The system of rearing, but also the type of feed administered by laying hens, affects egg composition to a very large extent.

Surai and Sparks (2001) report that there is a lack of knowledge about factors of the table egg chemical composition concerning a free-range or a range consisting of grassland.

Eggshell quality has a major economic impact on quality egg production because broken and cracked eggs mean an economic loss for farmers **(Yoho et al., 2008)**.

The abnormalities can be observed sometimes on the egg surface, on the shell. Eggshell surface abnormalities are assessed by altered shell surface, shell dilution, increased translucence, cracks, and cracks in the eggshell. These abnormalities, changes in quality and ultrastructure have been observed in flocks of hen laying in the experiment by **(Kursa et al., 2019)**.

The purpose of this study was to investigate selected indicators of the table eggs in small-scale breedings, focusing mainly on the eggshell and its contamination and damage.

Scientific hypothesis

Scientific hypothesis: balanced results selected indicators of table eggs in small-scale breedings, due to the small numbers of animals in breeding and outdoor free-range for carrying out natural activities.

MATERIAL AND METHODOLOGY

Object of research

Our object of study was eggs, shell, damage, and contamination of table eggs. Four small-scale breedings were randomly selected in Slovakia. These breeds were alternatively with an outdoor free-range.

Rearing conditions of the laying hens

Laying hens Dominant was bred in conditions of 4 small-scale breeders in Slovakia. Breeding conditions as well as nutritional conditions were ensured in these small-scale breedings of small-scale breeds in accordance with laying hens needs. Laying hens Dominant was reared in small-scale breedings No. 1, No. 2, and No. 3 in the 1st laying cycle, and No. 4 in the 2nd laying cycle. Henhouse with deep litter and free-range was a breeding house for laying hens. Laying hens had the opportunity to run daily in the summer from 6:00 am to about 7:00 pm. pm and in winter until 5:00 pm. The hen house equipment consisted of a watering-place, a feeder, a nest, and perch. To lay eggs, a nest was made for them to be made by hand collection. Drinking water and feed were part of the free-range. Laying hens were fed with a conventional feed mixture intended for laying hens, which was replenished at least 2 times a day. Sometimes laying hens were fed with food from the kitchen or crushed eggshells. Drinkers and feeders were washed daily. The eggs produced were harvested once a day in the summer in the afternoon and twice a day in the winter in the morning and afternoon.

Egg samples of 80 pieces were obtained from four selected small-scale breeders, i.e. 20 eggs from each small-scale breeder. Investigation of egg samples was carried out in a laboratory at the Department of Food Hygiene and Safety.

Characteristics to be collected on egg samples

Physical indicators of table eggs from small-scale breeders No. 1, No. 2, No. 3 and No. 4:

- the weight of egg – KERN PLE scales, max. 420 g, d = 0.001 g,
- the weight of eggshell – KERN PLE scales, max. 420 g, d = 0.001 g, dried eggshells in a drier at a temperature of 55 °C,
- shell thickness in 3 parts of the equatorial plane of the egg – DIAL INDICATOR, max. thickness 30 mm, d = 0.01 mm, dried eggshells in drier at 55 °C.

Contamination and egg damage under the light of a 100W table lamp from small-scale breedings 1, No. 2, No. 3, and No. 4: blood spots, droppings, pigment dots, other deposits, calcium deposits, bumps on the surface, and deformed egg shape.

Figure 1 Laying hens in the free-range.

Figure 2 Breeding equipment of hen house.

Statistical analysis

The results in the study are presented as mean – arithmetic mean ($\bar{x}$), variance range (R), which determines the difference between the minimum value (Min) and the maximum value (Max), the standard deviation (*SD*), and the coefficient of variation (cv, %).

Hypotheses about equality of mean values were tested using a one-factor analysis of variance (F) at significance levels $\alpha = 0.05$, $\alpha = 0.01$ and $\alpha = 0.001$. One-factor variance analysis (ANOVA) is the simplest form of ANOVA that examines the relationship between interval and nominal variables. It tests the null hypothesis of the mean equivalence, assuming that the selections have the same variance. The null hypothesis indicates that there is no relation between the interval and the nominal variable. If the calculated statistical value F is greater than the corresponding character value that divides the statistical set of a group with the same number of Fisher-Snedecor distribution elements FI-1, n-I, the hypothesis of equality of mean values is rejected.

Scheffe's test was used at a significance level of $\alpha = 0.05$ to compare the difference in the indicator between small-scale breedings. The Pearson correlation coefficient (r) reflects the relation between the two egg variable variables. The Pearson correlation coefficient (r) reflects the degree of the linear relation between the data of the two egg indicators. Its value is between -1 and +1. A +1 indicates that there is a high positive linear relationship between the two indicator data. A value of -1 means that there is a high negative linear relation, and value of 0 means that there is no linear relation between the two indicator data. The interpretation of the size of the correlation coefficient is given by **Cohen (1988)**.

Values of correlation coefficient (r) and strength of dependence between two variables: below 0.1 trivial (simple, light), 0.1 – 0.3 weak, 0.3 – 0.5 medium, above 0.5 strong. It is often reported in the publications that the correlation coefficient values of 0.7 – 0.9 represent a very strong relation and 0.9 – 1 as an almost perfect relation between two variables. The correlation coefficient results are statistically significant at $\alpha = 0.05$, $\alpha = 0.01$ and $\alpha = 0.001$. The SAS statistical package, version 8.2, was used to statistically evaluate the results.

RESULTS AND DISCUSSION

Egg weight

Average egg weight in individual small-scale breedings is given in Figure 3. Statistically evaluation of egg weight in individual small-scale breedings is given in Table 1.

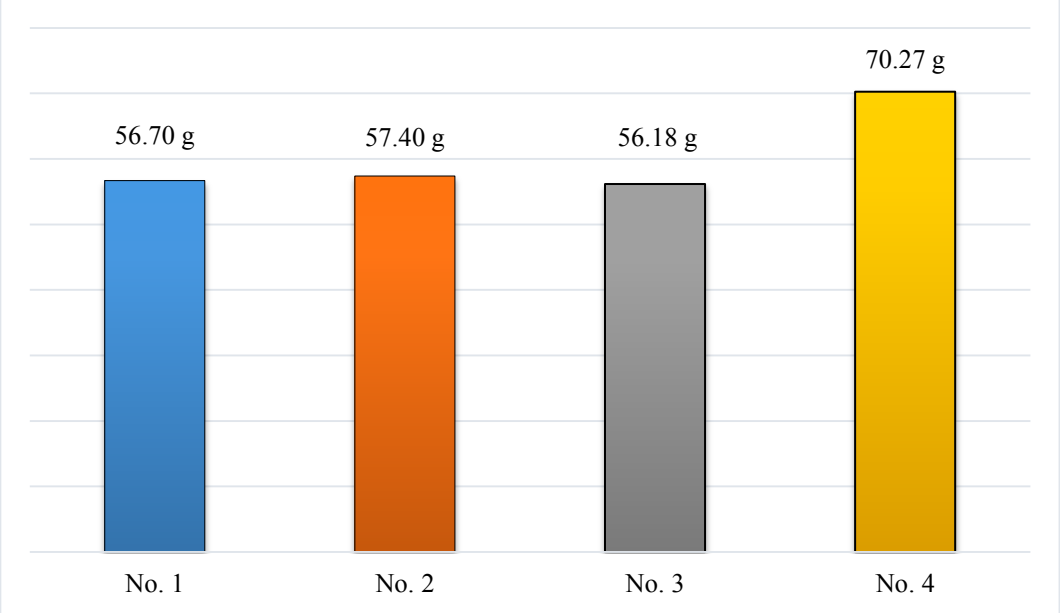

Figure 3 Average egg weight in individual small-scale breedings No. 1, 2, 3 and 4, g.

Table 1 Statistical evaluation of egg weight in individual small-scale breedings No. 1, 2, 3, and 4.

Small-scale breeding	F-test 61.97^{+++}				Scheffe´s test $p_{0.05}$		
	n	*SD*	c_v, %	R, g	No. 2	No. 3	No. 4
No. 1	20	3.03	5.35	53.08 – 64.11	-	-	+
No. 2	20	4.36	7.59	46.78 – 65.45		-	+
No. 3	20	4.07	7.25	51.98 – 66.72			+
No. 4	20	3.81	5.42	62.88 – 78.79			

Note: n – multiplicity; *SD* – standard deviation; c_v – coefficient of variation; R – variation range as the difference between the smallest and the largest value of the data distribution; +++: statistically significant difference among group means by analysis of variance (p <0.001); +: statistically significant difference among groups by Sheffe´s test (p <0.05); –: no statistically significant difference among groups by Sheffe´s test (p >0.05).

The average egg weight was found to be either the same or relatively balanced in small-scale breedings No. 1, No. 2 and No. 3. The measured values of egg weight were largely balanced in small-scale breeding No. 4. The values of the egg weight in this small-scale breeding were statistically significant (p <0.05) higher compared to the values of the egg weight of small- scale breedings No. 1, No. 2, and No. 3. Conclusions of the research and the knowledge published in scientific journals are not uniform as regards the impact of factors on eggshell quality.

Huber-Eicher and Sebö (2001) took the view that they showed a higher weight of eggs and their egg components, which were in a negative correlation with the stocking intensity (r = -0.27, p <0.01). The authors pointed out that if laying hens produced more eggs under industrial conditions, the lower the egg weight was recorded. At the end of their investigation, the authors concluded that laying hens that were kept under organic farming conditions, they laid eggs which were generally heavier due to the lower production intensity.

Eggshell weight

Average eggshell weight in individual small-scale breedings is given in Figure 4. Statistically, evaluation of eggshell weight in individual small-scale breedings is given in Table 2.

Egg colour is also an important factor in egg production, in our case brown. Colour shell of eggs can affect consumer choice due to regional or national cultural preferences for different colours, directly affecting eggs' production **(Wei and Bitgood, 1990; Joseph et al., 1999)**.

Thus, the determination of egg colour and eggshell strength is of importance. The average weight of eggshell was found to be either the same or relatively balanced in small-scale breedings No. 1, No. 2 and No. 3. The measured values of eggshell weight were largely balanced in small-scale breeding No. 4. The values of the eggshell weight in this small-scale breeding were statistically significant (p <0.05) higher, compared to the values of the eggshell weight of small-scale breedings No. 1, No. 2 and No. 3. Conclusions of the research and the knowledge published in scientific journals is not uniform as regards the impact of factors on egg shell quality.

Authors **Monira et al. (2003); Alsobayel et al. (2003)** and **Anderson et al. (2004)** agreed in a statement that the quality of the eggshell is sufficiently affected by the genotype and age of laying hens. In characterizing the effect of genotype on egg shell quality, the authors emphasize the significance of genotypic differences in egg weight and shell quality.

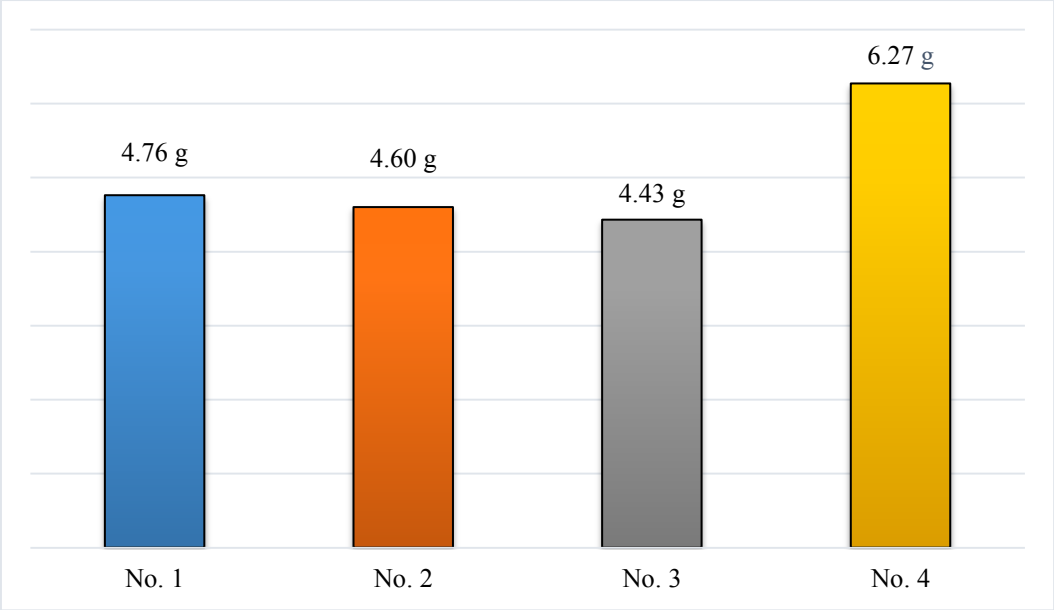

Figure 4 Average eggshell weight in individual small-scale breedings No. 1, 2, 3 and 4; g.

Such contradictory aspects may also be related to ensuring that laying hens are kept in line with their needs. Therefore, in our research, we focused on characterizing the laying hens and compared them with four small-scale breeders in Slovakia with a focus on selected indicators of the table eggs. Avian eggshells are commonly used in studies focusing on bioindication and environmental monitoring **(Lam et al., 2005; Ayas et al., 2008; Kim and Oh, 2014; Khademi et al., 2015; Simonetti et al., 2015)**.

Shell thickness in the equatorial plane of egg

The average thickness in the equatorial plane of egg in individual small-scale breedings is given in Figure 5.

Statistically evaluation of shell thickness in equatorial plane of egg is given in Table 3.

The average thickness in equatorial plane of egg was found to be either the same or relatively balanced in small-scale breedings No. 1, No. 2 and No. 3. The measured values in the three parts of the equatorial plane of egg were largely balanced in small-scale breeding No. 4. The values of the equatorial plane of the egg in this small-scale breeding were statistically significant (p <0.05) higher compared to the values of the equatorial planes of egg of small- scale breedings No. 1, No. 2 and No. 3

	No. 2						0.83^{+++}		
	No. 3							0.80^{+++}	
	No. 4								0.74^{++}

Note: **S-C B** – Small-scale breeding; numeric value – value r; $^{+++}$: statistically significant difference between the two variables (p <0.001); $^{+}$: statistically significant difference between the two variables (p <0.05); $^{-}$: no statistically very highly significant difference between the two variables (p >0.05).

Correlation relation between egg indicators in small-scale breedings

Correlation relation between indicators of the eggs in small scale breedings and statistically significant difference between the two variables are given in Table 4. Middle, a positive linear relation (small-scale breeding No. 1 and at the lower limit a strong positive linear relation (small-scale breeding No. 4) was found between egg weight and eggshell weight, statistically significant (p <0.05). A very strong relationship in all small-scale breedings (p <0.01, p <0.001) was found between eggshell weight and shell thickness in the equatorial plane of the egg.

Shell thickness in individual parts of the equatorial plane of the egg in small-scale breedings

Average shell thickness in individual parts of the equatorial plane of the egg in small-scale breedings is given in Figure 6. A statistically significant difference between the two variables is given in Table 5. The average thickness in equatorial planes 1, 2, and 3 of the egg was found to be either the same or relatively balanced in small-scale breedings 1, No. 2, and No. 3. The measured values in the three parts of the equatorial plane of egg were largely balanced in small-scale breeding No. 4. The values of the equatorial planes of the egg in this small-scale breeding were statistically significant (p <0.05) higher compared to the values of the equatorial planes of the egg of small- scale breedings No. 1, No. 2, and No. 3.

The eggshell is a natural protection for the egg, and thus it is significant to get a high value of eggshell strength **(Bain, 1990)**.

The eggshell strength, reflecting the resistance ability to

damage, can protect eggs when they are in collecting, packaging, storage, and transportation. It can be found the higher the eggshell strength, the stronger the resistance to damage. Cracked eggs can finally cause economic loss in two ways, one is that they cannot be sold at a high price, another is cracked eggs may raise the risk of bacterial contamination to intact eggs, which can even produce food quality and safety problems **(Bain, 2005; Mertens et al., 2006; Li, Dhakal and Peng, 2012)**.

Correlation relation between shell thicknesses in individual parts of the equatorial plane of the egg according to small-scale breedings

Correlation relation between shell thickness in individual parts of the equatorial plane of the egg according to small-scale breedings and statistically significant difference between the two variables are given in Table 6.

In shell thickness between individual parts of the equatorial plane of the egg in small-scale breedings, No. 1, No. 2, No. 3, and No. 4, an almost perfect positive linear relation was found, statistically very highly significant (p <0.001).

Correlation relation between shell thicknesses in individual parts of the equatorial plane of the egg together for all small-scale breedings

Correlation relation between shell thickness in individual parts of the equatorial plane of the egg together for all small-scale breedings and statistically significant difference between the two variables is given in Table 7.

Almost perfect positive linear relation, statistically very high significant (p <0.001), was found in the shell thickness between the individual parts of the equatorial plane of the egg in all examined small-scale breedings together.

Contamination and damage of table eggs

The percentage and number of eggs with damaged egg surface but also deformed and contaminated on the eggshell are given in Table 8.

Table eggs obtained from a small-scale breeder were subjected to an assessment of the hygiene aspect of the breeding environment. Table eggs can be considered as naturally packaged food. The eggshell serves to contain the egg contents. It is also the first barrier against bacterial penetration and must be free from defects in the order to optimize the safety of human consumption **(Mabe et al., 2003)**.

We found that table eggs were contaminated with blood (from 5 to 45%) and dropping (from 20 to 60%). We found sediments, pigment dots and calcium deposits on the surface of table eggs. Also table eggs from two farms had a deformed shape.

Solomon (2010) reported that the coated eggshell, it is common surface defect observed on the eggshell. There are observed additional calcium deposits or extra-cuticular coverings and possibly reflects the timing and magnitude of the stress or disturbance experienced by the flock. It is commonly observed an incidence of this defect of 1% and could be caused by the age of the laying hens, often younger flocks coming into production **(Coutts and Graham, 2007)**.

Figure 7 Contamination and damage of table eggs in small-scale breedings.

These damaged table eggs, but also deformed and contaminated on the surface, are related both to internal factors and to external factors, which the farmer can influence and take measures to improve laying hens living conditions. **Hincke et al. (2000)** reported that there are multiple factors affecting eggshell quality like the genetics of the hen, nutrition, and management of feed intake, disease, and environment challenge, and also equipment insult.

A decline in eggshell quality is detected as hens approach the end of a laying period **(Mazzuco and Hester, 2005)**. In this way, the condition of the eggshell at the oviposition time can influence the incidence of shell breakage. An interesting insight presents **Alves et al. (2007)**. When the laying hens are raised in conditions of greater thermal comfort, it can promote eggshell quality and decrease egg losses through cracks.

Hulzebosch (2004) states in his study that eggshell plays a very important role. It must form a good barrier against the intrusion of microorganisms into the internal egg content. Many research results confirm increased microbial contamination in alternative breeding compared to laying hens.

In alternative breeding, laying hens lay eggs more extensively outside the nest, into the litter. Such eggs show excessive contamination of their surface. Such eggs have a damaged shell, which can lead to the deterioration of the internal content of the egg and its contamination. There are two ways in which the contents of a table egg can be infected. It can be infected by an endogenous route and an exogenous route. **Engelmaierová, Tůmová and Charvátová (2010)** state that endogenous contamination occurs through sick laying hens, which affect the egg through the bloodstream. Exogenous contamination of table eggs is caused by microorganisms that are in the outdoor environment.

Görner and Valík (2004) in the study point out that there is a large number of spores on the surface of the eggshell that are highly permeable to air. The cuticle is an outer layer whose main function is to prevent microorganisms from entering the egg. When the eggs are brought into contact with the air, the cuticle is drawn into the spores, changing its shape, which results in deformation, causing penetration of the microorganisms through the shell into the internal contents of the egg. An important protective barrier is also represented by the membrane membranes. Their fibrous structure acts as a filter.

Their protective properties are associated with the chemical action of lysozyme and ovotransferrin. Microorganisms, by means of proteolytic enzymes, disrupt the membranes and penetrate the whites. The main role of egg white is to protect the egg yolk from contamination. Gram-positive bacteria are affected by egg white due to their antimicrobial and bactericidal effects. Egg yolk that has no antimicrobial properties is the perfect breeding ground for the reproduction of microorganisms. If a high incidence of contamination has been observed on the surface of the eggshell, there is a higher risk of contaminants penetrating the egg content. **Křepelka (2012)** points out that contaminated eggs are a major problem in terms of consumer protection, which must be constantly eliminated. In most cases, gram-negative bacteria, e.g. *Pseudomonas* spp., *Alcaligenes* spp. *Salmonella enteritidis* and *Escherichia coli* and gram-positive bacteria such as e.g. *Bacillus* spp. and *Staphylococcus*.

CONCLUSION

Table eggs from small-scale breeding are preferred by the consumer. Literary sources are poor and inconsistent in the knowledge of laying hens breeding conditions in small-scale breeding, and the quality and safety of table eggs. Because the food consumer likes table eggs from small-scale breeders, we have researched this issue. Based on the obtained and statistically evaluated results there were formulated the following conclusion:

(a) The average egg weight was equalized in three small-scale breedings and the fourth small-scale breeding was significantly higher. Higher egg weight is related to the higher age of laying hens.

(b) The average eggshell weight and shell thickness in the equatorial plane of the egg was balanced in three small-scale breedings and the fourth small-scale breeding was significantly higher. Higher eggshell weight may be related to improved conditions in breeding hygiene, as confirmed by the results of the investigation of contamination and damage of table eggs. These differences may also be related to nutrition.

PERCEPTION OF SENSORY ATTRIBUTES AND MARKETING TOOLS OF SELECTED MILK BRANDS

Alexandra Krivošíková, Ľudmila Nagyová, Andrej Géci

ABSTRACT
The research has shown that in the last 5,000 years the human evolution has made the greatest leap in the human history. As a result of these changes, thanks to relatively recent discovery of a specific gene, even adult Europeans can digest milk. In their nutritional guidelines based on the scientific evidence, the official health organizations and institutions recommend drinking milk and eating low-fat dairy products such as yoghurts or cheese. The human body absorbs the necessary amount of calcium in the easiest form from cow's milk. Calcium is the essential element not only for healthy bones and teeth but it is also the important factor for the transmission of nerve impulses, it supports heart activity, helps reduce high blood pressure and "bad" LDL cholesterol levels and alleviate allergic reactions. It has impact on proper blood clotting, affects sperm mobility, helps prevent arthritis or can also contribute to better sleep. Milk is a valuable food not only for calcium content but also for selenium which slows down the aging process and contributes to the protection of the immune system. Acid dairy products prevent the digestive disorders, protect against gastrointestinal infections and improve skin condition. Despite all these positive aspects the consumption of milk, as well as dairy products, has the downward trend in Slovakia. In the last decade, the consumption was at a historical minimum and below the recommended annual dose, which is 91 liters of milk per person. Therefore, the main objective of this research paper was to examine the quality of milk produced by two selected competing companies and identify the various factors affecting consumers´ decision-making process when purchasing milk and dairy products. The attention was concentrated on the sensory attributes (colour, appearance, smell, taste and quality) and marketing tools (brand, packaging, label and price). The primary data were obtained by the questionnaire survey, which was conducted in the Slovak Republic with 284 respondents. For a deeper analysis, the data were evaluated by the statistical methods. Based on the results of the blind testing it was determined that even though the quality of monitored milk is the same, the respondents prefer the sensory attributes of Rajo semi-skimmed milk. When it comes to brand, packaging, label and price Tami semi-skimmed milk also lagged behind.

Keywords: milk; consumers; Slovakia; Rajo semi-skimmed milk, Tami semi-skimmed milk

INTRODUCTION
Milk is a rich source of nutrients and energy. It is one of the complex foods and it can be called as a "superfood" because it contains the numerous nutrients. Most of the ingredients that are present in milk do not act in isolation but in interactions. Milk can contribute significantly to the intake of substances such as magnesium, selenium, riboflavin, vitamin B12 and pantothenic acid. The bioavailability of some nutrients in milk, such as calcium, is very high compared to other foodstuffs, and therefore, drinking milk in childhood is of a great importance in promoting growth and healthy bone development. Milk sugar, called lactose, participates in the formation of brain cells. Among other things, milk has a low sodium content and contains up to 87% water what makes it suitable for maintaining a daily drinking regime. In addition, milk does not contain the substances that inhibit the bioavailability of minerals such as phytates or oxalates. The recent research has highlighted the beneficial effects of milk on the health of the subjects **(Weaver, 2014)**, body weight **(Wang et al., 2014)**, and obesity related diseases including type 2 diabetes and cardiovascular disease **(Markey et al., 2014; O'Connor et al., 2014).** Therefore, the role of milk and dairy products has been the subject of debate in the recent years, both in the scientific and popular-scientific literature.

However, the opinions on the issue of drinking milk are divided into two contradictory streams today. According to **Norton (2015)** the most common reasons why people who can drink cow's milk tend to choose alternative sources of milk (plant based drinks) or even completely exclude milk and dairy products from their diet are following:

- milk quality – industrial packaged milk has the different taste and consistency and also lower nutritional value,
- the cows´ life quality (moral aspect) – life of cows on farms and in large-scale production

enterprises is often distinguished by suffering, because the animals are not treated properly,
- the impact of milk on human health – milk increases the pH level of organism and causes acidification. Then it uses calcium as one of the most effective means to achieve alkalinity when trying to balance pH,
- humans are "mammals" – they should drink just human breast milk during breastfeeding,
- veganism – not consuming meat or any other animal products.

On the positive side, the actual research done by **(Golian et al., 2019)** marks these upper mentioned reasons as myths and scientifically refuses them.

Milk and dairy products have been a traditional food of the people in our country since the time immemorial. This fact was confirmed in the publication written by authors **Podolák and Mjartan (1974)** who wrote about the ancestors of the Slovaks as breeders, since the history of dairy production has been developed for around more than 100 years. Milk along with cheese and yoghurt are three most commonly consumed dairy products. Most countries have the quantitative recommendations that usually range from 2 to 3 servings or cups of milk or yoghurt, or sometimes the equivalent serving of cheese a day. In 1989, according to **Kubicová, Kádeková and Dobák (2014)**, Czechoslovakia consumed nearly 80 kg of milk per capita but during 17 years (1995 – 2012) milk consumption as well as dairy products per capita had a downward trend. In the last decade, consumption **(VUEPP, 2019)** hit the historical lows (Figure 1) and it was below the recommended annual dose, which according to **Chlebo, Šrámková and Harasník (2009)** is 91 liters per person. The Slovak Republic has considerable reserves in this indicator, hence it is important to examine quality and marketing tools which can persuade people **(Chandon, and Wansink, 2012)** to buy and subsequently consume milk.

Scientific hypothesis

We assumed that:
- logos are easier to remember for people who know the chosen brands,
- there are differences in assessing of the selected categories related to packaging,
- the pricing strategies have the different effects.

H_0: there is not a correlation between awareness of brand and memorability of a logo.
H_1: there is a correlation between awareness of brand and memorability of a logo.

H_0: there are no differences in assessing of the selected categories.
H_1: there are differences in assessing of the selected categories.

H_0: The pricing strategies are identical.
H_1: The pricing strategies are different.

MATERIAL AND METHODOLOGY

The main objective of this research paper was to examine the quality of milk produced by two selected competing companies and identify various factors affecting consumers´ decision-making process when purchasing products. The focus was targeted at the sensory attributes (colour, appearance, smell, taste and quality) and marketing tools (brand, packaging, label and price).

The first part of this paper is a theoretical overview that allowed a better understanding of the topic. The secondary information was obtained by using the method of collecting data from publicly available information, the internet sources, literary sources of domestic and foreign authors, as well as articles by experts on consumer behavior on milk market.

	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018
Cow´s milk	47.5	52.3	51	52.2	47.3	46.2	46	44.4	44.3	44
Goat´s milk	0.6	0.6	0.6	0.6	0.6	0.6	0.7	0.7	0.7	0.7

Figure 1 Total consumption of drinking milk in Slovakia in liters per capita.

Since many authors are currently devoted to this topic, we have sorted the data by using selection and processed it into the appropriate form for this paper via deduction, analysis and synthesis. This theoretical overview became the basis for the realization of questionnaire surveys which served as a source of primary information and was supplemented with a blind testing. The aim of the questionnaire survey was to determine consumer habits in the process of purchasing and consumption of milk and sensory preferences of milk. The respondents were addressed in person and they filled in the electronical questionnaire form which was created in the Google Forms. Firstly, people were asked 8 classification questions and then 22 factual questions, which were primarily open or semi-open, with pre-selected options for answering. The data were collected from 284 respondents in the period from 4 February 2019 to 19 October 2019.

In total, 135 men and 149 women participated in the questionnaire survey. Maintaining representativeness was also important when categorizing respondents by age. The respondents of all ages were approached in order to copy the structure of the population of the Slovak Republic. The respondents aged from 36 to 45 (20.42%) represented the largest share. The same percentage of respondents (15.85%) identified the options 'from 46 to 55 years' and 'from 56 to 65 years'. 2% more (17.96%) were over the age of 66 years. The lowest representation was in the age category over 18 to 26 years. Only 32 respondents were included, which represents 11.27% of the sample in terms of percentage. The remaining 18.66% belonged to the age group from 26 to 35 years. The questionnaire form also included the question asking about the highest achieved education. 7 respondents (2.46%) completed only the elementary education. The secondary education without a school-leaving exam was marked by 16.20% and the similar education which ended with school-leaving exam by 53.87%. In the case of the higher education, the respondents had the choice of three alternatives. 11.27% completed university education of bachelor´s degree, 15.14% of master´s degree and 1.06% the doctoral university education. The fourth classification question was devoted to the economic activity of the respondents. The smallest groups were economically inactive respondents without any job (3.52%) and mothers in the maternity leave (4.93%). They were followed by 'self-employed or entrepreneur' with 8.45%. The category 'student' was the third biggest group with 15.85% and the second biggest group was that of pensioners (22.89%).

The majority of respondents (44.37%) were employed, who were also asked to write what position they were working at. Since this additional question was open, we received the different answers. The total income of household depended on the economic activity of the respondents. The most numerous groups earned from 1,001 to 1,500 € (30.28%) and from 501 to 1,000 € (26.06%). In terms of place of residence, 54.93% came from villages and 45.07% identified with the option city. All of these respondents were inhabitants of Slovakia.

Statistical analysis

Every question in the questionnaire was described verbally and some of them were also evaluated graphically. For a better understanding of the correlation, the methods of qualitative statistics were also used. The statistical evaluation program XLStat 2019.3.1 Build 60464 was used by Addinsoft to realise the following tests:

- Chi-Square Goodness of Fit Test,
- Chi-Square Test of Independence
- McNemar´s test,
- Friedman´s test,
- Nemenyi's procedure.

Traditionally, the following approach was applied to test the hypotheses:

- formulation of hypotheses H_0 and H_1 and determination of significance level α,
- after evaluating the distribution of relevant test statistics, the definition of the critical area at the significance level α,
- calculation the value of the test statistics based on empiric data,
- evaluation whether the value of the test statistics is from a critical area of the test. If it is, reject H_0 and if it is not, accept H_0.

RESULTS AND DISCUSSION

The consumers are familiar with Rajo and Tami brands in the selected market. Up to 97.54% of them knew the Rajo brand and 85.56% Tami. This high representation can be due to the fact that customers can find milk or other dairy products from at least one of these brands in almost every grocery store in Slovakia.

Majority of the respondents liked and were satisfied with the design of the Rajo and Tami logos. Only 13.03% are dissatisfied with the design of Rajo and 19.36% with the Tami design. In the following open question this minority stated that the Rajo logo is too simple, lacks colour and the used red color is very aggressive. On the other hand, the Tami logo is old-fashioned and many people have described it as "retro". In addition to the above-mentioned suggestions, the respondents who disliked logos agreed on an overall redesign that would change the font type and size, and in their opinion, it also lacked the slogan and image of something associated with milk (according to many respondents, it would be appropriate to add an image of cows).

According to the results of the questionnaire survey, the logos of selected brands are relatively easy to remember. Only 3.87% have trouble remembering the Rajo logo and 13.38% the Tami logo. Marketing and advertising agency **Navigation Advertising (2018)** claims that a logo must be easy to read, recognize, remember and reproduce. We tested this question using chi-square test for independence:

H_0: there is not a correlation between awareness of brand and memorability of logo.
H_1: there is a correlation between awareness of brand and memorability of logo.

Rajo: *p*-value = <0.0001
Tami: *p*-value = <0.0001

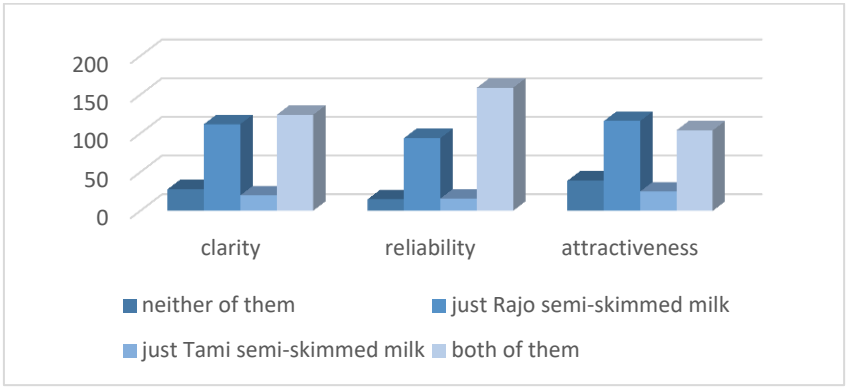

Figure 2 Assessment of packaging.

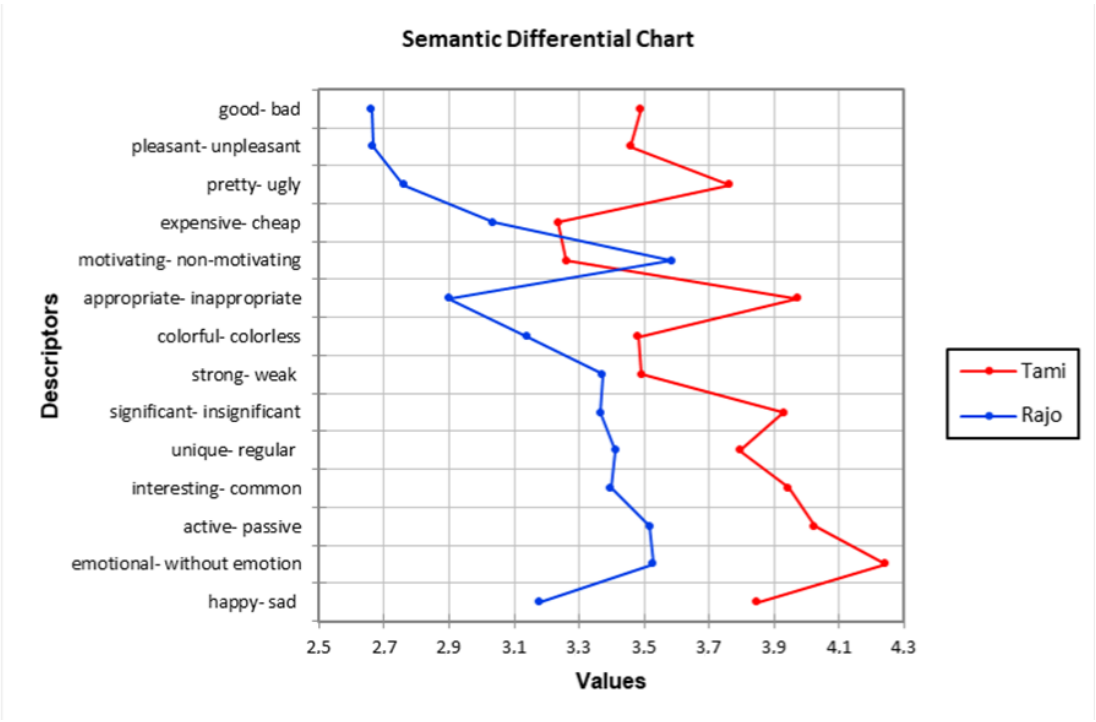

Figure 3 Assessment of selected categories.

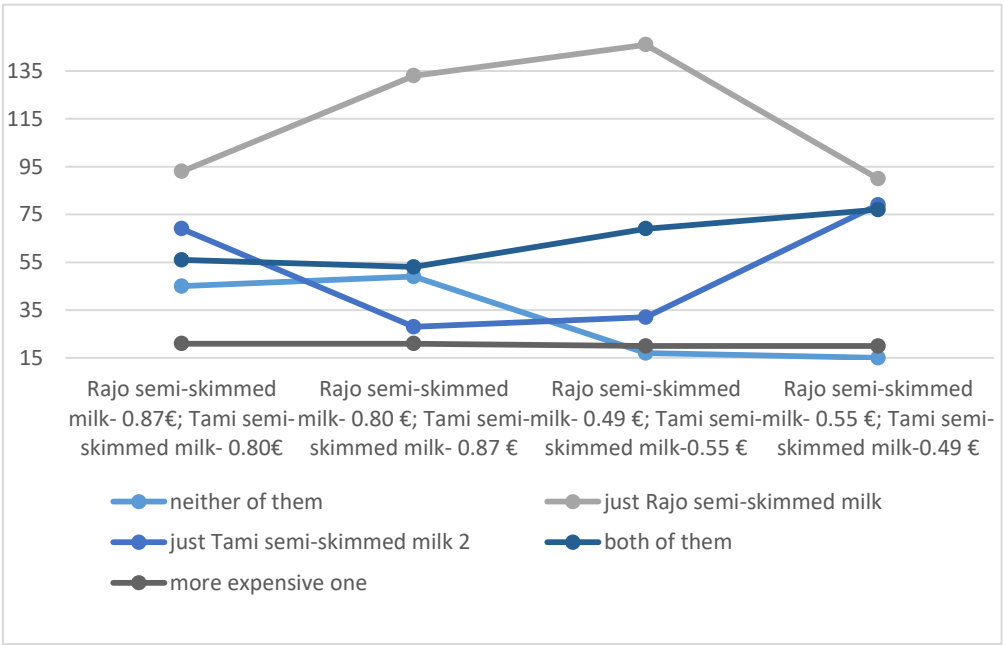

Figure 4 Selection of milk based on price.

Both tests showed that there is a correlation between awareness of brands and memorability of logos because *p*-value was smaller than alpha and we accepted the alternative hypotheses.

Approximately 60% of milk purchases are made based on brand. 21.83% of respondents targeted exclusively at Rajo and 9.51% at Tami Packaging.

Packaging

Three following questions of the questionnaire form were related to the expression of the respondents´ opinion on the clarity, readability and attractiveness of competing milk packaging, because when the right visual features and the right communication with the different segments of consumers are used, the promoted product can be successful in the market and consumers can be persuaded to make beneficial choices as well **(Rybanská, Nagyová and Tkáč, 2019)**. From the graph (Figure 2), it is evident that the direct comparison of chosen milk brands referring to clarity of packaging, more consumers inclined to Rajo (39.43%) and Tami was chosen just by 7.04%. In terms of readability, the situation is exactly the same, as Rajo was marked by 33.09%, while Tami just by 5.63%. The results of the packaging attractiveness are similar to the clarity.

In general, the respondents assessed both packaging and the ease to read, having appealed labels containing information useful to the customer, and last but not least, they appreciated the usage of an attractive blue-white color combination, which is also best suited for milk packaging according to **Clark (2016)** and **Rybanská et al. (2019)**. Moreover, blue is a favourite colour of 57% men and 35% of women, which also plays in favor of these types of packaging **(Ciotti, 2020)**. The majority agreed that "both types of packaging are attractive, even though they present milk differently and each of them addresses a different group of customers". The research conducted by **Horská et al. (2018)** showed that Slovak consumers prefer traditional packages connected with Slovak customs and traditions associated with nature, farming, home production and high quality **(Rybanská, Nagyová and Horská, 2019)** to more modern packages of milk.

The semantic differential was also used to further assessment of the appearance of the packaging, which consisted of a 7-degree scale by which individuals evaluated 14 bipolar pairs of adjectives. The adjectives by which the respondents expressed their attitude were categorized into dimensions: evaluation, strengths and activities. The dimension of evaluation is most important because it reflects the impression of packaging. The second dimension (strengths) represents the energy charge and the last dimension (activity dimension) focuses on dynamics assessing. The picture shows that Rajo was evaluated by respondents as a better one in almost all categories except for the motivation, where Tami won (Figure 3).

The Friedman´s test was used for each packaging to test the statistically proven difference in assessing each category:

H_0: there are no differences in assessing of the selected categories.
H_1: there are differences in assessing of the selected categories.

Rajo: *p*-value = <0.0001
Tami: *p*-value = <0.0001

The level alpha significance (0.05) is greater than the calculated *p*-values in both cases, so we confirm the alternative hypothesis, and the results of Nemenyi's procedure confirmed these differences too, since the variables were categorized to different groups where A was rated as the best (Table 1 and Table 2).

Price

According to **Kurajdová and Táborecká-Petrovičová (2015)** and **Kubicová, Predanocyová and Kádeková (2019)**, there is a relationship between the price factor and consumer behavior applied by Slovak consumers when purchasing milk, so for this reason the perception of the different price combinations of selected products and purchase decisions made by them were examined. If both types of milk were sold for the same price, more respondents (75.35%) tended to purchase Rajo semi-skimmed milk and Tami semi-skimmed milk was chosen by only 24.45%.

Subsequently, 4 situations were discussed (Figure 4). Two of them were real: Rajo semi-skimmed milk – 0.87 € and the pricing strategies are different in effect, Tami semi-skimmed milk – 0.80 €, when the current prices, which were observed on 21th January 2019 at Tesco were used and the discount prices (Rajo semi-skimmed milk – 0.49 € and Tami semi-skimmed milk – 0.55 €), and two simulated situations (Rajo semi-skimmed milk – 0.80 € and Tami semi-skimmed milk – 0.87 €; Rajo semi-skimmed milk – 0.55 € and Tami semi-skimmed milk – 0.49 €) when milk prices were exchanged. Approximately 7.39% of the respondents would buy another more expensive type of milk. Almost 50 respondents would not have bought any of the products during the assessment of current prices, but after a price reduction these numbers fell to one fourth. Quite the opposite situation occurred in the answer “I would buy both products" because when the prices changed to reduced ones, the numbers of respondents increased by almost a half. Looking at the exclusive purchase of the individual brands, Tami's deep drop of 59.42% was seen in the second situation (Rajo milk – 0.80 €; Tami milk – 0.87 €), when more questioned people would choose Rajo brand. A further increase in Rajo to 52.76% of the sample was due to a stock price lower than that of Tami milk. When Rajo was more expensive than Tami (in the last simulated situation), Rajo was also chosen by 14 customers more than Tami. We can assume that some consumers are price-sensitive so even those who have previously chosen Rajo would prefer to buy more affordable milk.

The effectiveness of price levels was tested by McNemar´s test, where the pairs of situations (normal price level with simulated replaced price level) were compared.

H_0: The pricing strategies are identical.
H_1: The pricing strategies are different.

p-value = <0.0001
alpha = 0.01

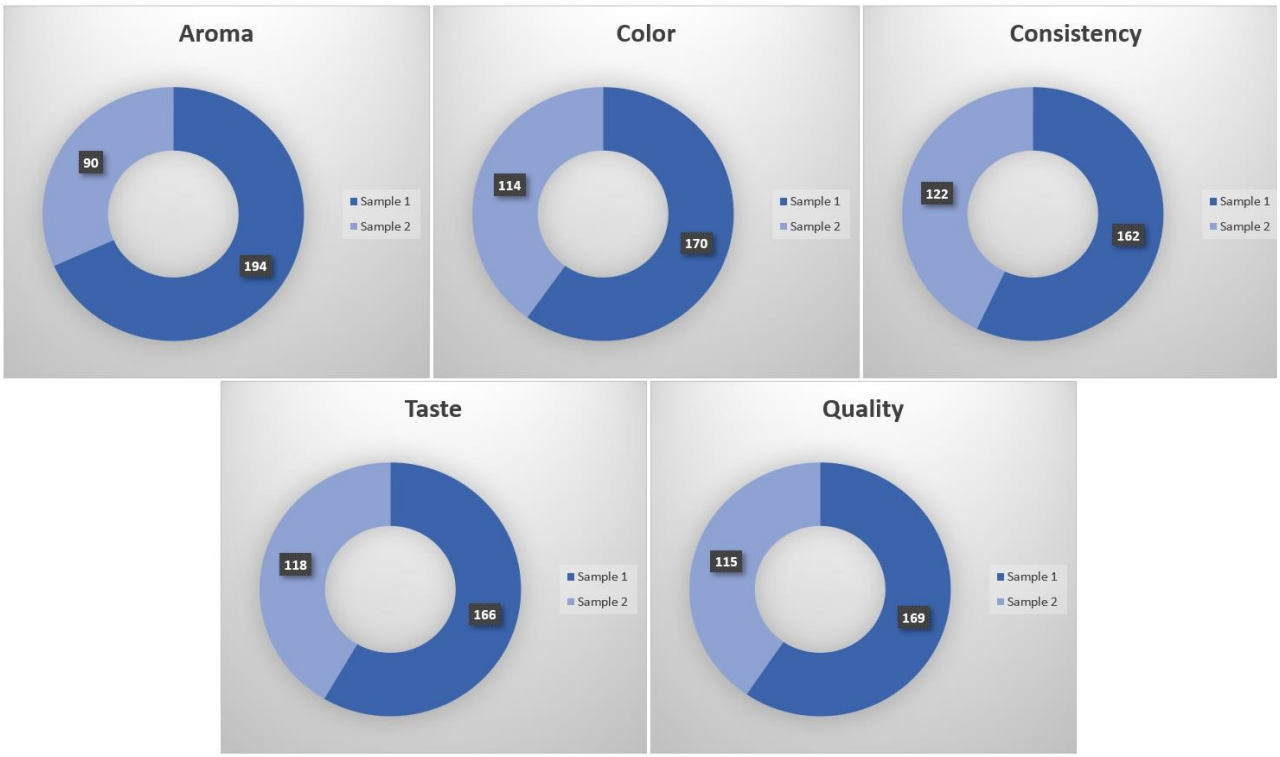

Figure 5 Results of blind testing.

Table 1 Classification of selected adjectives when evaluating the package of Rajo milk.

Rajo	Frequency	Sum of ranks	Mean of ranks	Groups					
good – bad	284	1,588.500	5.593	A					
pleasant – unpleasant	284	1,597.500	5.625	A					
pretty – ugly	284	1,671.000	5.884	A					
appropriate – inappropriate	284	1,800.000	6.338	A	B				
colorful – colorless	284	2,049.500	7.217		B	C			
happy – sad	284	2,105.500	7.414		B	C	D		
significant – insignificant	284	2,269.000	7.989			C	D

Table 3 Nutrition facts of chosen milks per 100 mL.

Nutrition facts per 100 ml			
Rajo semi-skimmed milk		**Tami semi-skimmed milk**	
Energy	200 kJ/48 kcal	Energy	194 kJ/46 kcal
Fat	1.5 g	Fat	1.5 g
of which Saturates	0.9 g	of which Saturates	0.9 g
Carbohydrates	4.9 g	Carbohydrates	4.9 g
of which Sugars	4.9 g	of which Sugars	4.7 g
Protein	3.4 g	Protein	3.2 g
Salt	0.15 g	Salt	0.2 g
Calcium	125 mg	-	

The results of both tests showed that with 99% probability the pricing strategies have statistically proven the different efficiencies (*p*-value is less than 0,0001), so we accepte the alternative hypothesis that there is the difference in efficiency of pricing strategies. In the first pair of situations, the Rajo brand is preferred and in the second pair the respondents inclined to purchasing a cheaper type of milk.

More than three quarters of the research sample (78.17%) is convinced that the price level at which selected products are sold in stores is adequate to their quality. According to the remaining 62 respondents, the price does not reflect the quality of neither examined product. **Andocsová (2019)** explains this difference in perception of prices as a result of the economic activity of respondents.

The respondents who marked the price as inadequate in the previous question were asked for an acceptable price level. 12.90% of respondents indicated the possibility of over 80 cents, paradoxically, as Rajo milk is sold for 0.87 € and Tami for 0.80 €, so these 8 respondents are most likely to be poorly informed about the current prices at which the selected products are realized on the market. The corresponding price of 71 to 80 cents sees 2.47%, from 61 to 70 cents 7.42% and 26.86% indicated the possibility of 51 to 60 cents. According to the majority of 36.04%, the common price should be the stock price, and 22.26% are in favor of not paying more than 40 cents for these products.

Blind testing

The authors **Kurajdová, Táborecká-Petrovičová and Nedelová (2019)**, **Krivošíková et al. (2019)** and **Kubicová, Predanocyová and Kádeková (2019)** emphasize that consumers living in Slovakia derive the quality of milk based on the real experience with its freshness and sensory perceptions. For this reason a blind testing was also used. It involved all 284 respondents who received 2 samples of room temperature milk in the same translucent plastic cups labeled 1 (Rajo semi-skimmed milk) and 2 (Tami semi-skimmed milk). It is important to highlight that the respondents did not know which number contained which brand during the testing. This information was provided after the testing was finished.

From the perspective of the conscious perception of the individual sensory attributes (Figure 5), which are the most important for consumers **(Krivošíková, Géci and Nagyová, 2019)**, up to 68% of the respondents preferred Rajo milk based on aroma. 60% of them selected Rajo milk semi-skimmed according to colour too, and it was also chosen by the majority because of its consistency (57%). Following this question, the respondents were asked to taste the submitted samples. Similarly, to the results of the previous questions, Rajo (58%) was repeatedly considered as tastier and higher quality product. An interesting finding was that most of the respondents, regardless whether they liked Rajo more or not, could clearly identify this brand of milk. After a personal interview, we found out that according to them it has a specific taste and smell. An unusual finding that although Tami is a big competitor of Rajo, it lags in the monitored milk properties, as the respondents chose the sample number 1 in all categories.

As Rajo semi-skimmed milk won the blind testing in all categories, we wondered whether there was a difference in nutrition facts per 100 mL of Rajo semi-skimmed milk and Tami semi-skimmed milk (which were also compared in the blind test). Table 3 shows that these two brands of milk are almost the same, nevertheless, Rajo is preferred.

CONCLUSION

The results of the questionnaire survey, the conducted blind testing and microbiological testing showed the following: the majority of respondents liked both logos (Rajo 86.97 % and Tami 80.64 %) and they also thought that they are easy to remember. Packagings were evaluated as clear, readable and attractive, but some respondents would make minor changes. When both types of milk are sold at full price, the respondents prefer Rajo semi-skimmed milk but when it comes to price reductions, they tend to be price-sensitive and purchase milk whichever is available for a lower price **(Merlo, 2015)**. The respondents preferred Rajo semi-skimmed milk in all categories and they identified it as the one with higher quality even though based on microbiological testing there was no difference between the examined samples. All of our assumptions were also confirmed by the statistical methods.

THE NOVA SYSTEM AND ULTRA-PROCESSED FOODS IN RELATION TO CONSUMER DECISION-MAKING IN FOODS CHOICE

Mária Angelovičová, Lucia Zeleňaková, Peter Zajác, Jozef Čapla

ABSTRACT

The purpose of the study was to investigate strawberry yogurt according to the NOVA food classification system. The object of research were strawberry yogurts from 6 different manufacturers, which are commonly available to food consumers, were randomly selected to investigate food samples under the NOVA food classification system. Based on this food, we present a methodology for assessing food safety with the application of the procedure. At the same time, we justify the classified food to Group 4, i.e. one of the 4 groups according to the NOVA system of food classification on a scientific basis, knowledge from the scientific literature. The evaluated results of the labeling of strawberry yogurt from various producers indicate that they are all classified as ultra-processed foods. Their characteristic feature is that they are industrial products with five or more, and usually many, items. Strawberry yogurt samples from various manufacturers evaluated contained 7 to 12 specific items that are not basic raw material, i.e. unprocessed or minimally processed food of Group 1.

Keywords: NOVA food classification system; strawberry yogurt; specific item; methodology; ultra-processed food

INTRODUCTION

The term ultra-processed foods come from the NOVA classification scheme, which divides foods into four groups:

Group 1: *unprocessed or „minimally processed" foods*, including fruit, vegetables, and meat. Foods in this group may be processed in a manner that does not add other ingredients. They may be cooked, ground, dried, or frozen.

Group 2: *processed culinary additives*; they are substances obtained directly from foods of group 1 or nature by processes such as pressing, refining, grinding, milling, and spray-drying; they are processed food items, including sugar, salt, and oils, when the items of this group are combined, for example by the production of salty butter, this product remains in this group.

Group 3: *processed foods*, represents the combination of unprocessed or minimally processed foods with processed culinary additives; i.e. Group 1 and Group 2. These are bread, wine, and canned vegetables. Additives are allowed provided they preserve the original characteristics of the food, such as ascorbic acid added to preserved fruit to prevent browning.

Group 4: *ultra-processed foods* do not have a strict definition, but the NOVA system points to some characteristics. They usually have five or more additives. They can be aggressively sold and highly profitable.

The risk of ultra-processed foods of Group 4 is from „substances which are not normally used in culinary preparations and additives intended to imitation the sensory properties of Group 1 foodstuffs or culinary preparations thereof or to mask (conceal) undesirable sensory properties of the finished product" **(Monteiro et al., 2016)**.

The risk of ultra-processed food of group 4 is from "substances not normally used in culinary preparations and additives intended to imitate the sensory properties of Group 1 foodstuffs or culinary preparations from these foods or mask (conceal) undesirable sensory properties of the final product" **(Monteiro et al., 2018)**.

Hall et al. (2019) followed hospitalized adult patients who received ultra-processed and unprocessed food every day for 14 days. The diet was compared for energy intake, sugar, fat, fiber, and macroscopic minerals. Ad libitum intake was 2,093.4 $kJ.day^{-1}$ (500 kcal) more for ultra-processed foods compared to unprocessed food. The body weight changes of these respondents were highly correlated with dietary differences in energy intake (see Figure 1).

The ultra-processed products listed in the second row are not variants of the food and meal mentioned above. They are composed of industrial food substances but contain little or no unprocessed food. They are unhealthy for their character and should be grouped. We should avoid these foods **(Monteiro et al., 2016)**.

The definition of ultra-processed foods has been gradually developed and improved over the years 2009 to

2017 **(Monteiro, 2009; Juul et al., 2018**; **Monteiro et al., 2010**; **Moubarac et al., 2014**; **Monteiro et al., 2010**; **Monteiro et al., 2016; Costa Louzada et al., 2015c; Martínez Steele et al., 2016)**.

In the publication of the team of **Monteiro et al. (2016)** the food groups 1, 2, 3, and 4 of the NOVA system are characterized in detail.

We focused on Group 4 foods, i.e. ultra-processed foods and drinks in our article.

Group 4 NOVA food products are food and beverage products that are fully processed. These are industrially manufactured products with five or more, and usually many, items. Additives often include those also used in processed foods such as sugar, oils, fats, salt, antioxidants, stabilizers, and preservatives.

Additives found only in ultra-processed products include those not commonly used in culinary preparations and additives. The purpose of the additives in ultra-processed foods is to imitate the sensory properties of Group 1 foods or culinary preparations from these foods or to mask the undesirable sensory properties of the final product. Foods in Group 1 are proportional or absent in ultra-processed products.

Substances that are only found in ultra-processed products are some directly extracted from foods such as casein, lactose, whey, and gluten and some derived from further processing of food ingredients such as hydrogenated or interesterified oils (fatty acid exchange in the triacylglycerol structure), hydrolyzed proteins, soy protein isolate, maltodextrin, invert sugar and high fructose corn syrup.

Food additives found in ultra-processed products include

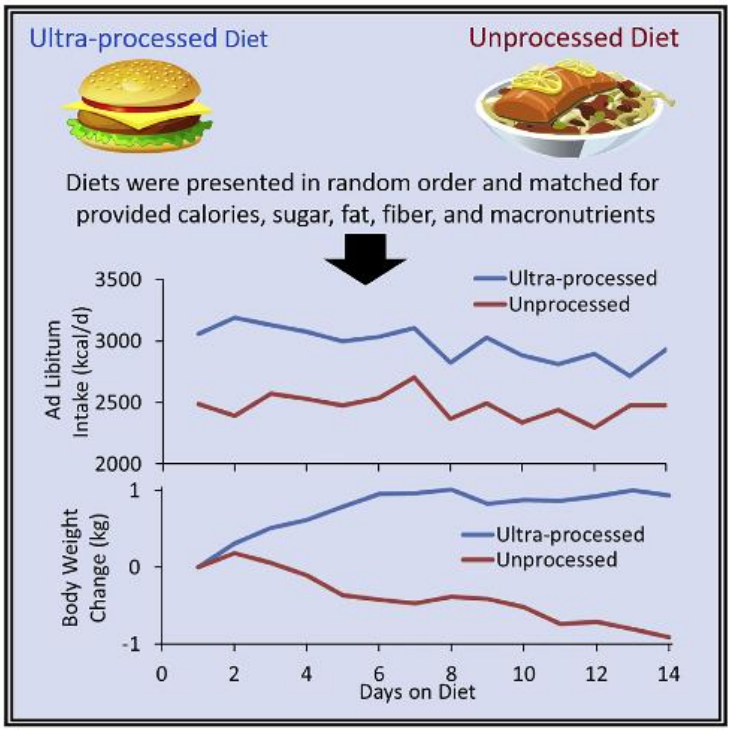

Figure 1 High correlation between intake of different energy content from ultra-processed and unprocessed foods ad libitum and body weight **(Hall et al., 2019)**.

Figure 2 Unprocessed (1st row) and ultra-processed foods (the 2nd row) **(Monteiro et al., 2016)**. Note: The first row: fruit; grains and legumes; stew with beans and vegetables; water. The second row: fruit flavored popsicles; breakfast cereals; reconstituted meat product; non-alcoholic drinks.

coloring, flavor enhancers, sugar-free sweeteners, and processing aids such as carbonation, firming, volume expansion and leveling, antifoams, anti-caking and glazing agents (e.g. palm kernel oil), emulsifiers, sequestrants, and humectants.

Some industrial processes without domestic equivalents are used to produce ultra-processed products such as extrusion and molding and pre-frying.

The main purpose of industrial ultra-processing is to produce products that are ready to be consumed, drunk, or heated and which can replace unprocessed or minimally processed foods that are naturally ready to be eaten, such as fruit and nuts, milk and water, and freshly prepared beverages and meals. Common features of ultra-processed products are excessive tastiness, sophisticated and attractive packaging, multimedia, and other aggressive marketing for children and adolescents, health claims, high profitability, and multinational corporations.

Examples of typical ultra-processed products are carbonated beverages; sweet or savory snacks; ice cream, chocolate, confectionery; meat packaged pastries; margarine and spreads; biscuits, pastries, cakes, and cake mixes; breakfast cereals, energy drinks; dairy drinks, „fruit' yogurts" and „fruit drinks"; cocoa drinks; meat extracts, including chicken and „instant" sauce; infant formulas, milk after milking, other products for infants; powdered or „enriched" meal substitutes; many ready-to-cook products, including pre-made cakes and pasta and pizza; poultry and fish „nuggets" and „sticks", sausages, hamburgers, hot dogs and other reconstituted meat products and powdered and packaged „instant" soups, noodles and desserts.

Where products produced exclusively from foodstuffs of Group 1 or 3 also contains so-called „food" cosmetic or sensory enhancing additives, such as plain yogurt with added fruit containing artificial sweeteners and breads with added emulsifiers, are classified here in Group 4. Where alcoholic beverages are identified as foods, these produced by fermentation of the foods of Group 1, followed by distillation of the resulting alcohol, such as whiskey, gin, rum, vodka, are classified in Group 4.

Advice based on NOVA knowledge on ultra-processed foods in the area of nutrition in relation to good human health, and the accumulated evidence of their effects in national dietary habits and welfare, it is relatively simple but significant to avoid consuming them. This issue of ultra-processed foods is elaborated e.g. in the official dietary recommendations for Brazilian citizens, where the issue is addressed not only in research but also in politics **(Brazilian Ministry of Health, 2014)**.

The importance of industrial processing in terms of methods and uses of food additives or produced by modern food science and technology in terms of food properties and the state of food in relation to human health, it is still undervalued. This state of so-called relative neglect is contained in reports and other documents that include recommendations on diet, epidemiological studies, and in policies and strategies aimed at improving nutrition and health of the population. In the first half of the last century, the guidelines on eating, they contained most of the meals that were a combination of foods with culinary additives and consumed as meals as such. But the second half of the last century is characterized by food packaging, labeling, and instructions for preparing for eating or heating. These „fast" or „profitable" foods became more and more preferred, they have become more important in the dietary models of high-income countries **(Monteiro et al., 2018).**

Monteiro (2009) published an opinion claiming that the scope and purpose of food processing had changed worldwide. These changes are leading to a harmful global food system and a pandemic of obesity and other nutritional causes of chronic non-communicable diseases.

The NOVA system classification scheme according to **Monteiro et al. (2016)**, which contains four groups of foods, according to the extent and purpose of the processing to which they are subject, includes physical, biological, and chemical processes. These processes occur after the separation of natural foods and before their consumption or use in the preparation of meals. The methods used in the culinary preparation of foods in household kitchens, restaurants, public catering in general, including the disposal of wastes from cooking meals, spices, and blending various foods, the NOVA classification scheme is not taken into account.

The purpose of the study was to investigate strawberry yogurt according to the NOVA food classification system.

Scientific hypothesis

Scientific hypothesis: Based on the evaluation of strawberry yogurt samples from different manufacturers, that these industrial products will contain items, which will be a characteristic attribute and count for inclusion in ultra-processed foods.

MATERIAL AND METHODOLOGY

Object of study

Strawberry yogurts, which are commonly available to food consumers, were randomly selected to investigate food samples under the NOVA food classification system. Based on this food, we present a methodology for assessing food safety with the application of the procedure. At the same time, we justify the classified food to Group 4, i.e. one of the 4 groups according to the NOVA system of food classification on a scientific basis, knowledge from the scientific literature.

Characterization of strawberry yogurt samples

Strawberry yogurt samples from 6 different manufacturers were investigated based on the NOVA food classification system according to **Monteiro et al. (2016)**. These authors have included fruit yogurts among the Group 4 foods, which are ultra-processed.

Method

Strawberry yogurt samples were assessment based on composition, i.e. labeling on the packaging. Each food ingredient that is characterized by Group 4 foods has been identified by a number in the order in which the strawberry yogurt items were listed. For assessment of strawberry yogurt, 6 pcs samples, were available. Each sample originated from a different manufacturer. Initially, the composition items for each strawberry yogurt sample indicated on the packaging were identified by the order

number. The final number of the sample composition item characterized the sum of strawberry yogurt items.

The NOVA food classification system according to **Monteiro et al. (2016)** contains fruit yogurts in Group 4 foods, i.e. in ultra-processed foods characterized by 5 or more specific items in the composition.

RESULTS AND DISCUSSION

The evaluated results of strawberry yogurt are given in Table 1.

The table shows the composition of strawberry yogurt from 6 different manufacturers. Given the risks associated with their consumption, which follow from the literature review, our effort was to propose a methodology for their identification, i.e. a simple way that would be understandable for food consumers. The food consumer selects the food itself when buying the food. He decides which food to choose from.

Several factors influence his choice, but one of the most important is a health-related choice. We aimed to assess risks from processed foods, including ultra-processed foods and facilitating decisions in choosing foods for consumers.

This is the initial work, which is closely linked to the tracing of food labels by food consumers, which is already a common part of food purchases.

The present study presents a broader link between consumer decisions in food choice and public health. Even now, in many cases, the food consumer is already deciding on the choice of food based on its composition. The scientific basis for this decision is based on the Nova system, which is presented in this article.

The evaluated results of the labeling of strawberry yogurt from various producers indicate that they are all classified as ultra-processed foods. Their characteristic feature is that they are industrial products with five or more, and usually many, items. Additives are used in them as in processed foods (sugar, stabilizers, and preservatives). Other items have been found in them, which are typical only for ultra-processed products and which are not commonly used in culinary preparations and culinary additives (such as aromas, coloring, acidity regulators, etc.).

Research from recent years confirms data that medicines are being processed, which are now the main shaping force, which has become a global food system and is a key determinant of eating methods and possible health and well-being **(Monteiro, 2009; Ludwig, 2011; Stuckler et al., 2012; Moodie et al., 2013)**.

Analysis of survey data confirmed findings from the consumption of ultra-processed foods **(Costa Louzada et al., 2015a, Costa Louzada et al., 2015b; Steele et al., 2015; Cespedes and Hu, 2015).**

Food classification according to the NOVA system it is clear, useful, understandable, and easy to use **(Monteiro et al., 2016)**.

According to **Rico-Campà et al. (2019)** the methodology of the NOVA system classification of foodstuffs was criticized, but according to these authors, there is no better alternative. It is also easy to use for reporting and reproducible and therefore beneficial to public health. Also, it is the best known and most commonly used classification of ultra-processed foods in epidemiological studies.

Therefore, these authors used the classification a NOVA system for identifying four different food groups by stage of processing. Their interest was in the fourth group under the NOVA system, which included ultra-processed food and beverages that tend to be nutritionally unbalanced due to several industrial process operations.

These foods are economically advantageous because the shelf life and hence the sale of these foods increases, but the quality of the nutritional value decreases. Ultra-processed foods are characterized by high energy, low fiber, and microscopic minerals and high added or free sugars, sodium, saturated fats, and chemical food additives **(Moubarac et al., 2013)**.

Intake of ready-to-eat, ready-to-drinks, ready-to-eat products has increased significantly in all countries, irrespective of economic level over the last two decades. This trend may have contributed to a worldwide increase in total cancer **(Fiolet et al., 2018)**, dyslipidemia **(Rauber et al., 2015)**, obesity **(Rauber et al., 2016)**, and hypertension **(Mendonça et al., 2017)**.

Srour et al. (2019) report in their publication results from the prospective cohort study NutriNet-Santé, during 5.2-year research and conclude that the results could explain some of the scientific hypotheses established in the research of ultra-processed foods in relation to cardiovascular diseases.

The first interpretation: Ultra-processed foods generally have worse nutritional quality than unprocessed or minimally processed foods because they tend to be richer in sodium, energy, fat, and sugar, and poorer in fiber **(Luiten et al., 2016; Moubarac et al., 2017; Cediel et al., 2018)**; they are also associated with a higher glycemic reaction **(Costa Louzada et al., 2015a)**.

Sugar sweeteners can delay the initiation of the inner satiety signal, which can lead to excessive energy intake **(DiMeglio and Mattes, 2000)**.

In a prospective NutriNet-Santé cohort study, participants included in the high consumption group of ultra-processed foods had lower fruit and vegetable intake. It is well known that a high intake of fruit and vegetables (food Group 1) together with respect for a healthy diet is beneficial for the prevention of cardiovascular diseases (high level of evidence) **(Mozaffarian, 2016)**.

The second interpretation: Refers to a wide range of additives in ultra-processed foods. Although the highest permitted levels protect consumers from the adverse effects of individual substances in certain foods **(World Health Organization, 2018)**, the effect of the cumulative effect of intake of all foods used and the potential or interaction effect remains largely unknown, unexplained **(Srour et al., 2019)**.

For some, from approximately 350 different permitted food additives in Europe, several adverse effects on cardiovascular disease have been identified in animal experiments or cell model studies.

Also, emulsifiers often found in ultra-processed foods, particularly carboxymethylcellulose and polysorbate **(Santé Publique France DREES, 2018)**, demonstrated potential effects of low degree in inducing inflammation and obesity or metabolic syndrome in mice **(Chassaing et al., 2015)**.

Table 1 Strawberry yoghurt samples from various manufacturers.

Sample	Basic raw material	Flavoring ingredient	Yoghurt culture
No. 1	**cream**	1 sugar 2 strawberry **thickening:** 3 maize starch, 4 strawberry concentrate 5 black carrot concentrate 6 aroma	**7 yes**
No. 2	**cream**	1 sugar 2 strawberries 3 glucose-fructose syrup 4 modified corn starch 5 water 6 aromas **thickening:** 7 pectins **coloring:** 8 carmines, 9 acidity regulators 10 citric acid 11 sodium citrates	**12 yes**
No. 3	**milk**	1 sugar 2 glucose-fructose syrup 3 strawberry puree 4 strawberry juice **stabilizer:** 5 modified starch 6 aromas **coloring**: 7 carmine 8 concentrate juice from beetroot **acidity regulators:** 9 citric acid 10 milk proteins	
No. 4	**milk, cream**	1 sugar 2 strawberries 3 water **thickening:** 4 modified corn starch 5 strawberry aroma identical to natural 6 natural coloring carmine **acidity regulators:** 7 sodium citrate	**8 yes** and 9 probiotic culture
No. 5	**milk**	1 strawberries 2 sugar **stabilizer:** 3 pectin 4 lemon juice 5 milk protein	**6 yes** and 7 Bifidobacterium, 8 *Lactobacillus acidophilus*
No. 6	**milk**	1 pieces of strawberries 2 water 3 sugar **coloring concentrates:** 4 of black carrot 5 of carrot 6 natural aroma 7 concentrated skimmed milk 8 sugar 9 milk proteins	**10 yes** and 11 „Bifidus“

Note: – the strawberry yoghurts are commonly available for food consumers and they are from different manufacturers; – the composition of the individual strawberry yogurt samples is used from their labelling on the package; – the number for the strawberry yogurt ingredient in the table indicates the order of the ingredients of the composition with the final number of ingredients.

Ultra-processed foods may be contaminated with contact materials (suspected of migrating from the packaging), including bisphenol A in some plastic packaging, which the European Chemicals Agency considers as „Substance of Very High Concern" **(European Chemical Agency, 2016)**. This substance is associated with an increased risk of cardiometabolic sequelae (especially hypertension and coronary artery disease) in a recent meta-analysis **(Rancière et al., 2015)**.

CONCLUSION

The NOVA food classification system is a simple and effective way of assessing food based on its division into 4 groups. Food group characterization is important. This way of assessment foods and dividing them into any of the 4 groups is important for the consumer to make their choices. Based on the assessment of strawberry yogurts that have been the subject of our research, it follows that, according to the characterization of the NOVA food classification system, they are included in Group 4, among ultra-processed foods. Strawberry yogurt samples from various manufacturers evaluated contained 7 to 12 specific items that are not basic raw material, i.e. unprocessed or minimally processed food of Group 1.

SENSORY EVALUATION AND ACCEPTANCE OF FOOD MADE OF EDIBLE INSECTS

Martin Adámek, Anna Adámková, Lenka Kouřimská, Jiří Mlček, Klára Vojáčková, Jana Orsavová, Martina Bučková, Oldřich Faměra, Martin Búran

ABSTRACT
This paper discusses the sensory analysis of food enriched with selected edible insect species which are labelled as a novel food – house cricket (*Acheta domesticus*) and mealworm (*Tenebrio molitor*). Energy bars of two different compositions with the addition of cricket flour and puff pastry bars sprinkled with the whole roasted mealworm larvae were evaluated by consumer tests performed via a questionnaire survey. Respondents represented both men and women in equal numbers and included consumers with the experience of the sensory analysis and edible insects to ensure accurate results. Sensory analyses revealed that respondents associated their tastes with already known flavors (salty, sweet, bitter, fish, French fries, chicken, and mushrooms). The most common answer from respondents was a salty taste, followed by a sweet taste. There were also unusual comparisons such as pine seeds. Consumers' positive attitude to these energy bars has been registered which shows that the Czech consumer accepts edible insects in a suitable form as a novel food and possible part of the food basket.

Keywords: edible insect; *Tenebrio molitor*; *Acheta domesticus*; sensory analysis

INTRODUCTION
Entomophagy is a practice of edible insect consumption **(Imathiu, 2020)**. The origin of this word comes from Greece, where ἔντομον éntomon means "insects" and φᾰγεῖν phagein is translated as "to eat" **(Kouřimská and Adámková, 2016)**.

Sensory properties comprise an important criterion for edible insect consumption **(Borkovcová et al., 2009; Adámek et al., 2017)**. In western countries, entomophagy is often associated with dirt and poverty, thus being considered unacceptable **(Looy, Dunkel and Wood, 2014)**. Many people disregard insects and they neglect its high nutritive value **(Siemianowska et al., 2013)**. Existing significant prejudices closely connect with a disgust factor representing a major repulsive force that is formed in the child age before 6 or 7 years. In contrast, an edible insect has been consumed in other cultures in Africa, Latin America, Asia **(Hanboonsong, 2010; Raheem et al., 2019)** and Australia **(Siemianowska et al., 2013)**. There are approximately two billion people in 113 countries consuming edible insects **(Lucas et al., 2020)**. Recently, around 2000 species of edible insects have been registered **(Megido et al., 2018)**. Countries with a common entomophagy practice include Zimbabwe, Japan **(Raheem et al., 2019)**, Thailand with more than 150 edible insect species **(Imathiu, 2020)**, and Mexico with approximately 550 species of edible insect consumed **(Siemianowska et al., 2013)**. Consuming edible insect is also supported by the fossils **(Kouřimská and Adámková, 2016)**. Technologies of insect mass rearing have been accepted in some countries, such as Holland, Denmark, Belgium, Kenya, and Vietnam **(Imathiu, 2020)**. In China, where entomophagy is practiced for more than 3,000 years **(Lucas et al., 2020)**, edible insect also gains the role of a food ingredient and is seen as a suitable alternative to further kinds of meat **(Kröncke et al., 2018)**.

The insect may be consumed indirectly in a form of extracts or products, such as honey, wax, pollen, and dyes **(Lucas et al., 2020)**.

The potential of edible insects has been growing due to positive environmental impacts **(Dossey, Morales-Ramos, and Rojas, 2016)**. The rearing of edible insects requires less water and space if compared to other livestock. What is more, the amount of produced greenhouse gas is considerably lower (**Lucas et al., 2020**). Another advantage of growing an edible insect is its high reproduction rate **(Imathiu, 2020)**. Apart from these significant benefits, edible insect as a part of a balanced diet could be a potential source of adequate food supplies due to its high feed conversion rate **(Belluco et al., 2013; Van Huis et al., 2013)**. Furthermore, according to studies, edible insect species provide great nutritional values as they are an excellent source of protein, fat, vitamins as well as minerals **(MacEvilly, 2000; Van Huis et al., 2013)**. Several

conditions can change the nutritional value of edible insects, such as the environmental conditions or different processes of heat treatment **(De Castro et al., 2018)**. The edible insect could be eaten in a raw form or could be processed by roasting, frying, or boiling **(Imathiu, 2020)**. Interestingly, frying may even improve the sensory quality of insects due to aromatic compounds, attractive colors, crust, and texture. Its hygienic quality may be enhanced by a cooking process thanks to the inactivation of possibly present pathogenic microorganisms **(Megido et al., 2018)**. Unfortunately, heating processes could affect nutritional values as well **(Montowska et al., 2019)** due to the processes including proteolysis, lipolysis, and lipid oxidation. **(Megido et al., 2018)**.

A prediction of a significant increase in edible insects on the global market is expected to reach 710 million dollars **(Roncolini et al., 2020)**. Mealworm larvae (*Tenebrio molitor*) and crickets (*Acheta domesticus*) are the species most commonly farmed in Europe. What is more, they are considered to be the most promising in the food and feed industry **(Imathiu, 2020)**.

Crickets (*Acheta domesticus*) contain a substantial amount of all-important constituents – proteins, fats, vitamins, and minerals **(Montowska et al., 2019)**.

Based on a questionnaire created by **Bednářová et al. (2013)**, the mealworm was evaluated as one of the most acceptable species for consumption in the Czech Republic. The field cricket was also assessed positively; however, some respondents dislike the feeling of biting into the soft insect body. Their opinion was influenced by the psychological aspect of considering cricket as the food of the poor. Furthermore, European consumers can be divided into two groups – one group prefers the possibility of consuming food with proper visibility of the larvae, while the latter prefers to consume insects in a hidden form **(Adámek et al., 2018)**. This way, the texture of the insect is not easily perceptible. Edible insects, particularly adult specimens, are partly composed of the exoskeleton causing the crunchiness during the consumption influencing the tactile and auditory effect resulting in, along with the chewing, a pleasant feeling similar to the consumption of pretzels, cookies, or other various durable pastry **(Ramos-Elorduy, 1998)**. A beneficial high content of chitin in the exoskeleton should be emphasized **(Aguilar-Miranda et al., 2002; Mlček et al., 2014)**. However, the human body can digest soft larvae after molting because their exoskeletons are not hardened yet **(Borkovcová et al., 2009)**. For this reason, the mealworm larvae were examined in this study.

The taste of the insect could be very diverse. It depends on many factors, such as the environment and the feed including fruits, vegetables, pastries, potatoes, rice, or grass. During the culinary treatment, insect absorbs different flavors of other ingredients which were proved as early as in 1971 by **Smith et al**. **(1971)**. What is more, if the insect is processed with spices, it will obtain a new flavor and the original taste will be weakened. If it is washed before the consumption, which is not recommended by **Ramos-Elorduy (1998)** due to the food safety point of view **(Bednářová et al., 2010)**, it will provide hardly any flavor since the pheromones on the insect surface are rinsed away. That is why to ensure full and rich taste it is necessary to serve insect alive. Due to the health and safety considerations, it is recommended to allow the insect to starve for at least 12 hours. This precaution is recommended particularly for grasshoppers, caterpillars, and beetle larvae **(Ramos-Elorduy et al., 1997)**.

This work aimed to explore the attitude of the general public towards entomophagy in the Czech Republic employing a questionnaire and to evaluate the sensory properties of selected food enriched with the edible insect.

Scientific hypothesis

Food enriched with edible insects is acceptable for consumers in the Czech Republic.

MATERIAL AND METHODOLOGY

Material for sensory analysis

Two species of edible insects were selected for the sensory analysis – mealworm (*Tenebrio molitor*) and house cricket (*Acheta domesticus*). Specimens of mealworm (*Tenebrio molitor*) were purchased in a pet shop and left to starve for 48 hours, killed with boiling water (100 °C), and dried at 105 °C. Subsequently, the insect was sprinkled on the puff pastry bars which were examined in the sensory analysis (Figure 1).

House cricket (*Acheta domesticus*) was sensory evaluated in a form of cricket flour. The sample of cricket flour was used in energy bars. Respondents were provided with two kinds of bars. Sample A contained dates, cricket flour, pineapple, cashew, coconut, psyllium, and lemon peel. Sample B included dates, cricket flour, cocoa powder, cashew, psyllium, and orange peel. Bars were cut into dices, spiked with toothpicks, and offered to the respondents for evaluation.

Survey methodology

Samples were subjected to the sensory analysis and evaluated using a questionnaire. In the first part of the research, the samples of mealworm (*Tenebrio molitor*) were evaluated focusing on the taste. The short form of the questionnaire, designed especially for the wide public, contained mainly questions about the respondent (age, gender) and the taste of insects. Respondents were asked to specify the taste of the sample. Thirty-two respondents participated in the first survey and 53% of them have already experienced food sensory analysis under the laboratory conditions. 25 respondents participated in the second survey with only 40% having the experience of the food sensory analysis.

Bars containing cricket flour were examined in the second part of the experiment using the third questionnaire. This survey was attended by 42 respondents, of which 59% were women and 40% were men. Participants in the lecture were provided with two samples of bars (samples A and B) and forms to evaluate the taste. The respondents were asked to evaluate the pleasantness of both samples by using an ordinal score scale from 1 (excellent taste) to 5 (annoying taste).

Figure 1 Puff pastry bars sprinkled with mealworm (photo Jan Gajdošík).

Statistical analysis

The data were analyzed using Excel 2013 (Microsoft Corporation, USA) and STATISTICA CZ version 12 (StatSoft, Inc., USA), and the results were expressed by mean ± standard error.

Considering cricket flour bars, the results were evaluated using a paired t-test to analyze differences between the means of the evaluation of samples A and B.

The dependency of the evaluation on the gender was evaluated using the χ^2 test which was applied to map differences of preferences between genders. For this test, a modified table was used with the preference marked as follows:

A = evaluator scored a better rating for the sample A,
B = evaluator scored a better rating for the sample B,
O = both samples gained the same score from the evaluator.

Puff pastry bars sprinkled with the mealworm larvae were evaluated by the percentage of the taste expressed by the respondent to the total number of answers.

RESULTS AND DISCUSSION

Puff pastry bars sprinkled with mealworm

During the first part of the sensory analysis, a questionnaire survey was used to evaluate samples of mealworm on puff pastry bars. In this first survey, the most significant amount of 31% of respondents described the taste as salty. Other respondents described the taste as sweet (almost nutty) (18.8%), which was the second most selected answer. A similar number of respondents tasted it as the whole grain bread (12.5%) and fish (12.5%). A slightly lower number of respondents opted for the taste of the fried potatoes (9.4%). A small percentage of respondents described the taste as similar to pine seeds, chicken, bitter or other. None of the respondents considered the taste like sour, fatback with skin, mushrooms, apples, raw corn caviar, or herring. A percentage representation of individual flavors is shown in Figure 2.

The results of the second part of the survey are depicted in Figure 3. Most respondents agreed on the option of the sweet taste (24%) and whole grain bread taste (24%).

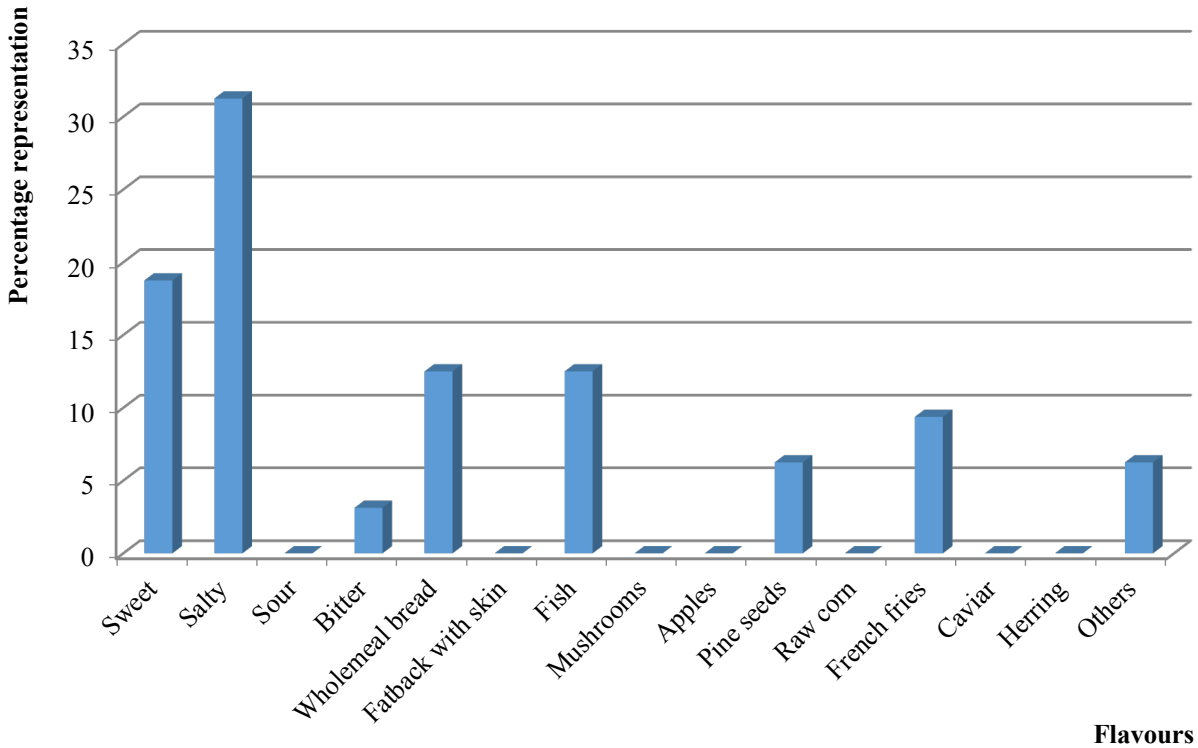

Figure 2 Percentage representation of individual flavours of mealworm samples on puff pastry bars in the survey no.1.

A slightly lower number of respondents (20%) selected salty taste and 16% of respondents described the taste as bitter; the taste was poorly represented in the previous survey. The taste of the pine seeds was selected by 8% of respondents, the option "other" was selected only by one respondent who described the taste as similar to chicken. These results are following the study by **Ramos-Elorduy (1998)** who states that the taste of mealworm (*Tenebrio molitor*) is similar to the taste of the whole grain bread.

There were some similarities in the descriptions of the tastes of both samples – in both cases, the participants selected sweet and salty flavor and the taste of the wholemeal bread and pine seeds. The second sample was characterized by the increase in the frequency of the selection of the sweet and bitter taste and the taste of the wholemeal bread. The flavors of fish and French fries were described only in the first sample. The options for the sour taste and the taste of mushrooms, apples, raw corn, or caviar were not selected by any participant during the analyses.

The edible insect is a highly popular delicacy, especially for its sensory properties **(Borkovcová et al., 2009)**. The flavor of insects varies from species to species, and it is affected by pheromones, the environment where insects live, and the feed they eat. **Ramos-Elorduy (1998)** stated a range of flavors from fishy to wheat bread in the case of major classes of edible insects, (adopted from **Mishyna, Chen and Benjamin, (2020)**). Generally, mealworms aroma is stated as nutty or whole wheat bread **(Ramos-Elorduy, 1998; Capponi, 2016; Elhassan et al., 2019)**. **Roncolini et al. (2019)** further specify that larvae fed flour or cereal bran have a characteristic sweet, almost nutty flavor, and a nutty, cocoa smell. In contrast, larvae which were as fed grass crickets have a strong crustacean-like, cooked legume-like, and earthy aroma.

The sweet flavor is in accordance with the results of this study because the producer fed the larvae with cereal bran. It has been assumed that the high value of the salty flavor is due to the dough on which the larvae were sprinkled.

Energy bars enriched with cricket flour

In the sensory evaluation of energy bars with the addition of cricket flour, two samples were examined. Sample A containing dates, cricket flour, pineapple, cashew, coconut, psyllium, and lemon peel, and sample B containing dates, cricket flour, cocoa powder, cashew, psyllium, and orange peel. There was no statistical difference between the results of each sample ($p > 0.05$). Furthermore, the results have shown a positive evaluation of both samples which approaches the overall average score 2 as can be seen in Figure 4.

Elhassan et al. (2019) described the flavor of crickets as umami, popcorn, chicken, mild, or creamy. On the other hand, **Capponi (2016)** characterized the flavor of cricket as fishy.

According to the results, the influence of gender on the sample evaluation has not been statistically significant ($p > 0.05$) for any of the samples. **Table 1** shows a small but statistically not significant difference ($p > 0.05$) as women preferred sample A from B, while men preferred B. The reason may be the content of cocoa powder in sample B which women like more than men, e.g. in the form of chocolate candies **(Kozelová et al., 2014)**.

In Hungary people who plan to eat less meat or who are looking for new food choice expect to eat edible insects as a substitute. In the study was also noticed that women have bigger neophobia than men **(Gere et al., 2017)**.

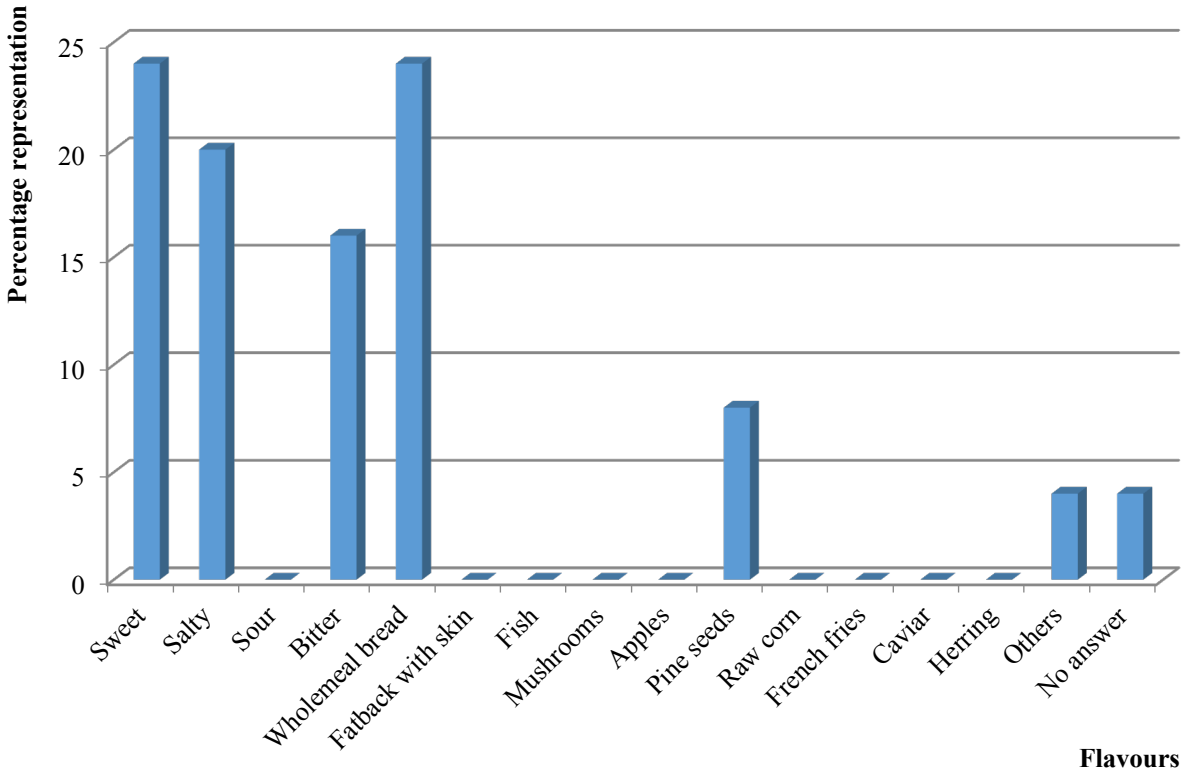

Figure 3 Percentage representation of individual flavours of for mealworm samples on puff pastry bars in the survey no. 2.

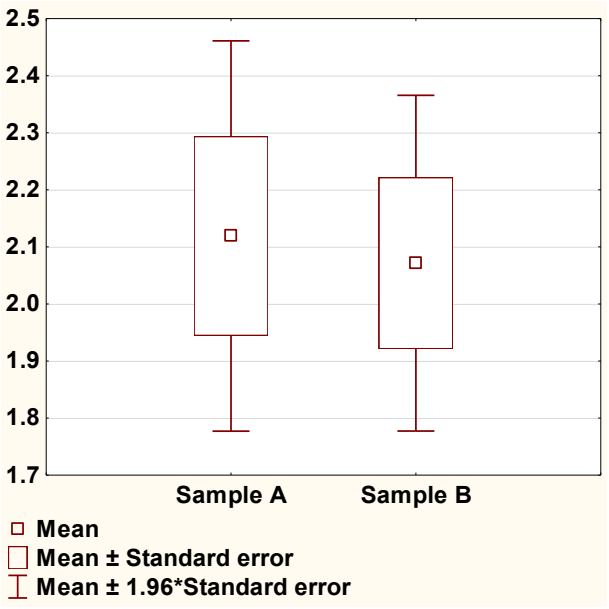

Figure 4 Sensory evaluation of the pleasantness of taste for energy bars enriched with cricket flour in the questionnaire survey no. 3. Note: Sample A – dates, cricket flour, pineapple, cashew, coconut, psyllium and lemon peel; Sample B – dates, cricket flour, cocoa powder, cashew, psyllium and orange peel.

Table 1 Differences of gender preferences for two samples of energy bars enriched with cricket flour in the questionnaire survey no. 3.

Gender	Preferences			
	Sample A (%)	Sample B (%)	Both samples (%)	Total (%)
Woman	40	48	12	100
Man	47	41	12	100
χ2 test	0.21	0.16	0.00	0.38

Note: 1) Preferences: A = better rating for the sample A, B = better rating for the sample B; 2) Critical value of tested criterium χ^2 for significance level 0.05 and 2 degrees of freedom was 5.991.

The study **Megido et al. (2013)**, which was focused on Belgian consumers, found out the people seemed to be willing to eat and cook insects in the future when it is connected with familiar flavors.

The positive result about the consumption of eating insect-containing products in the future is positively accepted by people in Italy and a slightly higher number of males were open to the idea of a product as an alternative source of protein **(Sogari, Menozzi and Mora, 2017)**. In the USA or India are people considering trying to eat some form of insect food and at the same time, men are more inclined to this idea **(Ruby, Rozin and Chan, 2015)**.

On the other hand, in Germany is still a prevalence of skepticism towards the consumption of edible insects. The acceptance is similar between both genders if the insect is in an invisible form **(Orsi et al., 2019)**. In the study, **Hartmann et al. (2015)** were examined the acceptance of edible insect in a comparison between Germany and China without noticeable differences between males and females. A similar study focused on the acceptance of edible insect was the comparison of people from Korea and Ethiopia, where was the acceptance of men higher than women in both studied nations **(Ghosh et al., 2020)**. Another research was done in a Danish college where the respondents were females. Even though in other studies males are more open to eating edible insects than females, in this research 81% of respondents (only females) tasted the mealworms **(Jensen and Lieberoth, 2018)**.

In the study by **Tuccillo et al. (2020)** and **Laureati et al. (2016)** was found that men are more open to entomophagy than women. The same result was mentioned in **Woolf et al. (2019)** where was investigated the opinion of consumption of insect-containing food. Positive willing to trying of insects as food among Dutch consumers were young males, who tried it before **(Tan, van den Berg, and Stieger, 2016)**. **Verbeke (2015)** calculated that the predicted acceptation of edible insects as a substitute for meat is 12.8 % for men and 6.3 % for women.

Megido et al. (2016) examined the acceptance of hybrid insect-based burgers where men were more open to eating burgers that contain edible insects.

The interest of consumption of edible insects in products is being investigated by **Gmuer et al. (2016)**, **Le Goff and Delarue (2017),** or **Hartmann and Siegrist (2016)** where the results were slightly positive. The higher acceptance of edible insects by males when females are mentioned in the study by **Verneau et al. (2016)** where the experiment was held in Denmark and Italy.

Edible insects and consumers in the Czech Republic

During the process of preparation, such as applying the boiling water and cooking edible insects, the original aroma is often removed and the insect acquires the smell and taste of other present ingredients **(Ramos-Elorduy, 1998)**. This could be the reason why the respondents also reported the salty taste of the sticks sprinkled with larvae of mealworms and the hazelnut taste was suppressed. Concerning energy bars enriched with the cricket flour, the flavor of the cricket flour was significantly suppressed by the fruit ingredients. Although the customer in the Czech Republic is currently sufficiently informed about edible insects from festivals, TV shows, or magazine articles, the difference between the perceived tastes of edible insects in the visible and hidden form was obvious. The invisible form (energy bars) was accepted without any problems by both men and women even though the respondents had been informed in advance about the flour of edible insects in the bars.

When evaluating the visible form (puff pastry bars sprinkled with mealworm), the initial hesitation was apparent and the male respondents overcame that faster. After the first tasting, the respondents showed no more hesitation to test another sample. This could stem from the above-mentioned suppression of insect flavor. Therefore, it is possible to conquer the initial fear to consume edible insects and to consider them as an interesting and acceptable novel constituent of the diet.

CONCLUSION

This study has confirmed a positive evaluation of selected food with the addition of edible insect employing a questionnaire survey of the general public in the Czech Republic. It has been proved that people welcome the opportunity to taste the samples of edible insects and do not exclude the possibility of conscious eating of the edible insect in the future. Regarding the conscious consumption of visible mealworm larvae on the puff pastry bars, the respondents associated their taste with known flavors of salty, sweet, and chicken, which may lead to further improvement in the attitude towards this commodity. Considering the examination of energy bars enriched with the cricket flour, both samples were positively evaluated. No statistically significant difference has been found between these two samples. Therefore, the results have shown that consumers in the Czech Republic are inclined to consume edible insect products, particularly if they can select the preferable form of the product and the included species.

THE EFFECT OF STORAGE ON THE QUALITY PARAMETERS OF BABY FOOD

Hyrije Koraqi, Namik Durmishi, Diellëza Azemi, Sara Selimi

ABSTRACT
The aim of this paper was focused on the quality changes of baby food stored at different temperature (4 °C, 20 °C, 40 °C and 60 °C) for 15 days. During storage, chemical and nutritional parameters analysis were carried out. Commercial fruits based baby food are the products usually made with fruits, sugar, and variable additives. As the foodstuffs intended for particular nutritional uses, baby foods for infants and young children conform to a set of strict guidelines e.g. nutritional quality, the addition of additives, labeling. However, being an important supplement to children's diet and for their progressive adaptation to ordinary food, the nutritional quality of commercial fruits baby food is very important. Samples of commercial fruits baby food from the market and pharmacies were analyzed by parameters: pH, total soluble solids, moisture, total acidity, vitamin C, proteins, sugars, and lipids. All samples of baby food are produced by foreign companies since currently, no Kosovo manufacturers are producing this range of products. The nutritional quality parameters are important to assess the quality of the product and how it can be safely stored. However, as a precaution, storage remarks in the product labels should always be followed.

Keywords: baby food; nutritional content; chemical composition; fruits

INTRODUCTION
Commercial fruits based baby food are the products usually made with fruits, sugar, water, and variable additives. Nutrient-rich baby foods are required with particularly high standards of quality and safety expressed through product specifications or attributes. As the foodstuffs intended for particular nutritional uses, baby foods for infants and young children conform to a set of strict guidelines e.g. nutritional quality, the addition of additives, labeling **(Čížková et al., 2009; Calabretti et al., 2017; Azemi et al., 2019)**. Commercial fruits baby food is suitable for use during the complementary feeding period. These foods are specifically formulated with appropriate nutritional quality to provide additional energy and nutrients to complement the family foods derived from the local diet by providing those nutrients which are either lacking or are present in insufficient quantities **(Codex Alimentarius, 1991)**. However, being an important supplement to children's diet and for their progressive adaptation to ordinary food, the nutritional quality of commercial fruits baby food is very important. Fruits-vegetable based foods are easy to digest and offer high nutrient density. The nutrition value of baby food deeply depends on the composition, what raw materials are used and what are the proportions of fruit or vegetable content **(Zein, ElSayed Bhnsawy and Arafa, 2019; Seidel et al., 2015)**. There is much evidence that the quality and composition of commercial baby food may contribute to the present and future health benefits of young children. Since infants between 6 months and 3 years of age are rather limited in their food choices, the commercial baby foods serve as an important source of energy, basic nutrients, fiber, vitamins, and minerals and establish their taste and eating patterns **(Čížková et al., 2009)**.

Infant fruits play an important role in the complementary feeding period. Infant fruits are defined as "processed fruit-based foods" that are divided into "simple fruits which are or have to be reconstituted with milk or other appropriate nutritious liquids''. Nutrition and dietary habits during infancy and early childhood play a role in shaping eating habits and health later in adolescence and into adulthood **(Walker and Goran, 2015; Prchalová et al., 2016)**. In many countries, infant fruits are among the first foods that are introduced at the beginning of the complementary feeding period. In recent decades, the reduction of time to be dedicated to the preparation of home meals has already led to the appearance of ready-to-eat food products on the market. The foods specifically manufactured for infants and young children have had an evolution. Prepared baby foods and formulas, intended for use of children aged between 4 months and 3 years, provide an appealing alternative for working mothers **(García et al., 2015; Garcia et al., 2014)**.

The aim of this paper was focused on the quality changes of baby food stored at different temperature (4 °C, 20 °C, 40 °C, and 60 °C) for 15 days.

The imbalance of calories and nutrients in some of the baby foods necessitates encouraging breast feeding at least

during the first 6 months. The high protein contents may damage the kidney and the quantity and quality of protein in baby foods should be adjusted to simulate human milk. The protein quality may be improved by improving the processing and storage conditions. To reduce the risk of dental caries, baby foods in which sucrose should be replaced by glucose or lactose may be selected **(Al-Othman, Khan and Al-Kanhal, 1997; Kohlboeck et al., 2012; Jackson, 2015)**. Nutrition education of mothers and health workers in kindergarten on the selection and preparation of the right type of baby foods and weaning practices will go a long way in improving the nutritional status of infants and children in the country.

Samples of commercial fruits based baby food from the market and pharmacies were analyzed by parameters: pH, total soluble solids, dry matter, total acidity, vitamin C, sugars (total sugars, reducing sugars), proteins, and lipids. All samples of baby food are produced by foreign companies since currently, no Kosovo manufacturers are producing this range of products. This is the first research of this type in Kosovo and it should give us a novel result. The nutritional quality parameters are important to assess the quality of the product and how it can be safely stored. However, as a precaution, storage remarks in the product labels should always be followed.

Scientific hypothesis

The scientific hypothesis of this study was focused on the quality changes of baby food stored at different temperature (4 °C, 20 °C, 40 °C, and 60 °C) for 15 days. During storage, chemical and nutritional parameters analysis were carried out. Quality parameters content was estimated at the beginning of the experiment and subsequently at 15 days interval.

MATERIAL AND METHODOLOGY

Sampling Preparation

Samples of commercial fruits based baby food with trade name: HiPP (Apple and Berry fruits), HiPP (Plum), HiPP (Apple and Banana), HiPP (Pear), FRUTEK (Banana), and HELLO (Carrot and Apple) were purchased from the market and pharmacies in Kosovo during the period June 2019. After samples collection, they were stored at different temperatures (4 °C, 20 °C, 40 °C, and 60 °C) for 15 days.

0.5 g of the product was diluted in 10 mL of acidified distilled water (1%) and extracted for 10 minutes. The solution was centrifuged at 3000 rpm for 10 minutes. The solid fraction, separated from the supernatant, was then subjected to a new extraction step. The liquid phases were collected and brought to a final volume of 10 mL. All analyses were performed in triplicate.

Nutritional analysis

Nutrient analysis was done for all collected samples. Determination of nutritional properties of commercial fruits baby food with trade name: HiPP (Apple and Berry fruits), HiPP (Plum), HiPP (Apple and Banana), HiPP (Pear), FRUTEK (Banana), and HELLO (Carrot and Apple) were performed according to the standard methods of the **AOAC (2005)** and **AOAC (2016)**. Total soluble solids content (TSS) measured using the Abbe refractometer calibrate against sucrose and expressed in °Brix. Titratable acidity (TA) was measured according to AOAC Method **(AOAC, 2005; AOAC, 2016)** and expressed as milligrams of citric acid. pH was measured using pH/mv meter, and dry matter (DM) was measured in triplicate by drying 5 g of the fresh fruits at 105 °C until constant weight (4 – 6 hours). The determination of lipids was done by Soxhlet extraction after digestion of the samples by hydrochloric acid hydrolysis, followed by extraction of the fats with petroleum ether. After the extraction, lipid content was determined by weighing **(AOAC, 2005)**. Protein was determined by the Bradford method with some modifications. Gelatin is commonly used to create the standard curve, and the absorption is measured at 545 nm in a spectrophotometer. Reducing sugar was determined using the method of Lane and Eynon and Fehling's solution as described by AOAC Methods **(AOAC, 2005; AOAC, 2016)**. Total sugars were determined by the phenol sulfuric acid method **(Nielsen, 2009)**. Glucose is commonly used to create the standard curve, and the absorption is measured at 490 nm. Vitamin C content was estimated using a spectrophotometric method with 2,4-dinitrophenyl hydrazine as an indicator **(AOAC, 2005; AOAC, 2016)**. Samples were homogenized with metaphosphoric acid (5% metaphosphoric acid in 10% acetic acid solution in water), filtered and treated with 85% sulphuric acid solution and 2,4-dinitrophenyl hydrazine, and then incubated at 60 °C for 60 min in a water bath. Absorbance was measured at 520 nm in a spectrophotometer (Genesys 10S UV-Visible) for the estimation of vitamin C in the fruits.

Statistical analysis

All data were expressed as the mean ± standard deviation of triplicate experiments. All statistical analyses performed using the MS Excel program and SPSS 22.0 statistics software Differences were tested for significance using the ANOVA procedure, with a significance level of $p < 0.05$.

RESULTS AND DISCUSSION

Samples of commercial fruits based baby food with trade name: HiPP (Apple and Berry fruits), HiPP (Plum), HiPP (Apple and Banana), HiPP (Pear), FRUTEK (Banana), and HELLO (Carrot and Apple) were purchased from the market and pharmacies in Kosovo during the period June 2019. The effect of storage on quality changes of baby food is given in Table 1, Table 2, and Figure 1.

The pH values of commercial fruits-based baby food were decreased during storage (Table 1). The average pH value ranging from 3.55 ±0.1 to 2.85 ±0.1 sample A2 HiPP (Plum), 3.88 ±0.1 to 3.68 ±0.1 to sample A4 HiPP (Pear), 3.93 ±0.1 to 3.69 ±0.1 sample A6 HELLO (Carrot and Apple), 3.94 ±0.1 to 2.94 ±0.1 sample A1 HiPP (Apple and Berry fruits), 3.98 ±0.1 to 3.55 ±0.1 sample A3 HiPP (Apple and banana) and highest 4.31 ±0.1 to 4.15 ±0.1 sample A5 FRUTEK (Banana). Statistical analysis showed that storage interval and temperature treatments had a significant ($p < 0.05$) effect on the pH value of all samples.

Table 1 The chemical composition of commercial fruits based baby food.

Sample	Temperature [˚C]	Time of Storage [Days]	pH	W(DM)/%	TSS/°Brix	TA/%	Vitamin C mg.100g^{-1}

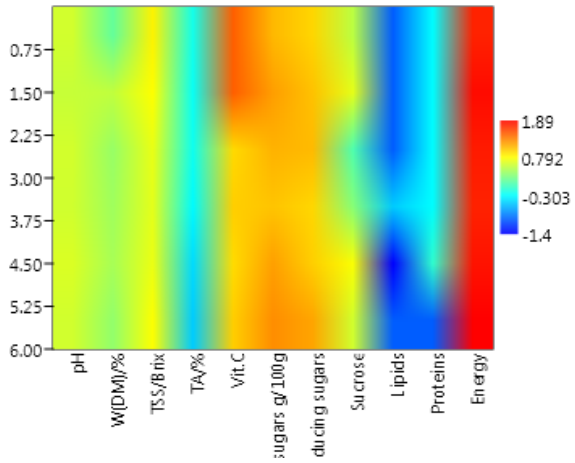

Figure 1 The 3D visualization data of chemical and nutritional parameters of baby food.

Our results correspond with the results of the work **Carbonell-Capella et al. (2014)**, **Zulueta et al. (2007)** reported that the pH values of commercial fruits-based baby foods in the range of 3.54 – 4.12 and pH range 2.96 – 4.11 respectively. Similar results reached **Usal and Sahan (2020)**, who report that the pH of the commercial baby food ranged from 3.55 – 5.24. **Touati et al. (2016)** reported that the pH values were significantly decreased during this period, independently of the temperature used. Prior storage, pH values were 3.88, 3.57, and 2.77. The pH of fruits is lower than vegetables and therefore vitamin C is less degraded in fruits **(Mesías-García, Guerra-Hernández, and García-Villanova, 2010)**.

The values for commercial fruits-based baby food of the total dry matter were decreased during storage (Table 1). The average value ranged from 1.34 ±0.1 to 1.08 ±0.1 sample A1 HiPP (Apple and Berry fruits) and increasing on other samples: 2.13 ±0.1 to 1.94 ±0.1 sample A6 HELLO (Carrot and Apple), 2.24 ±0.1 to 2.04 ±0.1 sample A3 HiPP (Apple and banana), 2.43 ±0.1 to 2.23 ±0.1 sample A4 HiPP (Pear), 2.61 ±0.1 to 2.43 ±0.1 sample A5 FRUTEK (Banana) and to be higher value is 3.35 ±0.1 to 3.35 ±0.1 sample A2 HiPP (Plum). Statistical analysis showed that storage interval and temperature treatments had a significant (p <0.05) effect on the total dry matter value of all samples.

Usal and Sahan (2020), reported that the dry matter levels of samples were varied between 81.41 and 93.10% depending on ingredients. When the dry matter of the samples was examined, the highest value was found in 14 (93.10%) sample and the lowest value in 11 (81.41%). These values are much higher than our results.

An increase was observed in soluble solids TSS/°Brix of samples of commercial fruits baby food throughout the storage (Table 1). The average value ranged from 4.75 ±0.1 to 5.90 ±0.1 sample A4 HiPP (Pear), and increasing on other samples: 5.0 ±0.1 to 6.2 ±0.1 sample A3 HiPP (Apple and banana), 5.1 ±0.1 to 6.4 ±0.1 sample A5 FRUTEK (Banana), 6.1 ±0.1 to 7.7 ±0.1 sample A6 HELLO (Carrot and apple), 6.2 ±0.1 to 7.5 ±0.1 sample A2 HiPP (Plum) and highest 7.0 ±0.1 to 8.2 ±0.1 sample A1 HiPP (Apple and Berry fruits). The increase in soluble solids TSS/°Brix value may be due to an increase in temperature and inversion of sucrose into glucose and fructose. Statistically, storage interval and treatments had significantly (p <0.05) effect on soluble solids TSS/°Brix value of all samples during storage.

Different authors have observed that the TSS/°Brix value increased during storage at different temperatures. **Zulueta et al. (2007)** reported that the TSS/°Brix ranged from 14.0 to 24.9. **Touati et al. (2016)** reported a significant increase in TSS/°Brix was observed for all the samples during storage 11.60 – 15.20. **Carbonell-Capella et al. (2014)** reported that the TSS/°Brix ranged from 12.0 to 24.9. Our results were the lowest of these studies.

The total acidity in samples of commercial fruits baby food was decreased during the storage period (Table 1). The average value for total acidity is lower ranged from expressed in % of citric acid and ranged from 0.30 ±0.2 to 0.15 ±0.2 sample A6 HELLO (Carrot and Apple) while the highest values of total acidity are in the sample A1 HiPP (Apple and Berry fruits) 0.61 ±0.2 to 0.41 ±0.2. The reason behind the increase in acidity is the degradation of non-reducing sugar which increases the acidity. Total acidity was statistically significantly (p <0.05) affected by storage intervals and temperature treatments.

Organic acids in fruits exhibit a low susceptibility to changes during processing and storage, combined with adequate stability compared to pigments and flavor compounds **(Fügel, Carle and Schieber, 2005)**. Many authors have been observed that fruit-based products showed acidic properties in studies conducted. The total acidity showed a decrease during storage in their studies **(Zulueta et al., 2007; Jie et al., 2013; Batkan, Kundakçi, and Ergönül, 2012)**. Our findings are similar to those found by them. Our results correspond with the results of the studies **Usal and Sahan (2020)** reported that the total titratable acidity (g of citric acid mg.100g^{-1}) was between 0.15 and 0.54 mg.100g^{-1}. Similar results observed **Carbonell-Capella et al. (2014)**, who report that the total acidity (g of citric acid per 100 g) of the commercial baby food was between 0.308 and 0.533 g of citric acid per 100 g.

Table 2 The nutritional composition of commercial fruits based baby food.

Sample	Temperature [°C]	Time of Storage [Days]	Total sugars g.100g^{-1}	Reducing sugars g.100g^{-1}	Lipids g.100g^{-1}	Proteins g.100 g^{-1}

Note: Data are expressed as average value ± standard deviation of three replicates.

Samples of commercial fruits baby food are a good source of Vitamin C. Some sample is fortified with Vitamin C and contains high value of Vitamin C. The stability of Vitamin C decreases with increasing temperature. A decrease in Vitamin C in samples of commercial fruits baby food during storage (Table 1). The highest average value of Vitamin C is A1 HiPP (Apple and Berry fruits) 30 ±0.2 to 20 ±0.2 also and sample A2 HiPP (Plum) 30 ±0.2 to 20 ±0.2. The relatively high amounts of Vitamin C also contain the samples: A4 HiPP (Pear) 10 ±0.2 to 1.6 ±0.2 and sample A6 HELLO (Carrot and Apple) 10 ±0.2 to 4.5 ±0.2, while the samples A3 HiPP (Apple and banana) value of Vitamin C is lower 8.9 ±0.2 to 7.2 ±0.2 and lower in the sample A5 FRUTEK (Banana) 8.7 ±0.2 to 6.3 ±0.2. Statistically, storage interval and treatments had significantly (p <0.05) effect on the Vitamin C value of all samples during storage.

It is known that losses of vitamin C occur during processing and storage. That these losses may be used as an indicator of the aggression to nutritional value suffered in the industrial or culinary process **(Mesías-García, Guerra-Hernández and García-Villanova, 2010)**. It is thought that vitamin C undergoes oxidation and substantial losses during processing, storage, and heat treatment of fruit and vegetables during the processing periods **(El-Ishaq and Obirinakem, 2015)**. To prevent such losses, vitamin C may be added to vegetable and fruit-based baby foods, and optimization of the pH value. If the pH value increases from 3 to 6, vitamin C oxidation increases **(Fan, 2005)**. **Uğur et al. (2020)** reported that the determined concentrations ranged from 0.1 to 8.5 mg.100g^{-1} in samples that were not-fortified with vitamin C. Also, the concentration of vitamin C was very low in samples that were not containing added vitamin C compared to other fruit and vegetable-based baby foodstuffs. **Silva et al. (2018)** found that vitamin C concentration in baby foods ranged from 1.50 to 144 mg.100g^{-1} and the measured amount of vitamin C was 50% higher than the reported concentration on the label. In the same study, all values were within the allowed limits in compliance with EU legislation. **Brandon et al. (2014)** revealed that determining vitamin C concentrations ranged from 97 to 147% of the declared concentration in infant formula. In the study conducted by **Mesías-García, Guerra-Hernández and García-Villanova (2010)** for vegetable-based baby foods, no vitamin C was found in any of the products and it was thought that naturally found vitamin C was completely lost during processing. **Carbonell-Capella et al. (2014)** revealed that vitamin C contents were between 1.9 and 71.5 mg.100g^{-1} in 23 fruit-based baby foods and the lowest vitamin C amounts (0 – 2.4 mg.100g^{-1}) were determined in fruit-based baby foodstuffs which were not-fortified with vitamin C. When the declared amount was subtracted from the analyzed amount, very small amounts of vitamin C were found in the samples. It is thought that vitamin C undergoes substantial losses in the processing periods. Our findings are congruent with the measured amount of vitamin C was generally the reported amount in vitamin C added and declared commercial fruits baby food. Our findings are congruent with the above-mentioned studies that the measured amount of vitamin C decreased during storage time and heat treatment.

Also, commercial fruits based baby food as a good source of sugars, and consequently, they are a good source of energy. A decrease was observed in the total number of sugars on these samples during storage (Table 2). The average value varied from 11.1 ±0.1 to 9.0 ±0.1 sample A4 HiPP (Pear), 12.4 ±0.1 to 10.2 ±0.1 sample A1 HiPP (Apple and Berry fruits), 13.2 ±0.1 to 11.1 ±0.1 sample A3 HiPP (apple and banana), 15.8 ±0.1 to 13.1 ±0.1 sample A5 FRUTEK (Banana), 16.0 ±0.1 to 13.9 ±0.1 sample A2 HiPP (plum) as well as higher in the sample A6 HELLO (carrot and apple) 18.9 ±0.1 to 18.3 ±0.1. During storage in different temperatures, sucrose in fruits is continuously converted into fructose and glucose which results in a reduction in the total number of sugars. Results demonstrated that storage and temperature treatment have a significant (p <0.05) effect on samples of baby food.

An increase was observed in reducing sugars during storage and temperature treatment (Table 2). The average value varied from 9.1 ±0.1 to 11.3 ±0.1 sample A4 HiPP (Pear), 9.2 ±0.1 to 11.3 ±0.1 sample A1 HiPP (Apple and Berry fruits), 12.1 ±0.1 to 14.3 ±0.1 sample A3 HiPP (Apple and banana), 9.9 ±0.1 to 11.9 ±0.1 sample A5 FRUTEK (Banana), 11.2 ±0.1 to 13.4 ±0.1 sample A2 HiPP (Plum) as well as higher in the sample A6 HELLO (Carrot and apple) 15.0 ±0.1 to 17.2 ±0.1. A raise in reducing sugars is due to the inversion of sucrose to reducing sugar because of acids. A conversation of pectin into fructose and glucose because of the rise in temperature during storage was observed. Storage and temperature treatment results were significant (p <0.05).

Many products that are frequently marketed to and consumed by infants and young children contain sugars that are far more than what is considered nutritionally beneficial and/or different from that stated on the nutrition label **(Walker and Goran, 2015)**. Total sugar content is positively correlated with fruit and vegetable content in commercial baby foods, particularly in spoonable foods (6.8 g sugar per 100 g), suggesting that they may be used as sweetening agents **(Garcia, McLean and Wright, 2016)**.

Our results were in concordance to those found by **Batkan, Kundakçi and Ergönül (2012)** reported that the average of total sugars was 9.94 – 10.97 g.100g^{-1} and that the average of reducing sugars was 8.39 – 10.08 g.100g^{-1}. It was found that the storage period significantly affected the total sugar and reducing sugar contents of all samples (p <0.05). In the period of storage, total sugar and reducing sugar contents of all samples showed an increasing trend. It is thought that this increase is related to the degradation of starch to glucose and maltose.

The values of proteins to samples of commercial fruits based baby food are lower. Fruits baby food do not count as protein foods and varied between 0.5 ±0.1 to sample A6 HiPP (Pear), 0.5 ±0.1 to sample A3 HiPP (Apple and Berry fruits), 0.5 ±0.1 to sample A5 HiPP (Apple and banana), 0.5 ±0.1 g.100g^{-1} to sample A4 HiPP (Plum) and the lowest of samples A8 HELLO (Carrot and apple) 0.1 ±0.1 while the highest 0.8 ±0.1 to sample A7 FRUTEK (Banana). No change in protein values was observed during storage and temperature treatment and statistically is significantly (p <0.05).

Also, commercial fruits based on baby food are not fat-rich foods. The content of lipids is low and varies from 0.04 ±0.01 to sample A7 FRUTEK (Banana), while in other samples its value is 0.1 ±0.01 to samples A3 HiPP (Apple and Berry fruits), A4 HiPP (Plum), A5 HiPP (Apple and banana), A8 HELLO (Carrot and apple)), while the highest value is in the sample A6 HiPP (Pear) 0.3 ±0.01. Also, no change in lipids values was observed during storage and temperature treatment and statistically is significantly (p <0.05).

It is very difficult to compare data with other authors because there is limited data in the literature about proteins and lipids to samples of commercial fruits-based baby food. Our results were the first in this study.

The obtained results can be useful in clarifying the changes in the quality of commercial fruits based baby food during storage in different temperature treatments (4 °C, 20 °C, 40 °C, 60 °C).

CONCLUSION

The samples of commercial baby food based fruits stored at refrigeration condition (4 °C) and room temperature (20 °C) had the maximum quality and maximum nutrients stability as compared to the treatment of increased temperature (40 °C and 60 °C) during 15 days of storage.

Samples of commercial fruits based baby food with trade name: HiPP (Apple and Berry fruits), HiPP (Plum), HiPP (Apple and Banana), HiPP (Pear), FRUTEK (Banana), and HELLO (Carrot and Apple) were purchased from the market and pharmacies in Kosovo during the period June 2019. However, as a precaution, storage remarks in the product labels should always be followed. All samples of baby food are produced by foreign companies since currently, no Kosovo manufacturers are producing this range of products.

This is the first research of this type in Kosovo and it should give us a novel result. Nutrition education of mothers and health workers in kindergarten on the selection and preparation of the right type of baby foods and weaning practices will go a long way in improving the nutritional status of infants and children in the country.

MATHEMATICAL MODELING OF THE OIL EXTRUSION PROCESS WITH PRE-GRINDING OF RAW MATERIALS IN A TWIN-SCREW EXTRUDER

Mikhailo Mushtruk, Maxim Gudzenko, Igor Palamarchuk, Volodymyr Vasyliv, Natalia Slobodyanyuk, Anatolii Kuts, Oksana Nychyk, Oksana Salavor, Anatolii Bober

ABSTRACT
The extrusion process of oil-containing raw materials using a twin-screw extruder is becoming increasingly common in food technology. The problem of high energy costs for the implementation of this process is solved by reducing the resistance of the process mass due to the preliminary grinding of raw materials. The classical theory of extrusion is based mainly on the use of theoretical solutions of mathematical models of processes, which are simplified and allow determining integral parameters using coefficients, the preparation of which for the calculation of the corresponding processes and equipment is a rather complicated and approximate procedure. Mathematical modelling of the movement of the technological medium at the individual stages of the processing of raw materials allows us to determine the analytical dependences for the power and energy parameters of the system and to carry out their effective technical and economic evaluation. Using the methods of mathematical analysis and data processing in the MathCAD software environment, graphical dependences of the power and energy parameters of the research technical system were obtained. By increasing the density of the oil-containing raw materials, which is extruded in the research extruder by 40.5% the pressure force increases by 41%, that is, there is an almost proportional relationship between the pressure force and the density of the processed raw material. With an increase in the angular velocity of the drive shaft ω more than 8 rad.s^{-1}, the pressure force in the research process increases sharply. With an increase in the density of raw materials, it is grinded before extrusion by 40%, the power consumption for the grinding process increases by 2.8 times for the recommended operating mode. Energy losses for pressing completely grinded raw materials are reduced by 2.52 times.

Keywords: process; extrusion; oil-containing; raw materials; energy consumption; extruder

INTRODUCTION
The theory of extrusion was developed mainly for the case of processing synthetic materials, which throughout the volume have a relatively uniform molecular weight and are characterized by a high level of dissipation of mechanical energy **(Shi et al., 2019)**. In the overwhelming majority of works on modelling the single-screw extrusion process, the inverse screw model is considered, which allows us to reduce the problem to a rectangular coordinate system, considering the screw to be stationary and unfolded on the plane, and the working cylinder to be moving relative to the screw and also unfolded on the plane **(Martin and Otakar, 2017)**. The classical theory of extrusion is based on the use of theoretical solutions of mathematical models of processes, which are simplified and allow us to determine, basically, integral parameters. In a significant part of the work, coefficients are introduced, the obtaining of which is rather difficult to calculate the corresponding processes and equipment **(Kudrin, 1997)**. The use of computer technology allows us to analyse more complex models, which make it possible to assess the influence of several factors on the extrusion process, but in many cases, it does not lead to significant refinement of the results, it requires the selection of factors that most significantly affect the extrusion process and satisfy the requirements of designers **(Herman, 1975)**. Many researches are devoted to the research of viscous-plastic mass flows along a conical channel, in cylindrical pipes, in channels of a rectangular, square, elliptical, screw, and complex section. In some works, the movement of viscoplastic food materials was analysed based on ideas about the dosing zone, and the effect of wall sliding was estimated **(Petrov and Slavnov, 2013)**. The research twin-screw press extruders are distinguished by longer helical shafts, due to the introduction of special mixing and grinding elements in their designs. In scientific works **(Palamarchuk et al., 2020; Zeleňáková et al., 2019; Shahbaz et al., 2017)**, based on researches conducted under industrial conditions, a dosing zone is described based on hydrodynamic analysis of flows within individual C-shaped volumes **(Sheiko et al., 2019)**. The leakage flows through gaps, compression of raw materials, the distribution of pressure in the channel and the influence of these factors on the

performance of the extruder as a whole are considered. In many scientific works **(Mushtruk et al., 2020; Tsagareishvili et al., 2019; Zheplinska et al., 2019)** the rheology of the behavior of raw materials is described in sufficient detail, formulas are given for the design calculation of twin-screw extruders, and the effect of mixing and crushing working bodies of twin-screw extruders on the processing of rubber compounds and plastics is described. Effective mathematical modelling of twin-screw extruders has long been limited to the development of geometric parameters and the justification of processing modes, based on practical experience and experimental data, due to the rather complicated design of the executive bodies **(Pugachev, Levina and Shalaeva, 2011)**.

The aim of this scientific work is a feasibility study of the implementation of the stage of preliminary grinding of oil-containing raw materials in the extrusion process of oil by a twin-screw extruder based on a theoretical graph-analytical analysis of the power and energy parameters of the process. To achieve this aim it is necessary to solve the following tasks:

- determination and assessment of power and energy characteristics for the implementation of the mechanical extrusion of the liquid fraction of oil-containing raw materials;
- obtaining graphical interdependencies of the research factors for the developed extruder circuit;
- substantiation of regime power and kinematic parameters of the executive bodies of the developed extruder.

Thus, the theoretical justification of the power and energy parameters during the implementation of individual stages of the extrusion process of oil-containing raw materials to reduce energy consumption and increase oil yield is quite an urgent task, which is solved in this scientific research.

Scientific hypothesis

Grinding of oil-containing raw materials before pressing and selection of the optimal operating mode of the extruder can increase the efficiency of its operation – increase the pressing force and oil yield and reduce energy consumption for the process.

MATERIAL AND METHODOLOGY

When operating screw presses, from the beginning to the end of the pressing of seeds, it passes from one physical state to another until the oil and oil meal come out. To research these processes, they used the method of separation or decomposition, examining them in stages. Although the individual stages are interconnected, each of them in a complex system of processing of raw materials can occur simultaneously, parallel or sequentially, which happens inside the extruder's press path, where the operations of transportation, grinding, mixing, heating and extrusion of the raw material are carried out.

When conducting a theoretical analysis and justification of the power, torque and energy characteristics of the developed twin-screw apparatus for oil extrusion, methods of mathematical analysis and data processing in the MathCAD software environment were used to obtain the necessary graphical and analytical dependencies describing the main operating parameters of the system.

Statistical analysis

The statistical evaluation of the results was carried out by standard methods using statistical software Statgraphics Centurion XVII (StatPoint, USA) – multifactor analysis of variance (MANOVA), LSD test. Statistical processing was performed in Microsoft Excel 2016 in combination with XLSTAT. Values were estimated using mean and standard deviations.

RESULTS AND DISCUSSION

In scientific works **(Kehinde, 2016; Sokolov et al., 2018)** various schemes of the process of reception of oils from seeds of various oil-containing cultures which have several lacks are presented **(Palamarchuk et al., 2019; Prashanth et al., 2019)**. The general scheme of the process of obtaining oil from seeds of oil-containing crops in a twin-screw press extruder (Figure 1) can be described as follows. A raw material (seeds of oil-containing cultures) through the neck of the hopper *1* by gravity are sent to the loading chamber of the extruder and fills the free space between the inner wall of the chamber and screw turns. The seeds are captured by the coils of the screw nozzles *2* and are moved to the heating chamber *3*, where it is gradually compressed, and in the area of the cam nozzles *4* is partially grinded and heated from the walls of the chamber. Then the raw material enters the grain chamber *5*, where it is pressed. Part of the oil flows through the grain of the hole, and the remaining raw materials are transported to the next extraction zone – heating chambers and extrusion. Screw nozzles along with the shaft alternate with grinding. To increase the yield of oil, pressing occurs in several stages with their repetition in the extrusion path. In the area of the cone nozzles *6* and matrix *7*, the oil meal is removed from the extruder in the form of petals or granules.

When describing the screw pressing mechanism, the principle of dividing it into sections is applied. In scientific works **(Polosin and Chistyakova, 2014; Shirazian et al., 2017; Chen et al., 2019)** this principle of division into sections was not used. A section can end with a matrix or a compression shutter – a section of the mechanism on which the screw turn is interrupted and the passage section of the extrusion path of the extruder is reduced **(Owolarafe, Osunleke and Odejobi, 2008)**.

In accordance with the specified method of separation into sections or elementary screw mechanisms with conditionally constant parameters of the pressing process, the press path of the research twin-screw press extruder was divided into four conditional sections: I, II, III, and IV. Each section ends with a section of the mechanism on which the bore of the extrusion path of the press is reduced or increased within the same type of working bodies. In section *I* there is a displacement of the material in the auger channel, in section *II* there is a partial grinding of production in the area of the triangular cam nozzles and the movement of the raw material in the compression gate, in section *III* – the extrusion of oil through the holes in the grain chambers, and ie section *IV* – the displacement of the material in the matrix.

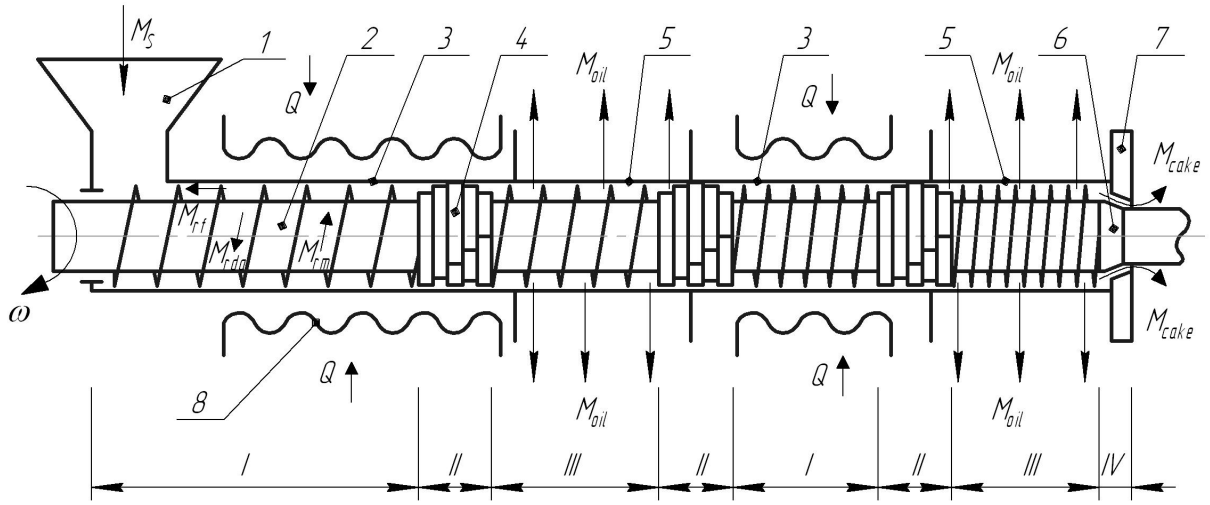

Figure 1 The design scheme of a twin-screw press extruder. Note: 1 – hopper, 2 – twin screw, 3 – heating chamber, 4 – grinding elements (nozzles), 5 – grain chamber, 6 – cone nozzle, 7 – matrix, 8 – electrical heating. Note: M_S – a mass of seeds; Q – the amount of heat supplied to the raw material; M_{rm} – a mass of the main flow of raw materials; M_{oil} – a mass of the pressed oil; M_c – a mass of oil cake; M_{rf} *a* – mass of the return flow of raw material directed along the gap between the cylinder and the screw; M_{rda} a – mass of the return flow of raw material directed along the channel of the profile of the auger.

Assuming that in the research process grinding of seeds is realized in the radial direction to the center of the seeds, it is possible to determine the geometric parameters of the grinding unit of the extruder, which are presented in Figure 2.

Using the calculated scheme of the interaction of the cams (Figure 3) we obtained that, $\sin\frac{\alpha}{2} = 0{,}5\sqrt{\frac{d_s}{r_{ge}}}$

In the research system, three main forces can be noted: grinding force F_P; a force of pressure created in the screws of the screw F_S; friction force F_f. The direction of the grinding force is taken normal to the seed, which is crushed (Figure 2). In scientific works **(Bako, Enyi, and Imolemhe, 2020; Soares, Zhang and Sacks, 2017)** the force of pressure created in the screws of the auger and the force of friction was determined, and in scientific works **(Bogaert et al., 2018; Tuta and Palazoğlu, 2017; Herak, 2013)** the force of friction and the force of demand were determined.

Given the regularities of the mechanics of movement of the executive bodies and the geometric characteristics of the extruder presented above (Figure 2), we write the expression for the projection of the pressure force on the *ox* axis in the form:

$$F_x = 0.393 n_S (D_S^2 - d_S^2) P_{\max} = 3.75 \omega (D_S^2 - d_S^2) P_{\max} \qquad (1)$$

Where: n_S and ω – respectively, the speed and angular velocity of the screw shaft; D_S – the outer diameter of the screw auger*;* d_S – the outer diameter of the auger body; P_{max} – the maximum pressure that develops the auger.

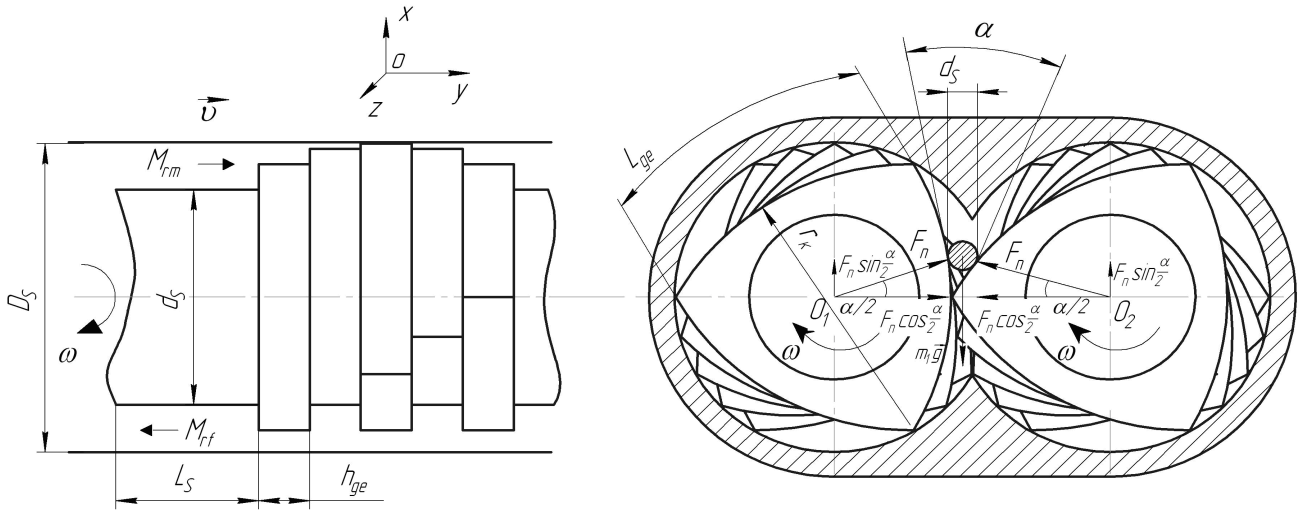

Figure 2 Scheme for determining the geometrical parameters of the seed grinding unit in triangular cam nozzles. Note: D_S – the outer diameter of the screw coil, d_S – the outer diameter of the screw body, L_S – the length of the screw nozzle, L_{ge} – the width of the cam nozzle, L_{ge} – the width of the cam nozzle length of cam nozzle, O_1, O_2 – centers of cams; r_{ge} – the radius of the cam; d_s – diameter of the seed, ω – the angular velocity of the shaft.

The friction force of raw materials on the inner surface of the extruder body can be described by the formula:

$$F_f = k \cdot F_d \cdot F_{ad} \tag{2}$$

Where: k_f – the coefficient of friction of the raw material on the inner surface of the housing; F_d – a force of deformation of raw materials: $F_d = F_x$; F_{ad} – adhesive force, which takes into account the adhesion of the product with the parts of the press is determined by the adhesive experimentally.

The projections of the momentum of the elements of the system under study along the coordinate axes are:

$$m_1 \upsilon_z = \left(F_S - F_S \cdot k_t - F_{ad}\right) t_1 \tag{3}$$

Where: m_1 – the mass of raw material;

$$m_1 \upsilon_x = \left(2F_P \sin\frac{\alpha}{2} + F_x - F_x \cdot k_t - m_1 g - F_{ad}\right) t_2 \tag{4}$$

It is obvious that $m_1 \upsilon_y = 0$

The axial velocity of the raw material along the auger channel can be determined by the formula

$$m_1 \upsilon_x = \left(2F_P \sin\frac{\alpha}{2} + F_x - F_x \cdot k_t - m_1 g - F_{ad}\right) t_2 \tag{5}$$

$$\upsilon_z = \frac{z \cdot n_S}{60} = \frac{z \cdot \omega}{2\pi}$$

The time of promotion of products to the section with grinding cams is $t_1 = \frac{z}{\upsilon_z}$, and at $z_{\max} = L_S$ that time will increase to $t_1 = \frac{L_S}{\upsilon_z}$. The grinding time of products between the surfaces of the cams is $t_2 = \frac{x}{\upsilon_x}$, and at $x_{\max} = L_{ge}$ this time is calculated as follows $t_2 = \frac{L_{ge}}{\upsilon_x}$.

Using the presented equations, the projections of the mass forces of a mechanical system on the coordinate axis can be represented as:

$$F_z = \frac{(F_S(1-k_t) - F_{ad})}{m_1} = \frac{\upsilon_z}{t_1} = \frac{\upsilon_z^2}{z} \tag{6}$$

Where: z – the current coordinate.

$$F_x = \frac{(2F_P \sin\frac{\alpha}{2} + F_x(1-k_t) - m_1 g - F_{ad})}{m_1} = \frac{\upsilon_x}{t_2} = \frac{\upsilon_x^2}{x} \tag{7}$$

Where: x – the current coordinate; g – the acceleration of gravity.

Obviously a component $F_y = 0$

Based on the developed calculation scheme of the grinding unit, efforts were found to grind the raw materials from the equation of conservation of the amount of its movement.

$$m_1 \upsilon_x = \left(2F_P \sin\frac{\alpha}{2} + \frac{P_x}{S}(1-k_r) - m_1 g - F_{ad}\right)\frac{L_{ge}}{\upsilon_x} \tag{8}$$

Then the grinding force can be found by the equation:

$$F_P = \frac{1}{2\sin\frac{\alpha}{2}}\left[\frac{m_1 \omega^2 r_{ge}^{\ 2}}{L_{ge}} - \frac{\omega^2 r_{ge}^{\ 2} \rho \ln L_K}{L_{ge} z_{ge} h_{ge}}(1-k_t) + m_1 g + F_{ad}\right] \tag{9}$$

or

$$F_P = \frac{1}{2\sin\frac{\alpha}{2}}\left[\frac{\omega^2 r_{ge}^{\ 2}}{L_{ge}}\left(m_1 - \frac{\rho \ln L_{ge}}{z_{ge} h_{ge}}\right)(1-k_t) + m_1 g + F_{ad}\right] \tag{10}$$

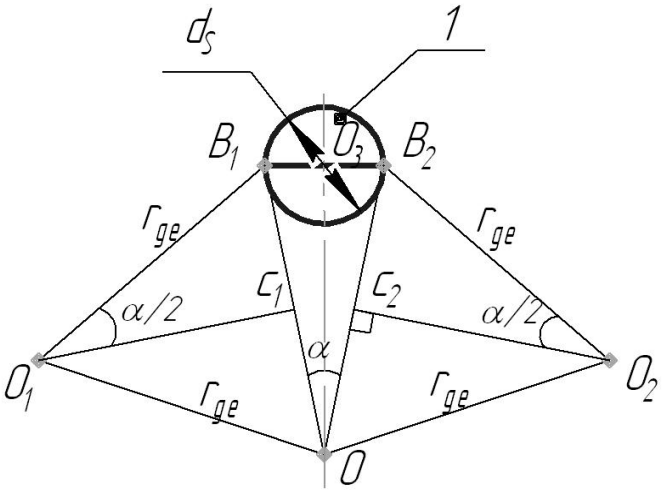

Figure 3 Settlement scheme of interaction of grinding cams. Note: *1* – seed; O_1, O_2 – the centers of the cams (grinding elements); r_{ge} – the radius of the cam (grinding elements); O_3 – the center of the seed; d_s – the diameter of the seed.

Based on the obtained equations and using the MathCAD software environment, graphical dependences for the force and power characteristics of the research process were obtained (Figure 4), of which it is evident that with increasing the density of the extruded slurry by 40.5%, the pressure force increases by 41%, i.e. there is a proportional relationship between the pressure force and the density of the raw material processed. In work **(Anderegg et al., 2019)** was installed the pressure force increases by 31%, in the work **(Troshin, 2017)** was installed the pressure force increases by 34.2%, in the work **(Leray, et al., 2016)** was installed the pressure force increases by 24.2%. With an increase in the angular velocity of the drive shaft ω more than 8 rad.s^{-1}, the pressure force on the raw material increases sharply, which justifies the recommended angular speed of rotation of the extruder shaft in the range ω = 4 – 7 rad.s^{-1}. The authors of the following scientific works **(Yang et al., 2018; Zhou et al., 2019)** recommend the angular velocity of rotation of the extruder shaft in the range ω = 8 – 12 rad.s^{-1}, but rational is the speed not exceeding 7 rad.s^{-1}. For the recommended regime of rotational movement of the extruder's executive bodies, the force of grinding products by working rolls F_p increases 3 times (Figure 4, a) during the extraction of raw materials, the density of which increases by 40%. Moreover, this force varies within 1.5 – 6 kH. The authors of the following scientific works **(Syryamkin et al., 2019; Kolyanovska et al., 2019)** investigated that the grinding force ranges from 5.5 to 16 kN.

With an increase in the density of raw materials, it is grinded before being extruded by 40%, the power consumption for the grinding process increases by 2.8 times and amounts to 0.7 – 2 kW for the recommended operating mode (Figure 4, b). In scientific works **(Cai and Liu, 2017; Mamanpush et al., 2018)** it is proved that with an increase in the density of raw materials, it is grinded before being extruded by 30%, the power consumption for the grinding process increases by 0.8 – 1.2 times and amounts to 0.1 – 0.8 kW **(Cherednichenko and Bal-Prylypko, 2019; Zheplinska et al, 2020)**.

To evaluate the effectiveness of preliminary grinding of seeds in the process of oil extrusion, the following calculation procedure was used **(Iuga et al., 2016)**, according to which the pressure is determined by the formula:

$$P = c \cdot \rho^m, Pa \quad (11)$$

For whole seeds $c = 1.76 \cdot 10^{-3}$, $m = 6.66$, that is $P_0 = 1.76 \cdot 10^{-3} \cdot \rho_0^{6.66}$, and for grinded seeds $c = 3.3 \times 10^{-32}$, m = 11.84, that is $P_1 = 3.3 \cdot 10^{-32} \cdot \rho_1^{11,84}$

Where: ρ_0 – density of whole seeds, ρ_0 = 1000 – 1050 kg.m^{-3}; ρ_1 – density of grinded seeds, ρ_1 = 1110 – 1150 kg.m^{-3}.

The ratio of the power consumption for pressing whole seeds N_0 and grinded N_1 is:

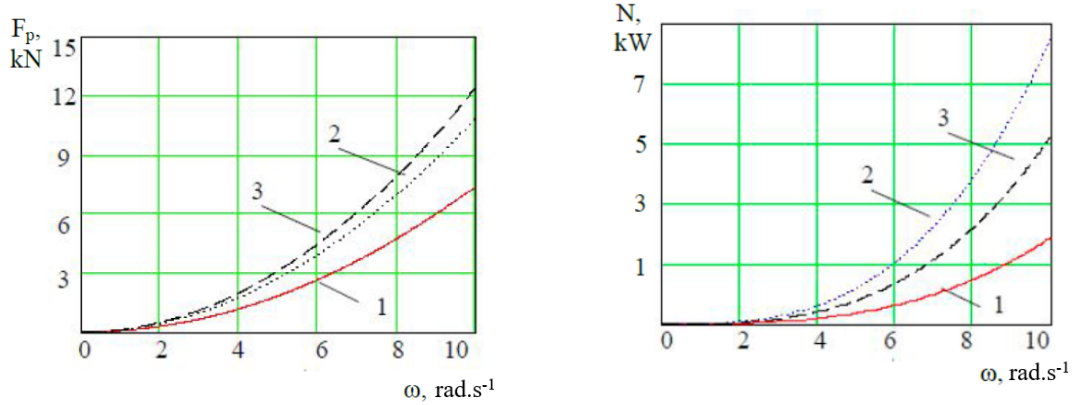
$$k_N = \frac{N_0}{N_1} = \frac{P_0}{P_1} = \frac{1.76 \cdot 10^{-13} \cdot \rho_0^{6.66}}{3.3 \cdot 10^{-32} \cdot \rho_1^{11.84}} = 294 \quad (12)$$

When the energy efficiency coefficient k_N was introduced to evaluate the research process, it was found that the coefficient c is inaccurate for the grinded material. After clarification for the grinded raw materials $c = 3.86 \times 10^{-30}$.

$$\text{Then} \quad k_N = \frac{N_0}{N_1} = \frac{P_0}{P_1} = 2.52$$

That is, the energy loss for pressing the grinded material for the research process of oil extrusion is reduced by 2.52 times. The rational design and technological parameters of the modernized press extruder were determined based on the experimental researches, which were: the temperature of the first and second heating zones of the buildings 115 – 130 °C, the gap in the matrix 0.0042 – 0.005 m, the angular speed of the screw shaft 4 – 7 rad.s^{-1}, the time of technological influence on the oil-containing material in the tract of the press is 45 – 75 s.

Application of new working bodies allows to increase the productivity of the machine and to reduce energy consumption for the process of oil extraction. The theoretical compression ratio of a press extruder with a set of new working bodies for the processing of sunflower, rapeseed and soybean seeds is 4.69; 3.36 and 2.55. This ensured the intermediate compaction of the oil-containing raw material, the intensification of its crushing, and the increase of oil yield to 3%.



a) b)

Figure 4 Dependences of the force of grinding of raw materials by working cams F_P (a) and the cost of power when grinding products by working cams N (b) of the angular velocity of the drive shaft ω during the extrusion of oil from seeds. Note: 1 – sunflower (ρ = 440 kg.m^{-3}); 2 – rapeseed (ρ = 650 kg.m^{-3}); 3 – soybeans (ρ = 740 kg.m^{-3}).

CONCLUSION

1. Based on mathematical analysis of the movement of raw materials at separate stages of the extrusion process of oil in the developed twin-screw extruder determined the power and energy parameters of the research process and proved that the energy losses under the conditions of pre-grinding of seeds and, accordingly, reduction of technological resistance of the dispersed medium during oil extrusion are reduced by 2.52 times.
2. The graphical dependencies obtained in the MathCAD computer software environment showed that with an increase in the density of raw materials, it is grinded before being extruded by 40%, the power consumption for the extrusion process increases by 2.8 times and amounts to 0.7 – 2 kW for the recommended operating mode of the extruder.
3. For the recommended angular velocity of the extruder actuators ($\omega = 4 – 7$ rad.s^{-1}), the grinding force of the raw materials by the work rolls F_p increases by 3 times.

DIFFERENCES BETWEEN MICROBIOTA, PHYTOCHEMICAL, ANTIOXIDANT PROFILE AND DNA FINGERPRINTING OF CABERNET SAUVIGNON GRAPE FROM SLOVAKIA AND MACEDONIA

Simona Kunová, Eva Ivanišová, Jana Žiarovská, Lucia Zamiešková, Soňa Felsöciová, Anka Trajkovska Petkoska, Daniela Nikolovska Nedelkoska, Miroslava Kačániová

ABSTRACT

This study aimed to evaluate the microbiota, phytochemical, antioxidant profile and DNA fingerprinting of Cabernet Sauvignon grapes from Slovakia and R. North Macedonia. There were used two samples of grape berries (one sample from Slovakia and one from Macedonia). Each sample was analyzed in triplicate. The bacteria were cultivated on Plate count agar (PCA), microscopic filamentous fungi were cultivated on Malt extract agar (MEA). MALDI-TOF MS Biotyper mass spectrometry was used for the identification of microorganisms (bacteria and yeasts) and microscopic filamentous fungi with manuals. DPPH method was used to determine of antioxidant activity of grape berries. Phytochemical and antioxidant profiles were evaluated in grape berries samples. Total genomic DNA was extracted from mature grapes by GeneJET Plant Genomic DNA Purification Kit. The number of bacteria was higher in the sample of Macedonian grape (4.13 log CFU.g^{-1}) in comparison to the grape from Slovakia as well as the number of yeasts was also higher in the Macedonian sample (2.57 log CFU.g^{-1}). Antioxidant activity of Slovak grape berries was 0.55 mg TEAC.g^{-1} and of Macedonian grape, berries was 0.51 mg TEAC.g^{-1}. Total polyphenol content was higher in grape from Slovakia (0.81 mg GAE.g^{-1}) than in grape from Macedonia (0.77 mg GAE.g^{-1}), while total flavonoid content was 0.57 and 0.17 mg QE.g^{-1} in Slovak grape and Macedonian grape, respectively. Total phenolic acid content was higher in the sample from Macedonia (0.40 mg CAE.g^{-1}) compared to the grape from Slovakia (0.24 mg CAE.g^{-1}). Total anthocyanin content was also higher in Macedonian grape (0.46 mg.g^{-1}) compared to the Slovak sample (0.05 mg.g^{-1}). The total polymorphism for all of the used primers of 87.5% was obtained for the Macedonian sample of Cabernet Sauvignon and 89.4% for the Slovak sample.

Keywords: grape berries; bacteria; yeasts; antioxidant profile; MALDI-TOF MS Biotyper; polymorphism

INTRODUCTION

Grapes have been used for winemaking since the ancient Greek and Roman civilizations **(Ma and Zhang 2017)**. The presence of biologically active substances in fruits brings considerable benefits to consumers, whether consumed raw **(Durec et al., 2019)**. Grapes are rich in phytochemicals with many proven health benefits **(Liang et al., 2014)**. They are one of the most widely grown fruits and the total production of grapes worldwide is approximately 60 million tons **(Matthäus, 2008)**. Grapes can be categorized into grapes with edible seeds, seedless, wine grapes, table grapes, and raisin grapes **(Girard and Mazza, 1998)**. Grape seeds are rich in phenolic compounds and have potentially beneficial effects for human health such as protection against peptic ulcers, oxidative stress, tissue damage, and inflammation **(Rodríguez Montealegre et al., 2006; Kim et al., 2013)**. Grape seeds have been reported to exhibit scavenge superoxide radicals. Grape seeds are rich in flavan-3-ol, including proanthocyanidins and catechins **(El-Beshbishy, Mohamadin and Abdel-Naim, 2009)**.

Biological activities and health-promoting benefits are mostly possessed by polyphenols, which are considered to be the most important phytochemicals of grape. The phenolic compounds mainly include anthocyanins, flavanols, flavonols, stilbenes (resveratrol) and phenolic acids **(Xia et al., 2010)**.

From the vineyard to the winery, microorganisms play key roles in wine production and quality. The grapevine (*Vitis vinifera*) phyllosphere harbors diverse microbes including yeasts, filamentous fungi and bacteria that substantially modulate grapevine health, growth, and grape and wine production **(Gilbert, van der Lelie and Zarraonaindia, 2014)**.

Microbes could originate from the vineyard soil **(Morrison-Whittle and Goddard, 2018)**, air, precipitation (rainfall, hail, snow), be transported by animal vectors (bees, insects, and birds) **(Francesca et al.,**

2012; Stefanini et al., 2012; Lam and Howell, 2015), and be resident in nearby native forests **(Morrison-Whittle and Goddard, 2018)**.

Microbes that are grapevine-associated and are transferred to the must-have a profound influence on wine composition, flavor and quality **(Barata, Malfeito-Ferreira and Loureiro, 2012)**. Fermentative yeasts (primarily *Saccharomyces cerevisiae*) and lactic acid bacteria (LAB, predominantly *Oenococcus oeni*) in the must modulate the flavor and aroma of wine **(Swiegers et al., 2005)**.

In the study of **Kačániová et al. (2018)** a total of 33 species of 8 Gram-negative (20.72%), 10 Gram-positive (31.53%) bacteria and 10 yeasts species of 8 genera (47.74%) were identified with MALDI-TOF Mass Spectrometry.

Inter Primer Binding Site (iPBS) polymorphism is generated on the biological background of plant pararetroviruses, which primer binding site (PBS) is complementary to the 3′ end of the primer tRNA. In plant retrotransposons, the PBS is either complementary to the 3′ end or an internal region of the primer tRNA. The method of whole genome iPBS amplification is based on the virtually universal presence of a PBS in LTR retrotransposons **(Kalendar et al., 2010)**. This technique has been proved to be a powerful DNA fingerprinting technology without the need for prior sequence knowledge **(Fang-Yong and Ji-Hong 2014; Kalendar, Amenov and Daniyarov, 2018)**. It has the potential to discriminate among close genotypes **(Antonius-Klemola, Kalendar and Schulman, 2006)** and is highly reproducible **(Guo et al., 2014)**. Polymorphism generated by iPBS works well for both, the Gypsy and Copia LTR retrotransposons **(Melnikova et al., 2012)**.

Scientific hypothesis

Grape berries contain various microorganisms. Bacteria, yeasts and molds could be identified with MALDI TOF mass spectrometry.

There are many biologically active compounds in grape berries – flavonoids, polyphenols, phenolic acid and anthocyanins.

MATERIAL AND METHODOLOGY

Two types of grapes were studied in this work: one from Slovakia and one from Macedonia.

The phytochemical and antioxidant profile of the grape

The fresh grape berries were used for the preparation of ethanolic extract; 1 g of each sample was extracted with 20 mL of 80% ethanol for 2 h and centrifuged at 4000 g (Rotofix 32 A, Hettich, Germany) for 10 min. The supernatant was used for the measurement of antioxidant activity (DPPH) and the detection of total polyphenol, total flavonoid, and phenolic acid content.

Chemicals

All chemicals were of analytical grade and purchased from Reachem (Slovakia) and Sigma Aldrich (USA).

DPPH Method—Radical Scavenging Activity

Radical scavenging activity of samples was measured using 2,2-diphenyl-1-picrylhydrazyl (DPPH) according to the procedures described by **Sánchéz-Moreno, Larrauri and Saura-Calixto (1998)**. An amount of 0.4 mL of extract was added to 3.6 mL of DPPH solution (0.025 g DPPH in 100 mL ethanol). The absorbance of the reaction mixture was determined using the spectrophotometer Jenway (6405 UV/Vis, England) at 515 nm. Radical scavenging activity of the samples was expressed as Trolox equivalent antioxidant capacity (mg TEAC.g^{-1}).

Total Polyphenol Content

The total polyphenol content of extracts was measured by the method of **Singleton and Rossi (1965)** using Folin-Ciocalteu reagent. A 0.1 mL of each sample was mixed with 0.1 mL of Folin-Ciocalteu reagent, 1 mL of 20% (w/v) sodium carbonate, and 8.8 mL of distilled water. After 30 min in darkness, the absorbance at 700 nm was measured using the spectrophotometer Jenway (6405 UV/Vis, England). Gallic acid was used as the standard and the results were expressed in mg.g^{-1} of gallic acid equivalents.

Total Flavonoid Content

Total flavonoids were determined using the modified **Willett** method **(2002)**. A 0.5 mL of sample was mixed with 0.1 mL of 10% (w/v) ethanolic solution of aluminium chloride, 0.1 mL of 1 M potassium acetate, and 4.3 mL of distilled water. After 30 min in darkness, the absorbance at 415 nm was measured using the spectrophotometer Jenway (6405 UV/Vis, England). Quercetin was used as the standard and the results were expressed in mg.g^{-1} of quercetin equivalents.

Total Phenolic Acid Content

Total phenolic acid content was determined using a method of **Polish Pharmaceutical Society (2005)**. A 0.5 mL of sample extract was mixed with 0.5 mL of 0.5 M hydrochloric acid, 0.5 mL Arnow reagent (10% $NaNO_2$ + 10% Na_2MoO_4), 0.5 mL of 1 M sodium hydroxide (w/v) and 0.5 mL of water. Absorbance at 490 nm was measured using the spectrophotometer Jenway (6405 UV/Vis, England). Caffeic acid was used as a standard and the results were expressed in mg.g^{-1} of caffeic acid equivalents.

Total Anthocyanin Content

Anthocyanin content was measured according to the method of **Fuleki and Francis (1968)** with modifications **(Lee, Durst and Wrolstad, 2005)**. For pH 1.0, a sample (0.4 mL) was diluted with 0.025 M of potassium chloride (3.6 mL). For pH 4.5, a sample was diluted (0.4 mL) with 0.4 M of sodium acetate. The absorbance of the sample was measured at 520 and 700 nm against the blank reagent (distilled water). The concentration (mg.g^{-1}) of total anthocyanins was calculated according to the following formula and expressed as cyanidin-3-glucoside (Cy-3-glc) equivalent:

A [mg.g^{-1}] = (A∗Mw∗1000)/(ε∗L), A[mg.g^{-1}] = (A∗Mw∗1000)/(ε∗L),

where: A is the absorbance difference = ($A_{520} - A_{700}$) pH 1.0 − ($A_{520} - A_{700}$), pH 4.5; M_W is the molecular weight of (Cy-3-glc) = 449.2 g.mol^{-1}; ε is the extinction coefficient of (Cy-3-glc) = 1700 cm.mol^{-1}; L the absorption; path length : 1 cm.

Microbiological analyses of grape berries samples

Five grams of berries from each grape samples were diluted in 45 mL of sterile physiological saline (0.85%). Berries were stirred on a horizontal shaker for 30 minutes. After that, the dilutions of 10^{-2} and 10^{-3} were prepared for cultivation with the spread plate method. A 0.1 mL of each dilution (10^{-2}, 10^{-3}) was placed on the surface of a solid cultivation medium. Bacteria were cultivated on Plate count agar (PCA) (Oxoid, UK), yeasts on Malt extract agar base (MEA) (Oxoid, UK) supplemented with bromocresol green (0.020 g.L^{-1}) (Centralchem®, Slovakia). Bacteria were cultivated at 37 °C for 24 – 48 h in aerobic condition, yeasts at 25 °C for five days in aerobic conditions. Growing colonies with macroscopic morphological differences were recultivated on TSA (Tryptic Soy agar, Oxoid®). Inoculated plates were cultivated at 30 °C for 48 h (TSA). After cultivation, the proteins were extracted from fresh bacterial colonies.

Sample preparation and MALDI-TOF MS measurement

One colony of each bacterial and yeast isolate was transferred into an Eppendorf vial and mixed in 300 µL of sterile water. After the addition of ethanol (900 µL), the suspension was mixed and centrifuged (13 000 g, 2 min). After removal of the supernatant, the pellets were dried at room temperature at least for 5 min. The bacterial and yeast pellets were resuspended in 20 – 50 µL of formic acid (70%) and the same amount of acetonitrile. After centrifugation (2 min at 13,000 g), a 1 µL of supernatant was spotted onto a sample position of a polished steel MALDI target plate and dried at room temperature. A 1 µL of MALDI matrix (solution of α-cyano-4-hydroxycinnamic acid (HCCA) in 50% acetonitrile/2.5% trifluoro-acetic acid) was added to the spot and dried.

The MALDI target plate was introduced into the MALDI-TOF mass spectrometer (Bruker, Germany) for automated measurement and data interpretation. MALDI-TOF profile mass spectra were imported into the MALDI Biotyper 3.0 software and processed automatically after measurement. The logarithm of the score (log[score]) was displayed as the matching result. The MALDI Biotyper output was a log(score) between 0 and 3.0, which was calculated from a comparison of the peak list from an unknown isolate with the reference MSP in the database. A log(score) ≥1.7 indicated identification at the genus level, log(score) ≥2.0 was set as the threshold for a match at the species level. Isolates with ≥2.0 were accepted as a correct identification.

DNA extraction and iPBS profiles amplification

Total genomic DNA was extracted from mature grapes by GeneJET Plant Genomic DNA Purification Kit (Thermo Fisher) following the instructions of the manufacturer. The iPBS primers 1845, 1846 and 1886 were used for the fingerprints amplification **(Kalendar et al., 2010)**. The following iPBS PCR profile was used for the Combi PPP 2x MasterMix (Top Bio) and 50 ng of DNA: 94 °C – 5 min; 35 cycles of : 95 °C 1 minute; 55 °C 2 minutes; 72 °C 3 minutes with final 72 °C 10 minutes. Amplified fragments were analyzed in 6% PAGE and scored for the presence or absence of amplicons in GelAnalyser software. UPGMA analysis and dendrogram construction was performed in SYNTAX software using a Jaccard coefficient of similarity to define relationships between individual obtained iPBS profiles for analyzed samples of Cabernet Sauvignon.

Statistical analysis

All experiments were carried out in triplicate and standard deviations for replication as well as T-tests were calculated using MS Excel.

RESULTS AND DISCUSSION

The phytochemical and antioxidant profile of studied grapes (or grape samples)

According to many authors, the antioxidant activity of grape berries and wines results mainly from their phenolics, whereas the phenolic content and composition depend on the grape variety, vineyard location, cultivation system, climate, soil types, vine cultivation practices, harvesting time, production process and aging **(Shahidi and Naczk, 1995).**

DPPH·method is one of the most popular methods for detecting the antioxidant activity of wine **(Wang, 2008)**. The experimental results indicate that the higher the amount of antioxidants, the lower is the concentration of remaining DPPH and the stronger is the radical-scavenging activity **(Jiang and Sun, 2018)**.

The antioxidant activity of Slovak grape berries was 0.55 mg TEAC.g^{-1} and antioxidant activity of Macedonian grape were 0.51 mg TEAC.g^{-1}. **Jiang and Zhang (2012)** reported that the contents of phenolic compounds and the levels of antioxidant activity in the wine samples greatly varied with cultivar and environmental factors of wine growth.

The value of total polyphenols was 0.81 mg GAE.g^{-1} in grape from Slovakia and 0.77 mg GAE.g^{-1} in grape berries from Macedonia. Total flavonoids were 0.57 mg and 0.17 QE.g^{-1} in Slovak and Macedonian grape berries, respectively. Phenolic compounds, which are abundant in grape berries and wines, play one of the most important roles in the quality of grapes and wines. They strongly contribute to the color, mouthfeel and palatability of red wines **(Lesschaeve and Noble, 2005)**. Moreover, polyphenols also exert many favorable effects on human health, such as the inhibition of atherosclerosis, coronary heart disease, and various cancer types **(Yilmaz and Toledo, 2004)**. Total phenolic acid content was 0.24 and 0.40 mg CAE.g^{-1} in grape from Slovakia and grape from Macedonia, respectively.

Table 1 Antioxidant activity, total polyphenol, flavonoid, phenolic acid and anthocyanin content of analyzed grape.

Samples	DPPH mg TEAC.g^{-1}	TPC mg GAE.g^{-1}	TFC mg QE.g^{-1}	TPAC mg CAE.g^{-1}	TAC mg.g^{-1}
Slovak Cabernet Sauvignon grape	0.55 ±0.01	0.81 ±0.05	0.57 ±0.05	0.24 ±0.07	0.05 ±0.01[a]
Macedonia Cabernet Sauvignon grape	0.51 ±0.15	0.77 ±0.09	0.17 ±0.02	0.40 ±0.01	0.46 ±0.03[a]

Note: *DPPH* - 2,2-difenyl-1-picrylhydrazyl *TPC* total polyphenol content, *TFC* total flavonoid content, *TPAC* total phenolic acid content, *TAC* total anthocyanin content, *GAE* gallic acid equivalent, *QE* quercetin equivalent, *CAE* caffeic acid equivalent, *FM* fresh matter; [a] significant difference of analysed parameter.

Figure 1 Amplification profiles of analysed samples of Cabernet Sauvignon.

Yang, Martinson and Liu (2009) analyzed the total phenolic contents of 14 wine grapes. Among all the grape varieties analyzed, Cabernet Franc and Pinot Noir had the highest total phenolic content (424.6 ±3.8 and 396.8 ±12.4 mg of gallic acid equivalents per 100 g of grape, respectively), followed by Concord, Sheridan, Chancellor, Marechal Foch, Catawba, DeChaunac, Riesling, Niagara, Vidal Blanc, Baco Noir, Cayuga White, and Chardonnay.

Mitić et al. (2012) measured the total flavonoid content of the 7 grape extracts, 'Cabernet Sauvignon' presented the highest flavonoid content (146.2 mg of CE.100 g^{-1} of f.w.), followed by 'Merlot', 'Vranac', 'Muscat Hamburg', 'Prokupac', 'Ribier', and 'Cardinal'. **Ivanova, Stefova and Chinnici (2010)** measured lower values 60.3 CE.100g^{-1} f.w. the average total flavonoids content of grape cultivars 'Vranec', 'Cabernet Sauvignon', and 'Muscat Hamburg'.

Anthocyanins are natural pigments, responsible for a wide range of colors in grapes and red wines. The anthocyanins in red grapes vary greatly with the species, maturity, production area, seasonal conditions, and yield of the fruit **(Mitić et al., 2012)**. The total anthocyanin content was 0.05 mg.g^{-1} in grape from Slovakia and 0.46 mg.g^{-1} in grape from Macedonia. Table 1 compares data related to antioxidant activity, total polyphenol, flavonoid, phenolic acid and anthocyanin content of analyzed grape. The statistical difference was found only in TAC.

Microbiota of grape

The surface of grape berries represents a comprehensive natural reservoir of bacterial microbiota originating from the surrounding environment **(Zarraonaindia et al., 2015)**. The value of bacteria was 3.57 log CFU.g^{-1} in Slovak grape and 4.13 log CFU.g^{-1} in Macedonian grape berries. The value of yeasts was 2.34 log CFU.g^{-1} in Slovak grape and 2.57 log CFU.g^{-1} in Macedonian grape (Table 2). Numerous yeast genera and species are found during the production of wine. The low pH of the wine, high sugar content, rapidly generated anaerobic conditions, and presence of phenolic compounds create the ideal environment to support the growth of yeasts and to enrich these organisms with other microbes **(Fleet, 2003)**.

Grapes have a complex microbial ecology including filamentous fungi, yeasts, and bacteria with different physiological characteristics and effects upon wine production. Some species are only found in grapes, such as parasitic fungi and environmental bacteria, while others can survive and grow in wines, constituting the wine microbial consortium. This consortium covers yeast species, lactic acid bacteria, and acetic acid bacteria **(Barata, Malfeito-Ferreira and Loureiro, 2012).**

Bacterial populations are usually several orders of magnitude lower than those of yeasts in sound grapes. Lactic acid bacteria have counts lower than 10^2 CFU.g^{-1} **(Francesca et al., 2011)**.

Table 3 presents microorganisms isolated from Slovak and Macedonian grape berries. Worldwide surveys indicate that sound grapes are colonized by a wide variety of yeast species without any obvious explanation. However, the variety may be reduced to relatively few groups of similar physiological characteristics. For instance, the ubiquitous *Candida* spp. and *Pichia* spp. are highly heterogeneous, and new species are likely to be found in each new survey due to the accuracy of molecular identifications is constantly increasing **(Rao et al., 2007)**.

Grapevine bacteria play a key role not only in plant health but also in crop quality and yields, which can influence the winemaking process **(Nisiotou et al., 2011)**. Numerous studies have analyzed the presence of yeast on the surface of grapes and many have indicated that *Saccharomyces cerevisiae* is only present in small numbers on healthy grapes **(Pretorius, 2000)**. *Saccharomyces* can be found in grape musts, but the populations are often less than 50 CFU.mL^{-1} **(König, Unden and Fröhlich, 2009)**. We did not isolate *Saccharomyces cerevisiae* in our study.

The yeast populations of grapes generally comprise between 10^2 and 10^4 cells.g^{-1} **(Fleet et al., 2002)**, but higher values have also been reported. *Hanseniaspora uvarum* appears to be the most common grape berry species worldwide, which is consistent with its predominance at the beginning of spontaneous must fermentations. Like yeasts, lactic acid bacteria are also found in vineyards **(Lonvaud-Funel, 1999)**.

The microbiota of grapes also includes fungi that may dominate under favorable weather conditions accompanied by inefficient phytochemical utilization. Fungal obligate parasites can penetrate through the intact grape skin by their own biochemical and mechanical activities and are responsible for high economic losses. The main species are the oomycete *Plasmopara viticola,* responsible for downy mildew, and the ascomycetes *Erysiphe necator* (powdery mildew), *Elsinoë ampelina* (anthracnose), *Guignardia bidwellii* (black rot) and *Pseudopezicula tracheiphila* (rotbrenner) **(Barata, Malfeito-Ferreira and Loureiro, 2012)**.

DNA fingerprinting

The variability in polymorphism length was inspected among the Macedonian and Slovak Cabernet Sauvignon grapes using an iPBS markers 1845, 1846 and 1886. The total number of obtained iPBS fragments was 57 which were distributed to 21 levels. The average number of fragments per primer was 9.5. Their size ranged from 378 bp up to the 882 bp. The level of the shortest fragments was present in both of the analyzed varieties for all of the used primers (Figure 1). The highest number of obtained fragments per one primer was 16 fragments for Cabernet Sauvignon from Slovak growing conditions analyzed by primer 1845. The lowest number – 6 fragments for Cabernet Sauvignon from Slovak growing conditions analyzed by primer 1846. One unique fragment was amplified for the Cabernet-Sauvignon from Macedonian growing conditions analyzed by primer 1845 with the length 787 bp.

The total polymorphism for all of the used primers of 87.5% was obtained for the Macedonian sample of Cabernet Sauvignon and 89.4% for the Slovak sample. The most similar iPBS profiles of Slovak and Macedonian samples of Cabernet Sauvignon grapes were obtained for the primer 1846 (Figure 2).

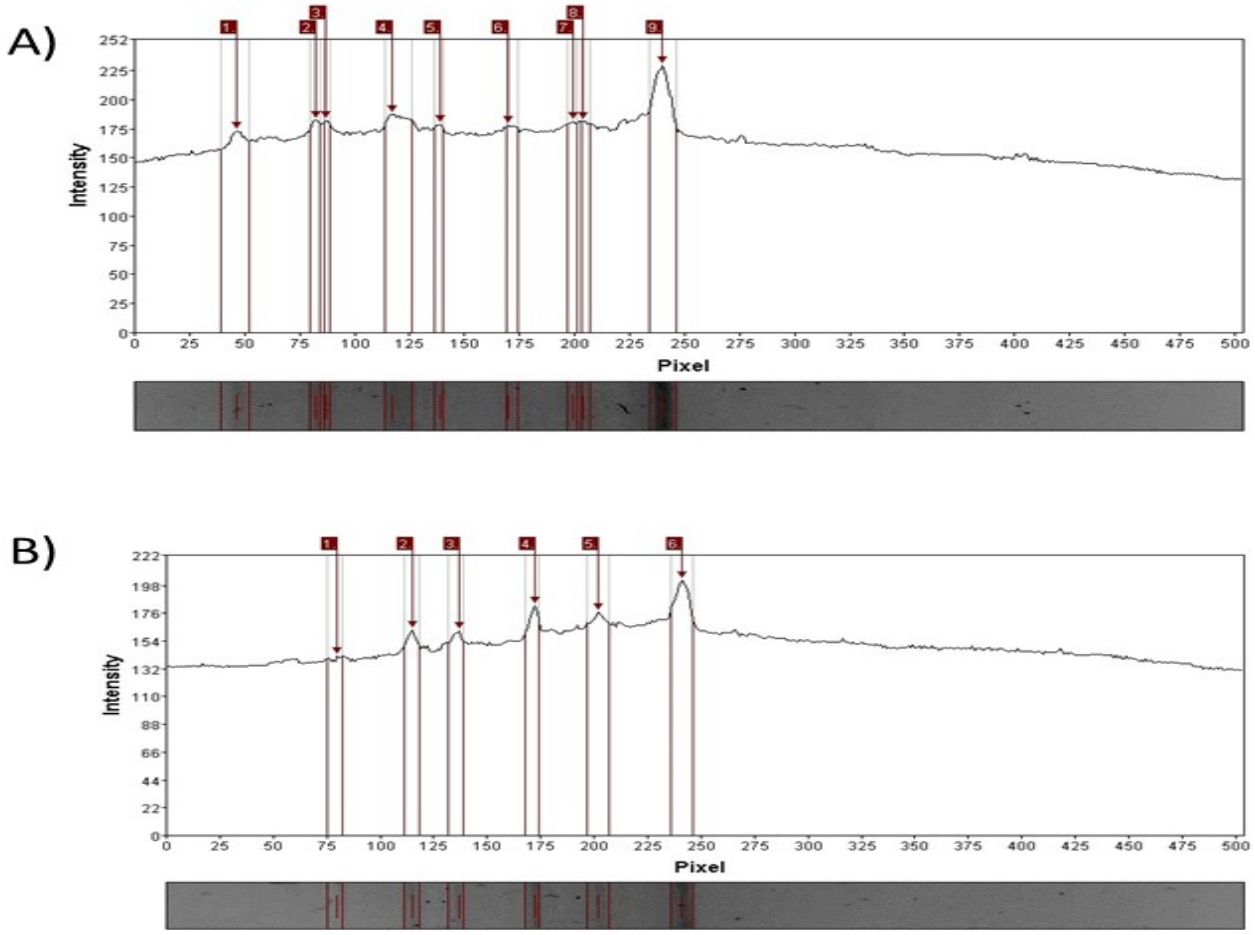

Figure 2 Analysis of length of obtained 1846 fragments for samples from Moldavia(A) and Slovakia (B) evaluated by software GelAnalyzer.

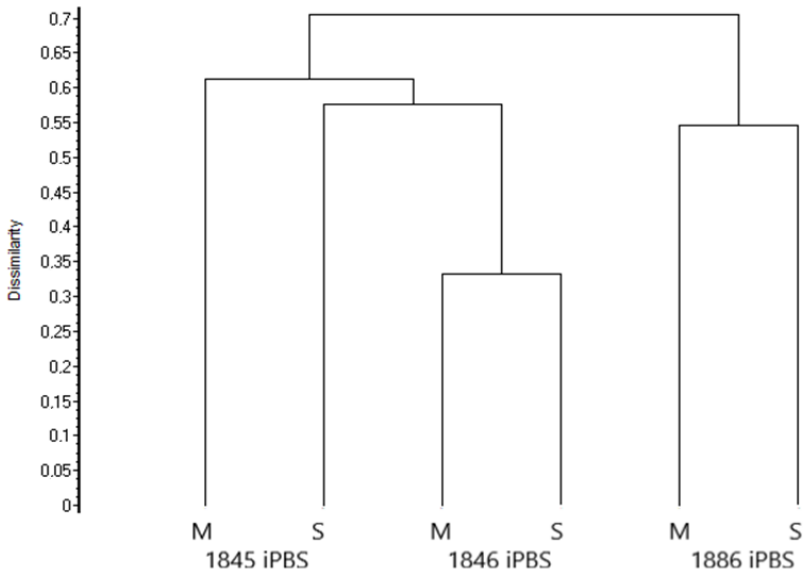

Figure 3 Dendrogram of obtained iPBS profiles of analysed samples of Cabernet-Sauvignon.

The analysis of the relationships of obtained iPBS amplicon profiles was performed by the clustering method using the UPGMA analysis (Figure 3). A clear effect of primer can be seen preferentially to the provenience of the analyzed samples. Profiles generated by primers 1845 and 1846 were grouped and the profiles of 1886 primer were separated as a new branch at the level of 0.7. Here again, the highest similarity of 1846 iPBS profiles of Macedonian and Slovak samples was confirmed.

The PBS primed PCR generated markers are reported to be very effective for extensive intraspecific polymorphism detecting, including in the study of clonal variability. Genotyping by iPBS markers was used for finding differences between varieties and their clones as well as one of the tools for grapevine collection management **(Butorac et al., 2018; Drori et al., 2017)**. Shannon index with the value of 0.137 was reported for Cabernet Sauvignon for six genotypes by **Milovanov et al. (2019)** when a total of 30 PBS primers were used.

CONCLUSION

In our study, the Slovak grape berries sample contained a higher concentration of polyphenols and flavonoids, but a lower concentration of phenolic acids and anthocyanins in comparison to the Macedonian grape. The number of yeasts and bacteria was higher in grape berries from Macedonia. Weather and cultivation conditions can affect the content of biologically active components as well as microorganisms in grape berries.

FLOW CYTOMETRY AS A RAPID TEST FOR DETECTION OF TETRACYCLINE RESISTANCE DIRECTLY IN BACTERIAL CELLS IN *MICROCOCCUS LUTEUS*

Elena Zayko, Dagmara Bataeva, Yuliya Yushina, Anzhelika Makhova, Mariya Grudistova

ABSTRACT

Correct effective doses of antibiotics are important in the treatment of infectious diseases. The most frequently used methods for determination of the antibiotic susceptibility of bacterial pathogens are slow. The detection of multidrug-resistant bacteria currently relies on primary isolation followed by phenotypic detection of antibiotic resistance by measuring bacterial growth in the presence of the antibiotic being tested. The basic requirements for methods of detection of resistance to antibiotics include speed and accuracy. We studied the speed and accuracy of flow cytometry for the detection of tetracycline resistance in the Gram-positive bacteria *Micrococcus luteus*. Detection of cell viability and reliability of antibiotic resistance was carried out on the Guava EasyCyte flow cytometer (Merck Millipore, Germany) with SYBR Green and PI dyes. *M. luteus* was exposed to tetracycline (at 30, 90, 180 and 270 μg.mL^{-1}) over 24 hours. Concentrations of live and dead cells were measured after 4 and 24 hours of incubation. The results revealed that the use of mixed dyes PI and SYBR Green allowed the division of cells into large subpopulations of live and dead cells and the DNA of destroyed cells. After 4 h exposure to tetracycline 30 μg.mL^{-1}, the subpopulation of live cells decreased by 47% compared to the positive control. Tetracycline at 90 μg.mL^{-1} decreased the subpopulation of live cells by 59% compared to the positive control. A continued increase in concentration caused a shift in the population and an increase in dead cells, indicating damage to the cells of the microorganism. Incubation of M. *luteus* with 180 and 270 μg.mL^{-1} tetracycline decreased the subpopulation of live cells by 82% and 94%, respectively, in comparison with the positive control. After incubation with 30 μg of tetracycline over 24 h the number of living cells decreased by 70% in comparison with the positive control. Tetracycline treatment (90 μg.mL^{-1} for 24 h) killed 71% of cells. After exposure to 90 μg.mL^{-1} tetracycline 29% cells were viable. The viability of living cells was confirmed by a microbiological test.

Keywords: antibiotics; flow cytometry; antibiotic resistance; Micrococcus luteus

INTRODUCTION

Antibiotics are one of the most beneficial discoveries in medicine and public health. However, the use, overuse and misuse of these drugs have led to increases in antibiotic-resistant bacterial infections. Antimicrobial resistance (AMR) poses a serious global threat of growing concern to human, animal and environmental health. This is due to the emergence, spread, and persistence of multidrug-resistant bacteria **(Davies and Davies, 2010)**. The O'Neill Review on Antimicrobial Resistance estimated that 700,000 people die from infections due to resistant organisms every year, and by 2050 AMR will surpass cancer as a cause of death **(O'Neill, 2016)**. Resistance to so-called critically important antibiotics used in medicine is of special concern **(Bataeva and Zaiko, 2016)**.

Fast, accurate antibiotic susceptibility testing is a critical need in addressing escalating antibiotic resistance, since delays in identifying multidrug-resistant organisms increase mortality **(Kadri et al., 2018)**.

Standard methods of detection of antibiotic sensitivity are labor- and time-consuming. Detection of multidrug-resistant bacteria currently relies on primary isolation followed by the phenotypic detection of antibiotic resistance by measuring bacterial growth in the presence of the antibiotic being tested. These conventional methods take a minimum of 24 hours to obtain results after the pure culture is isolated (the analysis typically lasts up to 72 hours) **(Akhmaltdinova, Lavrinenko and Belyayev, 2017)**. Working out express diagnostic methods is of importance, and currently, studies are made in various directions **(Wang et al., 2010)**.

One of these directions is the use of flow cytometry (FC) for the detection of microorganism viability and resistance. Flow cytometry was adopted for microbiological purposes almost 40 years ago, and the usefulness of this method for

the identification of microbial pathogens directly in clinical samples or the detection of specific antibodies in serum has been well studied **(Álvarez-Barrientos et al., 2000)**, as has its use in the study of antimicrobial activity of some animal-generated antimicrobial substances **(Kotenkova and Polishchuk, 2019)**.

The quantitative assessment of prokaryotic viability is essential, especially for the confirmation of the activity of novel antimicrobial substances **(Kotenkova et al., 2019)**. Flow cytometry can be used for the analysis of the individual population of cells; therefore, it can provide essential information about bacterial antibiotic resistance. Recently, investigations of bacterial antibiotic resistance seem to be most relevant in the clinical environment because of the problems in finding effective therapies. In comparison with traditional diagnostic methods, FC allows results to be obtained much more quickly **(Álvarez-Barrientos et al., 2000)**. Currently, there are reported experiences of antimicrobial susceptibility tests by FC **(Woźniak-Kosek and Kawiak, 2005; Faria-Ramos et al., 2013)**, but despite the significant progress of clinically significant protocols of FC application, there is insufficient scientific information on its continuous use in microbiology.

This manuscript reports the results of the use of FC with the dyes SYBR Green and PI for rapid assessment of cell viability and antibiotic resistance of the Gram-positive bacteria *Micrococcus luteus*.

Scientific hypothesis

There is a considerable need for new techniques that enable quick and specific diagnosis of pathogens resistant to antibiotics to guide correct treatment and to slow the development of resistance. Flow cytometry can provide quick essential information about the resistance to antibiotics of pathogenic microorganisms.

MATERIAL AND METHODOLOGY

Micrococcus luteus ATCC 4698 from American Type Culture Collection was used.

Sample preparation

Positive, negative and mixed controls of Micrococcus luteus ATCC 4698

Micrococcus luteus ATCC 4698 strain was obtained from the State Research Center for Applied Biotechnology and Microbiology (Obolensk, Moscow region, Russia). Cultures were grown on slanted Trypticase soy agar (TSA, Liofilchem) at 30 °C for 24 h. Cultures from the agar surface were removed with Trypticase soy broth (TSB, Liofilchem) and incubated at 30 °C for 24 h. Cultures were grown to exponential phase (OD_{600} 0.3). The received suspension was used as a positive control.

To obtain negative control, 1 mL suspension was heated at 100 °C for 10 min. To prepare mixed samples, 200 µL of positive control (live cells) and 200 µL of a negative control (dead cells killed by heating) were used.

Preparation of antibiotics

Cultures were grown to early exponential phase, at which time tetracycline (Sigma-Aldrich, USA) was added in various concentrations (30 $\mu g.mL^{-1}$, 90 $\mu g.mL^{-1}$, 180 $\mu g.mL^{-1}$ and 240 $\mu g.mL^{-1}$). Incubation was carried out at 37 °C for 24 h. Concentrations of live and dead cells were measured after 4 and 24 h of incubation with the antibiotic.

Flow cytometry analysis protocol

SYBR Green stock solution was prepared by dissolving 5 µL of SYBR ™ Green I Nucleic Acid Gel Stain, 10,000 X concentrate in DMSO (Thermo, USA) in 495 µL of deionized water. A PI working solution was prepared by dissolving 1 mg PI (AppliChem, Germany) in 1 mL of deionized water immediately before the study.

A volume of 975 µL of 1X pH 7.4 PBS (Santa Cruz, USA) was mixed with 10 µL of SYBR Green (Thermo, USA) and 5 µL PI (AppliChem, Germany), shaken vigorously, then 10 µL of *M. luteus* ATCC 4698 was added and mixed. The samples were incubated in the dark for 15 min and green and red fluorescence signals measured on a Guava EasyCyte flow cytometer (Merck Millipore, Germany) for up to 5000 events.

Microbiology test

Verification of cell viability was obtained by microbiological test by transferring 100 µL of each concentration onto a nutrient agar plate (TSA, Liofilchem). All plates were incubated for 3 – 5 days at 30 °C. The growth on nutrient agar was evaluated by the presence of viable cells in the sample.

Statistical analysis

Measurements were repeated three times. STATISTICA 10.0 software was used for statistical analyses. The results were calculated as mean ± standard deviation (M ±*SD*). Significant differences (comparison with positive control) were tested by one-way ANOVA *Dunnet* test. Differences with *p*-values less than 0.05 were considered as statistically significant.

RESULTS AND DISCUSSION

Routine techniques for the detection of resistance to antibiotics are based on a phenotypic study in which microbial growth is observed in the presence of different antibiotics. They yield results in not less than 24 h. In the last two decades, faster AST methods, such as PCR-based tests **(Barken et al., 2007)** and mass spectrometry-based methods **(Opota et al., 2015; Trip et al., 2015)** have been developed. However, they do not always provide relevant information on antibiotic susceptibility. For example, PCR-based tests rely on the detection of resistance mutations and genes. However, bacteria lacking resistance mutations and genes may still be able to tolerate and survive antibiotic treatments by utilizing many other mechanisms, some of which are non-genetic **(Javid et al., 2014; Sanchez-Romero and Casadesus, 2014)**. Changes in bacterial physiology caused by antibiotics can be detected using FC and fluorescent viability markers, as has been demonstrated by numerous studies **(Gant et al., 1993; Walberg et al., 1997; Gauthier et al., 2002; Ambriz-Avina et al., 2014)**.

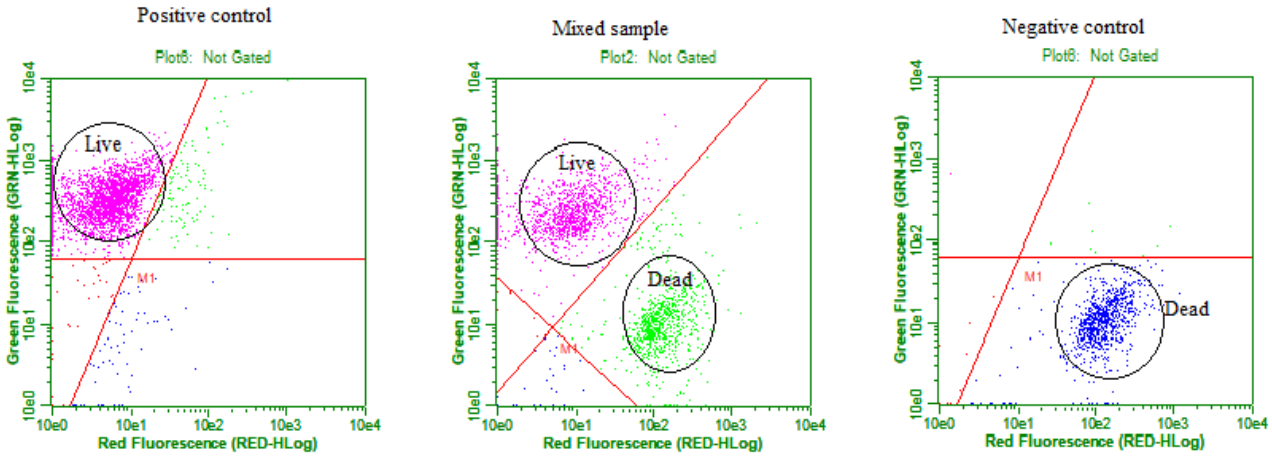

Figure 1 Result of flow cytometry analysis of positive, negative controls and mixed sample of *Micrococcus luteus* ATCC 4698 without antibotic influence .

M. luteus was the object of this study. It is a Gram-positive microorganism with cell walls consisting of two polymers, i.e., peptidoglycans **(Schleifer and Kandler, 1967)** and teichuronic acids (TUAs) **(Hase and Matsushima, 1972)**.

M. luteus can form dormant structures that allow for increased survival under stress. So, cold (4 °C), dryness (2.5% humidity) and starvation increase the survival of *M. luteus* **(Casida, 1980)**, possibly by creating unfavorable growth conditions, and thereby inducing dormancy **(Dib et al., 2013)**. Thus, cells can survive long periods under adverse environmental conditions **(Kaprelyants and Kell, 1993)**, which can allow the evaluation of the gradual transition of cells from living to die over time. PI and SYBR Green dyes can identify stained cells in different large subpopulations. Resistant organisms are more difficult to kill than susceptible organisms, and the SYBR Green/PI assay can distinguish resistant and susceptible categories based on the number of residual viable cells after drug treatment **(Feng et al., 2014)**.

Figure 1 presents the staining patterns of *M. luteus* control samples. Positive control *M. luteus* ATCC 4698 (live cells) displayed green fluorescence, and the corresponding counted events are located in the upper left square of the plot. Negative control (dead cells) displayed red fluorescence, and all counted events are located in the lower right square of the plot.

After 4 h exposure of *M. luteus* to tetracycline (at 30 µg.mL^{-1}, 90 µg.mL^{-1}, 180 µg.mL^{-1} and 270 µg.mL^{-1}) the mix of dyes identified the emergence of large subpopulations of live and dead cells and the DNA of destroyed cells (Figure 2).

In Figure 2 the red marker corresponds to live cells, blue to dead cells, and purple to the DNA of destroyed cells. There is an intensification in the displacement of the population of living cells beyond the red marker towards the blue, which indicates dead cells. Since PI and SYBR Green are DNA-binding dyes, it is possible to see a third population on the cytogram – the DNA of destroyed cells. The increase in the number of cells inside the blue marker shows a rapid decline in the numbers of viable bacteria after the addition of antibiotics.

Results of the FC analysis of *M. luteus* after 24 h incubation with various concentrations of tetracycline are presented in Figure 3. The difference in relative mean fluorescence intensity between live and dead cells increased further following 24 h of treatment. A further decrease in the number of living cells from the initially treated cells was noted, and the presence of a large amount of debris indicated that cell lysis was occurring.

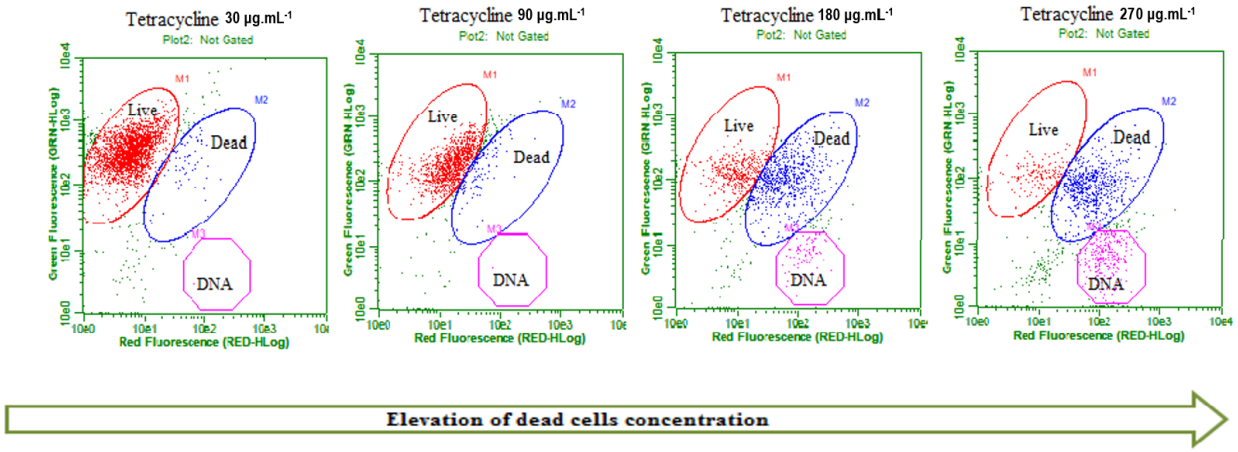

Figure 2 Results of flow cytometry after exposure of *M. luteus* to tetracycline (at 30 µg.mL^{-1}, 90 µg.mL^{-1}, 180 µg.mL^{-1} and 270 µg.mL^{-1}) during 4 h incubation.

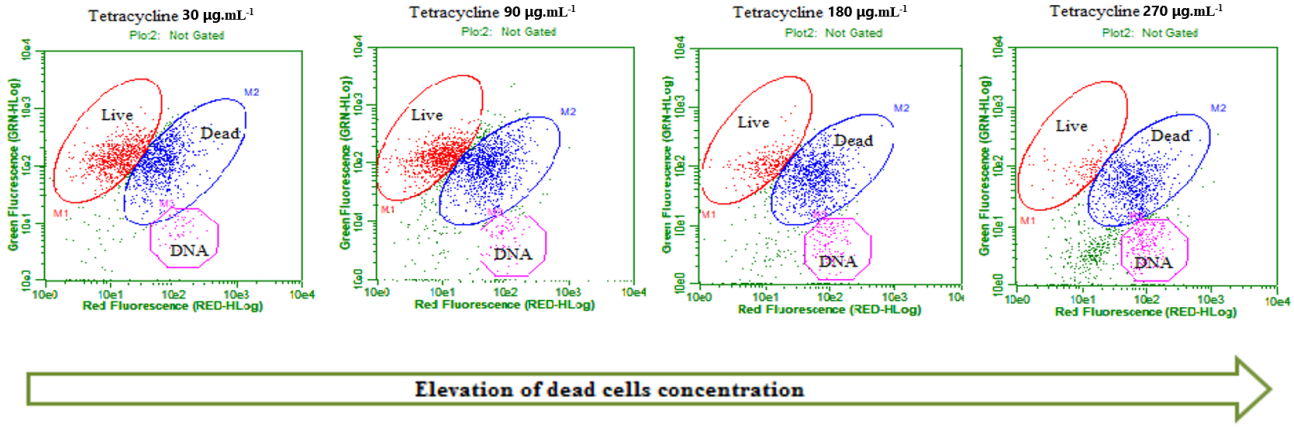

Figure 3 Results of flow cytometry after exposure of *M. luteus* to tetracycline (at 30 µg.mL^{-1}, 90 µg.mL^{-1}, 180 µg.mL^{-1} and 270 µg.mL^{-1}) during 24 h incubation.

After 4 h exposure to tetracycline at 30 µg.mL^{-1}, the subpopulation live cells decreased by 47.0% compared to the positive control (Table 1). Tetracycline solution at 90 µg.mL^{-1} decreased the subpopulation of live cells by 59.0% compared to the positive control.

A continued increase in concentration caused a shift in the population and an increase in dead cells, indicating damage to the cells of the microorganism. So, incubation of *M. luteus* with 180 µg.mL^{-1} and 270 µg.mL^{-1} tetracycline decreased the subpopulation of live cells by 82.0% and 94%, respectively, in comparison with the positive control. The viability of living cells was confirmed by a microbiological test at all concentrations of the antibiotic.

This completely coincided with the results of the cytometric analysis. In analogical research, FC was used for detecting resistant *E. coli* strains. Cytometry showed acceptable results on the model of *E. coli*. Relative accuracy was 88.8%, sensitivity – 85.7%, specificity 88.8%, and Cohen's kappa test showed a value of 0.524 **(Akhmaltdinova, Lavrinenko and Belyayev, 2017)**.

Cytometry analysis showed a decline in the numbers of viable bacteria after 24 h incubation of *M. luteus* with antibiotics. Incubation with 30 µg of tetracycline decreased the number of stained living cells by 70% in comparison with the positive control. Tetracycline treatment at 90 µg.mL^{-1} for 24 h killed 71.0% of cells. So, after exposure to 90 µg.mL^{-1} tetracycline, 29.0% of cells were vaible.

The viability of living cells was confirmed by a microbiological test. Incubation on the plate was increased to 5 days. A study by **Mukamolova et al. (1998)** reported that the viability of *M. luteus* cells was restored after some 96 h incubation of starved cells in a resuscitation medium.

After 24 h exposure to tetracycline (180 µg.mL^{-1} and 270 µg.mL^{-1}) the majority of the cells in the population had received antibiotic-induced damage. The number of stained living cells decreased by 89% and 98.9%, respectively, in comparison with the positive control **(Mukamolova, Kaprelyants and Kell, 1998)**. The viability of the remaining living cells was confirmed only at a tetracycline concentration of 180 µg.mL^{-1}. Such cell survival can be explained by the ability to transition to cell dormancy in unfavourable growth conditions **(Dib et al. 2013)**. In the study by **Nikitushkin et al. (2016)**, it was reported that in response to unfavourable growth conditions nonsporulating mycobacteria transform into the dormant state with the concomitant formation of specialized dormant forms characterized by low metabolic activity and resistance to antibiotics. This because *M. luteus* secretes a small protein called Rpf, which has autocrine and paracrine signaling functions and is required for the resuscitation of dormant cells **(Nikitushkin, Demina and Kaprelyants, 2016)**.

Dormancy is a protective state that enables bacteria to survive antibiotics, starvation and the immune system. Dormancy comprises different states, including persistent and viable but nonculturable (VBNC) states that contribute to the spread of bacterial infections **(Mali et al., 2017)**.

Food products are a source of antibiotic-resistant pathogenic bacteria, a way for the transmission of antibiotic-resistant 'food' pathogens through the food chain to humans **(Zaiko et al., 2019)**. There is an ongoing increasing antibiotic resistance crisis and new drugs and antibiotics are urgently needed to combat life-threatening antibiotic-resistant infections **(Feng et al., 2018)**.

Table 1 The results of measuring the number of cells by flow cytometry.

Time incubation	K «+»			Tetracycline											
				30 µg.mL^{-1}			90 µg.mL^{-1}			180 µg.mL^{-1}			270 µg.mL^{-1}		
	*10^7 cells.mL^{-1}														
	total	live	dead	total	live	dead	total	live	dead	total	live	dead	total	live	dead
4 hours	5.34^{a}	5.20	0.14	3.07^{b,c}	2.80	0.27	2.84^{b}	2.10	0.74	2.40^{b}	0.90	1.5	1.50^{b,d}	0.30	1.20
24 hours	22.28^{a}	22.00	0.28	3.30^{b,c}	1.60	1.70	3.40^{b}	1.50	1.90	2.58^{b}	0.58	2.0	2.06^{b,d}	0.26	1.80

Note: * – significant differences of experimental (tetracycline) doses compared with positive control (p <0.05).

Fast and accurate antibiotic susceptibility tests can significantly reduce mortality rates and reduce financial costs **(Barenfanger et al., 1999)**. Furthermore, the necessity of rapidly prescribing an initial empirical antimicrobial treatment while waiting for the susceptibility test results from time-consuming standard methods frequently leads to inappropriate treatments **(Ibrahim et al., 2000)**.

As to future work, the same strategy may usefully be applied to other microorganisms (including pathogens in difficult food matrixes and other antibiotics. However, the present work shows that one may indeed expect to be able to determine antibiotic susceptibility by FC methods. This could be a very useful tool in the fight against antimicrobial resistance.

CONCLUSIONS

The current conventional methods for the determination of minimal inhibitory concentration (MIC) rely on the growth of the test organism in the presence of the antibiotic, which can be time-consuming depending on the growth speed of the organism, ranging from days for fast-growing bacteria to weeks for slow-growing bacteria. We reported a rapid and novel antibiotic susceptibility testing methodology using FC. This study to demonstrate the feasibility of FC used SYBR Green/PI dyes to assay rapidly the viability of cells and to detect reliably the antibiotic resistance of the Gram-positive bacteria *Micrococcus luteus*.

THE EFFECT OF FORTIFIED *DADIH* (FERMENTED BUFFALO MILK) WITH VITAMIN D_3 ON CAECUM CHOLESTEROL CONCENTRATION AND HIGH SENSITIVITY C-REACTIVE PROTEIN (hs-CRP) LEVEL IN TYPE 2 DIABETES MELLITUS RAT MODEL

Ayu Meilina, Gemala Anjani, Kis Djamiatun

ABSTRACT
Type 2 diabetes mellitus (T2DM) may be developed by a cardiovascular complication. T2DM and its complications associated with a decrease in levels of 25 hydroxyvitamin D below normal. The level of 25-OH-D can increase and it can be gained by probiotics supplementation. *Dadih* is a probiotic useful as antidiabetic, antiatherosclerotic, and it can reduce serum cholesterol. Vitamin D is beneficial for T2DM since it improves insulin production, acts as an anti-inflammatory and prevents dyslipidemia thereby preventing cardiovascular disease. This research aims to investigate the effects of giving *dadih*-fortified-vitamin-D_3 toward caecum-cholesterol-concentration and hs-CRP-levels to T2DM-induced-rats. This study used a randomized pre-post test with control group design in 30 Wistar rats divided into 5 groups, namely T1, T2, and T3-treatment-groups. T3-group was given *dadih*-fortified-vitamin-D_3, while T1 and T2-groups were given vitamin-D_3 and *dadih*, respectively. The control groups were healthy-control (C1), and T2DM (C2). The intervention was given through oral sonde for 28days. The variables analyzed were caecal-*cholesterol*-concentrations using a spectrophotometer and hs-CRP using the ELISA method. The statistical tests were used for the caecum-cholesterol-concentration and hs-CRP levels. The mean of caecum-cholesterol-concentration in the T3-group (83.68 ±1.93mg.100g^{-1}), was higher than T1 (77.99 ±1.70; p = 0.004) and C2-control (24.39 ±1.47; p = 0.0001). The mean of hs-CRP-level post-intervention in the T3-group (4.21 ±0.41 ng.mL^{-1}), was lower than C2 (17.15 ±0.85;p = 0.0001), T1 (6.59 ±0.27; p = 0.0001) and T2 (5.43 ±0.39; p = 0.004). There is a very strong inverse correlation between the concentration of cholesterol and hs-CRP (r = -0.979, p = 0.0001). The conclusion is *dadih*-fortified-vitamin-D_3 –intervention is better than its single intervention as an anti-inflammation which might relate to the increased caecum-cholesterol-concentration.

Keywords: T2DM; *dadih*; vitamin D_3; caecum-cholesterol; hs-CRP

INTRODUCTION
Diabetes Mellitus (DM) as a chronic disease is marked by the increase of the amount of blood glucose that resulted from the incapability of the pancreas to produce insulin or the incapability of the human's body to use existing insulin effectively **(WHO, 2016)**. DM prevalence in 2014 is 422 million and increase to 425 million in 2017. In 2017, The International Diabetic Federation (IDF) informed that Indonesia belongs to ten big countries with 10.3 million of DM patients of 20 to 79 years old **(IDF, 2015)**. Type 2 diabetes mellitus (T2DM) is the one commonly emerged. It reaches 90% of the total cases of DM **(IDF, 2015)**. T2DM is caused by a decrease in the body responds to insulin, known as insulin resistance. The inability of pancreatic-β-cells to maintain stable glucose balance causes the increase of plasma glucose levels (hyperglycemia) **(IDF, 2015; Kahn, Cooper and Del Prato, 2014)**.

T2DM-patients have significantly lower 25(OH)D-concentrations than healthy people **(Stivelman and Retnakaran, 2012)**. The hypovitaminosis D is one of the causes of glucose intolerance and the decrease of insulin secretion of T2DM either directly by activating vitamin D receptors (VDR) or indirectly by calcemic hormones and inflammation **(Shang and Sun, 2017)**.

Vitamin D acts as an anti-inflammatory and immunomodulatory of various diseases like obesity, cardiovascular, and diabetes **(Jafari et al., 2015)**. Vitamin D is also able to proliferate and stimulate T cells. It is also able to reduce pro-inflammatory mediators like C-Reactive Protein (CRP) **(Wu et al., 2014)**. Generally, fortification of vitamin D is done to dairy products such as yogurt

(Jafari et al., 2015). Supplementation of vitamin D and yogurt fortified with vitamin D has been shown to successfully improve the glycemic status of T2DM-patients **(Nakashima et al., 2016; Jafari et al., 2015)**. Yogurt fortified with vitamin D even reduces inflammation in postmenopausal women with T2DM **(Jafari et al., 2016)**. *Dadih* is an Indonesian traditional milk fermentation which has been shown to have a good impact on animal models of obesity **(Kusuma et al., 2015)**. The success of *dadih* fortified with vitamin D, however, has never been proven in T2DM.

Dadih is a product of spontaneous fermentation of buffalo milk done under a temperature of 28 – 32 °C for 24 – 48hours inside the bamboo tube **(Wijayanti, Thohari and Purwadi, 2016)**. Type of lactic acid bacteria (LAB) like *L. plantarum subsp. plantarum, Lactobacillus subsp. lactis, Lactococcus lactis subsp. cremoris, Lactobacillus brevis, Lactobacillus viridescens, Lactobacillus buccheri*are invented by isolating *dadih* of Lima Puluh Kota district **(Wirawati et al., 2018; Wirawati et al., 2019)**. *Dadih* gives several benefits such as antidiabetic, antiadipogenic, antiatherosclerotics, reducing the level of cholesterol. It can also improve human immunity **(Han et al., 2012; Wirawati et al., 2018)**.

Fermentation of buffalo's milk produces a peptide 4 – 20 kDa that resists free radicals affected by chronic inflammation and pancreatic beta-cell apoptosis **(Mustopa, Andrianto and Faridah, 2017)**. LAB can balance intestinal microbiota that can inhibit the production and secretion of lipopolysaccharides (LPS). The decrease of LPS content in the intestinal epithelium caused a decrease of proinflammatory cytokines **(Chuengsamarn et al., 2017; Park et al., 2013)**.

Dadih mechanism can reduce cholesterol through probiotics in *dadih* that assimilate cholesterol then cholesterol gets into the membrane of bacteria cell wall Absorption of cholesterol inside small intestine diminishes then cholesterol gets into caecum and at last, it is discarded through feces **(Nuraida, 2015; Kumar et al., 2012)**.

This study aimed to determine whether the intervention of *dadih*–fortified-vitamin-D_3 increased caecum-cholesterol-concentration and decreases hs-CRP levels in T2DM rats induced by a high-fat diet (HFD), streptozotocin (STZ) and nicotinamide (NA) injection.

Dosage of fortified *dadih*-vitamin-D_3 in this study was 36 IU.day^{-1} vitamin-D_3 on *dadih* 4 g.kg^{-1} weight body.day^{-1}. The intervention of *dadih*-fortified-vitamin-D_3 was carried out for 28days **(Kusuma et al., 2015; Jafari et al., 2015)**.

Scientific hypothesis

Dadih-fortified-vitamin-D_3 increases caecum-cholesterol concentration and decrease hs-CRP levels in T2DM Wistar rats.

MATERIAL AND METHODOLOGY

Dadih-fortified-vitamin-D_3 preparation and intervention

Dadih was made from buffalo milk from farms in the Gadut area, West Sumatra Province. Buffalo milk was pasteurized at temperature 72 °C for 15seconds. The milk was then cooled to 30 °C and added 900 IU of vitamin-D_3 then put into a bamboo tube and then it covered with banana leaves for two days of fermentation. The bamboo used was betung bamboo with a diameter of 4 – 5 cm, a length of 20 cm, and a volume of 100 mL **(Ranieri et al., 2009)**. *Dadih*-fortified-vitamin-D_3 was given orally using a feeding tube given to experimental Wistar rats. The dosage was 4g.kg^{-1} BW.d^{-1} **(Kusuma et al., 2015)**.

Research design and experimental animals

This research was a true-experimental study with a randomized pre-post test with a control group design. Animals used were male Wistar rats, aged 8 weeks, the weight was 150 – 200 g. They were acclimatized at the laboratory of the Center for Food and Nutrition Studies at Gajah Mada University, Yogyakarta. The rats were placed in individual stainless-steel cages at regulated a temperature of 21 °C. The rats were fed with 15 g.d^{-1} of the Comfeed II standard-diet during the non-HFD period and intervention. Rats received ad libitum water during the experiment. Animal laboratory guidelines used were from the Central Laboratory for Food and Nutrition Studies, Gajah Mada University (UGM), Yogyakarta.

Thirty rats were divided into five groups which were healthy controlled (C1), T2DM controlled (C2), and T2DM intervention (T1, T2, and T3). The T2DM-condition was induced by HFD, STZ, and NA. After a week of acclimatization, rats were conditioned in T2DM with oral HFD 15 g.d^{-1} for 14 days then injected intraperitoneally with STZ 45 mg.kg^{-1} rat BW and NA 110 mg.kg^{-1} rat BW. T2DM condition was indicated by fasting blood glucose serum >250 mg.dL^{-1} **(Gheibi, Kashfi and Ghasemi, 2017)**. The T3-group was then treated with *dadih*–fortified-vitamin-D_3 in doses of 4 g.200g^{-1} BW.d^{-1} every day for the intervention of 28 days, while T1 and T2-groups were given vitamin-D_3 36 IU.d^{-1} and *dadih* 4 g.200g^{-1} BW.d^{-1}, respectively **(Kusuma et al., 2015; Jafari et al., 2015)**. This study was approved by the Health Research Ethics Diponegoro University Semarang through ethical clearance No. 140/EC/H/KEPK/ FK-UNDIP/XI/2019.

Determination of biochemical markers

The blood sample was taken first and at the end of the intervention, fasting blood glucose was taken through the retroorbital plexus. Blood glucose determination using GOD-PAP (BIOLABO SA). Determination of blood glucose after enzymatic oxidation by glucose oxidase. Blood samples were collected in a centrifugation tube and centrifuged 4000 rpm in 15 minutes (HerauesSepatech, Biofuge 15).

Caecum-cholesterol-concentration determination using the Lieberman Burchand method and analyzed by Spectrophotometer (Optima SP. 300). The sample's absorbance was further read by a spectrophotometer at 680 nm **(Plummer, 1971)**.

Figure 1 *Dadih* fermented.

Figure 2 *Dadih*-fortified-vitamin-D_3.

hs-CRP levels were determined using an enzyme-linked immunosorbent assay (ELISA) kit (Fine Test, Wuhan Fine Biotech, China) according to manufacturer instructions **(Fine Test, 2019)**. Briefly, Reagen adds samples 100 µL of the properly diluted sample into test sample wells. The plate sealed with a cover and incubated at 37 °C for 90 minutes. After incubation, the plate was rinsed 3 times with wash buffer and let the Wash Buffer stay in the wells for 1 – 2 minutes each time. 100 µL of Biotin-labelled antibody working solution into the above wells (standard, test sample, and blank wells), sealed with a cover, and incubate at 37 °C for 60 minutes. After incubation, remove the cover and wash the plate 3times with Wash Buffer. 100 µL of SABC (Streptavidin Conjugate) Working Solution added into each well, sealed with a cover the plate, and incubated at 37 °C for 30 minutes. After incubation Remove the cover and wash the plate 5times with Wash Buffer. 90 µL TMB Substrate added into each well, sealed with a cover the plate, and incubated at 37 °C for 10 – 20 minutes in dark. After incubation, 50 µL Stop Solution added into each well. The color will turn yellow immediately. The absorbance of samples in well plates was read by ELISA Reader at 450 nm (Zenic).

Statistical analysis

Data were analyzed using version 21 of the statistical package for the Social Sciences (SPSS). The results were expressed as mean ±*SD* (for normally distributed data) otherwise it expressed as median (min-max). Statistical difference was analyzed by using One-Way Analysis of Variance (ANOVA) followed by Post Hoc Bonferroni for normally distributed data, otherwise, the Kruskal-Wallis test followed by Mann Whitney test was used. The Differences before and after intervention were analyzed using a Paired *t*-test for normally distributed data, otherwise the Wilcoxon test. Pearson's correlative test was used to analyze the correlation between variables, and statistical analyses were performed by a computer. The differences and correlations were considered significant at $p < 0.05$ and 95% confidence intervals (CI). The strength of correlations was determined by the r value.

RESULTS AND DISCUSSION

The data processed in this study was obtained from 29 Wistar rats, which are divided into each group consisting of 6 rats. The use of *dadih* in this study referred to the kefir study. Kefir intervention. the study of T2DM patients indicates that LAB in kefir contributes to the regeneration of pancreatic beta cells and then it increases the ability to produce insulin. Further, insulin facilitates the glucose absorption into adipose and liver that glycogenesis and lipogenesis occur. This process might contribute to increasing the weight of T2DM receiving kefir **(Ostadrahimi et al., 2015)**.

The blood glucose levels are collected in all intervention groups (T1, T2, and T3). Before the intervention, all T2DM-rats showed significantly higher blood glucose than C1-group (Post Hoc Bonferroni test T1, $p = 0.0001$; T2, $p = 0.0001$; T3, $p = 0.0001$, Table 1). The blood glucose before the intervention also showed that there was no difference between the intervention group ($p < 0.05$). The blood glucose levels decreased significantly after treatment in all treatment groups (paired *t*-test; $p<0.05$). The post-intervention of blood glucose showed that all treatment group was significantly lower than C2-group (Post Hoc Bonferroni test T1, $p = 0.0001$; T2, $p = 0.0001$; T3, $p = 0.0001$). Additionally, those of treatment groups remained higher than C1-group (Post Hoc Bonferroni test T1, $p = 0.0001$; T2, $p = 0.0001$; T3, $p = 0.003$). This indicated that all interventions used improved glycemic status, although it had not reached a healthy yet at a group level. The post-intervention blood glucose level in the T3 group had the lowest level among intervention-groups and significantly different than the T1 group. Intervention with *dadih*-fortified-vitamin-D_3 was proved that the glucose level was able to decrease better than the single intervention (vitamin D_3).

The pre-post intervention change (Δ) of blood glucose levels was significantly different among the five groups (Kruskal-Wallis test, $p = 0.0001$). Results of the Mann Whitney test showed the significant differences in blood glucose levels ($p < 0.05$) between the intervention groups (T1, T2, T3) compared to the C1-group. The negative Δ blood glucose level of T3 was bigger than T1 and T2, and this was significantly different. This gave an additional finding that *dadih*-fortified-vitamin-D_3-intervention was not only better than the single intervention (vitamin-D_3) but also *dadih*.

The result of the One-way ANOVA test showed that there was a significant difference in caecum-cholesterol-concentration among groups in this study ($p = 0.0001$). Caecum-cholesterol-concentrations of T1, T2, and T3-groups was significantly higher than C2-groups (Table 2; Post Hoc Bonferroni test; $p = 0.0001$ in each group). These indicated that vitamin-D_3, *dadih,* and *dadih*-fortified-vitamin-D_3 the treatments contribute to the increased of caecum-cholesterol- concentrations of T2DM-rats. Interestingly, those of T2 and T3-groups were significantly higher than the T1-group ($p = 0.0001$ and $p = 0.004$). Also, those of the T2-group were significantly higher than the T3-group ($p = 0.003$). Therefore, *dadih*-intervention might have a predominant-effect in increasing caecum-cholesterol-concentration in T2DM-rats. Probiotics contribute to reducing cholesterol absorption in the intestine. This is based on the yogurt study. Probiotics assimilate cholesterol and get the cholesterol into the membrane of probiotic cells. As a result, the cholesterol absorption in the intestine reduces and the cholesterol will get into the cecum to be disposed of with feces **(Ejtahed et al., 2011; Nuraida, 2015)**. Probiotics can reduce cholesterol concentrations in vitro through the conversion of cholesterol into coprostanol by cholesterol reductase. This condition leads to the cholesterol excretion in feces increases, while cholesterol in the plasma decreases **(Lye, Rusul and Liong, 2010)**. Vitamin D mechanisms used in increasing caecum-cholesterol-level have not been elucidated. However, vitamin D involves the decline of blood cholesterol levels. Vitamin D inhibits HMG-CoA reductase, an enzyme function in endogenous cholesterol biosynthesis and it can also de-conjugate bile acids in the intestine, and subsequently, it reduces cholesterol concentration **(Kane et al., 2013; Ostadrahimi et al., 2015)**. The caecum-cholesterol-concentration in those treatment-groups (T1, T2, and T3) at the post-intervention was significantly lower than healthy C1-group ($p = 0.0001$, $p = 0.006$, and $p = 0.0001$). This suggests that improving interventions remain open for the benefit of T2DM-individuals.

All of the treatment-groups had lower hs-CRP levels at the post-intervention, and these differences were significant (Table 1; Wilcoxon test, $p = 0.028$ in each group). All of the treatment-groups had lower hs-CRP levels than C2-group at the post-intervention. The negative delta (Δ) of hs-CRP levels was bigger in those receiving treatments than C2-group (Mann Whitney test; T1, $p = 0.006$; T2, $p = 0.004$ and T3, $p = 0.004$). All of these showed that all interventions used in this study were associated with the reduction of blood hs-CRP levels. The post-intervention of hs-CRP levels in the T3-group (Mean ±*SD*; 4.21 ±0.41 ng.mL^{-1}), was lower than C2 (17.15 ±0.85; $p = 0.0001$), T1 (6.59 ±0.27; $p = 0.0001$) and T2 (5.43 ±0.39; $p = 0.004$). Thus, *dadih*-fortified-vitamin-D_3 intervention might have a better effect than its single intervention to decrease blood-hs-CRP levels in T2DM-rats. *Dadih*contains LAB and the previous studies show that LAB in fermented food involves mechanisms to reduce blood-CRP-levels. LAB induces the increase of production of several anti-inflammatory cytokines, and the decrease of COX-2 expression, an enzyme that catalyzes the production of prostaglandins from arachidonic acid, in which it stimulates cell proliferation and inflammatory processes **(SaeidiFard, Djafarian and Shab-Bidar, 2020)**. LAB balances the gut microbiota therefore, it inhibits the production and secretion of LPS. Decreased of LPS in the intestinal epithelium causes a decrease in proinflammatory cytokines **(Wirawati et al., 2019)**. Probiotics from *dadih* can also produce SCFA in the colon, while this SCFA can reduce the synthesis of CRP enzymes in the liver **(Asemi et al., 2013)**.

Vitamin D can provide a protective effect by reducing sensitivity to the circulating-CRP **(Zakharova et al., 2019).** Vitamin D does not only decrease CRP but also decreases proinflammatory cytokines including TNF-α, IL-6, IL-1β **(Mirhosseini et al., 2017)**. Vitamin D weakens the expression of proinflammatory cytokines involved in insulin resistance and regulates NF-Kb activities.

Table 1 BodyWeight, BloodGlucoseandhs-CRP Level.

T3	83.68 ±1.93 a,b,c,d

Note: Alphabetical superscripts showed a significance level of ^{a}: p <0.05 compared as C1; ^{b}: p <0.05 as compared to C2; ^{c}: p <0.05 as compared to T1; ^{d}: p <0.05 as compared to T2; ^{e}: p <0.05 as compared to T3.

Table 3 Correlation studies of caecum-cholesterol-concentration and hs-CRP levels with other biochemical markers.

	hs-CRP levels		Blood Glucose Level	
	r	***p***	**r**	***p***
Caecum-cholesterol-concentration	-0.979	0.0001	-0.988	0.0001
Blood Glucose Level	0.988	0.0001		

Vitamin D can also improve the composition and function of intestinal microbiota, reduce pathogenic bacteria, and increase bacterial diversity. Another study in Rotterdam shows that Vitamin D deficiency is prevalent in overweight and obese children and adolescents **(Zakharova et al., 2019)**. Additionally, the higher vitamin D levels are associated with the lower of CRP-levels in T2DM-patients **(Liefaard et al., 2015)**. However, the study has not proved a causal relationship between vitamin D and CRP-level. The recent study used interventions of vitamin D_3 and *dadih*-fortified-vitamin-D_3 was strengthening the role of vitamin D_3 to lessen CRP-level.

The Spearman test on all data from T2DM rats at the end of the study showed that a very strong positive correlation was observed between hs-CRP levels and blood glucose levels (Table 3), while a very strong negative correlation was found between caecum-cholesterol-concentration either with hs-CRP levels or blood glucose levels.

A very strong negative correlations was observed between caecum-cholesterol-concentration and hs-CRP-levels (r = -0.979, p = 0.0001, Table 3). Caecum cholesterol is the cholesterol that is secreted by the body and will be excreted with fecal. An increased concentration of cholesterol excreted from the body will reduce the bile acids returning to the hepatic cycle, and subsequently, the cholesterol in blood circulation will be consumed for synthesizing new bile acids **(Kumar et al., 2012; Kusuma et al., 2015)**. The very strong inverse relation between caecum cholesterol and hs-CRP levels may be mediated by the decline circulating cholesterol levels which relate to the decline in inflammation.

The increase of fatty acids or triglycerides in adipose tissue will cause enlargement in adipose tissue and activate the HF-1 gene. This gene increases the expression of Jun kinase and IkB kinase and triggers phosphorylation of IkB and activates NFkB. It will trigger the expression of proinflammatory cytokines such as TNF-α and IL-6. This

increase of cytokines will trigger the liver to secrete CRP **(Qatanani and Lazar, 2007)**. Plasma CRP levels are significantly correlated with high triglycerides and low HDL. CRP is synthesized in adipose tissue, the amount will increase in a state of obesity which will ultimately cause insulin resistance and diabetes **(Devaraj, Singh and Jialal, 2009)**.

A very strong negative correlation was observed between caecum-cholesterol-concentration and blood-glucose-levels (r = -0.988, p = 0.0001). Glucose levels increase in groups that had low caecum-cholesterol-concentration. T2DM is associated with changes in the composition of intestinal microflora, namely an increase in the number of gram-negative bacteria and a decreased proportion of Firmicutes. The individuals with T2DM, therefore, have lipid metabolism abnormalities **(Ejtahed et al., 2011)**.

Lipid metabolic disorders caused by insulin resistance affect Hydroxymethyl Glutarate Coenzyme-A (HMG-CoA) reductase and lipid metabolic pathways. Several studies have shown that insulin can affect the production of apolipoprotein in the liver and regulate the activity of lipase which causes dyslipidemia in diabetes mellitus **(Ozder, 2014)**. Excessive accumulation of fat in adipose tissue causes macrophage infiltration and increases the production of proinflammatory cytokines which contributes to the development of atherosclerosis **(Pei et al., 2017)**.

A very strong positive correlation was found between hs-CRP-levels and blood-glucose-levels (r = 0.988, p = 0.0001). This correlation showed that increase glucose levels relate to enhanced hs-CRP-levels. Hyperglycemia causes damage to all body tissues and affects the chronic inflammatory response such as hs-CRP. Also, hyperglycemia in cells causes damage to the mitochondria. It will increase Reactive Oxygen Species (ROS) so that the amount of free radicals increase in the body. Furthermore, hyperglycemia also increases the synthesis of diacyl glycerides (DAG) which causes activation of Protein Kinase C (PKC) and ultimately changes the expression of various genes that will damage blood vessels. Increased activity of PKC leads to activation of NF-kB and it induces various pro-inflammatory cytokines such as TNF-α and IL-6 which trigger the liver to produce CRP **(Nowotny et al., 2015)**.

CONCLUSION

Dadih-fortified-vitamin-D_3-supplementation has a better effect than either *dadih* or vitamin-D_3 in decreasing blood-glucose and hs-CRP levels. *Dadih*-fortified-vitamin-D_3supplementation has better effect than vitamin-D_3 in increasing caecum-cholesterol-concentration T2DM-rat. Both hs-CRP andglucose levels havea very strong inverse relationship withthe caecum-cholesterol-concentrations.

THE OCCURRENCE OF ELEVEN ELEMENTS IN DAIRY COW´S MILK, FEED, AND SOIL FROM THREE DIFFERENT REGIONS OF SLOVAKIA

Róbert Toman, Martina Pšenková, Vladimír Tančin

ABSTRACT

The objective of this study was to measure the concentrations of eleven essential, potentially toxic and toxic elements (arsenic – As, calcium – Ca, cadmium – Cd, copper – Cu, iron – Fe, mercury – Hg, magnesium – Mg, nickel – Ni, lead – Pb, selenium – Se, zinc- Zn) in raw cow's milk (spring, summer, and autumn season), feed (spring and autumn season) and soil (spring season) from three different environments by routine methods in the certified testing laboratory. The samples were collected in the undisturbed region around Novoť, the moderately disturbed region around Tulčík, and the strongly disturbed region around Čečejovce. The concentrations of all toxic elements (As, Cd, Hg, Ni, Pb) and two essential elements (Cu, Se) in milk were under the limits of quantification (LOQ) from all investigated areas and during all seasons. Concentrations of other elements in milk from the undisturbed and disturbed areas were significantly different, generally with the highest levels in summer. In soil samples, the significantly highest concentrations of Ca, Cu, Ni were found in a strongly disturbed area, Mg and As in moderately disturbed area, and Fe, Se, Zn, Hg, and Pb in an undisturbed area. Cadmium was under the LOQ. In feed, the concentrations of essential elements, except of Se, were higher in the autumn. The significantly highest concentration of As, Ni were recorded in a moderately disturbed area and Pb in the undisturbed area in both seasons. Cadmium and Hg were under the LOQ. Despite the higher level of some elements in soil (Fe, Mg, Ca) from all regions, there were not elevated concentrations of any element in feed or milk. The concentrations of all toxic elements in milk were under the permitted limits. Thus, the milk from all investigated areas was not contaminated with the elements posing a health risk for consumers and it is considered safe for human consumption.

Keywords: essential element; toxic metal; cow milk; feed; soil

INTRODUCTION

Milk is a well-known source of many compounds with a beneficial role in the human organism. It contains essential elements, vitamins, proteins, and other compounds important mainly for the children's health. However, except for these important compounds, it may contain also toxic or potentially toxic elements. **Hermansen et al. (2005)** analysed 45 trace elements and 6 macro elements (Ca, potassium – K, Mg, sodium – Na, phosphorus – P, sulphur – S) in cow milk. Authors found the differences between the organically produced milk and conventionally produced milk with elevated concentration of molybdenum (Mo) in organic milk, whereas the concentrations of barium (Ba), europium (Eu), manganese (Mn), and zinc (Zn) were significantly reduced compared with conventional milk. Differences in element concentrations based on animal species and regions reported **Zhou et al. (2017)**. Authors also found that the concentrations of elements in water and feed might contribute to those in milk. Toxic and potentially toxic elements in raw milk were associated with those in feed and drinking water. Results of meta-analysis made by **Zwierzchowski and Ametaj (2018)** show that concentrations of Pb were above the minimum-risk level (MRL) in the milk samples from Brazil, Croatia, Egypt, Mexico, Nigeria, Palestine, Romania, Serbia, and Turkey. Moreover, organic dairy farms are characterized by lower concentrations of toxic heavy metals in whole raw milk compared with those from the conventional production system.

A large proportion of the total amounts of the elements contains casein fraction in cow's milk but not in humans **(Fransson and Lönnerdal, 1983)**. Lead and As were found in the cow's milk from areas irrigated with wastewater in Mexico with Pb concentrations above the maximum limit as set by Codex Alimentarius and the European Commission standards **(Castro-González et al., 2018)**. **Castro-González et al. (2019)** warn that chronic heavy metal consumption in contaminated cow's milk can pose a serious

health risk for girls and children. The heavy metals in the milk had the following order Zn >As >Pb >Cr >Cu >Ni. Lead exceeded the Codex limits. Many of the metals occurring in the milk can cause cancer in humans. As, Cd, chromium (Cr), Pb, and Hg are considered systemic toxicants and are also classified as human carcinogens **(Tchounwou et al., 2012)**. Epidemiological studies have shown that As exposure is associated with a variety of human cancer of the skin, lungs, bladder, liver. Exposure occurs primarily via drinking water, but dietary exposure can also be substantial **(Zhou and Xi, 2018)**. Environmental quality and human activities (soil, water, river, industry, mining, and smelting) play a key role in the distribution of toxic metals in raw milk and contribute to Pb, As, and Cd contamination in animals and transfer to milk **(Kazi et al., 2009; Zhou et al., 2019a)**. In bovine milk, Hg is associated with two protein fractions, caseins, and beta-lactoglobulin **(Mata, Sanchez and Calvo, 1997)**. Mercury in cow milk samples in concentration 3.1 $ng.g^{-1}$ found **Najarnezhad and Akbarabadi (2013)**. Nickel was also found in cow milk and high concentrations of Ni in traditional farms compared to industrial farms could be attributed to the location of this industry in a rural area **(Arianejad et al., 2015)**.

Milk may be an important source of essential elements. The iron content of cow's milk is about 0.5 $mg.L^{-1}$ and is thus comparable to that of human milk **(Ziegler, 2011)**. However, cow's milk and Ca inhibit nonheme Fe absorption **(Domellöf et al., 2014)**. Copper is found in lower concentrations in milk. However, the concentrations of Cu in the meat and cow milk samples were higher than the maximum allowable concentration (MAC) of Cu in foods in Bangladesh **(Shaheen et al., 2016)**. Even higher Cu concentrations were found in Croatia **(Bilandžić et al., 2011)**. Milk can significantly contribute to the dietary Se intake in human. Higher milk Se concentrations have been measured in the Northern Ireland, but its content in milk is affected by geographical location **(O'Kane et al., 2018)**. Effect of parity, stage of lactation and breed on mineral composition of cow milk reported **Manuelian et al. (2018)**. Milk of primiparous cows had greater Ca, Mg, K, and P contents than milk of multiparous cows. Holstein-Friesian produced the lowest concentrations of Ca, Mg, and P content. Jersey yielded milk with the greatest Ca and Mg content.

Due to the importance of milk consumption and its content of essential and toxic elements mainly for children's health, the aim of this work was to analyse and compare the occurrence of 11 elements in raw cow's milk, feed and soil samples from different areas of Slovakia based on the environmental regional classification.

Scientific hypothesis

The concentration of toxic and essential elements in cow's milk is affected by the environmental quality.

MATERIAL AND METHODOLOGY

Sample collection

The cow's milk, feed and soil samples were collected in three different areas of Slovakia based on the environmental regional classification **(MESR and SEA, 2018)** (Figure 1). The location around Novoť is considered as a region with an undisturbed environment, the second analysed area of Tulčík is considered as a region with a moderately disturbed environment, and the third area considered as a region with a strongly disturbed environment is located around Čečejovce.

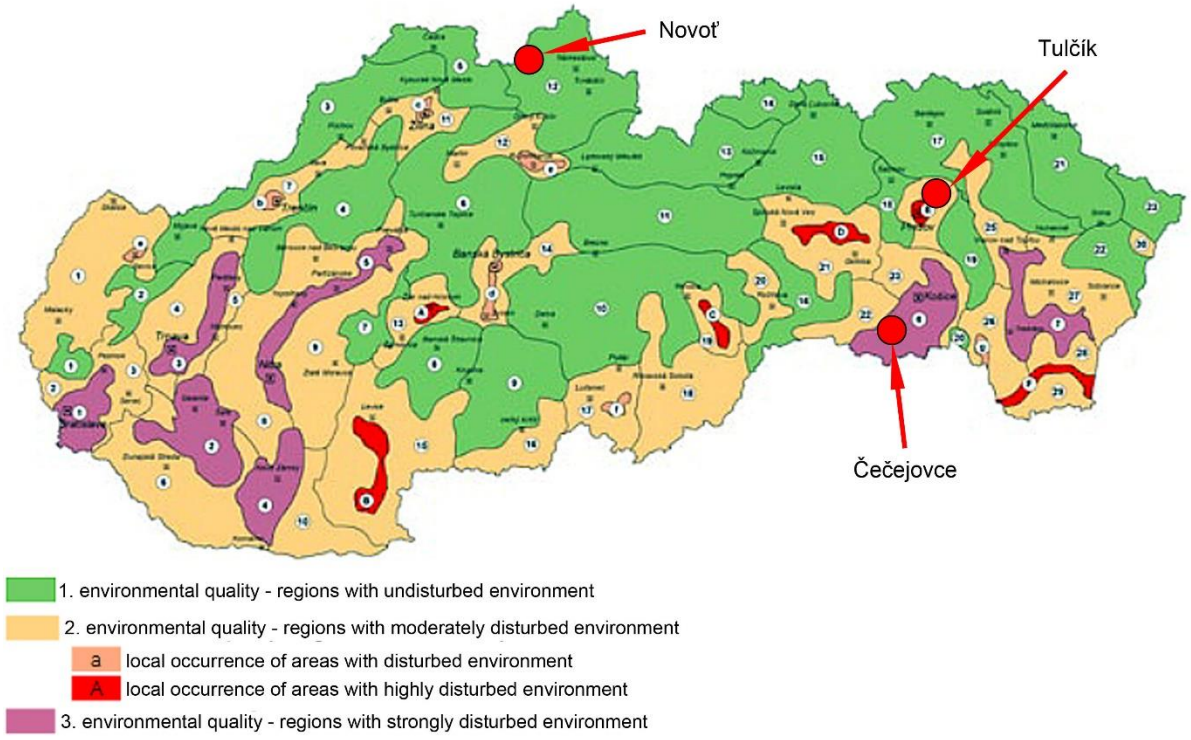

Figure 1 Environmental regional classification of Slovakia **(MESR and SEA, 2018)**. Note: Three investigated regions (Novoť, Tulčík, Čečejovce) are marked.

The tank milk samples were collected immediately after the cows were milked, in the morning and in the afternoon by an automatic milking system. Samples were collected three times a year; in spring (April), in summer (July), and in autumn (September). 500 mL of milk were collected directly from the milk tank during the two days (two times from morning milking and two times from afternoon milking). Five samples of milk were collected from each milking, in total 60 samples of pool milk (20 samples each season) from each location. The total number of the dairy cows were as follows: Novoť area (220 cows; crossbreeds: Slovak spotted breed × Red Holstein breed), Tulčík area (450 cows; Slovak spotted breed), and Čečejovce area (340 cows; Black Holstein breed). Average milk samples from these cows were obtained from milk tanks immediately after the end of milking. Samples were kept in PET bottles at -18 °C until analysis.

Ten feed samples (5 in April and 5 in September) of total mixed ration (TMR) were collected from each observed location. The feed was made at all farms from local components from these farms. Samples were stored in plastic bags at -18 °C until analysis.

Five soil samples were collected from different places at each farm during the spring season (April). Samples were stored in plastic bags at -18 °C until analysis.

Sample analysis

Milk samples for Ca, Fe, Mg, Cd, Ni, Pb, Cu, Zn analyses were mineralized by microwave decomposition with HNO_3 and H_2O_2 (microwave oven MARS 6 240/50). Milk samples for As analysis were prepared by dry mineralization with oxidation mixture (oxygen, oxides of nitrogen, ozone), heated at 300 – 400 °C. The ash was re-diluted in HCl solution. Milk samples for Se analysis were mineralized by microwave decomposition with HNO_3 and H_2O_2 (microwave oven MARS 6 240/50) and after removal of nitrous gases, cooling, and addition of HCl solution, Se^{6+} was reduced to Se^{4+} by heating at 90 °C.

Feed samples were prepared by dry mineralization in owen at 475 °C (Ca, Fe, Mg, Cu, Zn) or 580 °C (Cd, Ni, Pb) and the ash was diluted in HCl solution. Feed samples for As and Se analyses were prepared by magnesium nitrate and oxide suspension and mineralized with HNO_3 at 470 °C. The ash was diluted in the HCl solution. Se^{6+} was reduced to Se^{4+} by heating at 90 °C.

Soil samples for As, Se, Ca, Fe, Mg, Cd, Ni, Cu, Pb, Zn were extracted with aqua regia and cooled for 2 hours.

Arsenic and Se in milk, feed, and soil were analysed using the hydride generation atomic absorption spectroscopy (HG-AAS) method with SpectrAA-220 FS (The Netherlands). Calcium, Fe, and Mg in milk, feed, and soil samples were detected using the inductively coupled plasma-atomic emission spectrometry (ICP-AES, Varian 720-ES, USA). Cadmium, Pb, and Ni in milk and feed were analysed using the electrothermal atomization atomic absorption spectrometry (ETA-AAS, Agilent DUO AA 240Z/240FS, USA). Zinc and Cu in milk and feed and Cd, Ni, Cu, Pb, Zn in soil were analysed using the flame atomic absorption spectrometry (F-AAS, DUO AA 240Z/240FS, USA). Mercury in milk, feed, and soil samples was analysed using the Advanced Mercury Analyzer and atomic absorption spectrometry (AMA-AAS, AMA254, Altec, Czech Republic) without the need for chemical preparation of the sample. All analyses were conducted in certified testing laboratory Eurofins/Bel Novamann (Nové Zámky, Slovak Republic).

Quality assurance

For the validation of the analytical methods the limits of detection (LOD) and LOQ were evaluated (Table 1). LOD in digest was calculated as three times the standard deviation of the sample blank relative to the slope of the analytical curve. LOQ was calculated as 10 times the standard deviation of the sample blank relative to the slope of the analytical curve. LOD and LOQ were calculated separately for soil, feed, and for food in general. Based on the obtained LOD limits, LOQ limits according to the needs of **Commission Regulation (EC) no. 1881/2006** were obtained. LOQ limits were recalculated from $mg.L^{-1}$ (LOD) to $mg.kg^{-1}$ based on the sample weight and the final volume of the digest. The quality control (QC) during measurement was ensured by a parallel analysis of at least one sample and the method calibration was controlled before every measurement by the control sample from the calibration solution of certified reference material (CRM). The solution was prepared by diluting a standard solution (Ultra Scientific, USA) with a certified value of 1000 $mg.L^{-1}$ (multi-element solution).

Table 1 LOD and LOQ values for essential and toxic elements analysed.

Element	LOD ($mg.kg^{-1}$)			LOQ ($mg.kg^{-1}$)		
	milk	feed	soil	milk	feed	soil
Ca	2.0	2.0	2.3	6.0	6.0	7.0
Cu	0.017	0.17	0.3	0.05	0.50	1.0
Fe	0.17	0.17	3.0	0.50	0.50	10.0
Mg	0.33	0.33	0.3	1.0	1.0	1.0
Se	0.0067	0.017	0.06	0.03	0.050	0.20
Zn	0.17	0.17	2.0	0.50	0.50	6.0
As	0.01	0.017	0.06	0.03	0.050	0.20
Cd	0.0013	0.0067	0.13	0.0040	0.10	0.40
Hg	0.00067	0.0033	0.003	0.002	0.010	0.010
Ni	0.03	0.033	0.8	0.10	0.10	2.5
Pb	1.0	0.033	1.0	0.01	0.10	3.0

A standard from a different supplier was used to prepare the QC sample, and then the standard was used to prepare the calibration solutions.

The accuracy of the method, CRM, skimmed milk powder (ERM-BD151) was analysed for the determination of elements in milk, CRM, poultry feed-proximates and elements (LGC7173) and pig feed (BCR-709) for elements in feed and quality control material (CQM) river sediment (Metranal TM 1) for elements in soil samples.

Statistical analysis

Statistical analysis of the data was performed using SAS 9.2 (SAS Institute Inc., USA). Differences in concentrations of the analyzed elements in feed, soil, and cow's milk between seasons and three investigated areas were compared by the ANOVA and Student's t-test. All data were expressed as mean, standard deviation, and coefficient of variation. A probability level of $p < 0.05$ was considered statistically significant.

RESULTS AND DISCUSSION

Except of Cu and Se, all analysed essential elements were present in all milk samples (Table 2). The significantly highest Ca concentration was found in the undisturbed area of Novoť in spring and summer in comparison to the other two areas. Significantly lowest Ca concentration in spring was found in milk from the Tulčík area ($p < 0.01$), in summer and autumn in the Čečejovce area ($p < 0.001$ and $p < 0.05$, respectively). The effect of season on Ca concentration in cow milk is contradictory in the literature. **Lin et al. (2017)** reported that season had no significant effect on total Ca in milk. Also, **Chassaing et al. (2016)** did not confirm the seasonal changes of mineral contents in cow milk. The concentrations of Ca in cow milk vary and ranged from 1203.5 to 1316.1 mg.kg^{-1} **(Toffanin et al., 2015)**, 1043 – 1283 mg.kg^{-1} **(Gaucheron, 2005)**, 1409.86 – 2156.45 mg.kg^{-1} **(Pilarczyk et al., 2013)** up to 3789.7 mg.L^{-1} **(Capcarova et al., 2019)**, and in our analyses, they ranged from 981 mg.kg^{-1} (Tulčík in spring) to 1930 mg.kg^{-1} (Novoť in summer). Moreover, **Toffanin et al. (2015)** found that Ca milk content decreased between March and May. Similar trends in Ca milk concentration were found in our analyses and are supported by findings of **Hurtaud et al. (2014)** and **Poulsen et al. (2015)**. **Boudon et al. (2016)** suggest that long and sunny days could explain part of the seasonal decrease in milk Ca content in summer.

Significantly lowest Fe concentration in milk was found in the Čečejovce area in spring ($p < 0.01$) and in autumn ($p < 0.05$). Significantly lowest Mg concentration was found in Tulčík in spring and summer ($p < 0.001$) and in Čečejovce in autumn ($p < 0.01$). The highest Mg concentration was found in Tulčík during the autumn season ($p < 0.001$) in comparison to the undisturbed area of Novoť, where the Mg concentration was lowest in autumn. The same and lowest Zn concentrations in milk were recorded around Tulčík and Čečejovce with a significant decrease in spring ($p < 0.001$). In summer, the lowest Zn concentration was found in the Tulčík area ($p < 0.01$) and in autumn in the Čečejovce area ($p < 0.01$). In the previous study, **Pšenková et al. (2020)** detected in the strongly disturbed environment of the Čečejovce area in 2016 only Ca, Mg, and Zn in the cow milk. In our study, the Ca, Mg, and Zn concentrations were about 2 – 3 times higher. High level of variability in the Ca, Cu, Fe, Na, Ni, and Zn contents in cow milk found **Capcarova et al. (2019)** in Slovakia (SK) and Czech Republic (CZ). The concentrations of observed elements in SK and CZ milk built an order of increasing concentrations: Ni <Cu <Fe <Zn <Mg <Na <K<Ca. The same trend was observed in our experiments, no matter the season and area. A similar concentration of Zn in cow milk was found by **Wiking, Larsen and Sehested (2008)**, **van Hulzen et al. (2009)**, **Stocco et al. (2019)**. The Mg concentrations in milk were in the normal range 97 – 146 mg.kg^{-1} as described **Gaucheron (2005)** with slightly higher levels in summer (154 – 164.2 mg.kg^{-1}) in all areas. Similar results recorded **Pilarczyk et al. (2013)** at an organic farm in Poland. The concentrations of essential elements in milk from all areas were in the normal range meaning there was no obvious contamination. A different situation was recorded in Egypt. The analyses of Fe (16.38 mg.kg^{-1}), Zn (10.75 mg.kg^{-1}), and Cu (2.83 mg.kg^{-1}) showed that most of the cow milk samples from the different sites contained all the studied metals with a concentration higher than those recommended for milk by the international dairy federation standard and Codex **(Malhat et al., 2012)**. The element with the highest frequency of occurrence in cow milk in Turkey was Zn, followed by Cr = As >Al >Se >Fe >Ni >Cu >Pb = Cd, in decreasing order. The lowest concentration among the essential elements was seen in Cu. Al and As were very often found but Pb and Cd were not found in the milk samples **(Totan and Filazi, 2020)**. In our samples, the lowest concentration of the essential elements was found in Fe in the range of 0.404 – 0.626 mg.kg^{-1} aside from the season and area. On the contrary, average concentrations of Fe in all samples of milk analyzed in Palestine were the highest (2.01 – 3.86 mg.kg^{-1}) **(Abdulkhaliq et al., 2012)**. In our study, the concentrations of toxic and potentially toxic elements (As, Cd, Ni, Hg, Pb) in cow milk from all analyzed areas and in any season were under the LOQ (Table 1). It is important information due to the toxic nature of these elements. The milk from the investigated areas was not contaminated with the elements posing a health risk for consumers and it is considered safe for human consumption. In contrast, **Pilarczyk et al. (2013)** found Pb content in the milk of cows of two breeds two times higher than the permissible concentration of 0.02 mg.kg^{-1} in the raw milk given by the standards of the **Commission Regulation (EC) no. 1881/2006**. **González-Montaña et al. (2019)** also found some of the metals in milk (aluminium – Al, As, Mo) in the area with various anthropogenic activities (industrial, mining, traffic density). **Datta et al. (2012)** warned that consumption of milk from the contaminated areas might have produced arsenicosis and may be considered as an alternative source of arsenic contamination. Milk samples collected from the nonindustrial region of Turkey in the summer had higher Cr, Mn, and Zn concentrations than the polluted region. However, industrial activities and seasonal changes had no significant effect on selected element concentrations on cow milk **(Erdogan, Celik and Erdogan, 2004)**. **Qu et al. (2018)** found relative high toxic metal levels from provinces with heavy industry. The average of milk exposure concentration for As, Pb, Cr, Hg, Al, and Ni was 1.35, 8.50, 34.58, 2.31, 284.16, and 10.78 μg.L^{-1}, respectively. Ni in milk is accumulated in fat.

This probably essential element was found in cow milk from Turkey in a concentration of 8.71 μg.kg^{-1} **(Totan and Filazi, 2020)** and from Spain 4 – 25 μg.kg^{-1} **(Llorent-Martínez et al., 2012)**.

The occurrence of contaminants in animal milk is connected with environmental quality. Metals are transferred from soil to water and/or feed to milk. **Zhou et al. (2019b)** note that different kinds of heavy metal contamination in raw milk may travel through complex pathways from the environment, directly or indirectly, via drinking water and soil. Heavy metals in silage may be the main contributor to milk contamination, as Pb, As, Cr, and Cd in silage all showed positive correlations with those in milk. The authors found that water may be the source of Pb and As in the milk, while Cr and Cd are transferred from the soil. The levels of elements in soil samples are shown in Table 3. The highest level of Ca, Cu, and Ni in soil was recorded in the strongly disturbed environment of the Čečejovce area. The source of metals may be an industrial activity (steel production, mining, waste combustion). The concentrations of Pb, Hg, Cd, As, Cu in the soil in this area exceeded the maximum limits in 2016 **(Juhasová et al., 2017)**. However, the concentrations of those metals

Table 2 Concentrations of essential and toxic elements in cow's milk in spring, summer and autumn in different environment.

Element	Undisturbed area (mg.kg^{-1} ±SD)	Moderately disturbed area (mg.kg^{-1} ±SD)	Strongly disturbed area (mg.kg^{-1} ±SD)

Note: *SD* – standard deviation; [a]differences between undisturbed area and moderately disturbed area; [b]differences between undisturbed area and strongly disturbed area; [c]differences between moderately disturbed area and strongly disturbed area; **p* <0.05; ***p* <0.01; ****p* <0.001; [1]Values below LOQ (limit of quantification).

recorded in our analyses were much lower or not detected (Cd).

Cd was also not detected in any of the milk samples collected dairies in the proximity of mines in Gauteng and North West Provinces of South Africa. This indicates the absence of Cd related toxicological risks in studied dairy farms **(Ataro et al., 2008)**. Arsenic concentration in soil samples was significantly highest (p <0.001) in the Tulčík area, Hg and Pb were found highest (p <0.001) in the Novoť area, Ni was significantly highest (p <0.001) in the Čečejovce area. The detailed biological cycle which causes the uptake of trace elements from the feed into milk or other dairy products is not well understood **(Herwig et al., 2011)**. **Rey-Crespo et al. (2013)** assume that the significantly higher As (65%) and Fe (13%) concentrations in cow milk found in the winter is probably related to higher consumption of concentration feed and soil ingestion when grazing. **Zhou et al. (2017)** also note that toxic and potentially toxic elements in raw milk were associated with those in feed and drinking water. Trace elements Mn, Fe, Ni, Ga, Se, Sr, Cs, U in water and Co, Ni, Cu, Se, U in feed were significantly correlated with those in milk. Moreover, the toxic and potentially toxic elements Cr, As, Cd, Tl, Pb in water and Al, Cr, As, Hg, Tl in feed were significantly correlated with those in milk. An analysis of cow's feed and milk at wastewater-irrigated agricultural farms in Pakistan revealed that contaminated fodder like maize and Brassica plants grown with wastewater and contaminated soil are common sources contributing the heavy metal contamination in raw milk **(Iqbal et al., 2020)**. Pb, Fe, Cu, and Zn were higher in the milk samples collected from the industrial region around Bursa, a province of Turkey, but no Hg was detected **(Simsek et al., 2000)**. Surprisingly, the TMR feed from strongly disturbed area contained significantly lowest concentrations (p <0.001) of all detected toxic and potentially toxic elements (As, Ni, Pb) in our analyses in spring. In autumn, the concentrations of these metals in feed were slightly higher in the Čečejovce area than in spring, but not the highest among the investigated areas. On the contrary, the „cleanest" area, officially classified as an area with an undisturbed environment, contained significantly highest (p <0.001) levels of As in spring and Pb (p <0.001) in spring and autumn in the feed. The occurrence of toxic metals in soil and feed did not affect their levels in cow milk as their concentrations in milk from all observed areas were under the LOQ. The concentrations of As in soil decreased in the order: moderately disturbed > undisturbed > strongly disturbed area. The same order was recorded in the feed in spring. The concentrations of Pb in soil and feed decreased in the same order: undisturbed > moderately disturbed > strongly disturbed area. The Ni concentration in soil in spring decreased in the order: strongly disturbed > undisturbed > moderately disturbed area, but in the feed, it decreased as follows: undisturbed = moderately disturbed > strongly disturbed area. The Hg concentration in soil in spring decreased in the order: undisturbed > strongly disturbed > moderately disturbed area but Hg in feed was under LOQ both in spring and autumn. These results confirm the variability of feed and soil contamination in different areas. Variable concentrations of Al, As, Ni, Hg, Pb, and Cd among most of the investigated regions of Egypt reported **Diab et al. (2020)**. The reason for these differences is probably different soil accumulation characteristics for different metals. Different soil accumulation characteristics for Cd, Cu, Zn, Pb, Ni, and Cr found **Zhang et al. (2018)**. Anyway, **Vidovic et al. (2005)** found a direct influence of atmospheric deposits on Cd and Zn distribution in the chain soil-cattle feed-milk. A significant decrease of the Cd and Zn concentrations in atmospheric deposits, originated mostly from vehicle traffic, resulting in a decrease of these metals in cow's feeds, milk, and soil in the Kikinda region, Serbia.

The concentrations of elements in feed analysed in three different regions are summarized in Table 4. Significant increases in milk Se concentration were observed with an increasing level of Se in the diet of cows and thus the concentration of Se in bovine milk is related to Se concentration in the feed **(Givens et al., 2004; Haug, Høstmark and Harstad, 2007)**. The Se content in the soil in Slovakia and Central Europe is generally low **(Ducsay, Ložek and Varga, 2009; Sager, 2006)** but there is a difference between the regions and soil types.

Table 3 Concentrations of essential and toxic elements in soil in spring in different environment.

Element	Undisturbed area (mg.kg^{-1} ±SD)	Moderately disturbed area (mg.kg^{-1} ±SD)	Strongly disturbed area (mg.kg^{-1} ±SD)

Note: *SD* – standard deviation; [a] differences between undisturbed area and moderately disturbed area; [b]differences between undisturbed area and strongly disturbed area; [c]differences between moderately disturbed area and strongly disturbed area; *p <0.05; **p <0.01; ***p <0.001; [1]Values below LOQ (limit of quantification).

In Slovakia, the Se content in soil ranges from 0.04 to 0.80 mg.kg^{-1} but in the Nitra region, Se soil concentration exceeded the limit value 1.25-times **(Hegedusova et al., 2016)**. Our results (0.18 – 0.308 mg.kg^{-1}) show that Se in soil from all observed regions was in the range of average levels of Se in Slovakia. Very low (under the LOQ) concentrations of Se in milk is also caused by the low transfer of Se from soil to feed. In TMR feed, the Se concentrations were about 10-times lower than that in the soil in spring and slightly higher (up to 0.336 mg.kg^{-1}) in autumn. A similar trend was recorded in Cu concentration. Despite the fact, that Cu was under the LOQ in milk, we have found Cu in soil and feed samples from all investigated areas. The significantly highest Cu levels in soil were found in the strongly disturbed area in comparison to moderately disturbed (p <0.001) and undisturbed area (p <0.01). In feed, the significantly highest Cu concentration (p <0.001) was found in a moderately disturbed environment in spring and autumn in comparison to the undisturbed area. The limit value for soil varies by the soil type from 30 to 70 mg.kg^{-1} **(Regulation no. 508/2004)**. The concentration of Cu in the soil in Slovakia is 17 mg.kg^{-1} and at the cinnabar mine site, it ranges from 20.7 to 24.9 mg.kg^{-1} **(Kulikova et al., 2019)**. Our results are comparable to these values found in the country.

Soil Fe levels are not limited in Slovakia. Relatively high Fe concentrations were found in soil samples from all observed areas with significantly highest (p <0.001) concentration in the undisturbed area. **Khan et al. (2011)** reported a non-significant effect of sampling periods on soil Fe content, however, a higher transfer of Fe to pastures was found during October. Iron feed levels were higher in autumn in comparison to spring samples. The significantly highest (p <0.001) concentrations were found in the undisturbed area in spring and a moderately disturbed environment in autumn. Soil-derived elements like Fe may be ingested during grazing **(Orjales et al., 2018)** but we did not find an increase in Fe milk concentration above the normal levels.

Concentrations of Mg in soil did not differ between the spring and fall and ranged depending on the depth from 390 to 426 mg.kg^{-1} **(Hristov, Hazen and Ellsworth, 2007)**. About 10-times higher concentrations of Mg in soil samples were found in our study. The significantly highest (p <0.001) Mg level in soil was recorded in the moderately disturbed area in comparison to the undisturbed area of Novoť. Much higher concentrations of Mg (33.8 – 38.4 g.kg^{-1}) were found in contaminated soil at a magnesite mining region in China **(Wang et al., 2015)**. Concentrations of Mg in the soil are not limited in Slovakia. The feed contained generally higher Mg levels in autumn with the significantly highest levels in the moderately disturbed area which is in accordance with Mg levels in the soil. Plant Mg content in plant feeds varies between 0.7 and 3 g.kg^{-1} **(Haaranen, 2003)**. Our analyses show that the cow's feed contained around 3 g.kg^{-1}.

Table 4 Concentrations of essential and toxic elements in feed in spring and autumn in different environment.

Element	Undisturbed area (mg.kg^{-1} ±SD)	Moderately disturbed area (mg.kg^{-1} ±SD)	Strongly disturbed area (mg.kg^{-1} ±SD)

Note: *SD* – standard deviation; [a]differences between undisturbed area and moderately disturbed area; [b]differences between undisturbed area and strongly disturbed area; [c]differences between moderately disturbed area and strongly disturbed area; *p <0.05; **p <0.01; ***p <0.001; [1]Values below LOQ (limit of quantification).

These concentrations agree with the soil Mg levels and did not cause the elevation of Mg in raw cow milk.

Zn concentration in bovine milk is significantly affected by the dietary intake of fat and the transfer of fat from diet to milk might facilitate the transfer of Zn from diet to milk. **(Wiking, Larsen and Sehested, 2008)**. The authors also found a similar trend in the variability of Zn levels in the feed as we have found in our analyses. The significantly highest (p <0.001) Zn concentration in feed was found in spring and autumn in a moderately disturbed area and in a strongly disturbed area. These findings may correspond to the mining and industrial (metallurgy) activities in these areas and using of pesticides containing metals like Zn. Mean Zn concentrations in soil in the cinnabar mining site in Slovakia found by **Kulikova et al. (2019)** ranged from 58.1 to 61.6 $mg.kg^{-1}$, which are comparable to levels in disturbed areas in our study. However, the limit value for soil Zn by the soil type ranges from 100 to 150 $mg.kg^{-1}$ **(Regulation no. 508/2004)** and our results show Zn levels in the soil below the lowest permitted limit in disturbed areas. On the contrary, the significantly highest (p <0.001) Zn concentration in soil was found in the undisturbed area. The concentrations of Zn in soil and feed do not correspond. Lower levels of Zn in soil recorded **Khan et al. (2006)** in Pakistan, but **Baranowska, Barchańska and Pyrsz (2005)** found Zn content in the soil in the higher range of 9.15 – 424.5 $\mu g.g^{-1}$ in Poland.

CONCLUSION

The positive findings of this study are, that the concentrations of all toxic elements in milk were under the limits of quantification from all investigated areas regardless of the environmental contamination level. We found seasonal variations in occurrence of essential elements with the highest levels in summer. The significantly highest levels of some elements in soil were recorded in the undisturbed environment. In feed, the higher concentrations almost all elements were found in the autumn. Higher levels of some elements in soil did not cause their elevation in the feed and milk. The milk from the investigated areas was not contaminated with the elements posing a health risk for consumers and it is considered safe for human consumption. Despite the fact, that all concentrations of analyzed elements were under the permissible limits, there is a constant need to monitor an environmental burden of metals in the different, even undisturbed regions of Slovakia with animal production to recognize another, hidden sources of metal contamination that may impact the food chain and human health.

PROCEDURES FOR THE IDENTIFICATION AND DETECTION OF ADULTERATION OF FISH AND MEAT PRODUCTS

Jozef Čapla, Peter Zajác, Jozef Čurlej, Ľubomír Belej, Miroslav Kročko, Marek Bobko, Lucia Benešová, Silvia Jakabová, Tomáš Vlčko

ABSTRACT

The addition or exchange of cheaper fish species instead of more expensive fish species is a known form of fraud in the food industry. This can take place accidentally due to the lack of expertise or act as a fraud. The interest in detecting animal species in meat products is based on religious demands (halal and kosher) as well as on product adulterations. Authentication of fish and meat products is critical in the food industry. Meat and fish adulteration, mainly for economic pursuit, is widespread and leads to serious public health risks, religious violations, and moral loss. Economically motivated adulteration of food is estimated to create damage of around € 8 to 12 billion per year. Rapid, effective, accurate, and reliable detection technologies are keys to effectively supervising meat and fish adulteration. Various analytical methods often based on protein or DNA measurements are utilized to identify fish and meat species. Although many strategies have been adopted to assure the authenticity of fish and meat and meat a fish products, such as the protected designation of origin, protected geographical indication, certificate of specific characteristics, and so on, the coverage is too small, and it is unrealistic to certify all meat products for protection from adulteration. Therefore, effective supervision is very important for ensuring the suitable development of the meat industry, and rapid, effective, accurate, and reliable detection technologies are fundamental technical support for this goal. Recently, several methods, including DNA analysis, protein analysis, and fat-based analysis, have been effectively employed for the identification of meat and fish species.

Keywords: food fraud; adulteration; detection method; protein technologies; DNA technologies

INTRODUCTION

At present, there is no harmonized definition of food fraud in the European Union (EU) 2017. However, it is commonly accepted that the term 'food fraud' covers any violation of food law that is an intentional and deceptive misrepresentation of food for financial gain **(van Ruth et al., 2017; EC, 2019.** Food fraud is about "any suspected intentional action by businesses or individuals to deceive purchasers and gain undue advantage therefrom. **Spink and Moyer (2011)** have elaborated on this definition and describe seven types of food fraud: adulteration, tampering, over-run, theft, diversion, simulation, and counterfeit. These intentional infringements to the EU agri-food chain legislation may hinder the proper functioning of the internal market and may also constitute a risk to humans. However, existing databases that monitor food fraud Such as the Rapid Alert System for Food and Feed (RASFF) and HorizonScan have their categorizations **(Bouzembrak et al., 2018)**. RASFF has six categorizes for fraud (Improper, fraudulent, missing or absent health certificates; illegal importation; tampering; improper, expired, fraudulent or missing common entry documents or import declarations; expiration date; mislabeling) as does HorizonScan (adulteration/substitution, fraudulent health certificate/documentation, produced without an inspection, unapproved premises, expiry date changes). Four key operative criteria are referred to for distinguishing whether a case should be considered as fraud or as non-compliance: if a case matches all four criteria, then it could be considered a suspicion of fraud: violation of EU rules, deception of customers, undue advantage and intention. Meat and fish are food categories that are highly vulnerable to adulteration. Although there are various national and international laws for supervising the quality and safety of fish, meat, and meat and fish products, meat adulteration is still widespread. Most meat adulteration is economically motivated, such as the low-cost addition of duck meat and fish to mutton **(Wang et al., 2019a),** which causes consumers to suffer economic losses. Meat and fish adulteration may lead to serious public health risks, such as exposure to toxins, pathogens, or allergens in these products **(Magiati et al., 2019; Spink and Moyer, 2011)**.

MEAT AND FISH ADULTERATIONS

The demand for meat and fish products is high and as a result, meat is one of the most highly-priced food commodities; therefore, a prime target for food fraud **(Cawthorn et al., 2013)**. The examples of adulteration are presented in Table 1.

Table 1 Scholarly reports on fish and meat ingredient fraud and analytical methods for detection.

Ingredient Category	Ingredient	Adulterant	Type of fraud	Publictation year	Reported detection method and reference
Meats	Chicken meat (cornfed)	Chicken meat fromnon cornfed chickens	Replacement	2010	IRMS (13C/12C) on extracted protein and lipid fractions of meat **(Rhodes et al., 2010)**
Meats	Meat products	Chickpea flour	Replacement	2009	HPLC for isoflavones, phytic acid, and galactooligosaccharides (adulterant markers) **(Vanha et al., 2009)**
Meats	Meat products	Pea flour	Replacement	2009	HPLC for isoflavones, phytic acid, and galactooligosaccharides (adulterant markers) **(Vanha a et al., 2009)**
Meats	Meat products	Rice flour	Replacement	2009	HPLC for isoflavones, phytic acid, and galactooligosaccharides (adulterant markers) **(Vanha et al., 2009)**
Meats	Meat products	Soy flour	Replacement	2009	HPLC for isoflavones, phytic acid, and galactooligosaccharides (adulterant markers) **(Vanha et al., 2009)**
Meats	Minced meat (beef)	Ox offal tissue (kidney or liver)	Replacement	1999	MIR with chemometrics **(Al-Jowder et al., 1999)**
Meats	Minced meat (chicken, pork, or turkey)	Meat from non-authentic species	Replacement	1999	MIR with chemometrics **(Al-Jowder et al., 1999)**
Meats	Processed meat product	Soybean protein	Replacement	2005	Perfusion reversed phase chromatography with UV detection on extracted protein for adulterant marker detection **(Castro- Rubio et al., 2005)**
Seafood	Anglerfish	Anglerfish of non-authentic species	Replacement	2008	Review of methods: HPLC-MS/MS, ELISA, dients ed compounds extractive electrospray ionization timeofflight MS, and GC-MS **(Tittlemier, 2010)**
Seafood	Canned tuna	Bonito (*Euthynnus affinis*)	Replacement	1996	Sequence and restriction site analysis of PCR mitochondrial DNA **(Ram, Ram and Baidoun, 1996)**
Seafood	Canned tuna	Frigate mackerel (*Auxis thazard*)	Replacement	1996	Sequence and restriction site analysis of PCR mitochondrial DNA **(Ram, Ram and Baidoun, 1996)**

Table 1 Scholarly reports on fish and meat ingredient fraud and analytical methods for detection. Continue.

Ingredient Category	Ingredient	Adulterant	Type of fraud	Publictation year	Reported detection method and reference
Seafood	Crab (species specific)	Crustacean of non- authentic species	Replacement	2007	UV-Vis spectrometry with chemometrics **(Gayo and Hale, 2007)**
Seafood	Crab meat	Surimi-based artificial crab meat	Replacement	2006	UV-Vis spectrometry with chemometrics **(Gayo and Hale, 2006)**
Seafood	Eel	Fish of non-authentic species	Replacement	2008	DNA based method using fluorogenic ribonuclease protection assay to detect single nucleotide polymorphisms **(Kitaoka et al., 2008)**
Seafood	Fish	Melamine	Replacement	1982	Wet-chemical method with UV detection **(Cattaneo and Cantoni, 1982)**
Seafood	Fish	Non-authentic species	Replacement	2001	Isoelectric focusing electrophoresis for protein fingerprinting **(Etienne et al., 2001)**
Seafood	Grouper (*Epinephelus guaza*)	Wreck fish (*Polyprion americanus*) or Nile rRNA gene by PCR followed by single perch (Lates strand conformational polymorphism niloticus)	Replacement	2001	DNA analysis using mitochondrial 12S rRNA gene by PCR followed by single strand conformational polymorphism analysis **(Asensio et al., 2001a)**
Seafood	Prawns	Crustacean of non-authentic species	Replacement	2008	PCR **(Pascoal et al., 2008)**
Seafood	Scampi (*Neplirops norvegicus*)	Crustacean of non-authentic species	Replacement	1995	SDS electrophoresis on protein extract **(Craig, Ritchie and Mackie, 1995)**

Uncovering of adulterated meat products is important for several reasons. Allergic individuals and those who hold religious beliefs that specify allowable intake of certain species have a special interest in proper labeling. Proper labeling is also important to help fair-trade. The need for analytical species-specific methods is clearly illustrated by the following examples: **Hsieh, Chai and Hwang (2007)** found, with the use of immunoassays, meat from undeclared animal species in 15.9% of cases in raw products and 22.9% of cases in cooked products analyzing a total of 902 meat products. In a more recent investigation performed on 100 meat products, also with the use of immunoassays, meat from undeclared species was found in 22.0% of cases, primarily with poultry substituting beef **(Ayaz et al., 2006)**. The provenance of food, especially meat products, is a sensitive topic but there are tools available to support producers in demonstrating compliance with legislators and other authorities. Since the level of awareness about food quality and safety has recently increased, food fraud has become a major global issue. Hence, the identification of meat and fish products adulteration with unfavorable and inappropriate animal species is important from health, economic, and religious points of view **(Mousavi et al., 2015)**. Currently, the protein-based techniques (e.g. electrophoresis, isoelectric focusing, ELISA, and chromatography) have been utilized for meat and fish adulteration. These methods are laborious, expensive, and sophisticated instrumentation

with great technical proficiency **(Calvo et al., 2002, von Bargen et al., 2014)**.

Numerous analytical techniques which rely on protein analysis have been developed for fish species identification: electrophoretic techniques such as isoelectric focusing or SDS-PAGE **(Ataman, Celik and Rehbein, 2006, Mackie et al., 2000)**; chromatographic techniques **(Horstkotte and Rehbein, 2003, Knuutinen and Harjula, 1998)** and immunological techniques such as immunodiffusion and ELISA **(Fernández et al., 2002a, Ochiai et al., 2001)**. Therefore, the development of advanced detection methods constitutes an important first line of defense for both detecting and deterring food fraud **(Moore, Spink and Lipp, 2012)**. Although most of these methods are of considerable value in certain instances, they are not suitable for routine sample analysis because proteins lose their biological activity after animal death, and their presence and characteristics depend on the cell types. Furthermore, most of them are heat-labile. Thus, for fish species identification in heat-processed matrices, a DNA method rather than protein analysis is preferable **(Lockley and Bardsley, 2000)**.

DNA TECHNOLOGIES

As a prerequisite for accurate species quantification, DNA has to comply with minimum requirements about yield, purity, and integrity. Yield is an important parameter since food DNA has to be in a sufficient amount to allow the reliable and repeatable downstream analysis of meat species **(Heydt et al., 2014)**. The concentration and purity of DNA extracts are critical factors dominating the results of real-time PCR. DNA quantification is typically measured by either spectrophotometric or fluorometric methods, with the former representing the most commonly used technique **(Costa et al., 2017)**. DNA integrity determines the fraction of DNA that can be amplified by PCR **(Gilbert et al., 2007)** and it can be evaluated based on the average size distribution of fragmented DNA. Although often underestimated, DNA isolation is a crucial step for molecular analysis of food due to its heterogeneity in terms of composition and processing. The presence of chemical inhibitors, proteins, and/or damaged DNA are common situations in meat food analyses. Moreover, the extraction methods themselves can further influence the yield, purity, and integrity of DNA depending on the type of food matrix **(Şakalar et al., 2012)**. The final consequence is that the amount of species DNA determined in the product would not reflect the real amount in the source material, impairing quantitative measurements **(Primrose et al., 2010)**. DNA exists in all tissues of individual animals and is more conserved than proteins **(Kumar et al., 2015; Xiang et al., 2017)**. More importantly, DNA fragments have shown better thermal stability than that of proteins in processed meat, so they could be chosen as markers for authenticity determination in processed meat **(Kaltenbrunner, Hochegger and Cichna-Markl, 2018; Kang and Tanaka, 2018; Kumar et al., 2015; Ruiz-Valdepeñas Montiel et al., 2017; Xu et al., 2018)**. Of the different DNA markers used for fish species identification, mitochondrial DNA (mtDNA) possesses several advantages over nuclear DNA for studies of speciation in fish products. It is relatively more abundant in total nucleic acid preparations than nuclear DNA, with the copy number of the mitochondrial genome exceeding that of the nuclear genome several folds **(Alberts et al., 1994)**. Research on fish mitochondrial DNA (mtDNA, mitogenome) has led to substantial advances in the fields of species authentication and population biology **(Miya et al., 2001)**. Mitochondrial DNA tends to be maternally inherited so that individuals normally possess only one allele and thus sequence ambiguities from heterozygous genotypes are generally avoided. The relatively high mutation rate compared to nuclear genes has tended to result in the accumulation of enough point mutations to allow the discrimination of even closely related species. It should however be noted that mitochondrial DNA also exhibits a degree of intraspecific variability and so care has to be taken when studying differences between organisms based on single base polymorphisms **(Chow and Inogue, 1993)**. However, the use of nuclear markers may be useful for fish species discrimination because of the existence of introns of different sizes which allow sometimes the amplification of species-specific DNA fragments **(Ferguson et al., 1995)**. The comparative analysis of the commonly applied meat adulteration DNA techniques is present in Table 2.

Polymerase chain reaction-restriction fragment length polymorphism

Polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) is a technique for variation analysis by using restriction endonuclease digestion to identify specific sequences of conserved regions of DNA amplified by using PCR. PCR-RFLP is a sensitive, accurate, and versatile method for meat authenticity verification **(Hsieh, Chai and Hwang, 2007; Rashid et al., 2015)**, and more simple and time-saving than real-time PCR **(Ali et al., 2018)**. The result is that each meat species displays its typical restriction profile **(Fajardo et al., 2006)**. Several studies have demonstrated that LAMP might be a fast, efficient, and economical method for meat adulteration detection **(Azam et al., 2018; Cho et al., 2014; Deb et al., 2016; Ran et al., 2016; Sul, Kim and Kim, 2019; Wang et al., 2019b; Xu et al., 2017; Zhang et al., 2019)**. Using LAMP combined with colorimetric detection technology for the COI gene, 0.1% of horse meat could be detected from processed meats **(Wang et al., 2019a)**.

Loop-mediated isothermal amplification

Loop-mediated isothermal amplification (LAMP) is a newly developed meat adulteration identification technology based on DNA markers in recent years **(Lee et al., 2016; Zhang, Lowe and Gooding et al., 2014)**. LAMP is simple and easy to perform once the appropriate primers are prepared, requiring only four primers, a DNA polymerase, and a regular laboratory water bath or heat block for reaction **(Notomi et al., 2000)**.

PCR

The direct PCR method has the characteristics of high sensitivity, high resolution, and specificity, so it is commonly used in meat authenticity and origin traceability **(Bhat et al., 2016; Ha et al., 2017)**. **Ha et al. (2017)** developed species-specific PCR methods of the mitochondrial D-loop to detect pork adulteration in

commercial beef and/or chicken products, and the methods were able to detect as little as 1% pork in heat-treated pork-beef-chicken mixtures. However, the conventional single-species PCR method could only detect one specific species of adulterant in products **(Kumar et al., 2015)**, which is of low commercial value because there might be many other adulterants in the products. This method provides very accurate and reproducible quantitation of gene copies. Unlike other quantitative PCR methods, real-time PCR does not require post-PCR sample handling, preventing potential PCR product carry-over contamination and resulting in much faster and higher throughput assays **(Heid et al., 1996)**. Multiplex PCR assays with multiple species-specific primers have been greatly developed since they offer multiple target detection in a single reaction **(Ali et al., 2015; Böhme et al., 2019; Dai et al., 2015; Hou et al., 2015)**. PCR-SSCP has proved successful for the identification of fishery products such as salmon, trout, eel, and sturgeon **(Rehbein et al., 1997)**, canned tuna species **(Rehbein et al., 1999, Weder et al., 2004)**, flatfish species **(Céspedes et al., 1999)**, grouper, Nile perch and wreckfish fillets **(Asensio et al., 2001b)**, clam species **(Fernández et al., 2002b)** and codfish **(Comi et al, 2005)**, among others.

PCR-RFLP

In PCR-RFLP, a conserved region of the DNA sequence is amplified using PCR, followed by digestion with restriction enzymes, which can reveal genetic variation between species **(Partis et al., 2000)**. In a search for fast and simple genetic techniques, PCR-RFLP has gained acceptance among fish species identification methods, since it is much easier to perform and less costly than conventional DNA sequencing and nucleotide sequence analysis **(Meyer et al., 1995)**. This method has been used for the discrimination of mackerel species **(Arahishi, 2005)**, commercial canned tuna species **(Lin and Hwang, 2007, Pardo and Pérez-Villarea, 2004)**, eel species **(Rehbein et al., 2002)**, flatfish species **(Céspedes et al., 1998, Comesaña et al., 2003)**, cephalopod mollusks **(Colombo et al., 2002)**, or different processed fish products **(Akasaki et al., 2006, Chakraborty et al., 2007, Hsieh, Chai and Hwang, 2007)**.

Real-time PCR

Real-time PCR is performed by monitoring the fluorescence signal, which allows for deducing the initial quantity of the target genes without additional steps **(Xu et al., 2018)**. The real-time PCR method has a very large dynamic range of starting target molecule determination (at least five orders of magnitude). Real-time quantitative PCR is extremely accurate and less labor-intensive than current quantitative PCR methods **(Heid et al., 1996)**. SYBR Green and TaqMan technology are commonly used in quantitative methods (the working principle is outlined in the review of **Kumar et al., 2015**). SYBR Green technology can only detect a single species, but the detection cost was lower than that of TaqMan technology. **Li et al. (2019)** developed a novel reference primer-based mitochondrial 12S rRNA for the quantitative determination of goat meat adulterated with pork by using real-time PCR. The method showed high specificity and sensitivity for goat meat mixed with pork within the 10% to 100% mixture-level range. TaqMan technology has higher specificity and sensitivity than those of SYBR Green technology. More importantly, it can be used for multispecies detection **(Xu et al., 2018)**.

Droplet digital PCR

Droplet digital PCR (ddPCR) is a new method for nucleic acid detection and quantification. The principle of this method is to perform independent PCR on a large number of small reactors in the form of droplets that contain or do not contain one copy of the target molecule template in each reactor, to achieve "single-molecule template PCR amplification" **(Cai et al., 2017; Li et al., 2018a; Pohl and Shih Ie, 2004)**. After amplification, the number of copies of the target sequence can be counted by the number of positive reactors based on the fluorescence signal.

RAPD

The RAPD technique involves PCR amplification with a single primer to generate a collection of DNA fragments or fingerprint, which is expected to be consistent for the same primer, DNA, and conditions used **(Williams et al., 1990)**. This technique has been used for the discrimination of populations of Hilsa shad **(Dahle et al., 1997)**, species of Anguilla **(Takagi and Taniguchi, 1995)**, tilapia fish species and subspecies **(Bardakci and Skibinski, 1994)**, species of the genus Barbus **(Callejas and Ochando, 2001)**, grouper, Nile perch and wreckfish **(Asensio et al., 2002)**, salmonids **(Jin et al., 2006, Yamazaki et al., 2005)**, among others **(Dinesh et al., 1993, Partis and Wells, 1996)**. The main advantages of RAPD are (i) it does not require previous knowledge of DNA sequences of the species under study and (ii) it targets many sequences in the DNA of the sample, producing DNA patterns that allow comparison of many loci simultaneously. However, RAPD analysis presents some disadvantages: (i) it may not be practical to identify the species of origin in products containing mixtures of species **(Martínez and Malmheden Yman, 1998)** and (ii) it does not seem to be adequate for analysis of severely degraded material, as in autoclaved samples **(Martínez and Malmheden Yman, 1998)**.

DNA barcoding and next-generation sequencing

The above reviewed DNA-based technologies are mainly targeted detection methods, but in meat adulteration detections, many unknown meat species should be identified **(Cottenet et al., 2020)**. Following this need, an untargeted detection technology named DNA barcoding had been developed **(Cavin et al., 2018; Hebert et al., 2003)**. DNA barcoding is particularly successful when applied to seafood because of several reasons:

i) in comparison to other animal sources (e.g. cattle, sheep, goat, horse) the number of species is higher, so the effectiveness of the technique is enhanced;

Table 2 Comparative analysis of the commonly applied meat adulteration DNA techniques.

Techniques	Specificity	Sample preparation	Detection time	Multispecies detection	Operator requirements	Detection costs	Commercial availability	Application locations
Direct PCR	High but vulnerable	Sampling→smashing or ground→DNA extraction→ purification→ quantification	Time-consuming	Yes	Professional	High	Commercial kits available	Lab
Real-time PCR	High	Sampling→smashing or ground→DNA extraction→ purification→ quantification	Time-consuming	Yes	Professional	High	Commercial kits available	Lab
PCR-RFLP	High	Sampling→smashing or ground→DNA extraction→ purification→ quantification	Time-consuming	Yes	Professional	High	Commercial kits available	Lab
LAMP	High	Sampling→smashing or ground→DNA extraction→ purification→ quantification	Less time-consuming	Yes	Professional	High	Commercial kits available	Lab or onsite
Protein mass	High	Sample ground→ protein extraction→ purification→ digestion	Time-consuming	Yes	Professional	High	No	Lab
ddPCR	High	Sampling→smashing or ground→DNA extraction→ purification→ quantification	Less time-consuming	Yes	Professional	High	No	Lab
A barcoding	High	Sampling→smashing or ground→DNA extraction→ purification→ quantification	Less time-consuming	Yes	Professional	High	Public databases available (BOLD)	Lab
ELISA	High	Sample ground→protein extraction→ quantification	Less time-consuming	No	Simple training	Low	Commercial kits available	Lab or onsite
Protein immunosensor	High	Sample ground→protein extraction→ quantification	Less time-consuming	No	Simple training	Low	No	Lab or onsite

ii) classical identification approaches are not useful in many cases (following industrial processing, morphological characteristics are often lost and classical identification processes are no longer effective) and

iii) identification can often proceed beyond species level, allowing the identification of local varieties and hence the origin of the product. Through PCR amplification and sequencing of specific gene fragments, and then search it in the Barcode of Life Data (BOLD) system and the U.S. National Center for Biotechnology Information database, the adulterated meat species could be identified **(Fiorino et al., 2018)**. The early DNA barcoding technology mainly relied on Sanger DNA sequencing for an approximately 650 bp region of COI and the CtyB gene of the animal species **(Böhme et al., 2019)**. DNA Barcoding application can be applied to authenticate labeling and certification labels. This technique has aided several researchers in discovering mislabeled/substitution incidences, for example, **Filonzi, et al., (2010)** found halibut were substituted with pangasius However, when there are multiple adulterated ingredients in meat products, the traditional Sanger sequencing will generate multiple or overlaying sequencing peaks, resulting in false sequence information. Therefore, a DNA metabarcoding method had been constructed to implement multispecies identification in complex samples using next-generation sequencing (NGS) technology. Furthermore, for processed meat products, DNA can be degraded to small fragments (<200 bp) depending on the treatment **(Cavin et al., 2018)**. Thus, a mini-barcoding method, which focuses on shorter DNA fragments (100 to 200 bp), had been developed by using NGS technology **(Böhme et al., 2019; Hu et al., 2018)**. Compared to the early DNA barcoding technology, mini-barcoding has the advantages of higher throughput and higher sensitivity **(Böhme et al., 2019; Hu et al., 2019)**. Also, it is applicable for meat identification even on highly processed meat products when targeting small fragments **(Cottenet et al., 2020).** Recently, **Cottenet et al. (2020)** successfully applied a commercial NGS Food Authenticity Workflow to identify untargeted meat species, 46 pure and mixture meat species were successfully tested, including some close-related species, such as bison versus beef and red deer versus reindeer. Furthermore, the method was also suitable for processed (grounded, cooked, and canned) samples identification. However, DNA barcoding technology also has some disadvantages, such as expensive sequencing costs, time-, and sample-consuming **(Fiorino et al., 2018)**.

PROTEIN TECHNOLOGIES

Meat adulteration detection by using PCR methods is usually affected by many factors, such as poor trace quantitative analysis, sampling pollution, and DNA degradation in meat processing **(Di Pinto et al., 2015; Li et al., 2018a; Naveena et al., 2017)**. Moreover, DNA extraction is time-consuming and must be optimized for each particular case to ensure that enough DNA was obtained for the analysis **(Song et al., 2017)**. Protein is the main component of meat. The specific protein composition and three-dimensional structure of specific proteins have certain conservation and specificity between species, which is suitable for meat adulteration detection. Moreover, some protein molecules are tissue-specific and can be used for the identification of less valuable additives, such as connective tissue, blood plasma, or milk preparations **(Jiang et al., 2018; Montowska and Spychaj, 2018; Ofori and Hsieh, 2015)**. The comparative analysis of the commonly applied meat adulteration protein techniques is present in Table 3.

Enzyme-linked immunosorbent assay

EIA/ELISA uses the basic immunology concept of an antigen-binding to its specific antibody, which allows detection of very small quantities of antigens such as proteins, peptides, hormones, or antibodies in a fluid sample. There are two kinds of immunoassay techniques used in meat adulteration detection: enzyme-linked immunosorbent assay (ELISA) and immunosensors. ELISA is the most widely applied immunoassay method of meat adulteration detection **(Thienes et al., 2018)**. The commonly used ELISA methods for meat adulteration detection are direct ELISA **(Mandli et al., 2018; Seddaoui and Amine, 2020)**, sandwich ELISA **(Ayaz et al., 2006; Hsieh and Ofori, 2014; Thienes et al., 2018; Zvereva et al., 2015)**, and indirect competitive ELISA **(Hsieh and Ofori, 2014; Jiang et al., 2018; Mandli et al., 2018)**. Compared to DNA-based detection technologies, ELISA methods show the simplicity of sample preparation, low cost, and less time consumption. Also, ELISA detection does not require complex equipment and is easily feasible for onsite monitoring **(Mandli et al., 2018; Thienes et al., 2019)**.

Immunosensors

However, immune techniques are characterized by their simplicity of sample preparation, absence of the need for complex equipment and qualified personnel, and high productivity of serial testing. As well, for food authentication, electrochemical immunosensors are an alternative detection tool and are highly feasible for on-site usage; therefore, there is only one previously reported immunosensor for meat authentication **(Lim and Ahmed, 2016)**. The principle of immunosensor methods is similar to that of ELISA methods, but the former uses a biosensor to transmit and amplify the optical, electrical, or other signals of the immune response to a detectable signal, so the sensitivity of the method is better than that of ELISA. The immunosensor technique has been widely used in food allergy, pesticide residue, and milk adulteration analyses, among others. However, only a few reports have utilized immunosensing for meat adulteration detection **(Kuswandi et al., 2017; Lim and Ahmed, 2016; Mandli et al., 2018; Masiri et al., 2016)**.

Protein mass spectrometry analysis

Modern mass spectrometers can accurately measure thousands of compounds in complex mixtures over a given liquid chromatography method, depending on the desired outcome and method duration. This stream of analytical chemistry has wide-ranging applications across food, pharma, environmental, forensics, clinical, and research **(Broadbent et al., 2020)**. Recently, mass spectrometry technologies based on protein and peptide analysis have rapidly evolved and have been increasingly applied for meat species identification.

Table 3 Comparative analysis of the commonly applied meat adulteration protein techniques.

Detection items	Detection technology	Immunogen and antibody	Method sensitivity(limit of detection)	References
Pork adulteration in beef	Direct ELISA	Porcine immunoglobulins G (IgG) and polyclonal antibodies	0.01% (w/w) of pork in beef	**Seddaoui and Amine (2020)**
Pork adulteration in meat	Indirect competitive ELISA	Porcine IgG and polyclonal antibodies	0.1% of pork adulteration	**Mandli et al. (2018)**
Porcine hemoglobin in meat products	Indirect competitive ELISA	Mammalian hemoglobin 13F7 and monoclonal antibodies (MAbs 13F7)	0.5 ppm of P_{Hb}	**Jiang et al., (2018)**
Pork fat protein in other animal meats	Indirect ELISA	Thermal stable-soluble protein (TSSP) and monoclonal antibodies (MAbs PF 2B8-31)	1% (w/w) of pork fat adulteration	**Kim et al. (2017)**
Fat adulteration in cooked and noncooked of pork, beef, and chicken	Indirect ELISA	Skeletal muscle troponin I (smTnI) and monoclonal antibodies (commercial ab97427)	ND	**Park et al. (2015)**
Cooked wild rat meat in pork, beef, and chicken	Sandwich ELISA	Rat heat-resistant proteins and polyclonal antibodies	0.01 μg/L based OD values	**Chen et al., (2020)**
Heated mammalian meats adulterated in poultry meats	Sandwich ELISA	Mammalian skeletal troponin and monoclonal antibodies (MAbs 6G1 and 8F10)	1% (g/g) of heated meats adulterated in poultry meats	**Jiang et al., (2020)**
Cooked beef in the pork, horse, chicken, goat, and sheep meat	Sandwich ELISA	ND	0.1% (w/w) of the cooked products	**Thienes et al., (2019)**
Cooked chicken/turkey in pork, horse, goat, or sheep meat	Sandwich ELISA	ND	0.1% (w/w) of the cooked products	**Thienes et al., (2019)**
Pork is cooked horse, beef, chicken, goat, and lamb meats	Sandwich ELISA	ND	0.1% (w/w) for cooked samples	**Thienes et al. (2018)**
Wheat protein in ground chilled pork and beef mixture	Sandwich ELISA	Gliadin and monoclonal antibodies	1% (w/w) for spiked samples	**Petrášová et al. (2017)**
Soybean proteins in surimi products	Sandwich ELISA	Soybean trypsin inhibitor (STI) and monoclonal antibodies	13.6 mg/kg samples	**Jiang et al. (2015)**
Mammalian muscle tissues in raw meat and meat products	Sandwich ELISA	Skeletal muscle protein troponin I (TnI) and monoclonal antibodies	4.8 ng/mL of bovine TnI	**Zvereva et al. (2015)**
Pork adulteration in beef meatballs	Electrochemical immunosensor	Porcine IgG and polyclonal antibodies	0.01% of pork adulteration	**Mandli et al. (2018)**
Pork adulteration in cooked meatballs	Lateral flow immunosensor	Porcine IgG and polyclonal antibodies	0.1% (w/w) for pork in beef meatballs	**Kuswandi et al. (2017)**
Horse meat adulteration in meat products	Lateral flow immunosensor	Horse serum albumin (HSA) and polyclonal antibodies	0.01% and 1.0% adulteration for raw and cooked horse meat	**Masiri et al. (2017)**
Pork adulteration in raw meat	Label-free electrochemical immunosensor	Porcine serum albumin (PSA) and polyclonal antibodies	0.5 pg/mL PSA in buffer solution	**Lim and Ahmed (2016)**

Table 3 Comparative analysis of the commonly applied meat adulteration protein techniques. Continue.

Detection items	Detection technology	Immunogen and antibody	Method sensitivity(limit of detection)	References
Bovine adipose tissue in meat products	Label-free electrochemical immunosensor	Ruminant-specific muscle protein and polyclonal antibodies	2% bovine fat-in-pork fat 1% bovine fat-in-porcine meat-and-bone meal 0.5% bovine fat-in-soy meal mixtures	**Hsieh and Gajewski (2015)**
Duck, goose, and chicken in processed meat products	LC–ESI–QTOF–MS LC–ESI–QQQ–MS/MS	Hemoglobin alpha for duck: FMCAVGAVLTAK Hemoglobin beta for goose: FFSSFGNLSSPTAILGNPMVR Myosin-binding protein C for chicken: LDVPISGEPAPTVTWK	ND	**Fornal and Montowska (2019)**
Grain proteins adulteration into meat products	HPLC-MS/MS	Barley: IETPGPPYLAK, Oat: DFPITWPWK, Rice: ELGAPDVGHPMSEVFR, Rye: TPFASTVAGIGGQ, Wheat: SVAVSQVAR	Oats and rye: 5 mg/kg meat product; barley and wheat: 10 mg/kg meat product	**Jira and Munch (2019)**
Porcine blood plasma to emulsion-type pork sausages	UHPLC-MS/MS	Plasma peptide marker of ISEPLATETVR GSLDEFFHR, ISPLPDITPADFK, DPFPDFFSPVLK	0.7% (w/w) meat substitution by porcine plasma	**Stader et al., (2019)**
Shrimp species in seafood	SWATH-MS	Myosin heavy chain type a for *Marsupenaeus japonicas*: AAVELDDLHASAER Arginine kinase for *Fenneropenaeus Chinensis*: GTYYPLTGMGK Sarco/endoplasmic reticulum Ca^{2+}-ATPase for *Litopenaeus vannamei*: IGVFGENEETAGK	ND	**Hu et al. (2018)**
Pork, beef, lamb, chicken, duck, soy, peanut, and pea adulteration in meat products	UPLC-MS/MS	Conglutin/Ara h 6 for peanut: EIMNIPQQCNFR, Alpha subunit of beta conglycinin for soy: ESYFVDAQPK, P54 protein for pea: GIIGLVAEDR, Myoglobin for duck: HGVTVLTQLGK, Creatine kinase M-type for chicken: DLFDPVIQDR, Hemoglobin subunit beta for sheep: VDEVGAEALGR, Carbonic anhydrase 3 for beef: LVNELTEFAK, Hemoglobin subunit beta for pig: VNVDEVGGEALGR	0.5% adulterations of any of the eight species	**Li et al. (2018b)**
Horse, pork, and beef meat in smoked sausages	Infusion MS	Myosin-1 for pork: SALAHAVQSSR, Myoglobin for beef: HPSDFGADAQAAMSK, Myoglobin for horse: VEADIAGHGQEVLIR	5% (w/w) for pork and beef in the three-component matrix and 1% (w/w) for horse meat	**Montowska and Spychaj (2018)**

Table 3 Comparative analysis of the commonly applied meat adulteration protein techniques. Continue.

Detection items	Detection technology	Immunogen and antibody	Method sensitivity (limit of detection)	References
Duck, pig, cattle, chicken, and sheep in cooked meats	UPLC-TripleTOF-MS UPLC-MS/MS	M-protein, striated muscle for chicken: FWIQAESLSPNSTYR, Alpha-enolase for duck: LMLDMDGSENK, Trifunctional enzyme subunit alpha (mitochondrial) for pig: FAGGNLDVLK, Stress-induced-phosphoprotein 1 for bovine: ALDLDSNCK, Hemoglobin subunit beta for sheep: FFEHFGDLSNADAVMNNPK	ND	**Wang et al., (2019b)**
Pork gelatin adulteration in meat products	High-resolution MS	Type I collagen: TGETGASGPPGFAGEK, HGNRGEPGPAGSVGPAGAVGPR	0.1% (w/w) of undesired pork gelatin	**Yang et al., (2018)**
Buffalo, sheep, and goat meat in minced meat and meat products	MALDI-TOF MS	Myosin light chain 1 for sheep: EAFLLYDR, Myosin light chain 2 for buffalo: NMWAAFPPDVGGNVDYK, Myosin light chain 1 for goat: EAFLLYDR	1.0% for raw meat and 0.1% cooked samples	**Naveena et al. (2017)**
Chicken blood in sheep whole blood samples	Internal extractive electrospray ionization mass spectrometry (iEESI-MS)	Hemoglobin for blood samples, peptide marker Not determined	2% chicken blood in sheep blood	**Song et al. (2017)**
Water buffalo and sheep meat in raw and cooked ground meat mixtures	MALDI-TOF MS UPLC-QTOF	Myosin light chain 1 for sheep: EAFLLYDRTGDGK, Myosin light chain 2 for sheep: FSQEEIR; Myosin light chain 1 for sheep: EAFLLFDRTGECK, Myosin light chain 2 for sheep: FSKEEIK	0.5% (w/w) of buffalo meat in sheep meat	**Naveena et al. (2017)**
Beef and pork meat is highly processed food matrices	HPLC/ESI-MS/MS	Collagen a2-chain for beef: IGQpGAVGPAGIR, Collagen a2-chain for pork: TGQpGAVGPAGIR	2% pork meat in Bolognese sauce	**Prandi et al. (2017)**
Chicken, duck, and goose meat in processed meat products	Nano-LC-QTOF-MS/MS	Pyruvate kinase for chicken: EPADAMAAGAVEASFK, Alpha-enolase for duck: NYPVVSIEDPFDQDDWGAWK, Hemoglobin alpha-A for the goose: TYFPHFDLQHGSAQIK	1% (w/w) of chicken or pork in chicken, duck, and goose meat mixture, 0.8% (w/w) beef proteins in commercial poultry frankfurters	**Fornal and Montowska (2019)**
Meat adulteration in mammalian meat samples	Q Exactive Orbitrap LC-MS/MS	Myoglobin for pork: HPGDFGADAQGAMSK, Myosin-1 for horse: TLALLFSGPASADAEAGGK, Myosin-2 for beef: TLAFLFSGTPTGDSEASGGTK, β-Hemoglobin for lamb: FFEHFGDLSNADAVMNNPK, β-Hemoglobin for chicken: FFASFGNLSSPTAILGNPMVR	1% (w/w) of pork or horse meat in a mixture before and after cooking	**Orduna et al. (2017)**

Since the amino acid sequence of peptides is more stable than DNA during meat processing, they have an incomparable advantage in meat adulteration identification, especially for highly processed meat products and similar meat species **(Prandi et al., 2017)**.

CONCLUSION

Food adulteration occurs globally and in many facets and affects almost all food commodities. Adulteration not only constitutes a considerable economic problem but also may lead to serious health issues for consumers. Many of the methods for detection of food adulteration require elaborate steps of sample preparation before analysis involving high-end technologies and that makes the whole process difficult to perform and time-consuming. As the methods of adulterating foods have become more sophisticated, very efficient, and reliable techniques for the detection of fraudulent manipulations are required. The analytical techniques commonly used for meat and fish species identification can be broadly divided into protein-based and deoxyribonucleic acid (DNA)-based techniques. The protein-based methods include immunological assays, electrophoretic, and chromatographic techniques. These methods are fast and easy to perform and the investment in equipment is much less compared to DNA-based methods. Food chain transparency and full raw material traceability are primordial for an effective food fraud prevention system.

INVESTIGATING CHEMICAL CHANGES DURING SNAKE FRUIT AND BLACK TEA KOMBUCHA FERMENTATION AND THE ASSOCIATED IMMUNOMODULATORY ACTIVITY IN *SALMONELLA TYPHI*-INFECTED MICE

Elok Zubaidah, Vania Valencia, Muhaimin Rifa'i, Ignatius Srianta, Ihab Tewfik

ABSTRACT

This study uncovered the chemical changes during kombucha's fermentation process and revealed the associated immunomodulatory activity in *Salmonella typhi*-infected mice. The snake fruit juice and black tea extract were processed into kombucha (a beverage known for its health benefits) by fermentation with SCOBY culture at room temperature for 14 days. Snake fruit kombucha showed high changes in fermentation parameters (total acidity, pH, and total sugar), as well as bioactive compounds and antioxidant activity. *Salmonella typhi* demonstrated a reduction in the population of CD8+TNFα+ and CD4+IFNγ+ of infected experimental animals. Both snake fruit kombucha and black tea kombucha have the potential to be utilized as an immunomodulator to circumvent unstable conditions of the immune system caused by *Salmonella typhi*. Black tea kombucha and snake fruit kombucha cancan raise the production of CD8+TNFα+ and CD4+IFNγ+ in mice infected with *Salmonella typhi*. In the group of normal mice, black tea and snake fruit kombucha were able to lower down the production of CD8+TNFα+, which is a potent mechanism to modulate the immune system. Further research is required to highlight the mechanism and role of black tea kombucha and snake fruit kombucha in the immune response that modulates and treats infection by *Salmonella typhi*.

Keywords: kombucha; snake fruit; black tea; immunomodulator; *Salmonella typhi*

INTRODUCTION

Snake fruit (*Salacca zalacca* (Gaerth.) Voss) is a popular tropical fruit in South East Asian countries. In addition to its appetizing taste, snake fruit provides many health benefits due to its sugar content, dietary fiber, selected vitamins and minerals, and antioxidant compounds **(Aralas, Mohamed and Abu Bakar, 2009; Suica-Bunghez et al., 2016)**. In our previous studies, we demonstrated that snake fruits have the potential to be processed into Kombucha **(Zubaidah et al., 2018a)**.

Kombucha is a fermented tea beverage, black tea is commonly used which is fermented by a symbiotic culture of bacteria and yeast (SCOBY) **(Jayabalan et al., 2014)**. Kombucha has shown several beneficial effects, such as inhibit pathogenic bacteria growth **(Sreeramulu, Zhu and Knol, 2000)**, acts as an antioxidant, protects hepar, in addition to its anti-cancer property **(Dufresne and Farnworth, 2000)**. Furthermore, it reduces inflammation severity, prevents arthritis, and enhances the immune system as an 'immunomodulator' **(Jayabalan et al., 2014)**. An immunomodulator is a compound that can modulate the immune system, which is needed to overcome the unstable condition of health complications caused by antigen. Clinically, immunomodulation mechanisms are categorized as immunoadjuvant, immunostimulant, and immunosuppressant. On the other hand, instability in the immune system caused by bacterial invasion increases the occurrence of serious disease, e.g. typhoid **(Abbas, Lichtman and Pilai, 2007)**. *Salmonella typhi* is a pathogenic bacteria that causes typhoid fever – a serious health issue globally **(Crump, 2019; Thung et al., 2017)**. It spreads through non-hygienic consumption of water and food. The bacteria can invade gut mucosal through microfold cells and infects the area without resulting in any clinical symptoms. Lack of inflammation response caused a late treatment and worsened the condition of the patient **(Khan et al., 2012)**.

Studies reported that snake fruit kombucha can lower fasting blood glucose, increases superoxide dismutase, reduces malondialdehyde level, and promotes pancreatic beta-cell- regeneration in the hyperglycemic rat. Furthermore, snake fruit kombucha was proven to have a similarly significant effect compared to metformin in treating diabetic rats with a dosage of 5 $mL.kg^{-1}$ bodyweights per day given orally for 28 days. These positive effects of snake fruit kombucha known to be related with its chemical composition such as phenol, tannin, hexane, 1-methyl-2, 2-furancarboxaldehyde, glucopyranose, and caffeine, which are produced during the

fermentation process **(Zubaidah et al., 2018b; Zubaidah et al., 2018c)**.

These beneficial effects of snake fruit kombucha, which have been reported, lacked scientific evidence to ascertain its potential immunomodulatory effect. Thus, this study aimed to investigate the chemical changes during fermentation of kombucha and its immunomodulatory activity in *Salmonella typhi*-infected mice, which will be ascertained through the population of CD4+TNFα+, CD4+IFNγ+, CD8+TNFα+, and CD8+IFNγ+.

Scientific hypothesis

The fermentation affects the chemical characteristics of the kombucha. The kombucha administration raises the production of CD8+TNFα+ and CD4+IFNγ+ in mice infected with *Salmonella typhi*.

MATERIAL AND METHODOLOGY

Material

Snake fruit (*Suwaru salak* cultivar) was obtained from a local farmer in Malang, East Java, Indonesia. Black tea was purchased from the local market. SCOBY culture was bought from Wiki Kombucha, Bali, Indonesia. *Salmonella typhi* was obtained from a national culture collection.

Snake fruit kombucha and black tea kombucha preparation

Peeled snake fruit was separated from its seed, cut, and washed with distilled water. Snake fruit was juiced in a food processor with distilled water at a ratio of 1:1 (w:v), then filtered. The juice was added with 10% sucrose (w/v) and brought to boil. While black tea extract was prepared by eight grams of black tea immersed in 1 L of boiling water, added with 10% sucrose (w/v), and let sit for 15 minutes. The prepared snake fruit juice or black tea extract was poured aseptically into a sterilized glass container, cooled until it reached room temperature, and then inoculated with 10% SCOBY culture (v/v). The container was covered with a sterile cloth and let aside to undergo fermentation at room temperature for 14 days. The cellulose layer was aseptically separated and the solution was subjected to chemical and immunomodulatory activity evaluation.

Chemical Analysis

Total acidity, total sugar, total dissolved solids [TDS] was analyzed according to **AOAC (1995)**. pH was measured by using a pH meter. Total phenolic content was determined according to **Yang, Paulino and Janke-Stedronsky (2007)**. Total flavonoid content was evaluated according to **Atanassova, Georgieva and Ivancheva (2011)**. Antioxidant activity (DPPH scavenging activity) was analyzed according to **Pinsirodom, Rungcharoen and Liumminful (2010)**. All analyses were carried out on a day 0 and day 14 of the fermentation process to ascertain any changes in both black tea kombucha and snake fruit kombucha.

Immunomodulatory activity evaluation

Thirty female Balb-C mice aged 12 weeks were adapted for 7 days given food and water ad libitum, then randomly categorized into 6 groups: Normal (N, healthy group), N-BTK (normal + black tea kombucha), N-SFK (normal + snake fruit kombucha), Infected with *Salmonella typhi* (I), I-BTK (infected + black tea kombucha), and I-SFK (infected + snake fruit kombucha), with each group, consists of 5 mice. The experimental protocols and procedures of care and use of animals used in the present study were approved by the Ethics Committee (ethical clearance No. 1059-KEP-UB). The National Institutes of Health guide for the care and use of laboratory animals (NIH Publications No. 8023, revised 1978) was followed in this experiment. Kombucha was given orally as much as 0.007 $mL.g^{-1}$ body weight per day for 21 days. On day 22, *Salmonella typhi* infection was carried out intraperitoneally with a dosage of 0.1 mL per mice with a concentration of 10^8 cells per mL. On day 29, lymph organ was taken for flow cytometry analysis to assess the population of CD4+TNFα+, CD4+IFNγ+, CD8+TNFα+, and CD8+IFNγ+.

Statistical analysis

The chemical characteristics data were analyzed with ANOVA at a significance level of 0.05% with SPSS. Flow cytometry data were analyzed with BD cell quest ProTM and statistically analyzed with ANOVA at a significance level of 0.05% with SPSS. A significant result was furtherly analyzed with Tukey.

RESULTS AND DISCUSSION

Chemical changes during fermentation

The fermentation process is a metabolic process that triggers simultaneously changes to characteristics of the medium including its nutritional contents and antioxidant activity. Changes in both black tea kombucha and snake fruit kombucha are presented in Table 1. The increase in total acid at the end of fermentation is the result of the culture metabolism which converts sugar into organic acids, mainly acetic acid as the primary metabolite. Other acids were also produced during bacteria metabolisms such as acetic acid, gluconic acid, glucuronic acid, L-lactic acid, malic acid, tartaric acid, and citric acid.

Table 1 Changes in chemical characteristics of black tea kombucha and snake fruit kombucha during fermentation.

Parameter	Black Tea Kombucha		Snake Fruit Kombucha	
	Day 0	Day 14	Day 0	Day 14
Total Acid (%)	0.21 ±0.02*	0.42 ±0.08*	0.83 ±0.07*	1.11 ±0.01*
pH	5.06 ±0.05*	4.90 ±0.02*	4.01 ±0.01*	3.07 ±0.01*
Total Sugar (%)	10.99 ±0.01*	8.27 ±0.04*	13.00 ±0.11*	8.09 ±0.03*
TDS (°Brix)	13.79 ±0.01*	11.79 ±0.01*	14.45 ±0.01*	12.23 ±0.01*

Note: Data is the average of 3 replications ±*SD*. A notation of * shows significant different at each parameter in the same day at significant level of $p > 0.05$.

High total acid increment in Snake fruit kombucha was predicted and caused by native acid in salak such as ascorbic acid **(Jayabalan, Marimuthu and Swaminathan, 2007; Jayabalan et al., 2014; Malbasa et al., 2011; Supapvanich, Megia and Ding, 2011)**.

Higher accumulation of organic acids during fermentation is related to lower pH value owing to acid ability to release H+ and cause a drop in pH level. By the end of the fermentation process, total sugar and total dissolved solid levels in the medium were lower compared to their levels at the beginning of fermentation as sugar is considered the primary carbon source for microorganisms that facilitates metabolism during fermentation. The reduction of TDS might be also caused by sedimentation of protein, pectin, pigment, and minerals.

The fermentation process not only changed the chemical characteristics of a medium, but also its bioactive components such as phenolic content, flavonoid content, and antioxidant activity **(Jayabalan, Marimuthu and Swaminathan, 2007; Bhattacharya, Gachhui and Sil, 2013)**. Changes in bioactive characteristics of black tea kombucha and snake fruit kombucha are presented in Table 2. Kombucha fermentation has been known to produce several enzymes such as invertase, cellulase, and amylase that catalyzes the breakdown of the chain between phenolic and medium complex that contributed to the increase of phenolic content after fermentation. On the other hand, epicatechin in tea and salak is known to undergo isomerization and depletion form microbes cell during fermentation resulting in in an increase of total flavonoid by the end of fermentation **(Essawet et al., 2015; Jayabalan, Marimuthu and Swaminathan, 2007; Supapvanich, Megia and Ding, 2011; Apriyadi, 2017)**. The antioxidant activity also increased during fermentation as the phenolic and flavonoid contents increased.

Animal Observation

The effect of treatment on mice body weight was monitored and evaluated on day 0, 7, 14, 21, and 28 the data were presented in Table 3.

Weight gain was observed in the healthy group, black tea kombucha, and Snake fruit kombucha (Normal, N-BTK, N-SFK). On the contrary, *Salmonella typhi* infection has led to

Table 2 Changes in bioactive characteristics of black tea kombucha and snake fruit kombucha during fermentation.

Parameter	Black Tea Kombucha		Snake Fruit Kombucha	
	Day 0	Day 14	Day 0	Day 14
Phenolic content (mg.L^{-1} GAE)	181.18 ±0.98	407.14 ±1.43*	280.48 ±0.55	534.94 ±0.24*

weight loss among an infected group, black tea kombucha, and snake fruit kombucha (Infected, I-BTK, I-SFK). Weight gain in the healthy group was related to the efficiency of gut activity in absorbing nutrients.

Moreover, high phenol, flavonoid, and antioxidant activity enhanced the body's metabolism to positive energy balance **(Fuller, 1989)**, thus healthy mice treated with snake fruit kombucha noted the highest weight gain (34.00 g).

Weight loss was a clear indication of *Salmonella typhi* infection. *Salmonella typhi* invade the gut mucosal surface and impaired the gastrointestinal tract absorption activity causing diarrhea, nausea, and vomit. The bacteria have also produced enterotoxin which stimulates gut epithelium to metabolize adenyl cyclase enzyme and c-adenosine monophosphate, which facilitated the secretion of chloride, natrium, and water from the gut lumen into the cell. In response to such conditions, hyperperistaltic occurred reduce excess water in the intestine thus diarrhea case has been established **(Ukhrowi, 2011; Nurhalimah, Wijayanti and Widyaningsih, 2015)**. Phenolic and flavonoid are known to have a bactericidal activity which is important to minimize the severity of diarrhea through inhibiting the growth of pathogenic bacteria **(Damayanti and Suparjana, 2007; Clinton, 2009; Loresta, Murwani and Trisunuwati, 2012)**. Acetic acid as the result of kombucha fermentation also correlates with inhibition of *Salmonella typhi* growth thus increases the efficiency of nutrient absorption, leading to weight gain **(Sreeramulu, Zhu and Knol, 2000)**.

Immunomodulatory effect of Black Tea Kombucha and Snake Fruit Kombucha

Figure 1 demonstrated the relative percentage of CD4+TNFα+, CD8+TNFα+, CD4+IFNγ+, and CD8+IFNγ+. Statistical tests noted that both *Salmonella typhi* infection and kombucha treatment did not reveal a significant effect on the relative percentage of CD4+TNFα+ and CD8+IFNγ+.

TNFα is an important cytokine produced in response to acute inflammation response stimulated by lipopolysaccharide. TNFα is needed to reduce pathogenic bacteria infection by inhibiting cell replication and destroying the infected cell. In the case of *Salmonella typhi* infection, TNFα+ mainly produced by CD8+ **(Oppenheim and Ruscetti, 2003; Bhuiyan et al., 2014)**. **Buttler and Girard (1993)** reported that TNF, IL-1, and IL-6 were increased as the response to *Salmonella typhi* infection. But, in this study we noticed that TNFα producing CD8+ has decreased. It is predicted that 3 – 7 days post-infection, macrophage effectively kill *Salmonella typhi* and eliminate dead cell **(Keuter, 1998)**, thus the expression of CD8+TNFα+ were lower (for instance, in the infected group), thus it can be inferred that both kombuchas have immunostimulant activity toward CD8+TNFα+.

Also, we revealed an immunosuppressant activity by both black tea kombucha and snake fruit kombucha. On the other hand, the non-infected group of mice treated with kombucha showed a lower CD8+TNFα+ relative percentage than the normal group. This may be due to bioactive components like flavonoid that causes lower expression of NF-kB transcription, followed by lower pro-inflammation cytokine production such as IL-17, IFNγ, and TNFα **(Saini, Sivanesan and Keum, 2016)**.

IFNγ is mainly produced by T- lymphocyte cells (CD4+ and CD8+) and natural killer cells which are activated as a response to antigen. High production of IFNγ increased the efficiency of macrophage to scavenge and kill microbes, initiate Th1 development, increase natural killer cells activity to lyse infected cell, increase MHC I expression which is needed by CD8+ to identify antigen, and increase MHC II expression to enhance the antibacterial activity **(Oppenheim and Ruscetti, 2003; Samuel, 2001)**.

Several immunological studies noted an increased level of IFNγ especially by CD4+ cells as a response to *Salmonella typhi* infection **(Sheikh et al., 2011)**. In this study, the population of IFNγ was decreasing compared to the normal group. Both black tea kombucha and snake fruit kombucha reported raising the population of CD4+IFNγ+ in which can be an alternative way to overcome the infection of *Salmonella typhi* since increasing IFNγ+ correlates to increasing activity of macrophage **(Abbas, Lichtman and Pilai, 2007)**.

Flavonoids also are known to have the ability to induce secretion of cytokines related to CD4+ cells and modulate its regulation by IL-2 production and increase CD8+ production **(Lyu and Park, 2005)**. Moreover, IL-2 is known to trigger CD8+ activation to produce perforin and grazin to support CD8+ function in destroying infected cells and *Salmonella typhi* antigen. Flavonoids are recognized to have immunostimulant activity by affecting macrophage and T cell and eliminate an infection. Flavonoids were able to activate the natural killer cell to trigger the production of IFNγ and increase the phagocytosis activity of macrophage. Also, phenols were proclaimed to initiate the production of IL-12 which activate natural killer cells to produce IFNγ and furtherly activate macrophage to kill antigen through the mechanism of oxygen-dependent- and oxygen-independent- **(Abbas, Lichtman and Pilai, 2007; Amit et al., 2017; Sulistiani and Rahayuningsih, 2015; Ramadhan, Mahfudh and Sulistyani, 2020)**.

CONCLUSION

Snake fruit kombucha triggers higher changes in chemical parameters during the fermentation process when compared to black tea kombucha. Moreover, snake fruit kombucha has higher bioactive components at the end of fermentation compared to black tea kombucha. Both products have the potential to be utilized as an immunomodulator to circumvent the unstable conditions of the immune system caused by *Salmonella typhi*.

DIVERSITY OF WINTER COMMON WHEAT VARIETIES FOR RESISTANCE TO LEAF RUST CREATED IN THE V. M. REMESLO MYRONIVKA INSTITUTE OF WHEAT

Hanna Kovalyshyna, Yuliia Dmytrenko, Oksana Tonkha, Oleksandr Makarchuk, Oleksandr Demydov, Oleksandr Humeniuk, Natalia Kozub, Anatolii Karelov, Igor Sozinov, Mikhailo Mushtruk

ABSTRACT

The results of the investigations of resistance winter common wheat varieties to leaf rust are given. The high resistance to the pathogen manifest varieties that contain resistance genes: *Lr9*, *Lr19*, *Lr37*, *Lr42* + *Lr24*, *Lr43* (*Lr21* + *Lr39*) + *Lr24*, *Lr9* + *Lr26*, *Lr10* + *Lr24* are ascertained. The genes *Lr13*, *Lr34*, *Lr37* in combination with other resistance genes provides long-term protection to leaf rust wheat. Winter wheat varieties, created at the V. M. Remeslo Myronivka Institute of Wheat, contain resistance genes *Lr23*, *Lr24*, *Lr26*, *Lr34*. The varieties Vesta, Snizhana, Demetra are protected by the resistance genes *Lr26* + *Lr34*, variety Zolotokolosa– *Lr24* + *Lr34*, Ekonomka – *Lr3* + *Lr26*, Myronivska storichna – *Lr3* + *Lr23* + *Lr10* + *Lr26*. The allele *Lr34* (+) is contained in varieties: Kryzhynka, Vesta, Snizhana, Volodarka, Demetra, Vdiachna, Pamiati Remesla, Sviatkova, Podolianka, Berehynia myronivska, MIP Dniprianka, and Balada myronivska. Sustainability is an important element of an integrated system of plant protection against many diseases, and to ensure increased yields it is necessary to create and distribute sustainable varieties that will be an environmentally promising way to develop the agro-industrial complex of Ukraine.

Keywords: common winter wheat; breeding; variety; resistance; rust; genes

INTRODUCTION

The leaf rust (*Puccinia recondita f.* sp. *tritici* Rob. Ex Desm.) is one of the most common and harmful wheat diseases. The disease leads to significant losses of grain yield **(Novohatka, 1979)**. The level of wheat yields loss to 30% during the epiphytotic rust according to the Food and Agriculture Organization of the United Nations (FAO) **(El-Khoury, 2009)**. The population of the pathogen *Puccinia recondita* differs from the high adaptive ability. High variability virulence of the fungus leads to the accumulation of pathogens that capable of the genes of wheat resistance **(Palamarchuk et al., 2019)**.

The most justified, economically sound, and environmentally safe method of fighting to disease is to creating resistance varieties. The effectiveness of breeding to rust resistance can be improved by using different Lr – genes **(Zheplinska et al., 2019)**.

More than 90 resistance genes to the rust-leaf pathogen are identified and characterized by chromosomal localization and efficiency at the wheat genome and its relatives **(Kovalyshyna and Dmytrenko, 2017)**, which information is collected annually and is published in the Catalogue of gene symbols for wheat **(McIntosh et al., 2003a; McIntosh et al., 2007b; McIntosh et al., 2008c; McIntosh et al., 2009d; McIntosh et al., 2010e; McIntosh et al., 2011f; McIntosh et al., 2012g; McIntosh et al., 2014h; McIntosh et al., 2016i; McIntosh et al., 2017j; McIntosh et al., 2018k; McIntosh et al., 2019l)**. Most genes of resistance to rust causative agents identified in cultivars of wheat descend from their wild relatives. Thus, according to the information provided in the catalogs of genetic symbols, about half of the known resistance genes to leaf rust are allogenic, introgressive into *Triticum aestivum* species from different types of wheat, aegilops, wheat grass, and others **(Leonova et al., 2013)**. The almost all effective rust resistance genes at the territory of Ukraine, except *Lr10* and *Lr23*, are allogenic, transferred to *Triticum aestivum* from other species: *Aegilops speltoides* – *Lr28, Lr35, Lr36, Lr47, Lr51, Lr66; Aegilops tauschii* – *Lr1, Lr21, Lr22a, Lr32, Lr39, Lr42; Triticum timopheevii* – *Lr18, Lr50; Thinopyrum elongatum* – *Lr19, Lr29, Lr24; Secale cereale* – *Lr25, Lr26, Lr45; Aegilops umbellulata* – *Lr19, Lr76; Triticum spelta* – *Lr44, Lr65, Lr71; Triticum dicoccoides* – *Lr53, Lr64; Aegilops triuncialis* – *Lr58, LrTr; Triticum timopheevii* spp. *viticulosum* – *LrTt1; Aegilops ventricosa* – *Lr37; Aegilops kotschyi* – *Lr54; Elymus trachycaulis* – *Lr55; Aegilops sharonensis* – *Lr56;*

Aegilops geniculate – Lr57; Aegilops peregrine – Lr59; Triticum turgidum – Lr61; Aegilops neglecta – Lr62; Triticum monococcum – Lr63. Therefore, in breeding must be taken into account the fact that in the wheat genome the effective *Lr*-genes are introduced not in its "pure" form, but closely linked with other genes that are undesirable to use in breeding **(Dinh et al., 2020; Lodgering et al., 1970)**.

It is a rather difficult task creating such varieties, and over time, they lose their resistance by the emergence of new races, pathogenic strains, and climatic changes. Trends in climate warming affect on the deterioration of the phytosanitary condition of crops **(Mushtruk et al., 2020)**.

Scientific hypothesis

The scientific hypothesis is founded on identifying nature inheritance and manifest resistance genes to exciter of leaf rust. It is attaining by investigation of composition population exciter of disease and identifies resistance genes at collectible samples soft wheat. It is making it possible to increase the resistance gene pool and creating new heterogeneous varieties of soft wheat.

MATERIAL AND METHODOLOGY

The assessment varieties (Table 1) of winter wheat were created at the V. M. Remeslo Myronivka Institute of Wheat for resistance to leaf rust made in conditions of the artificial infectious background of the wheat pathogen. Experiments were in the field conditions at a field infectious nursery of the Plant Protection Department of the V. M. Remeslo Myronivka Institute of Wheat. The climate is temperate continental. The average annual air temperature is 7.6 °C. The sum of effective temperatures above 5 °C is 3000 °C. The duration of the frost-free period becomes an average of 165 days. The average annual amount of decline is 310 – 570 mm.

A suspension of a mixture of spores isolated from the local leaf rust population was used for inoculation. Wheat varieties were inoculated a mixture of spores with talc in the ratio of 1:100 by a technique of **Geshele (1971)** in a tubing phase – beginning form ears in condition artificial infectious nursery. The spore load was 0.015 kg of urediniospores per one m^2 of sowing. The assessment of resistance was conducted dynamically every 10 days **(Tkachyk, 2014)**. The variety Myronivska 10 was used as a susceptible standard. The accounts defeat by the causative agent were evaluated on the scale according to **Trybel et al. (2010)** and **Bober et al. (2020)**. A DNA was isolated from weight 25 – 40 mg of the plant material, obtained by grinding of 5 grains in ceramic mortars to a homogeneous powder and the further selection and weighing **(Babaiants, 2011)**. DNA isolation was conducted using sets of Diatom™ DNA Prep100 (NEOGENE, Ukraine) according to a standard procedure with certain modifications **(Trybel et al., 2010)**.

The caSNP12 marker was used in investigations of genetic material for identification allelic status of the resistance gene to wheat leaf rust Lr34, **(Radchenko and Odintsova, 2008)**. PCR was performed on the amplifier GeneAmp® PCR System 2720 (Thermo Fisher Scientific, Massachusetts, USA) using sets GenPak® PCR Core according to the manufacturer's method. The primer sequences are as follows: for caSNP12F – 5'-TCCCCAGTTTAACCATCCTG-3'; for caSNP12R – 5'-CATTCAGTCACCTCGCAGC-3' (NEOGENE, Ukraine).

The conditions of the PCR were in line with the requirement recommended by the developer. As a result of PCR with a mixture of primers flanking the caSNP12 marker **(Strahov, 1951)**. The stable allelic state of the markers (- Lr34 +) answered amplicons with a length of 234 p. n., the sensitivity was the absence of amplicons **(Vyerchenko et al., 2019)**.

Fragments received from PCR were separated in 1.8% agarose gel. Ethyl bromide was used as an intercalating agent for DNA monitoring in an ultraviolet. The system VISION Gel (Scie-plas, Great Britain) was used for gel documentation. The length of the clearest and reproducible bands was determined using DNA marker O'Gene Ruler 50 bp Plus DNA Ladder (Fermentas, Lithuania).

Statistical analysis

To obtain information on the number and interaction of resistance genes, the obtained ratios of classes of resistant and susceptible plants (actual) were compared with one of the theoretically expected cleavages using the chi-square (χ^2) correspondence criterion. The assumption that the difference between the actually obtained and theoretically expected splits is random was rejected if $\chi^2_{fact.}$ exceeded the critical $\chi^2_{st.}$ ($\chi^2_{0.05}$ = 3.84). An error of results in statistical analysis p = 0.05. Statistical processing was performed in Microsoft Excel 2016 using the analytical application XLSTAT from Addinsoft for Microsoft Excel. Values were estimated using mean and standard deviations.

RESULTS AND DISCUSSION

The genes of high efficiency against the pathogen are *Lr9, Lr19, Lr37, Lr42+Lr24, Lr43 (Lr21+Lr39) +Lr24, Lr9+L26, Lr10+Lr24* discovered by investigation the population of leaf rust on varieties of carriers of effective resistance genes **(Leary et al., 2018; Ramanathan et al., 2018)**. The resistance of the varieties protected by the Lr24 genome is lost. We observed a slight defeat by the pathogen of the carriers of the Lr19 gene, indicating that the population has virulent clones against it. The pustules of leaf rust were marked also on varieties protected by the genome Lr9 in some years. The genes *Lr37*, *Lr42 + Lr24* and *Lr43* (*Lr21 + Lr39*) + *Lr24* have high efficiency in recent years. The *Lr13*, *Lr34*, *Lr37* genes provide the long-term protection of wheat against rust in combination with other genes **(Dorofee, 1972; Bharti et al., 2016)**. The varieties with these genes remain resistant for 20 – 30 years in different countries of the world **(Leppik, 1970)**.

10 highly resistant endemic species of wheat and its relatives with the highest immunity to rust, in particular: *Triticum monococcum*, *T. timopheevii*, *T. militinae*, *T. Zhykovski*, *T. fungicidum*, *Haynatriticum*, *Aegilops umbellulata* are distinguished **(Varella et al., 2017; Jafary, Szabo and Niks, 2006)**.

Table 1 Genetic diversity of winter wheat varieties for resistance to leaf rust.

Variety	Owner of Variety	Entry into the State Register, year	*Lr*- genes	Plant damage, %, the average for 2015 – 2018 pp.	Resistance, number
Ukrainka 0246	MIW[1]	1929	*Lr16*	13.8	6

Remeslo Myronivka Institute of Wheat of the National Academy of Agrarian Sciences of Ukraine; 2 IPPG – Institute of Plant Physiology and Genetics of the National Academy of Sciences of Ukraine; 3 IPP – Institute of Plant Protection of the National Academy of Agrarian Sciences of Ukraine.

In the works **(Casey et al., 2016; Marryat, 1907; Davoyan et al., 2012)** found forms immune to rust, powdery mildew, and soot among *Triticum dicoccum*.

The principles of researching gene pool of wheat resistance against leaf rust, based on **(Flor, 1971)** theory of "gene-for-gene", developed **(Berlyand-Kozhevnikov et al., 1985)**.

In Ukraine, wheat breeding for rust resistance is conducted for more than 40 years. Scientific researches on the study of genetic signs of resistance to the causative agent of leaf rust actively unfolded in the late 70's – the early 80's of the twentieth century **(Morgounov et al., 2011)**. The greatest successes have been achieved at the V. M. Remeslo Myronivka Institute of Wheat of the National Academy of Agricultural Sciences of Ukraine, the Plant Breeding and Genetics Institute – National Center of Seed and Cultivar Investigation of the National Academy of Agricultural Sciences of Ukraine, the Institute of Plant Protection of National Academy of Agrarian Sciences of Ukraine and the Plant Production Institute nd. a. V. Ya. Yuryev of National Academy of Agrarian Sciences of Ukraine **(Khaneghah et al., 2018; Kirilenko, 2014)**.

We conducted researches on the detection of the resistance gene to leaf rust in winter wheat varieties of Myronivka's breeding. The *1BL/1RS* wheat-rye translocation, which carries the resistance gene to leaf rust Lr26, as well as resistance genes to stem rust Sr31, powdery mildew Pm8, yellow rust Yr9 were found in the following varieties: Myronivska 61, Myronivska 27, Myrleben, Myronivska 28, Myronivska 30, Myronivska 31, Myronivska 33, Myrych, Myronivska 65, Myronivska 66, Kryzhynka, Myronivska 67, Vesta, Snizhana,

Table 2 Allelic status of the *Lr34* gene in new winter wheat varieties of MIW by results of PCR on the marker *caSNP12*, 2017.

Variety	Entry into the State Register, year	Allelic status of the gene *Lr34**
Svitanok Myronivskyi	2014	-

Hratsiia myronivska	2018	-
MIP Assol	2018	-

Note: * "+" – Associated with allele resistance *Lr34* (+); "-" – allele present in susceptible varieties Lr34 (-).

Pereiaslavka, Demetra, Favorytka, Pyvna, Kalynova, Kolos Myronivschyny, Monotyp, Ekonomka, Myronivska storichna, Lehenda Myronivska according to the results of investigations by **Kovalyshyna et al. (2020)**, **Lisova (2012)** and **You-Xiong et al. (2009)**. The *Lr26* gene does not provide high resistance of varieties to leaf rust causative agent, since this gene has lost its effectiveness against the population of the disease as the data in Table 1 show.

The availability of wheat-rye translocation *1AL/1RS* in the genotype of winter wheat provides resistance to fungal diseases, because it carries a complex of resistance genes – to leaf rust *Lr24*, stem rust *Sr1RS*, powdery mildew *Pm17*. This translocation was detected in varieties: Kolumbiia, Smuhlianka, Vesnianka, Zolotokolosa, Yasnohirka, Slavna, Yavoryna **(Vlasenko, Koliuchyi and Chebakov, 2005; Landjeva et al., 2006)**. The *Lr24* gene provides moderate resistance to leaf rust, varieties have damage of 2.8 – 17.2%.

The varieties Vesta, Snizhana, Demetra are protected by the *Lr26* and *Lr34* genes, and the Zolotokolosa – by the *Lr24* and *Lr34*. The combination of these resistance genes inhibits the development of leaf rust on winter wheat varieties, damage of the leaf surface is within 10 – 17.5%

The Myrliena variety contains the gene *Lr23*, and the Myronivska storichna – *Lr3, Lr23, Lr10,* and *Lr26* are ascertaining according to the analysis of the genealogy of varieties. The Lr3, Lr24 genes, protects the Ekonomka variety.

The gene *Lr34*, which belongs to the group of genes that provide partial resistance in the phase of adult plants, is found in the following varieties: Kryzhynka, Vesta, Snizhana, Volodarka, Demetra, Vdiachna, Pamiati Remesla, and Sviatkova **(Kozub et al., 2017; Pirko et al., 2012)**. Eight varieties exhibit polymorphism for the gen *Lr34* – Illichivka, Myronivska 30, Myronivska 32, Myronivska 65, Myronivska 66, Pyvna, Ekonomka, Lehenda Myronivska. Perhaps a small frequency of the dominant allele of the *Lr34* gene in the varieties of MIW is related to the difficulty of identifying it in field conditions in the Right-Bank Forest-Steppe zone of Ukraine with the use of classical breeding methods, since for varieties of the Plant Breeding and Genetics Institute – National Center of Seed and Cultivar Investigation of the National Academy of Agricultural Sciences of Ukraine frequency is much higher. The varieties Zolotokolosa and Podolianka also contain the gene *Lr34* according to **Radchenko and Tishchenko (2010)** and **Krattinger et al. (2016)**.

We found that among the 15 newly created varieties, only 3 varieties – Berehynia myronivska, MIP Dniprianka, and Balada myronivska contain the *Lr34* allele (+), which is only 20% of the investigated varieties according to the PCR results, using the *caSNP12* marker (Table 2).

CONCLUSION

It has been established that effective against the pathogen of leaf rust the are genes: *Lr9, Lr19, Lr37, Lr42+Lr24, Lr43 (Lr21+Lr39) +Lr24, Lr9+L26, Lr10+Lr24*. The genes Lr13, Lr34, Lr37 in combination with other genes, provide the long-term protection of wheat against leaf rust.

The wheat-rye translocation *1BL/1RS* was identified in the following varieties: Myronivska 61, Myronivska 27, Mirleben, Myronivska 28, Myronivska 30, Myronivska 31, Myronivska 33, Myrych, Myronivska 65, Myronivska 66, Kryzhynka, Myronivska 67, Vesta, Snizhana, Pereiaslavka, Demetra, Favorytka, Pyvna, Kalynova, Kolos Myronivschyny, Monotyp, Ekonomka, Myronivska storichna, Lehenda Myronivska.

The availability of wheat-rye translocation *1AL/1RS* was found in varieties: Kolumbiia, Smuhlianka, Vesnianka, Zolotokolosa, Yasnohirka, Slavna, Yavoryna.

The *Lr34 (+)* allele is presented in varieties: Kryzhynka, Vesta, Snizhana, Volodarka, Demetra, Vdiachna, Pamiati Remesla, Sviatkova, Podolianka, Zolotokolosa, Berehynia myronivska, MIP Dniprianka, and Balada myronivska according to the results of the research. As a result of research, it was found that the wheat variety Myronivska Ukrainian selection is quite productive in comparison with other varieties and resistant to pathogens of various diseases, especially to the pathogen (brown rust).

SUBSTANTIATION OF FOAMY STRUCTURE FORMATION IN A GLUTEN-FREE BISCUIT

Igor Stadnyk, Olena Kolomiiets, Oksana Dziana

ABSTRACT

A promising way to create gluten-free foods based on purposeful use of ingredients with a wide range of technological properties is analyzed. Steps to regulate the structural and mechanical properties of gluten-free dough have been determined. These steps allow to improve the structural-mechanical and organoleptic characteristics of the biscuit semi-finished product, to adjust the nutritional value. To determine the technological effect, we considered the connection between the recipe components and the properties of the dough when forming a foamy structure of gluten-free cupcake products. The influence of the design parameters of the mixer (independent factors xi) on the foaming process (Q) has been determined, that is, determining the productivity magnitude from the changes of three main factors: from the attack angle of the frontal surface of the plate working body α, the distance between the plates (step) t and the rotation frequency of working body n. The stability of the foam formed and the rate of its settling and the role of the liquid phase of the dough during short storage before baking were investigated. The comparative characteristics of the microstructure of wheat flour (WF) and extruded corn flour (ECF) in the ratios are presented: a) WF – 100 wt.%; b) WF: ECF – 80:20 wt.%; c) ECF – 100 wt.%. In the tested mixtures, the moisture-holding capacity increases for the sample containing 20% by weight of extruded corn flour two and a half times, and three times for the sample with extruded flour to 100% by weight. With an increasing proportion of extruded corn flour in the flour mixture, the dough density increases and the optimum value is in the range of 0.444 – 0.446 kg.m^{-3}. The comparative characteristic of the microstructure of the samples is given, which has the appearance of foam with the existing and even distribution of air bubbles which later form the porous structure of the biscuit of the semi-finished product. Thus, the size of the formed bubbles of air with the content of wheat flour and starch have a large difference in diameters, in the sample of biscuit dough using ECF 100 wt.% – almost the same size, and between the channels are formed that promote the equalization of air pressure in the middle of the foam system of biscuit dough. It was found that the use of 20 wt.% and 100 wt.% of corn extruded flour contributes to the formation of a fine porous structure of biscuit dough.

Keywords: dough; adhesion; adhesive; substrate; forming channel; deformation; stress

INTRODUCTION

Today, the popularity of healthy eating is increasing every year. This requires the creation of products that contain ingredients with wellness properties. The tissues of the human body include mineral compounds that make up about 3.5% of its mass. Therefore, when consuming food, they should contain the required amount of salt, phosphorus, calcium, iron, etc. The daily requirement of the human body in trace elements is measured in milligrams (zinc: 10 – 15, manganese: 5 – 10, copper: 2, molybdenum :0.5). Their physiological value is quite significant, as these trace elements play the role of coenzymes of some enzyme systems.

An analysis of the literature shows that the share of gluten-free food on the Ukrainian market is quite small, and the percentage of people who go to health care establishments with increased sensitivity to gluten is increasing, even among children. Also, there is increasing public awareness of gluten intolerance, that is why people choose gluten-free foods as an attribute of healthy eating. In western countries, the consumption of gluten-free products is becoming a lifestyle, which contributes to increasing their production. Thus, according to experts, in the UK in 2019, the market for gluten-free products reached 1 billion dollars. In Ukraine, however, the industrial production of gluten-free products is not established, but to provide the category of people with coeliac disease, specialized food needs constantly.

Considering the directions of technological process in the food industry **(Lamacchia et al., 2014)**, determined in particular by public policies on healthy nutrition, economic and social change in society, new technological opportunities, and competition in the food market, there is a need not only for the improvement of traditional food technology but for the creation of new generation foods which are enriched with important nutrients and have

a longer shelf life. Also, an important role is played by equipment, which creates the appropriate conditions for modern technological requirements. Semi-finished flour confectionery products form the basis or constituent of products **(Murray, 2007)**, and significant demand from the population for these products makes them considered important food products.

Today, in particular **(Liu, Willför, and Xu, 2015; Kobets et al., 2015)**, the range of gluten-free food produced in domestic production is insufficient. The range of gluten-free flour products on the Ukrainian market is formed mainly due to imported products, which have a fairly high cost. To solve the problem of nutrition for patients with coeliac disease in Ukraine products of the firm "DR. SCHAR" (Italy), "BEZGLUTEN" (Poland), "3PAULY" (Germany) are certified but their use is limited because of the high price. The range of food products for people suffering from genetically caused and allergic diseases in our country is not wide enough and is about 2%. This indicates that the issue of developing special-purpose technology products, including for the nutrition of people with coeliac disease, in Ukraine is quite acute and relevant. Therefore, one of the promising directions of expanding the range of flour confectionery products is the creation of biscuit semi-finished products, bagels with the development of structural and technological conditions of the process with the complete replacement of gluten-containing wheat flour with extruded corn flour (ECF).

ANALYSIS OF THE LATEST RESEARCH

In the general structure of the market of flour confectionery products (FCP) cupcakes and bagels occupy up to 15% of the total volume of production. These products have a pleasant appearance and taste, are well absorbed by the human body and therefore are popular with the population. Analysis of the literature indicates that the use of gluten-free flour in the production of pastry, including muffins on chemical baking powder causes many technological problems and requires a variety of tools to improve the structure of the gluten-free dough. The fact is that gluten of wheat flour has unique technological properties that play an important part in the formation of flour dough structural and mechanical qualities and texture of finished products. Wheat Glyadine (Prolamine) is responsible for the dough's consistency as well as Gluten (Glutinine) is responsible for the resistance of the tensile test. The combination of these two proteins gives the dough unique viscoelastic properties and the ability to hold gas. After hydration and mixing, proteins of gluten-free flour varieties do not develop into a viscoelastic network **(Kobets et al., 2015)** as wheat proteins.

During the development of the cupcakes, it was found that simply replacing the wheat flour with rice does not allow the product to have the necessary structural characteristics. It has been established **(Stojceska et al., 2010; Drobot, Pysarets and Kravchenko, 2013)** that reducing the amount of rice flour by 10% is sufficient to improve the structure of the cake. The product has a developed porosity and a high specific volume.

The possibility **(Rus'kina et al., 2017)** of using protein and protein-calcium concentrates from white and brown rice in the technology of gluten-free oil cake has been investigated. The obtained rice concentrates were characterized by high foaming capacity and foam stability, which allowed them to be used in the amount of 50% by weight of egg melt in oil cake technology to increase its biological value and structural and mechanical quality indicators.

The main problem of manufacturing gluten-free flour products is an imitation of the structure-forming properties of gluten-containing raw materials. Since the biscuit semi-finished product is a structured foam-emulsion dispersive system, the formation of the necessary rheological properties that provide a texture adequate to a traditional product is an important task for its creation. In the technological aspect, the solution of this problem is to find the optimal ratio of structure-forming components, the choice of design conditions for the formation of a stable structure of the food system, its structural and mechanical qualities, characterized by viscosity, elasticity, plasticity.

Corn flour starch **(Stojceska et al., 2010)** is pasteurized at higher temperatures, more easily attacked by amylase, contains less own sugars, less sugar-forming, and gas-forming ability.

Many studies by several scientists **(Stojceska et al., 2010; Drobot, Pysarets and Kravchenko, 2013)** have developed measures for the use of a mixture of wheat and corn flour while maintaining pre-mixing corn flour. They consist of soaking, brewing, fermenting with mesophilic or thermophilic lactic acid bacteria, adding unfermented malt, phosphates, concentrates, or enzymes to the dough. However, these measures extend the duration of the process and do not provide the significant effect of improving product quality at considerable cost. Recently **(Stojceska et al., 2010; Drobot, Pysarets and Kravchenko, 2013)** began to develop measures for the use of whey.

The availability of fundamental developments in the production and use of various types of extruded flour in food production **(Brekhov and Riazhskykh, 2012; Yehorov, Mardar and Bordun, 2014; Zip Diagnostic, 2012)** indicates the possibility of its use in biscuit technology and production of bagels. The use of plant-based ingredients, such as non-traditional flour types, which could provide valuable nutritional value to the product, may be considered a promising development of interest to confectioners and bakers.

Because of the valuable chemical composition of the ECF, it is possible to predict the positive impact of this raw material on the course of the technological process.

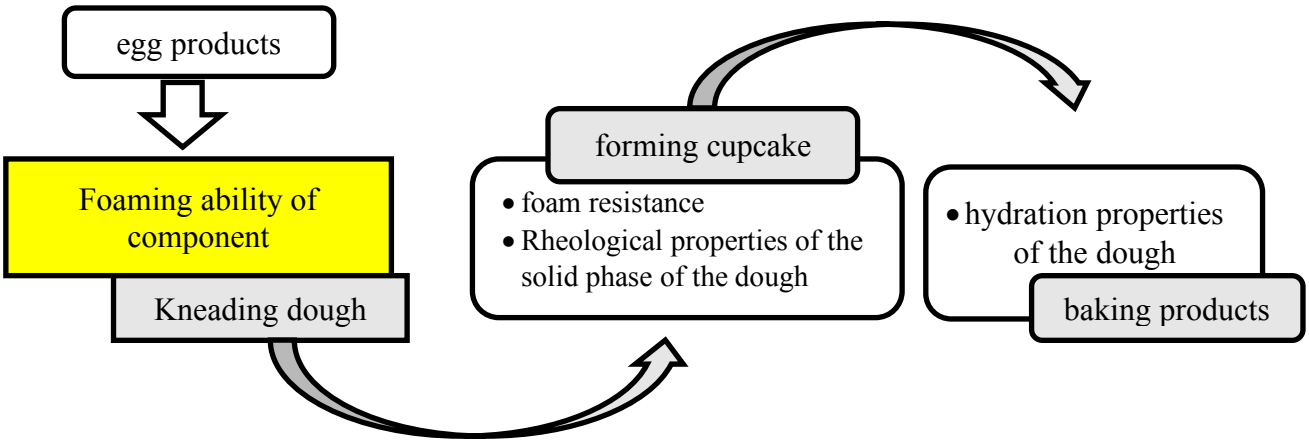

Figure 1 The relationship between recipe components and properties of the dough mass and the foamy structure formation.

In the technological process of mixing the biscuit semi-finished product as a foaming agent, egg mélange is most often used. Due to the saturation of the protein mass with air, the knockdown causes the denaturation of the protein's native structure, which in its turn unfolds the protein chains without destroying their covalent structure. In the process of denaturation, the protein's inherent three-dimensional structure breaks down **(Renzjaeva and Bakirova, 2017),** the polypeptide chain unfolds, simultaneously forming bonds between the polypeptide chains, which generally contributes to the stability of the foam. The foamy structure of the biscuit semi-finished products is due to a greater extent to the presence in their recipe of a considerable quantity of egg products that is almost twice more than flour (Figure 1). This makes it possible to assume that wheat flour will be completely replaced by non-baking flour.

Therefore, biscuit dough is a complex dispersed system consisting of air bubbles separated by liquid pellicle. In this system, the dispersed medium is an egg-sugar mixture and the dispersed phase is air. The technological process **(Drobot, Pysarets and Kravchenko, 2013)** involves dispersion of the egg-sugar mixture, which is saturated with air bubbles and leads to an increase in volume, development of the inner surface of the system, and creation of a foam system.

The main characteristics **(Renzjaeva and Bakirova, 2017; Drobot, Pysarets and Kravchenko, 2013)** that comprehensively characterize the foam system are – foaming solution, foam multiplicity, foam stability, and foam dispersion, i.e. distribution bubbles by the size or surface of the solution-gas separation, per unit volume of foam. The patterns that cause the formation of foam vary significantly depending on the conditions of mixing components.

The beating of the egg-sugar mass in ECF technology is one of the separate operations which results in the formation of a system that is a confectionery foam. The formation of thick foam is positively affected by the surface activity of egg polar white molecules and a noticeable stabilizing effect is present in the sugar mixture. As a result, solid pellicles are formed around the air bubbles which enhance the foam's stability. Increases the marked effect of increasing the viscosity of the liquid when sugar is added.

Along with the prescription components, the duration of the whipping and the speed of rotation of the working organs are influenced by the foam volume and its dispersion, the foaming ability, and the foam resistance. As the whipping time increases, the volume of foam also increases; the whipping rate is directly proportional to the foam dispersion.

Today, a considerable amount of theoretical and applied aspects of foam production **(Holovchenko, Lopatin and Kovbasa, 2001)**, physicochemical properties, structure characterizing the geometric shape of air bubbles and their stability have been accumulated. The structure of the foams is determined by the ratio of the volumes of liquid and gas phases and, depending on this ratio, the foam cells have a spherical or polyhedron shape. Usually, freshly prepared foam of the egg-sugar mixture has a spherical shape of cells separated by thick walls of liquid, because the volume of the gas phase exceeds the volume of the liquid by no more than 10 – 20 times. As the foam ages, the spherical shape of the foam bubbles becomes multifaceted with thin flat pellicles as a result of fluid draining. At the same time, the specific surface of the foam changes due to the diffusion of gas from small bubbles into larger ones, due to the difference in capillary pressures.

In the paper **(Holovchenko, Lopatin and Kovbasa, 2001)**, it is noted that although the foam state with polyhedral cells is close to equilibrium, such foam has greater stability than the one with spherical cells. However **(Holovchenko, Lopatin and Kovbasa, 2001; Mancebo, Rodriguez and Gómez, 2016)**, by reducing the number of small bubbles, the total number of air bubbles in this volume of foam decreases, that is, the coalescence of foam occurs, which reduces its stability. Carried out studies **(Mancebo, Rodriguez and Gómez, 2016)** show that with increasing foam concentration, the viscosity of the solution decreases and foaming improves, and the density of the foaming mass decreases due to more air being drawn into the system.

A characteristic feature of biscuit dough is that in its composition, in addition to foaming agents other recipe components are included that have a significant impact on the quality of the biscuit semi-finished product. The main

component that has a significant impact on the quality of the biscuit cake mix is flour.

Compared to the duration of the whisking of the egg-sugar mass, the kneading with the flour lasts only a few seconds, but the flour has a significant effect on the quality of the semi-finished product. The properties of gluten flour and its content significantly affect the quality of the baked semi-finished product, because when kneading occurs the hydration of gluten proteins and longer kneading leads to the tightening of the dough and compacting the structure of the biscuit semi-finished product.

The research **(Stojceska et al., 2010)** identified the steps of regulating the structural and mechanical properties of gluten-free dough. First of all, it is the use of flour mixtures, not certain types of gluten-free flour, which can significantly improve the nutritional and biological value as well as product structure but to expand the raw material base and finished product range. To establish the technological effect, we considered the relationship between the recipe components and the properties of the dough masses in the formation of the foamy structure of gluten-free cupcake products (Figure 1).

In physics and chemical sense, foam is a two-component gas-liquid system. In the process of foam formation, there is a powerful development of the liquid and gaseous phase interface. The surface tension force always seeks to minimize the total surface of the section. In the dough foam mass, the flour component actively absorbs the moisture from the liquid phase contained in the foam. This leads to the rupture of the pores pellicles, followed by their merging into pores of larger sizes. Hence there is the formation of heterogeneous porosity in the finished products prepared based on flour.

In the production of the cupcake, when the mixture turns into the dough, gluten forms a viscoelastic network capable of trapping and storing carbonated bubbles. The state of aeration of the dough immediately after mixing has a huge impact on the texture of the cupcake. And the aerated dough architecture is governed by different physical principles related to foam formation and stabilization.

The specificity of the production of gluten-free dough by beating is that the foam obtained is subjected to unwanted external influences that lead to a decrease in its stability. Such factors include mixing the whipped mixture with flour and placing the dough in molds (Figure 4). In such circumstances, it is important not only to obtain a foam system with the required characteristics but also to preserve them during the technological process. Thus, in our view, it is important to investigate the foaming ability and foam resistance to structure destruction comprehensively.

According to current scientific concepts **(Drobot, Pysarets and Kravchenko, 2001; Haliasnyi, Gavrish and Shanina, 2018)**, in the absence of a hydrated gluten network, one of the important factors for optimizing and stabilizing the process of retaining gas formed in the gluten-free dough is sufficient water amount to hydrate the biopolymers of the dough and obtain the desired viscosity. It is possible to increase the hydration capacity of gluten-free dough by adding protein substances.

For the formation of a stable foam structure, it is necessary to weaken the counteraction of the system surface tension which is achieved by introducing into the mass of the surfactants which can significantly reduce the surface tension at the interface. We have developed **(Stadnyk et al., 2019)** a method of attenuating the surface tension forces of a system by using a discretely pulsed mixing machine. Its purpose is to intensify the technological process by reducing the time of beating the egg-sugar mixture. It should be noted that obtaining a well-loosened dough structure is the first but not the only technological task. Also important is the preservation of the formed structure which determines the corresponding rheological properties of the dough.

Scientific hypothesis

The idea of the development is to establish the relationship of wheat and extruded corn flour (ECF) in the process of mixing the recipe components on the developed mixer with characteristic differences in the formation of a stable foam structure in the technology of cupcakes.

MATERIAL AND METHODOLOGY

Materials

Extruded Corn Flour (ECF) of maize crop (2018, 2019) was grown in Chernihiv region. ECF is a dry mixture of homogeneous consistency in powder and fine grains with taste, smell, and color inherent to raw materials, made by grinding grain parts (endosperm, aleurone layer, fruiting membranes, with pre-removed embryo) and hot extrusion method. Wheat flour of the highest grade with a crude gluten content of 23.0 ±0.4% and a crude gluten deformation value of 60 ±1.1% etc., potato starch, chicken eggs, white crystalline sugar. The characteristics of the batches of flour used in the experimental studies are shown in Table 1.

Research methods

Standard, conventional, special, and modified physics and chemical, microbiological, and organoleptic research methods were used to perform the work.

Wheat and FCE quality were established in each consignment based on the results of the average sample analysis according to **DSTU 3355-96, DSTU ISO 9001:2015 IDT**.

Sampling and sample preparation for laboratory testing of The raw materials was carried out in accordance with a single methodology for the study of domestic food. The test and control samples were prepared from one batch of raw materials (Table 2).

The experimental part of the work was carried out in the research laboratories of the Department of Food Technology, TNTU University, and the laboratory of grain quality at the Institute of Plant Growing named after V.Ya. Yurjev of the National Academy of Agrarian Sciences of Ukraine.

The prototyping technology includes the following operations: the egg-sugar mass is beaten to a 2.5 – to 3-fold increase in volume, ie approximately 30 – 40 × 60 s. Then gradually add the premium wheat flour mixed with starch or extruded corn flour. The mixing was carried out in the developed machine (Figure 2) with a duration not exceeding 35 s.

Ready-made biscuit dough is baked immediately in capsules and on sheets, as the biscuit dough settles when stored. Biscuit dough was placed in shapes at ¾ of their height because when baking it increases in volume Figure 3.

Baking biscuit dough was carried out at a temperature of 200 – 210 °C. Baking time in capsules was 50 – 60 × 60 s. Baked biscuit cake was cooled 20 – 30 × 60 s and removed from the molds. The biscuit semi-finished product is left at 8 – 10 × 60 c2 for standing, after which it is possible to cut and carry out the following technological operations.

The structural and mechanical qualities of the dough include elastic and flexible and viscous and plastic qualities. The elastic and flexible qualities of the dough were determined using a farinograph "Brabender", which describes the process of dough formation and its behavior under continuous machining conditions, and the viscous and plastic qualities on the alveograph "Chopin". The foam resistance of the egg and sugar mixture with the addition of the test flour mixtures was determined as the ratio of the foam column height after holding for 24 × 602 s at a temperature of 18 – 20 °C to the total foam column height of the sample, expressed as a percentage, calculated by the formula: (1)

$$СП = \frac{Bn^{24\cdot 60^2}}{Bn} \times 100\% \quad (1)$$

Where:
СП is foam resistance,%;
Bn60 is the height of foam column 24 × 602 s after cessation of whipping, m;
Bn is the initial foam height, m.

The specific volume of products was calculated as the ratio of their volume to mass ($m^3.kg^{-1}$). Baking was defined as the difference between the weight of the dough before baking and the weight of the finished semi-finished product.

The degree of batch penetration of baked semi-finished products after baking and during storage was examined on a Labor Penetrometer (Hungary) according to the standard method. Microscopic studies of the structure of the product were performed **(Rochow and Rochow, 2012)** using a digital binocular microscope series "MicroMed" equipped with a built-in lighting system. The micrographs of the samples were taken at the following magnifications: 40 times, 100 times, 400 times, 1000 times. The porosity of the samples of the biscuit cake **(Stadnyk et al., 2015)** – control (basic biscuit) and extruded corn flour were carried out by measuring the effective pore diameters on the biscuit cross sections by visualizing the microstructure of the biscuit, processing the digital images.

Statistical analysis

The assessment of the basic regularities of changing the qualities of biscuit dough is based on the optimal parameters and modes of its formation. They are based on the initial values of the process, which determines the probability of the obtained results of the structure required to describe the consumer properties. The features of the influence on the treated environment in the formation of the foamy structure of the dough and the conditions to achieve rational parameters of the mixing in the working compartment, it is possible to predict the performance of the mixer. To clarify the role of individual factors of the system, planning and setting up of computational experiments were performed to obtain the corresponding regression equations. Determination of the influence of the design parameters of the mixer (independent factors xi) on the foaming process (Q), conducted full factorial experiments FFE 3^3. They aim to determine the magnitude of productivity and to establish its effect on the structure when mixing components that depend on changes in the three main factors: the frontal surface of the plate working body α, the distance between the plates (step) t and the speed of rotation of the working body *n*. The construction of the plan-matrix of the planning of experiments indicated the conditional factors of the upper, lower, and zero levels of variation, respectively +1, -1, 0. The results of the encoded factors and their levels of variation are shown in Table 3. The construction of this table is as follows. The input values of the FFE 3^3 variable factors are:

-the speed of the plate n (rpm), which is encoded by the index x_1;

-the angle of attack of the frontal surface of the stroke of the plate α (deg) encoded by the index x_2; is the step between the plates t (m) encoded by the index x_3.

Statistical analysis of the results was performed to analyze the dependencies obtained with the help of the software package on the PC "Statistica 6.0". Determinations of the mathematical variance of random variables D were estimated by standard methods. The regression dependence of the performance on the change in the speed of the shaft n, the angle of attack of the frontal surface of the stroke of the plate α, deg and the pitch of the plates t, ie Q X_1 X_2 X_3 = f (n α t), for the encoded values of the factors for mixing has the form:

$$Q_{(n,\propto,T)} = 2.185 - 0.0031x_1 - 0.114x_2 + \\ +1.559x_3 + 0.000012x_1x_2 + \\ +0.000031x_1x_{3+} + 0.00036x_2x_3 \\ +0.0000023x_1^2 + 0.00071x_2^2 - 0.0723x_3^2$$

For the natural values of the factors of the regression equation (4.1) for mixing takes the form:

$$Q_{(n,\propto,T)}=1.224+0.0061n-0.106\propto_1+1.591T_2+0.00071\propto_1^2-0.0723T_1^2$$

The obtained regression equation can be used to determine the performance of the mixer for different formulations (Q), depending on the change of speed of the shaft with the working bodies n, the angle of attack of the frontal surface of the stroke of the plate α and the step between the tariaks t within the following limits of change of input factors:

$348 \leq n \leq 696$ (rpm); $30 \leq 1\ \alpha \leq 60$ (deg); $0.9 \leq t \leq 0.14$ (m).

From the obtained regression equations it was found that the factors that influence x1, x2, (n, α), and their combination are the biggest influence factors on the

change in performance. Productivity is reduced to 20% by increasing the value of factor x2 (α) (Table 3).

By increasing the speed of the shaft and decreasing the angle of attack of the frontal surface of the plate stroke, the performance of the mixer is increased.

The response surfaces and their two-dimensional sections are built on the regression equations obtained to determine the performance from the change in the two factors for x3 = const. The results of the performance dependencies obtained with the Statistica-6.0 program are shown in Figure 4 and Figure 5.

The statistical processing of the experimental results and the obtained regression dependencies adequately reproduce the research processes for determining the mixing performance of the components which is the quality of the whipping of the foaming biscuit dough.

Figure 4 and Figure 5 show that as the shaft speed increases, the value of productivity increases, with the highest productivity being achieved when mixing gluten-free flour. Minimum performance value with minimum shaft speed and maximum attack angle of the frontal surface of the stroke of the plate.

RESULTS AND DISCUSSION

To analyze consumer properties and establish rheological dependencies, the studies were directed in such a sequence as to justify the feasibility of using an ECF.

Features of the methods of mixing we have chosen, the composition and state of the liquid phase of the dough, allow us to solve several technological problems. First, the liquid phase is the binding component for the formation of a continuous dough network. Second, the properties of the liquid phase actively influence the process of foam formation and its retention in the dough. Also **(Lisovska, Chorna and Dyakov, 2016)**, it is an important flavor component of the cupcake recipe.

The authors' research **(Kobets et al., 2015)** established the effect of a mixture of fibers and emulsifiers on the gluten complex of wheat flour by physicochemical quality indicators of the biscuit semi-finished product. To regulate the set quality of confectionery dough, the authors **(Mancebo, Rodriguez and Gómez, 2016)** believe that you can use different ratios of starch and protein.

The results of the authors' research **(Egorova and Reznichenko, 2018; Dorohovych, Hrytsevich and Isakova, 2018)** reflect the influence of technological and design factors on the model systems of biscuit semi-finished products. They analyzed the effect on the volume and shape of the finished products, the structure of their porosity, as well as the nature of the structural, and mechanical properties of the dough, the actual time of dough formation, its stability, degree of depression, consistency and elasticity.

Thus, research **(Haliasnyi, Gavrish and Shanina, 2018)** is aimed at finding structure-forming components for gluten-free flour confectionery. They conducted a comparative analysis of changes in the fractional composition of flour dough proteins with different types of flour raw materials and liquid phases. Problems related to changes in the structural and mechanical properties of the environment and the impact of structural elements and methods of the process, discussed in detail **(Szwedziak et al., 2019)**, taking into account empirical data, theoretical dependences, and the results of physical experiments.

The specificity of the production of gluten-free dough cakes by intensive mixing (whipping) is that the resulting foam structure is subjected to unwanted external influences that lead to a decrease in its stability. Such factors include mixing the whipped mixture with flour and placing the dough in molds. In such circumstances, it is important not only to obtain a foam system with the required characteristics but also to preserve them during the technological process. Accordingly, in our view, it is important to comprehensively investigate the foaming ability and foam resistance to structure destruction. It should be noted that obtaining a well-loosened dough structure is the first but not the only one technological task.

The issue **(Lisovska, Chorna and Dyakov, 2016)** of the preservation of the formed structure, which determines the corresponding rheological properties of the dough is also important. It should be noted **(Lisovska, Chorna and Dyakov, 2016; Dickinson, 2015)** that, unlike the traditional confectionery foam (for example, in the preparation of biscuits, where the amount of sugar is much higher), in gluten-free cupcakes, recipe sugar level is much lower. Therefore, the issue of effective foaming is extremely important.

In their studies **(Murtini and Putri, 2017)** to improve the volume as emulsifiers egg yolk substitute was added that is a suspension of edamam (Glycine max L. Merill). Five different proportions of edamam suspension were added to the dough and their effect on specific volume, porosity, water content, oil absorption, hardness texture, and elasticity was observed. It should be noted that many works **(Lisovska et al., 2020)**, considered the foam structure of the dough for cupcakes with the establishment of the main technological and design parameters of the interaction of prescription mixtures. They substantiated the quality of the cake with the ratio of the main recipe components: egg content (51%); sugar content (24.4%) and content of extruded corn flour (24.6%).

Along with the prescription components, the duration of the whipping and the speed of rotation of the working organs (machine productivity) are influenced by the foam volume and its dispersion, the foaming ability, and the foam stability.

As the whipping time increases, the volume of foam also increases; the whipping rate is directly proportional to the foam dispersion. We chose the traditional mode at high foam whipping.

Table 1 Chemical composition of extruded corn flour and wheat flour of the highest grade, %.

Product	Moisture content	Protein content	Fat content	Starch content	Ash content	Fiber content
Extruded corn flour	9.0 ±0.01	6.1 ±0.02	8.1 ±0.02	70.9 ±0.03	4.8 ±0.03	1 ±0.02
Wheat flour of the highest grade	14.5 ±0.03	11.4 ±0.05	1.08 ±0.04	67.7 ±0.05	0.5 ±0.03	0.1 ±0.01

Because the offered introduction of ECF to the recipe mixture affects the stability of the system, we conducted a set of experiments to study the dependence of the effective viscosity of biscuit dough samples with the addition of ECF on the velocity and shear voltage. In the tested mixtures, the moisture-holding capacity increases for the sample containing 20% by weight of corn extruded flour by two and a half times, and three times for the sample with extruded flour by 100% by weight. This tendency of change is explained by the swelling of whole starch grains due to the absorption and retention of moisture. With an increasing proportion of corn extruded flour in the flour mixture, the dough density increases and the optimum value is in the range of 0.444 – 0.446 $kg.m^{-3}$. An increase in the flour of corn extruded above 20% by weight leads to a considerable density of the dough, but in the absence of wheat flour of the highest grade indicates the possibility of creating a biscuit gluten-free semi-finished product.

From Figure 6 it is confirmed that the foam stability depends on the flour used. The use of corn extruded flour significantly affects the stability of the sponge dough foam. Foam resistance monotonically increases almost 1.5 times with the complete replacement of wheat flour, which corresponds to a large volume and a thin uniform porosity of the biscuit cake. This ability will help to stabilize the foam of the biscuit dough during mechanical influences during its molding.

The stability of the dispersed system is due to the structural and mechanical properties of the adsorption layers and the thermodynamic stability of the liquid layers. These adsorption layers slow the flow of liquid in the pellicles, reducing the rate of their thinning. This is confirmed in the work **(Zhou et al., 2015)** that revealed the effect on the moisture-holding capacity of the system of flour mixtures. At the same time, it was noted **(Zhou et al., 2015)** that free starch polymers dissolve to form a dispersed system.

Also, these layers give the foam pellicle a high structural viscosity and mechanical strength, creating a framework that gives the foam certain physical and chemical properties of the solid.

An important rheological characteristic of biscuit dough as the foam is the viscosity that acts as a structural and mechanical barrier in the formation and destruction of the foam structure. The dependence of the maximum viscosity of the suspension on the contents of the ECB in flour mixtures is shown in Figure 7.

The stability of the dispersion system, which is a biscuit dough largely due to the strength and resistance to loading, i.e. the creation of an elastic frame, which gives the system certain physical and chemical properties of the solid. Analysis of the studies showed that when adding 5 and 10% of the ECF there is a maximum viscosity, which indicates the starch binding during a large amount of water. When using 100% ECF (Figure 7), the viscosity decreases, because the starch binds a small amount of water during swelling and pasteurization. The water is free in the dough and released when coagulated with protein substances, which promotes the formation of a wetter crumb cake mix.

In the works of authors **(Lisovska, Chorna and Dyakov, 2016; Murray and Ettelaie, 2004)**, it is noted that the schematic structure of the foam is the packing of gas bubbles with thin pellicles of the main fine particulate filler, which is covered with pellicle substance with surfactants. Figure 9 shows the comparative characteristics of the microstructure of the following samples: wheat flour (WF) and extruded corn flour (ECF) in the ratios: a) WF – 100 wt.%; b) WF: ECF – 80:20 wt.%; c) ECF – 100 wt.%.

The thermodynamic correlation relative to the gas phase makes it possible to determine its volumetric deformation, which is the basis for determining the rigidity of the system.

Many studies **(Sandri et al., 2017)** proved that the moisture content of the dough in the case of rice and corn flour should be reduced compared to the moisture content of the dough with wheat flour, in the case of buckwheat flour it should be increased to obtain products high quality. They established and calculated the range of change in viscosity with increasing shear stress according to the viscosity curves.

For example, in the study **(Murray and Ettelaie, 2004)**, it is noted that the destruction of the air bubble film is directed toward the larger bubble because its pressure is lower than that of the small bubble.

On these microstructures of biscuit dough (Figure 9) of prototypes, it has the appearance of foam with an existing and uniform distribution of air bubbles, which later form a porous structure of biscuit semi-finished products. The sizes of the formed air bubbles with the content of wheat flour and starch have a large difference in diameters, that is, some bubbles are almost twice the size of the others. In the sample of biscuit dough using ECF 100 wt.% Figure 9 (4) foam bubbles are practically the same size and channels are formed between them, which help to equalize the air pressure in the middle of the foam biscuit dough system. The sample with an ECF content of 20 wt.% is also characterized by the same size of gas bubbles, which contributes to the stabilization of the foam system.

This leads to an improvement in the structural and mechanical characteristics of ready-made biscuit products.

After baking the samples (Figure 8), a semi-finished biscuit with a volume at the level of the sample of wheat flour with a fine uniform porosity was obtained. The use of 20 wt.% (Figure 8, number 2) and 100 wt.% (Figure 8, number 3) corn extruded flour contributes to the formation of a fine porous structure of biscuit dough.

Thus, the total area of large pores with a size of 0.7 – 1.5 mm in the sample with WF – 100 wt.%. It is equal to 15.36 mm^2 in the field of view and in the test samples variant WF: ECF – 80:20 wt.% and ECF – 100 wt.% is 3.69 and 2.94 mm^2 accordingly.

At the same time, the number of small and very small pores (less than 0.5 mm) is significantly increasing, mostly in the sample with ECF – 100 wt. %. The obtained data are correlated with the data on foaming capacity, which is the highest ECF that is 100 wt.%.

The above indicates that the proposed additives to improve gluten-free dough, improve the porosity of the foamy structure, forming a fine porous structure of the cake. This effect is due to the ability of high-quality deformation impact of the working bodies of the machine.

Note: Dough samples containing: WF and ECF in the ratios: a) WF – 100 wt.%; b) WF: ECF – 80:20 wt.%; c) ECF – 100 wt.%; 1 – air bubbles; 2 – potato starch grains; 3 – wheat flour starch grains; 4 – channels between air bubbles.

CONCLUSION

Therefore, it can be concluded that the use of the obtained results allows regulating the technological properties of flour mixtures, depending on the concentration of them in the ECB and recommend them in the production of confectionery flour health products.

Stabilization of the rheological properties of the foam system of biscuit gluten-free dough is achieved due to the properties of partially pasteurized starch of extruded flour. Gluten-free biscuit recipe composition is optimized: 51% of egg product content; 24.4% of sugar content and 24.6% of flour content of extruded corn.

The presence of stable hydrodynamic parameters of gas-liquid systems under the action of the geometry of the machine gives reason to consider them metastable. The motive factor is determined by the product of the external pressure on the cross-sectional area of the working room, and the opposing force in the deformation of the gas-liquid medium is the elastic forces and the forces of internal friction.

RELATIONSHIP BETWEEN THE ACTIVITY OF GUAIACOL PEROXIDASE AND THE CONTENT OF PHOTOSYNTHETIC PIGMENTS IN TEA LEAVES

Nataliia Platonova, Oksana Belous

ABSTRACT
The dynamics of guaiacol peroxidase and photosynthetic pigments in 3-leaf sprouts (flushes) of tea plants were studied. The presence of declines and peaks in the activity of the enzyme associated with the meteorological conditions of each month was noted. It is shown that there is a direct relationship between the increase in enzyme activity and hydrothermal factors. The most significant correlation was found between the activity of GPO in a 3-leaf tea flush and the amount of precipitation (r = 0.86). The highest activity of guaiacol peroxidase during the entire vegetation period is distinguished by the Sochi variety and form 582. The lowest activity was observed in forms 3823 and 2264, which indicates a low intensity of redox reactions in these plants in stressful situations. Determining the dynamics of the pigment complex revealed its dependence on hydrothermal factors. Studies have shown that precipitation is a significant factor affecting the pigment complex of tea plants. It was found that the largest amount of green pigments is synthesized by leaves at the beginning of active vegetation (May). The participation of the pigment apparatus in the adaptation of the tea plant is directly related to carotenoids, the increase in the number of carotenoids coincides with the period of drought. In the content of photosynthetic pigments and the activity of guaiacol peroxidase manifest genotypic features. The revealed patterns are common to all tea plants.

Keywords: tea; chlorophyll; carotenoid; guaiacol peroxidase; air temperature; precipitation; correlation; stability

INTRODUCTION
One of the most important problems of phytophysiology is the study of the mechanisms of plant resistance to adverse environmental factors **(Foyer and Noctor, 2000; Kareska, 2009; Belous and Platonova, 2018a)**. One of the consequences of stress is the formation of reactive oxygen species (ROS). In a comfortable state of the cell, the ROS content is maintained at a low level, thanks to the work of special antioxidant enzyme systems that utilize reactive oxygen species. The amount of ROS that is not eliminated by enzymes, accumulated in the cell, and causing damage to it, is called oxidative stress. Oxidative stress is a non-specific reaction of plants to the action of stress factors **(Kareska, 2009; Belous and Platonova, 2018c)**. Under the action of stressors, the content of ROS in cells increases significantly, especially in heat-loving plants, which include all subtropical crops, such as tea.

Several authors noted an increase in the activity of peroxidases, especially when inactivating certain antioxidant enzymes, such as catalase **(Krasensky and Jonak, 2012; Eremchenko, Kusakina and Luzina, 2014; Kaur and Asthir, 2017; Belous, Klemeshova and Malyarovskaya, 2018; Belous and Platonova, 2019)**. It is no accident that recently special interest has been directed to the study of peroxidases – enzymes of the class of oxidoreductases that catalyze the oxidation of various substances with the help of hydrogen peroxide. The level of peroxidase activity in plant organs is used to characterize their functional state in response to extreme environmental factors **(Bukhov et al., 2001; Kapchina-Toteva et al., 2004; Ladygin and Shirshikova, 2006)**. An increase in peroxidase activity in the photosynthetic organs of plants indicates active photosynthesis during stress.

An important question for us is related to the fact that the peroxidase substrates are phenolic compounds, ascorbic acid, a number of aromatic acids, carotenes, etc. **(Kasote et al., 2015)**. All these compounds are significant components of the antioxidant system of tea and determine its nutritional value **(Fedotova, 2009; Mulgund, Doshi and Agarwal, 2015; Belous and Platonova, 2018b)**. But the main substrate is phenols, which under the action of the enzyme are oxidized to polyphenols and quinones, which are strong oxidizers **(Rogozhin, 2004)**. Quinones are capable of polymerization, resulting in dark-colored compounds. This process is especially active at the stage of enzymatic oxidation of raw materials (3-leaf sprout) in the production of black tea.

The effectiveness of the photosynthetic apparatus in stressful conditions is due to the peculiarities of the

pigment complex. This is one of the most important indicators of the adaptive potential of plants since carotenoids are important components of the antioxidant system and play an important role in protecting plants from photo-oxidative processes. Carotenoids take part in redox processes; normalize oxygen consumption by plant tissues. These pigments are effective antioxidants because they absorb singlet molecular oxygenized radicals.

The composition of the antioxidant system of tea includes the main components that determine the taste of the finished product, the importance of these substances for humans is undeniable and the study of the patterns of their accumulation is necessary **(Belous and Platonova, 2018b)**. Tea plants in the conditions of subtropical Russia are often exposed to stress factors during the active vegetation period; the study of the regularities of the formation of components of the antioxidant system of tea is undoubtedly relevant.

The picture of tea sprout is presented in Figure 1, black tea from Krasnodar sprout is presented in Figure 2 and the tea harvesting on the experimental plantation is presented in Figure 3.

Scientific hypothesis

There is a relationship between the activity of guaiacol peroxidase and hydrothermal factors.

A decrease in the activity of guaiacol peroxidase is unfavorable for the stability and quality of tea plants.

Hydrothermal factors influence the content of photosynthetic pigments.

The ratio of the amount of chlorophyll to carotenoids indicates the degree of adaptation of tea plants to adverse conditions.

MATERIAL AND METHODOLOGY

Objects of research – 3-leaf sprouts (flushes) of tea plants (*Camellia sinensis* (L.) O. Kuntze) varieties of Sochi and forms of Institute selection 3823, 582, 855, and 2264, grown on the experimental collection and breeding site of the Russian Institute of Floriculture and Subtropical Crops in the village Uch-Dere (Lazarevsky district, Sochi, Russia). Control – Colchida variety. The plantations are located at an altitude of 280 m above the sea. Soils in the Krasnodar region where tea plantations are located are brown forest slightly unsaturated. In the humid subtropical zone of Russia, the driest period coincides with the period of active vegetation – June and August. Weather conditions in recent years differ significantly from the long-term norm, both in terms of precipitation and air temperature. Thus, the precipitation deficit in May – August is on average 28.5 – 87.0 mm; the absolute maximum temperature is in the range of 35.5 (in June) – 32.3 (in August) °C, at that time, an average monthly average temperature of 22.3 ±1.2 °C. The average duration of sunshine is 244 hours per month (May – August), which corresponds to almost completely cloudless days in summer.

The selection of flushes was carried out in 3-fold field repetition in the period from May to August 2017 – 2019. The determination of laboratory analyses was performed in 3-fold repetition in the laboratory of plant physiology and biochemistry. All chemicals were analytical grade and obtained from LENREACTIV (Russia).

Determination of pigments

We used a spectrophotometric method for determining the content of chlorophyll and carotenoids with the extraction of pigments with 96% ethanol and using the calculated formulas of Smith and Benitez **(Shlyk, 1971)**. The optical density of extracted pigments was measured using a PE-5400VI spectrophotometer, manufactured by EKROSHIM LLC (Russia) at a wavelength of 665 and 649 nm for chlorophylls a and b, and 440.5 nm for carotenoids in cuvettes with a layer thickness of 10 mm.

Determination of the activity of guaiacol peroxidase

The activity of guaiacol peroxidase (GPO) was determined by the spectrophotometric method, taking into account the rate of utilization of hydrogen peroxide in the reaction mixture, into which the plant material is introduced. The intensity of utilization of hydrogen peroxide was judged by the rate of extinction reduction at a wavelength of 440 nm against the phosphate buffer (pH 6.7) **(Vorobyov et al., 2013)**.

Statistical analysis

The arithmetic mean values of the measured values and their standard deviations are shown in Figures and Tables. The correlation between the samples was estimated by calculating the Spearman rank correlation. To check the significance of correlation and estimate statistical values, an analysis was performed using the ANOVA package in STATGRAPHICS Centurion XV (version 15.1.02, StatPoint Technologies) and MS Excel 2007. Statistical analysis included a one-dimensional analysis of variance (a method for comparing averages using variance analysis, t-test). The significance of the difference between the average values at $p < 0.05$ was considered statistically significant.

RESULTS AND DISCUSSION

When determining the activity of guaiacol peroxidase in freshly harvested 3-leaf tea flushes during the active vegetation period, the presence of declines and peaks in the activity of the enzyme associated with the meteorological conditions of each month was noted (Figure 4 and Figure 5). At the beginning of the growing season (May), the activity of the enzyme was low – in the range of 0.363 to 0.607 unit.g^{-1}·sec.

In June, there is a decrease in activity, which, however, is not significant and is due to the biological characteristics of the tea culture. After the May surge in growth processes in tea plants, there is a period of rest, in which the metabolic processes are somewhat slowed down. As a rule, in the future, in our zone there is a stressful period under hydrothermal conditions, which affects the functional state of plants; in particular, we can note an acute water deficit. This leads to the manifestation of oxidative stress, which is expressed in an increase in the activity of GPO, as a non-specific reaction to a stress factor **(Birben et al., 2012; Keshari et al., 2015; Ognik et al., 2016)**.

Figure 1 Tea sprout.

Figure 2 Black tea from Krasnodar sprout.

We performed a correlation analysis that showed a direct relationship between increased enzyme activity and hydrothermal factors (Table 2). At the same time, the most significant correlation was found between the activity of GPO in freshly harvested 3-leaf tea flushes and the amount of precipitation (r = 0.86).

However, the dynamics of enzyme activity in a 3-leaf sprout is variety-specific (see Table 1). The highest activity of guaiacol peroxidase during the entire vegetation period is characterized by the Sochi variety and form 582 (about 0.56 unit.g^{-1}·sec).

The lowest activity was observed in forms 3823 and 2264, which indicates a low intensity of redox reactions in stressful situations, under the influence of changing environmental factors on plants. Tea sprouts are used to prepare a drink whose nutritional value is made up of substances formed both in the process of photosynthetic reactions and in the process of processing raw materials, the basis of which is redox enzyme reactions **(Chen and Asada, 1989; Pandey et al., 2017; Skhalyakhov et al., 2019)**. Given this fact, a lower level of activity of guaiacol peroxidase is a negative phenomenon, both for the stability of the plant itself and for the quality of the finished tea.

One of the indicators of plant response to changes in hydrothermal conditions is the quantitative content of chlorophyll and carotenoids – the main photoreceptors of the photosynthetic cell **(Fedotova, 2009; Eremchenko, Kusakina and Luzina, 2014)**. Stress factors, including lack of precipitation and high positive temperatures, significantly increase the probability of photo-oxidative damage in chloroplasts **(Foyer and Noctor, 2000; Mittler, 2002; Kapchina-Toteva et al., 2004; Ladygin and Shirshikova, 2006; Kareska, 2009; Nikolaeva et al., 2010)**. Only by studying the pigment system of plants can we fully identify the biological and adaptive capabilities of the culture. As shown by research, a significant factor that affects the pigment complex of tea plants is the amount of precipitation.

Determination of the dynamics of the pigment complex showed its dependence on hydrothermal factors: the largest amount of green pigments is synthesized by leaves at the beginning of active vegetation (May). In July, after short rains of a stormy nature that do not cover the water deficit in the soil, growth processes in tea resume, but less actively than in May. There is an increase in new sprout; green pigments which are intensively synthesized in leaf blades, which manifest itself in an increase in their number. In August, the drought increases, which affects not only the inhibition of growth processes but also a significantly lower accumulation of the green group of pigments (LSD ($p \leq 0.05$) = 0.12).

Air temperature, °C	0.42	0.54	0.38
Amount of precipitation, mm	0.86	0.27	0.68

The participation of the pigment apparatus in the adaptation of the tea plant is directly related to carotenoids (Figure 5); as can be seen from Figure 5, a slight increase in the number of carotenoids coincides with the period of drought and the natural June decay of growth processes. In August, with significant water scarcity there has been a sharp increase in the synthesis of carotenoids, because of the continuous drought period, followed by increasing the temperature to 30 degrees or more, and reduced atmospheric humidity of 50 – 60%, what is the tea plant even bigger stressor than lack of soil moisture. Increasing the synthesis of carotenoids leads to a significant decrease in the ratio of the amount of chlorophyll to the number of carotenoids.

The identified patterns are common to all tea plants. However, the content of photosynthetic pigments also shows genotypic features (see Table 1).

The main photosynthetic pigment is chlorophyll-a **(Ognik et al., 2016; Potoroko et al., 2017; Platonova and Belous, 2019)**. Significant accumulation of chlorophyll in the leaves is characteristic of the control cv. Colchida. While the studied mutant forms contain chlorophyll a significantly lower (Table 1). The content of chlorophyll b indicates the level of adaptation of plants to low light **(Ognik et al., 2016; Potoroko et al., 2017; Steinman et.al., 2017; Platonova and Belous, 2019)**. For tea plants, this is not relevant, since the crop is grown in open spaces and pruning the trellis stimulates the growth of leaves on the upper part of it. But often a tightly closed trellis restricts the space open to sunlight, and many of the leaves of the side surfaces are in shadow. In this case, increased content of chlorophyll b is preferable for the photosynthetic activity of leaves of this tier **(Beneragama and Goto, 2010; Biswal et.al., 2012)**. We noted the same pattern as with chlorophyll a: more chlorophyll b accumulates in the control variety; and the differences are significant or at the border of materiality, as in the case of forms 3823 and 2264. Important is not only the content of pigments but also their ratio. In all the tea plants studied, the a-b ratio ranges from 2.81 mg. g^{-1} to 3.36 mg. g^{-1} and the differences between the forms are insignificant (Table 1).

The ratio of the amount of chlorophylls to carotenoids is a more informative sign since it indicates the degree of adaptation of plants to adverse conditions **(Thongsook and Barrett, 2005; Potoroko et al., 2017)**. The stability of the variety is higher than the ratio is lower. According to this indicator, all new forms of tea can be classified as fairly stable, in their flushes, the ratio of the amount of chlorophyll to carotenoids is significantly lower than in the cv. Colchida (see Table 1).

CONCLUSION

Thus, we determined the change in the activity of GPO and photosynthetic pigments in a freshly collected 3-leaf sprout. The presence of declines and peaks in the activity of the enzyme, which are associated with meteorological conditions of vegetation, is noted.

The existence of a close correlation between increased enzyme activity and precipitation is shown. The stressful period under hydrothermal conditions affected the functional state of plants.

The acute water deficit led to the manifestation of oxidative stress, which is expressed in an increase in the

activity of GPO, as a non-specific reaction to a stress factor.

The dynamics of GPO activity in a 3-leaf sprout is determined by the genotypic features of the variety: the lowest activity was observed in forms 3823 and 2264, which indicates a low intensity of redox reactions in stressful situations in these plants.

The participation of the pigment apparatus in the adaptation of the tea plant is directly related to the content of carotenoids. With a significant water deficit, there is a sharp increase in their synthesis. The ratio "chlorophylls/carotenoids" is an informative sign of the degree of adaptation of tea plants to adverse conditions. The revealed patterns are common to all tea plants.

TRANSFER EFFICACY OF *ESCHERICHIA COLI* O157:H7 BETWEEN SURFACES OF GREEN MATURE TOMATOES AND COMMON FOOD PROCESSING MATERIALS

Oleksandr Tokarskyy, Mykhaylo Korda, Halyna Lukyantseva

ABSTRACT

The objectives of this study were: a) to evaluate *E. coli* O157:H7 survival on green mature tomatoes and squares of common food processing materials – stainless steel, plastic (HDPE), and vinyl conveyor belt (PVC) – post-drying, stored at 25 ºC in the humidified environment for four days; b) to determine pathogen transfer rates (wet, 90 minutes, or 24-hours drying post-inoculation), from inoculated tomato surfaces to uninoculated steel, plastic, and vinyl conveyor belt squares and conversely. It was shown that *E. coli* O157:H7 did not survive well on the surface of tomatoes, resulting in a decline from 5.3 $\log_{10}$ CFU.mL^{-1} 90 minutes post-drying to 1.4 $\log_{10}$ CFU.mL^{-1} on day 4. Similarly, the pathogen did not survive well on the surface of food processing squares, with numbers declining over 4 days from 4.04, 4.44, and 4.19 CFU.mL^{-1} of rinsate 90 minutes squares post-drying to 0.72, 0.50, 0.83 $\log_{10}$ CFU.mL^{-1}, which is close to the detection limit, for the steel, vinyl belt, and plastic, respectively. Successful cross-contamination between tomatoes and food processing surfaces was achieved during wet transfer; while transfer after 90 minutes inoculum post-drying and 24 hours were less successful. This can be explained by both lack of liquid media with suspended bacteria for transfer and fast pathogen die-off after desiccation. Dry transfers, as shown by the percentage of "positive" for pathogen presence tomatoes and squares, as well as bacterial counts, were more successful from tomatoes to squares, but not conversely. Special concern raised vinyl conveyor belt, where the surface picked up the most pathogen cells from the surface of tomatoes, resulting in 100% positive during 90 minute-dry transfers, followed by plastic (66.7% positive) and steel (55.6% positive). To summarize, we presented data on the possibility of cross-contamination between mature green tomatoes and common food processing surfaces, which may be interesting for the processors for risk evaluation.

Keywords: tomatoes; steel; vinyl conveyor belt; plastic; *E. coli* O157:H7; survival; transfer; cross-contamination

INTRODUCTION

Several investigations concluded that consumption of contaminated raw tomatoes can lead to enteric pathogen outbreaks, especially *Salmonella spp.* **(CDC, 2002; Cummings et al., 2001; Croby et al., 2005)**. There is significant consumption of raw tomatoes worldwide, for example, 42% of this commodity is eaten raw in the U.S., a total of 29.6 pounds of tomatoes consumed per person in 2016 alone **(USDA-ERS, 2016)**. **Beuchat and Ryu (1997)** noted that the sources of enteric pathogens on the tomatoes can be irrigation water, wash water, handling by workers, or contaminated surfaces. Various groups of bacteria exist on the surface of green mature tomatoes as it was shown by **Tokarskyy and Korda (2019a)**. This contamination can be removed by high-temperature treatment **(Tokarskyy et al., 2009)** or by gamma irradiation **(Schilling et al., 2009)**, which are often undesirable, creating processed, but not a fresh product. Gram-negative enteric pathogens will grow in the tomato at room temperature only if introduced into the flesh through abrasions, wounds, and stem scars **(Wei et al., 1995; Zhuang, Beuchat and Angulo, 1995; Daş, Gürakan and Bayindirli, 2006; Shi et al., 2007)**. Regarding the fate of the pathogens on the healthy tomato skin, it is believed that counts of Gram-negative enteric bacteria will decline over time, depending on tomato storage temperature, resuspension medium, and humidity **(Tokarskyy et al., 2018; Tokarskyy and Schneider, 2019)**. To the best of our knowledge, *E. coli* O157:H7 has not been implicated in tomato-related foodborne outbreaks, therefore, most research related to tomato safety was done with *Salmonella.* **Hirai (1991)** wrote that *Salmonella* spp. have always been regarded as having better survival rates after desiccation compared to *Escherichia coli*, therefore, data might be comparable at a first glance. For example, **Lang, Harris and Beuchat (2004)** showed that spot-inoculated tomatoes with *Salmonella* spp. or *E. coli* O157:H7 showed counts decline by 2.20 and 3.17 log, respectively, after twenty-four hours inoculum post-drying.

A review by **Kramer, Schwebke, and Kampf (2006)** suggested that lower temperatures, higher inocula, and the presence of protein, serum, or other organic matter favor the survival of bacteria on inanimate objects. **Hirai (1991)** showed that *E. coli* K12 resuspended in deionized water, inoculated on cotton lint and dried, died off upon desiccation (3.5 log reduction on day 1 and 4.5 log reduction on day 3), while resuspension in 2% Bovine Serum Albumin or 5% horse serum caused only ca. 2.0 log reduction on day 4. On the other hand, the humidity effect might be more complicated, as **Møretrø et al. (2010)** showed that shigatoxin-producing *E. coli* dried on plastic or steel had the highest inactivation rate at 85% RH, while survived the best at 98% and 70%. It can be argued that microorganisms in the dried up inoculum survive better at low humidity (no metabolic activity) compared to high humidity, where exhausted stationary culture, still metabolically active, slowly dies off. However, at low inoculation level and high organic matter high humidity might stimulate growth. **Møretrø et al. (2010)** showed that twelve Shiga-toxin producing *E. coli* strains, each analyzed separately, declined upon desiccation in Brain Heart Infusion broth (BHI) on the stainless steel (type 304) from 6 – 7 logs to 3 – 5 logs on day 1 and 2 – 3.5 logs on day 7. Follow-up studies comparing BHI and water, 12 °C and 20 °C, 70% RH, and 80% RH, showed a beneficial effect of BHI, 12 °C, and 70% RH for *E. coli* survival.

Mature green tomatoes contact with various food processing surfaces during processing steps, such as stainless steel (sorting tables), polyvinyl chloride surfaces (PVC, vinyl conveyor belts), high-density polyethylene (HDPE) parts of the various processing equipment. There is a possibility that a single tomato, highly contaminated with *E. coli* O157:H7, can transfer pathogen to other surfaces, while these surfaces, in turn, can contaminate hundreds of uncontaminated tomatoes. Therefore, the question of possible cross-contamination by *E. coli* O157:H7 between tomatoes and such food processing materials as stainless steel, HDPE, and PVC, remains open.

The first objective of the current study was to determine survival rates of *E. coli* O157:H7 on the surface of unwashed and undamaged green mature tomatoes, as well as on the surface of common packaging materials (plastic, HDPE; vinyl belt, PVC; and stainless steel) at summertime room temperature (25 ºC) within four days of storage. The second objective of the study was to investigate transfer rates of *E. coli* O157:H7 from the inoculated surface of tomatoes to the surface of these common food processing materials and vice versa, as influenced by the timing of the transfer.

Scientific hypothesis

We hypothesize that there is a potential of survival of *E.coli* O157:H7 on the surface of tomatoes and common food processing surfaces, and there is a significant possibility of pathogen transfer between surfaces not only when surfaces are wet, but also when they are dry.

MATERIALS AND METHODOLOGY

Rifampin preparation

0.4 grams of rifampin (Fisher Scientific, BP26795) was dissolved in 40 mL methanol (HPLC grade, Fisher Scientific), filter-sterilized (0.2 micron nylon filter, Fisher Scientific) to prepare sterile 10,000 ppm stock solution, and stored refrigerated (4 °C) in the darkness for no longer than a month. Rifampin stock solution was added to the cooled autoclaved Difco™ tryptic soy agar (TSA, Becton, Dickinson, and Co) or Bacto™ tryptic soy broth (TSB, Becton, Dickinson, and Co.) to yield 100 ppm final rifampin concentration, such as 0.1 mL rif stock to 10 mL TSB tube, or 10 mL rif stock to 1,000 mL TSA medium.

Tomato and food processing materials preparation

Green mature tomatoes variety Florida 47, unwashed and unwaxed, were acquired from local packinghouse (DiMare Company, Ruskin, Florida, U.S.A). Stainless steel squares (7.6 x 7.6 cm) were purchased from a local welding shop. Vinyl belt squares (7.6 x 7.6 cm, PVC-120, white polyester, one-side coated with PVC) were purchased from WL Deckert Co, Inc (Milwaukee, WI, U.S.A.). High-density polyethylene (HDPE, plastic) sheets (0.16 cm thick) were purchased from US Plastic Corp (Lima, OH, U.S.A.) and manually cut into 7.6 x 7.6 cm squares. All squares were run through the Lancer dishwasher (Lancer USA, Longwood, FL, U.S.A.), and manually rinsed twice with deionized water before drying. Therefore, food processing surfaces were classified as used. Stainless steel and vinyl belt squares were also reused after autoclaving.

Escherichia coli O157:H7 culture preparation

Two rifampin-resistant (200 ppm) strains of *Escherichia coli* O157:H7 (MDD20, MDD326) and two rifampin-sensitive strains (MDD19 and MDD 327NA), were kindly provided by Dr. Michelle Danyluk's lab from the University of Florida. ATCC 35150 rifampin-sensitive strain was acquired from American Type Culture Collection (Manassas, WI, U.S.A.). All three rifampin-sensitive strains were mutated to acquire rifampin resistance by transferring a pure culture from TSA plates (37 °C, 24 hours) to 10 mL TSB-rif 5ppm broth (37 °C, 24 hours), followed by sequential transfer of 0.1 mL aliquot to TBS containing 10, 20, and 40 ppm rifampin. Final turbid cultures (40 ppm rifampin) were streaked on TSA-rif200 plates (37 °C, 24 hours), and a single colony was transferred to TSB-rif200 broth to confirm growth. Five rif-resistant *E. coli* O157-H7 strains were maintained on TSA-rif80 ppm slants at 4 °C with bi-weekly transfers to fresh TSA-rif80 slants.

For each replication of the experiments, five strains were streaked on TSA-rif100 plates (37 °C, 24 hours), followed by three consecutive one-loopful transfers to 10 mL TSB-rif100 tubes (37 °C, 12 hours, 12 hours, and 18 hours). A pathogenic cocktail (10 mL, 10^9 CFU.mL^{-1}) was prepared by mixing 2 mL of each culture from the third broth. The cocktail was centrifuged (4,300 g, 10 minutes, Sorvall RC-5B centrifuge, DuPont Instruments) and washed once in 10 mL Dulbecco A phosphate-buffered saline (PBS, Oxoid, Hampshire, England), followed by

final centrifugation (4,300 g, 10 minutes) and resuspension in 10 mL 0.1% peptone (Bacto peptone, Becton Dickinson and Co, Sparks, USA). Inoculum concentration was confirmed by serial dilutions in Buffered Peptone Water (BPW, Becton, Dickinson, and Co.) and pour plating using TSA-rif100.

Tomato inoculation and storage experiment

Fifteen mature green tomatoes were inoculated with 0.1 mL of the pathogenic cocktail as 10 spots of equal size around the blossom end each (10^8 CFU.tomato^{-1}). One set of four tomatoes plus one tomato for immediate sampling was left uninoculated and served as negative controls. The procedure was carried out in a biosafety hood and tomatoes were allowed to dry for 90 minutes before moving into a 25 °C incubator. A shallow pan with water was placed inside the incubator to humidify the environment, while temperature and humidity were recorded for four days with 10-minute sampling intervals (Hobo® U12 data logger, Onset Computer Corp, Pocasset, MA). Sets of three inoculated and dried tomatoes with one negative control tomato were tested immediately after drying in the biosafety hood (day 0). Other tomatoes were sampled on day 1, day 2, day 3, and day 4 from a 25 °C incubator.

Food processing surfaces inoculation and storage experiment

Squares (7.6 cm by 7.6 cm) of the described earlier materials were spot inoculated with 0.03 mL of 10^9 CFU.mL^{-1} five strains rif-resistant *E. coli* O157:H7 cocktail in 0.1% peptone. The inoculum was allowed to dry for 90 minutes in the biosafety hood before squares were moved into a 25 ºC incubator. A shallow pan with water was placed in the incubator to humidify the environment and temperature/humidity were monitored for four days as described previously. Sets of three inoculated plus one negative control squares of each type were plated immediately after drying (day 0), as well as on day 1, day 2, day 3, and day 4.

Tomato and squares inoculation for the transfer studies

Two separate studies, involving transfers from tomatoes to food processing materials surfaces and vice versa, were performed. Mature green tomatoes were surface inoculated on a healthy circle-marked spot with a single 30 µL drop of pathogenic bacterial cocktail inside biosafety hood (3 x 10^7 CFU.tomato^{-1}). Two sets of three steel, vinyl belt, or HDPE squares were firmly pressed against tomato surface for one second (one square per each tomato) either immediately (wet transfer), 90 minutes after the inoculum has dried up on the surface, or 24 hours after tomato inoculation. The first set of wet transfer was analyzed immediately (W, day 0), while the second set of squares was placed under the biosafety hood to allow transferred liquid to dry on squares for 90 minutes. The second set was then moved to a 25 °C incubator and analyzed 22.5 hours later (W, day 1). Similarly, one set of 90 minutes dry transfer squares (90 min dry, day 0) was analyzed immediately and another set was placed in a 25 °C incubator and tested for *E. coli* 22.5 hours later (90 min dry, day 1). The last set of tomatoes was placed for an additional 22.5 hours incubation at 25 °C following 90 minutes drying period inside biosafety hood before two sets of steel, vinyl, and HDPE squares were pressed against inoculated spots and analyzed for pathogen transfer efficiency either immediately (24 h dry, day 0), or 24 hours later (24 h dry, day 1) after storage in the same incubator (25 °C). The shallow container filled with water was placed inside a 25 °C incubator for the duration of the study to humidify the atmosphere and temperature/humidity was monitored as described previously with Hobo® U12 data logger.

On each of three days, a set of negative control squares (one of each) was touched to the marked surface of uninoculated tomatoes and analyzed as a negative control to ensure the absence of rif-resistant microflora on tomatoes and squares.

Transfers from squares to tomato surfaces were done as described previously but in the opposite direction of inoculation and transfer.

Escherichia coli O157:H7 recovery from tomatoes and squares

To recover pathogen, a single tomato or a square was transferred to 20 mL BPW in a stomacher bag and vigorously manually shaken for 30 seconds, rubbed for 30 seconds, and shake again for 30 seconds. The rinsate was plated directly or serially diluted in 9 mL BPW tubes before plating using the pour plate method and TSA-rif100 medium. The plates were incubated for 24 hours at 37 ºC before counting.

Statistic analysis

Escherichia coli O157:H7 survival on tomatoes (three replications) and the squares (four replications) results were analyzed separately using one-way ANOVA (factor "day": day 0; day 1; day 2; day 3; day 4) with means separated using Fisher LSD procedure. Transfer studies were repeated three times and count data were analyzed using one-way ANOVA and treatment factor (W day 0; W day 1; 90 min dry day 0; 90 min dry day 1; 24 h dry day 0; 24 h dry day 1) labeled by each material (steel, belt, plastic). Samples yielding no counts were assigned a limit of detection count. Percent positive samples were calculated for transfer studies as well, for each treatment for each square, combining data from three replications. Statistical analysis was done using commercially available software Statistica ver.10.0 (StatSoft, Tulsa, OK, USA).

RESULTS AND DISCUSSION

For tomato surface survival studies, *E. coli* O157:H7 numbers declined 1.4 log units from theoretical inoculation level of 6.8 log units per mL of rinsate to 5.3 logs upon 90-minute drying, and continued to decline significantly and rapidly during storage at 25 ºC (p <0.05), resulting in final counts of 1.5 logs on day 4 (Figure 2). Similarly, **Lang, Harris and Beuchat (2004)** showed that *E. coli* O157:H7 counts in 5% horse serum on the dried spot-inoculated tomatoes decreased 1.07 logs after 1-hour drying and 3.17 logs 24 hours post-drying from initial 7.22 $\log_{10}$ CFU.tomato^{-1}.

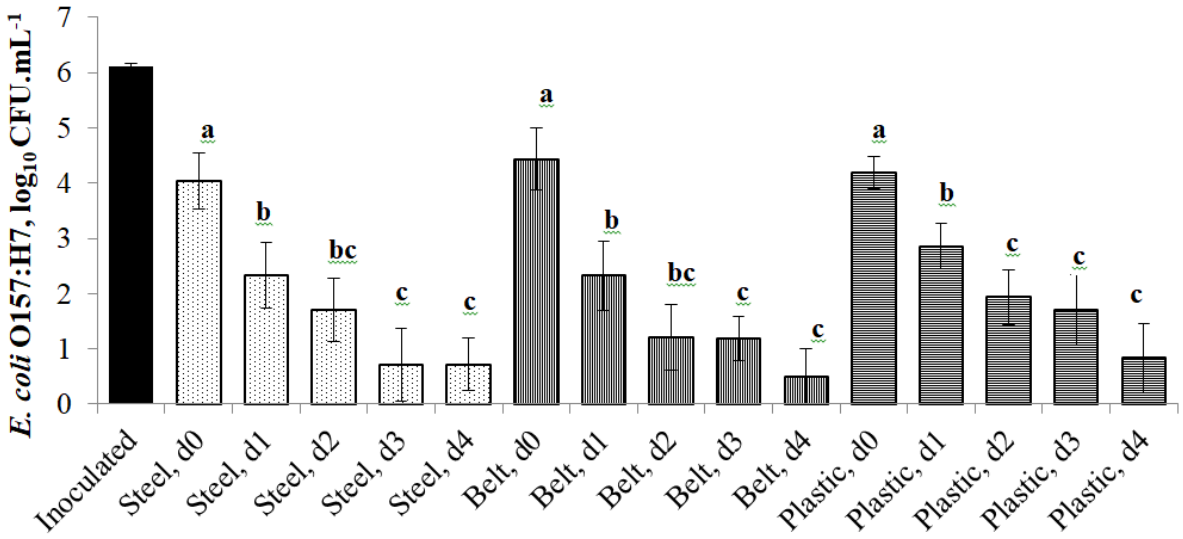

Figure 1 Recovery of *E. coli* O157:H7 from squares either immediately after drying (d0), or after storage for four days (d0-d4) at 25 ºC. Note: Counts expressed as log10 CFU.mL^{-1} recovered from 20 mL rinsate. Inoculated level calculated theoretically based on stationary culture and is shown for reference. The same letters within the same material (steel, belt (PVC), or plastic (HDPE)) mean no significant difference (p >0.05). *Average air relative humidity ±SD: replication No 1 = 67.4 ±2.2%; replication No 2 = 70.8 ±2.0%, replication No 3 = 71.6 ±2.1%, replication No 4 = 73.2 ±1.9%.

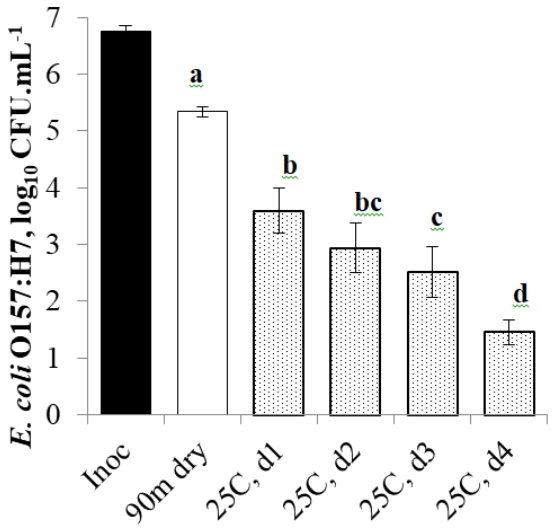

Figure 2 Recovery of *E. coli* O157:H7 from inoculated tomatoes either immediately after drying (90 min dry), or after storage for four days (d1-d4) at 25 ºC. Note: Counts expressed as $\log_{10}$ CFU.mL^{-1} recovered from 20 mL rinsate. Inoculated level calculated theoretically based on stationary culture concentration and is shown for reference. The same letters mean no significant difference (p >0.05). *Average air relative humidity ±SD: replication No 1 = 58.8 ±3.6%, replication No 2 = 59.4 ±3.8%, replication No 3 = 59.5 ±4.1%.

Table 1 Percentage of squares and tomatoes yielding at least 1 CFU.mL^{-1} of *E. coli* O157:H7 in rinsate after inoculated tomatoes touched squares or inculated squares touched tomatoes. Cross-contaminated items were checked for *E. coli* either immediately after the transfer (d0), or stored 24 h after the transfer at 25 ºC (d1).

Note: W – wet; 90 m – 90min dry; 24 h – 24 h dry. P – plastic; B – belt; and S – steel. *T2S – Tomatoes to Squares transfer; S2T – Squares to Tomatoes transfer.

Similar results were obtained by **Tokarskyy and Korda (2019b)** for surface inoculated tomatoes with *E. coli* O157:H7 and stored for four days in a high humidity incubator at 25 °C. They noted better survival of pathogen if final inoculum was prepared in less hygroscopic 0.1% diluted peptone water, compared to buffered peptone water, where pathogen declined from 5.4 $\log_{10}$ CFU.mL^{-1} in 90 min dry tomatoes to 1.4 $\log_{10}$ CFU.mL^{-1} on those stored for four days at 25 °C **(Tokarskyy and Korda, 2019b)**. The decrease in numbers of viable *E. coli* O157:H7 on the surface of bruised and unbruised tomatoes at 20 °C was even more drastic when a low contamination level was used (4.0 $\log_{10}$ CFU.tomato^{-1}), where counts dropped to below detection level in just three days **(Tokarskyy et al., 2018)**.

To summarize, *E. coli* O157:H7 did not survive well on the intact surface of tomatoes at 25 °C.

Survival of *E. coli* O157:H7 on the surface of common food processing materials is shown in Figure 1. The counts declined from theoretical inoculation level of 6.1 $\log_{10}$ CFU.mL^{-1} as calculated per mL of the rinsate to 4.0, 4.4, and 4.2 $\log_{10}$ CFU.mL^{-1} for steel, belt, and plastic, respectively, upon drying (p <0.05). After four days incubation period at 25 °C, the counts on average felt below 1.0 $\log_{10}$ CFU.mL^{-1} for all squares. These data are similar to **Kusumaningrum et al. (2003)**, who showed that *Salmonella enteritidis* was recovered from inoculated steel squares after drying for at least 4 days at a high contamination level (10^5 CFU.cm^{-2}), while at a moderate level (10^3 CFU.cm^{-2}) and low level (10 CFU.cm^{-2}) inoculation counts went below detection limit within 24 hours and 1 hour, respectively. **Møretrø et al. (2010)** showed that STEC *E. coli* inoculated on stainless steel in water or BHI and dried declined by ca 1.6 and 3.6 logs, respectively, at 20 °C after 24 hours post-drying. The authors noted that results for polyoxymethene copolymer were not significantly different from stainless steel **(Møretrø et al., 2010)**. It might be noted that food-grade (type 304) stainless steel was used for the study, as different metal alloys might impact survival. As was shown by **Jiang and Doyle (1999)**, *E. coli* O157:H7 inoculated in 0.1% peptone and dried on glass and coins at 4.7 $\log_{10}$ CFU.coin^{-1} declined at room temperature to below detection level on day 4, 7, 9, 11, and 11 for glass, pennies, nickels, dimes, and quarters, respectively. Contrary, **Tokarskyy and Korda (2019b)** showed better survival of *E.coli* O157:H7 on the surface of unwaxed cardboard, with counts declining from 4.5 to only 2.5 $\log_{10}$ CFU.mL^{-1} after 4-day storage at 25 °C, what can be attributed to the porous and water-absorbing nature of cardboard surface.

To summarize, little to no potential of *E. coli* O157:H7 survival was shown in the current study for common impervious food processing surfaces.

Several research groups used different approaches and techniques to measure transfer rates of enteric pathogens from inanimate surfaces to produce and conversely **(Buchholz et al., 2012; Soares et al., 2012; Brar and Danyluk, 2013; Jensen et al., 2013; Todd-Searle et al., 2020).** Going further, **Buchholz et al. (2012)** even used pilot pant settings for transfer studies and showed that *E. coli* 0157:H7 continuously cross-contaminated lettuce through flume tank, conveyor tank, and shredder, considering that all surfaces remained wet through the processing line and sanitizer was not applied. **Brar and Danyluk (2013)** studied Salmonella transfer from contaminated plastic gloves to tomatoes and conversely, after 24 hours inoculum drying on the surfaces. They did not find any difference between transfers from dirty and from clean reusable gloves (**Brar and Danyluk, 2013)**.

Results of our transfer studies were expressed either as percent positive (where at least one typical *E. coli* O157:H7 CFU per 1 mL of rinsate was detected) or as counts, total $\log_{10}$ CFU.item^{-1} (either a food processing surface square or a tomato), and are shown in Table 1 and Figure 3 and Figure 4. Samples yielding no counts were assigned a limit of detection count. Overall, wet transfers (W) yielded the most consistent data, with 100% transfers being positive on both day 0 and day 1 (Table 1). Dry transfers (90 min dry and 24 h dry) appeared to be less efficient, partially because of lack of wetness with liquid carrying bacteria and having adhesive properties, and possibly due to the pathogen number decline during drying and storage. **Burnett, Chen, and Beuchat (2000)** hypothesized that *E. coli* O157:H7 may firmly attach to the surfaces of fruits as evidenced by confocal scanning laser microscopy and may evade decontamination and detachment, which could be one of the explanations why dry transfer was not efficient in our study. However, dry transfers from tomatoes to squares appeared to be more efficient than vice versa (Table 1, Figure 3 and Figure 4), possibly due to the hydrophobic properties of the tomato peel surface. Interestingly, the vinyl belt picked up the most pathogen cells from the surface of tomatoes, resulting in 100% positive during 90 min dry transfers, followed by plastic (66.7% positive) and steel (55.6% positive). Subjectively, the vinyl belt appeared to have a "sticky" surface. Similarly, dry transfers at 24 h storage were the most efficient from tomatoes to the vinyl belt, followed by plastic (Figure 3). Similar results were shown by **Tokarskyy and Korda (2019b),** who showed that wet transfer of *E.coli* O157:H7 was more efficient between tomatoes and cardboard comparing to dried surfaces, as well as transfer from tomatoes to cardboard was more efficient than vice versa. **Todd-Searle et al. (2020)** showed that the transfer of Salmonella between tomatoes and plastic mulch or soil was dependent on the dryness of the inoculum, contact time, and contact surface. They also noted that transfer from plastic mulch was greater than from soil, possibly due to the surface characteristics, while wet and 1-hour dry transfers were more efficient than 24-hours dry transfers **(Todd-Searle et al., 2020)**. **Soares et al. (2012)** showed that *Salmonella* spp. easily transferred from wet poultry skin to the cutting surfaces made of wood, stainless steel, and plastic (100% positive for contamination), and then from those contaminated surfaces to the red tomatoes (also 100% tomatoes became contaminated), unless cutting surfaces were washed with soap followed by surface sanitation. **Jensen et al. (2013)** noted that freshly inoculated lettuce or celery transferred more bacteria (ca. 2 % to ca. 25 % of the inoculum) comparing with freshly inoculated carrots or watermelon (ca. 1% to 8%) to the surfaces made of ceramic, stainless steel, glass, and plastic. Such high transfer rates were probably due to the residual moisture left after fresh inoculum application.

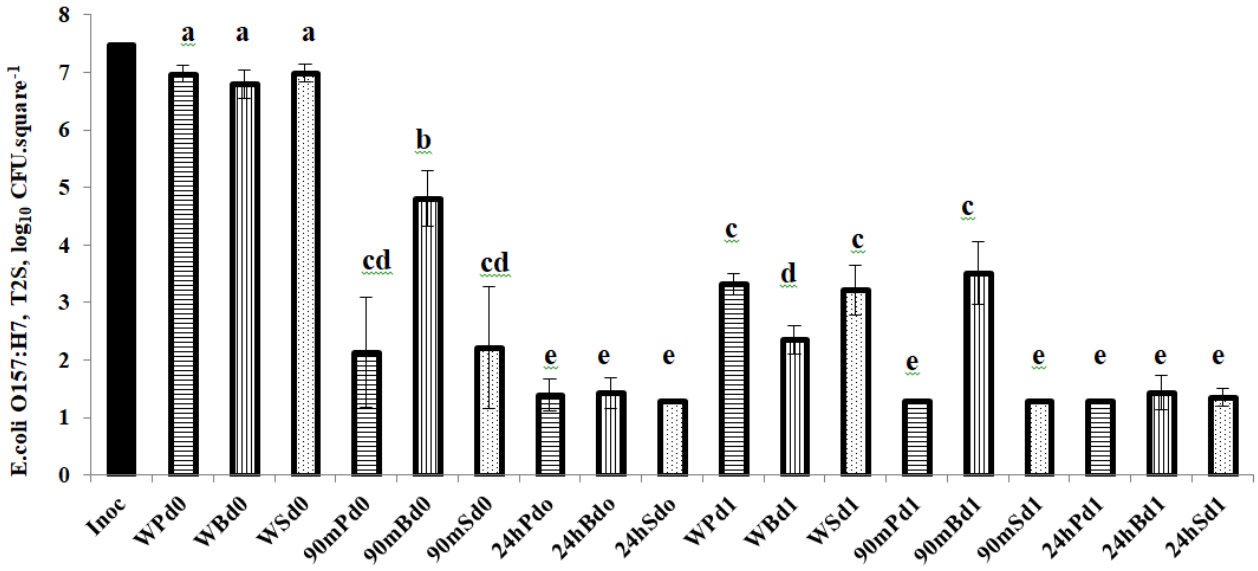

Figure 3 Total *E. coli* O157:H7 counts per square after pathogen transfer from tomato compared to total inoculated log_{10} CFU.tomato^{-1} (Inoc). Note: Tomatoes (W – wet; 90 m – 90 min dry; 24h – 24 h dry) touched squares (P, plastic; B, belt; and S, steel) which were analyzed either immediately (d0) or 24 hours later (d1). Detection limit 1.3 log per item. The same letters mean no significant difference (p >0.05). Tomato inoculation level calculated theoretically based on inoculum concentration and is shown for reference. T2S – Tomatoes to Squares transfer. *Average air relative humidity ±SD: replication No 1 = 61.1 ±9.0%, replication No 2 = 68.3 ±8.1%, replication No 3 = 66.2 ±6.2%.

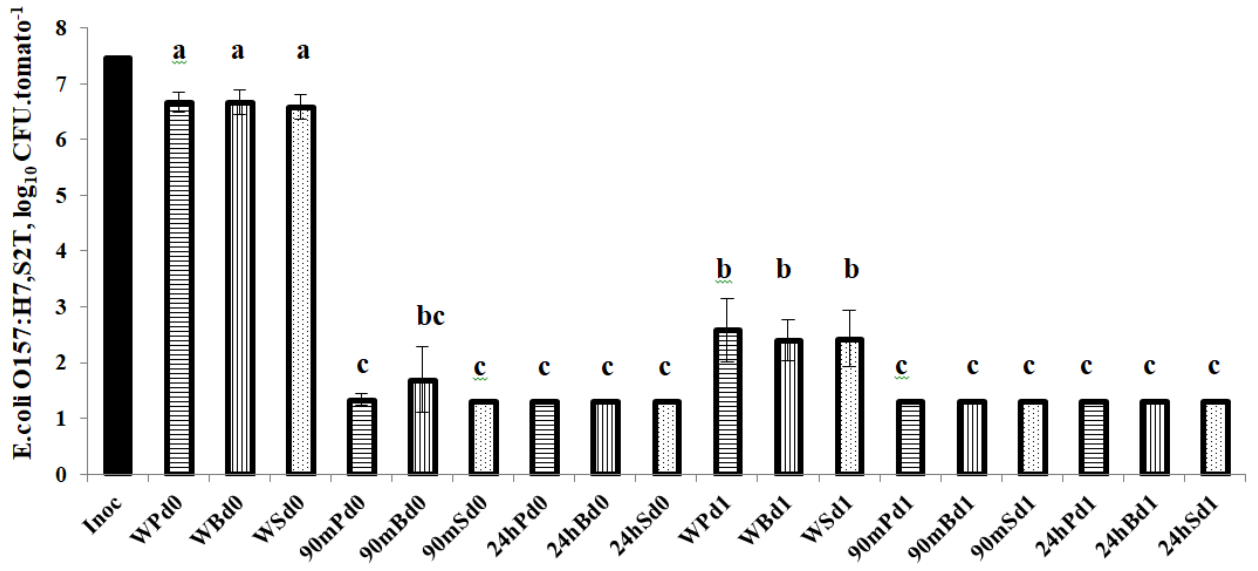

Figure 4 Total *E. coli* O157:H7 counts per tomato after transfer from inoculated squares. Note: Squares (W – wet; 90 m – 90 min dry; 24 h – 24 h dry) of different types (P, plastic; B, belt; and S, steel) touched tomatoes which were analyzed either immediately (d0) or 24 hours later (d1). Detection limit:1.3 log10 CFU per item. The same letters mean no significant difference (p >0.05). Square inoculation level (Inoc) calculated theoretically based on inoculum concentration and is shown for reference. S2T – Squares To Tomatoes transfer. *Average air relative humidity ±SD: replication No 1 = 62.9 ±6.7%, replication No 2 = 70.2 ±7.0%, replication No 3 = 70.4 ±6.3%.

However, after one hour of drying time, the transfer rate from inoculated celery, carrot, and lettuce decreased significantly to less than 0.01 to ca. 5% and to less than 1% to ca. 5% for watermelon **(Jensen et al., 2013).** The authors concluded that the surface moisture and the direction of the transfer had the greatest influence on microbial transfer rates **(Jensen et al., 2013).** To support this statement, **Todd-Searle et al. (2020)** also emphasized that tomatoes should be harvested dry, not wet, to avoid cross-contamination.

To summarize, the dry transfer is limited and is more efficient from the tomatoes to the packaging squares, and less efficient from packaging squares to tomatoes. Speaking of risks involved, the vinyl belt appeared to be the most affected. The study has limits in accuracy, as chances of getting 1 CFU.plate^{-1} are not statistically profound.

CONCLUSION

Pathogen transfers are of great concern if the surface is wet, but less of a concern if the surface is dry. Because pathogens do not survive well under the conditions tested, prolonged storage reduces the chances of cross-contamination. Dry transfers from tomatoes to food contact surfaces are more efficient compared to transfers from food contact surfaces to tomatoes. This could be due to the hydrophobic nature of the tomato surface. The results suggest that the vinyl belt (PVC) might represent a higher risk. Overall, we partially failed our hypothesis, showing that there is a low possibility of pathogen transfer if surfaces are dry after prolonged tomato storage under proposed model conditions.

EFFECT OF SOMATIC CELL COUNT ON MILKABILITY AND MILK COMPOSITION OF EWES

Lucia Mačuhová, Vladimír Tančin, Juliana Mačuhová, Michal Uhrinčať, Marta Oravcová, Martina Vršková, Kristína Tvarožková

ABSTRACT
The trial aimed to study the effect of somatic cell count, breed, milk flow type, and parity on the milkability and milk composition of ewes. The flock consists of purebred Lacaune ewes (LC; n = 29) and crossbreds ewes of Improved Valachian (IV x LC; n = 35) and Tsigai (TS x LC; n = 37) with LC (with a genetic portion of Lacaune 25 and 50%). Ewes were assigned according to somatic cell count (SCC) to one of the following three groups: SCC ≤300,000 cells per mL (SCC Group 300,000), SCC between 300,000 and 1000,000 cells per mL (SCC Group 300,000 – 1000,000), SCC ≥1000,000 cells per mL (SCC Group 1000,000). 56% of evaluated ewes had less than 300,000 cells per mL and 29% more than 1000,000 cells per mL in milk. No significant differences were observed between different groups of SCC in total, machine milk yield, and the proportion of milk yield in 30 s and 60 s. The significant differences were observed between SCC Group 300,000 and SCC Group 300,000 – 1000,000 in the proportion of machine stripping from total milk yield (41 ±2 vs. 57 ±4%). Milk flow type had a significant effect on all evaluated milkability parameters but not on milk composition. Ewes on fourth parity had the highest proportion of machine stripping from total milk yield then ewes on third, fifth, and sixth and higher (60% vs. 47, 45, 46%; resp.). Effect of SCC Group on milk composition manifested only in solids not fat. The significant differences were observed between SCC Group 1000,000 to SCC Group 300,000 and SCC Group 300,000 – 1000,000 (10.75 ±0.08% vs. 11.05 ±0.06 and 11.15 ±0.11%, $p \leq 0.0004$).

Keywords: ewe; somatic cell count; milk composition; SCC

INTRODUCTION
In ewes and other dairy animals, somatic cells are an important natural component of milk. Their number is used as an indirect predictor of udder health status and milk quality as they are involved in the protection of the mammary gland from infection as part of the innate immune system **(Rupp and Boichard, 2000; Guzel et al., 2017; Tančin et al., 2006; Tančin et al., 2007; Tančin, Ipema and Hogewerf, 2007)**. Somatic cell count (SCC) in milk is influenced by several factors: animal species, production level, physiological processes (such as estrus or stage of lactation), animal individuality, and also environmental factors and farm management **(Rupp and Boichard, 2000; Tančin et al., 2016; Tančin et al., 2017; Paape et al., 2007; Margetín et al., 2013)**. According to **Ranucci and Morgante (1996)** and **Bergonier et al. (2003)**, somatic cells in healthy ewe milk consist of macrophages, polymorphonuclear neutrophil leukocytes (which have an important biological function of phagocytic activity), lymphocytes, and, to a lesser extent other cell types (eosinophils, epithelial cells, and unidentifiable cells). As in dairy cows, also in goats or sheep, an increase in SCC has been reported as a consequence of infection **(Poutrel et al., 1997; Paape et al., 2001; Paape et al., 2007; Bergonier and Berthelot, 2003; Bergonier et al., 2003; Luengo et al., 2004; Moroni et al., 2005; Koop et al., 2010)**. During mastitis, milk SCC increases mainly as a result of increased migration of leukocytes from blood to mammary tissue **(Leitner et al., 2003; Le Roux, Laurent, and Moussaoui, 2003)**. Because there is a strong relationship between udder health and the amount of somatic cells in milk, limits have been set for SCC in milk in many countries. These limits determine which milk can be on the market or what penalties in the contractual terms of payment are imposed by the milk producer when the milk does not meet the required criteria **(Berger et al., 2004; Haenlein, 2002; Kalantzopoulos et al., 2004; Raynal-Ljutovac, Gaborit and Lauret, 2005)**. However, there are no limits to SCC in sheep's milk as it is in cow's milk in Slovakia **(Tančin et al., 2017)**. The major income from dairy animals is derived from milk; therefore, factors that reduce milk quantity and quality can cause high economic losses to the farmers **(Sutera et al., 2018)**.

The trial aimed to study the effect of SCC on the milkability and milk composition of ewes. Possible effects of breed, milk flow type, and parity were evaluated too.

Scientific hypothesis

In this study, we hypothesized that ewes, which had lower SCC than 300,000 mL^{-1} (SCC Group 300,000), would have better parameters of milkability and milk composition than ewes with the higher SCC. The second hypothesis was that ewes with two peaks and plateau milk flow types would have a higher milk production and milk fat content than ewes with one peak and plateau II. The third hypothesis was that breed affects the production parameters. The fourth hypothesis was that parity affects the production parameters and SCC.

MATERIAL AND METHODOLOGY

Animal and experimental design

The study was carried out in June in the flock of 101 mid-lactated ewes (102 ±5 days in lactation) their 3rd – 9th parity at one evening milking. The flock consists of purebred Lacaune ewes (LC; n = 29) and crossbreds ewes of Improved Valachian (IV x LC; 35) and Tsigai (TS x LC; 37) with LC (with a genetic portion of Lacaune 25 and 50%). The ewes were milked in a one-platform milking parlour with 24 stalls and one milking unit per 2 milking stalls. The milking machine was set to provide 160 pulsations per minute in a 50:50 ratio and a vacuum level of 39 kPa. During each milking, ewes received 0.1 kg concentrate per head in the parlour. Ewes were milked routinely twice daily at 8:00 and 20:00 without any udder preparation. At the end of milking, machine stripping was performed (machine stripping started when milk flow rate declined to 0 $L.min^{-1}$ but not earlier than 70 s from the beginning of milking). Short manual udder massage was performed by machine stripping.

Milk flow recording and samples analysis

Milk flow kinetic was recorded using an electronic jar that collected the milk during the next three consecutive evening milkings. Within the jar, there was a 2-wire compact magnetostrictive level transmitter (NIVO-TRACK, NIVELKO Ipari Elektronika Rt, Budapest Hungary) connected to a computer. The milk level was continuously measured by a transmitter that recorded the position of the float in the jar on a computer once per second. The milk flow patterns were drawn by using a formula by **Mačuhová et al. (2008)**. The following parameters of milkability were evaluated: total milk yield (L), machine milk yield (L), machine stripping yield (L), machine stripping yield from total milk yield (%), milking time (i.e. time from attaching of clusters until the milk flow ceased before stripping; s), milk yield in 30 s (L), and milk yield 60 s (L).

According to SCC, ewes were assigned to one of the following three groups: SCC ≤300,000 cells per mL (SCC Group 300,000), SCC between 300,000 and 1000,000 cells per mL (SCC Group 300,000 – 1000,000), SCC ≥1000,000 cells per mL (SCC Group 1000,000).

Milk flow curves were evaluated according to **Marnet, Negrao and Labussière (1998)**, **Rovai et al. (2002)** and **Mačuhová et al. (2008)** into 4 milk flow types; 1 peak (1P; without notable milk flow after 40 s of milking), 2 peaks (2P; two separate milk emissions), plateau (PL; milk flow with longer duration of steady phase and milk flow rate during plateau phase >0.4 $L.min^{-1}$ at least for 20 s), and plateau low (PLII; milk flow curves with steady milk flow during milking for 20 s but with milk flow rate ≤0.4 $L.min^{-1}$ or >0.4 $L.min^{-1}$ shorter than for 20 s at plateau phase). In 1 animal no milk flow occurred, and the curve of milk flow type could not be identified.

Individual milk samples were collected after milking from the jar for composition analysis. Milk composition was analyzed for the percentage of fat, protein, lactose, solids, and solids-not-fat with MilkoScan FT120 (Foss, Hillerød, Denmark). SCC was analyzed with Somacount 150 analyzer (Bentley Instruments, lnc, Chaska, Minnesota).

Statistical analysis

The data set consisted of 101 measurements belonging to 101 ewes. Mixed model (Mixed procedure; SAS/STAT 9.1, 2002 – 2003) was applied to study the influence of the sources of variation in studied traits (parameters of milkability and milk composition).

$$y_{ijkl} = \mu + \text{SCC GROUP}_i + \text{FLOW}_j + \text{BREED}_k + \text{PARITY}_l + e_{ijkl}$$

where: y_{ijkl} – individual observations of studied parameters of milkability and milk composition, μ = overall mean, SCC GROUP_i = fixed effect of SCC group (i = 1 to 3; ≤300,000, between 300,000 and 1000,000, ≥1000,000 cells per mL), FLOW_j = fixed effect of milk flow type (j = 1 to 4; 2P, 1P, PL, PLII) + BREED_k = fixed effect of Breed (k = 1 to 3; TS x LC, LC, IV x LC) + PARITY_l = fixed effect of parity (l = 1 to 4; 3, 4, 5, ≥6), e_{ijkl} = random error, assuming $e$ijkl ~ N(0, I σ_e^2).

The fixed effects of the model were estimated using the LSM (Least Squares Means) method. Statistical significance was tested by Fischer's F-test and differences between the estimated levels of effects were tested by Scheffe's multiple range tests.

RESULTS AND DISCUSSION

In Table 1, there are presented basic statistics of studied traits and in Table 2, *p*–values for the statistical significance of tested factors on evaluated parameters. SCC has been described in numerous studies as a useful method for diagnosing intramammary infection in monitoring udder health. In this study, animals were classified according to SCC in three groups (SCC Group ≤300,000 cells per mL; SCC Group between 300,000 and 1000,000 cells per mL; SCC Group ≥1000,000 cells per mL). 56% of evaluated ewes had SCC lower than 300,000 cells per mL and 29% more than 1000,000 cells per mL. SCC Group had no significant effect on parameters of milkability (except machine stripping yield from total milk yield; Table 3) or parameters of milk composition (except for solids not fat (%)) (Table 5). There is a discussion on the SCC threshold level for diagnostic purposes **(Raynal-Ljutovac et al., 2007; Albenzio et al., 2012; Rovai et al., 2015; Tvarožková et al., 2019)**.

the SCC over 600,000 cells per mL is considered as high.

However, in most studies, 300,000 or even 400,000 cells per mL are considered as normal values in sheep's and goat's milk **(Kern et al., 2013; Tančin, 2017; Oravcová, Mačuhová and Tančin, 2018)**. On the other hand, whereas **Kern et al. (2013)** indicate already 400,000 cells per mL in meat breeds and 300,000 cells per mL in dairy breeds as a threshold level to assist the farmer in detecting of the udder health problems, in the studies of **Tančin et al. (2017)** and **Oravcová, Mačuhová and Tančin (2018)**, Only by 1000,000 cells per mL is milk considered as mastitis milk **(Tančin et al., 2017)** or ewe as infected **(Berthelot et al., 2006)**.

The significant differences were observed between SCC Group ≤300,000 and SCC Group 300 – 1000,000 in the proportion of machine stripping from total milk yield (41 ±2 vs. 57 ±4%). The tendency of the longest milking time was observed in SCC Group 300,000 and 1000,000 in comparison to SCC Group ≥1000,000 (59 vs. 47 s).

Rovai et al. (1999) found out that the height of cisterns correlated with teat angle and distance between teats. Thus, udders with higher cisterns have deeper and show bigger teat angles. Consequently, the udder emptying can be negatively affected during machine milk, and a higher stripping fraction is observed in ewes with this udder morphology. Moreover, they found out that parity had a significant effect on cistern height **(Rovai et al., 1999)**. In SCC Group 300,000, only 14% of ewes were observed on sixth or higher lactation, but 73% in group 300,000 – 1000,000.

Table 4 shows parameters of milkability and Table 5 parameters of milk composition according to milk flow type, breed, and parity. The milk flow type had a significant effect on all tested parameters of milkability, but non on milk composition parameters. The total milk yield was lower in ewes with 1P and PL II milk flow type than in ewes with 2P and PL type in this study (Table 4). The analysis of the milk flow curves shows that the milk ejection reflex does not occur every time during milking in ewes **(Bruckmaier et al., 1997; Dzidic, Kaps and Bruckmaier, 2004; Mačuhová et al., 2008; Mačuhová et al., 2012; Tančin et al., 2011)**. 1P flow type is supposed to represent milk flow without alveolar milk ejection when only cisternal milk fraction is removed in response to machine milking **(Marnet, Negrao and Labusière, 1998; Mačuhová et al., 2008)**. This support also significantly shorter milking time ewes with 1P type of milk flow than in ewes with 2P, PL, and PL II (29 vs. 67, 54, and 66 s; resp.) as observed also in previous studies of **Mačuhová et al. (2008)** and **Mačuhová et al. (2012)** and **Tančin et al. (2011)**. 2P and in most cases also PL represent the milk flow types with milk ejection **(Mačuhová et al., 2012)**. Even the second peak is not observed in PL type of milk flow, it is supposed that milk ejection occurs in ewes with this milk flow **(Marnet, Negrao and Labussière, 1998; Rovai et al., 2002; Tančin et al., 2011)**. According to **Marnet, Negrao and Labussière (1998)**, the occurrence of the PL type of milk flow rises in consequence of the genetic selection for higher milk production or decreased

average milk flow rate. Thus, this type of milk flow can be observed when the second peak (i.e. the removal of an alveolar fraction) is masked because the cistern fraction has not yet been completely removed from the udder at the time of milk ejection **(Marnet, Negrao and Labussière, 1998)**. In the study of **Bruckmaier et al. (1997)**, high machine stripping yield was observed in ewes with 1P milk flow is possibly caused by a late response to milking and oxytocin release after the end of milking. This does not seem to be the case in this study. Machine stripping yield from total milk yield (%) was highest in PL II, whereas it did not differ among other milk flow types. However, whereas the data of this study support that no oxytocin was released during machine milking or stripping in ewes with 1P milk flow type, it is possible that oxytocin was released during milking or machine stripping in ewes with PL II milk flow type. Ewes with PL II had the lowest milk yield in 30 s (significantly) 60 s (in tendency) (Table 3). Low milk yield in 30 and 60 s could be caused by some health problems or deformity of the teat canal **(Mačuhová et al., 2008)**.

The breed influenced significantly machine milk yield, milking time, milk yield in 30 and 60 s, and machine stripping yield from total milk yield (%), and also lactose and solids not fat (Table 4 and Table 6). The machine milk yield and milk yield in 30 and 60 s were significantly higher in crossbreds IV x LC than in TS x LC (Table 4). This does not correspond to results in previous studies **(Mačuhová et al., 2008; Mačuhová et al., 2017)** where no differences were found in these parameters and also machine stripping yield from total milk yield. However, whereas the total milk yield did not differ between crossbreds in this study, machine stripping from total milk yield was higher in TS x LC than IV x LC. The reason for it could be possible worse udder morphology for milking in TS x LC ewes in comparison to IV x LC ewes of the same crossbreds observed previously.

The parity (Table 4, Table 5 and Table 6) had a significant effect only on machine stripping yield from total milk yield (%), log SCC, and solids (%). The ewes on the fourth parity have significantly higher machine stripping from total milk yield than ewes on lower or higher parities (60% vs. 47, 45, 46%). This could signalize that udder worsened with increasing parity (fourth vs. third parity). However, on higher parities (≥5) only "better" ewes (healthy, with good udder morphology, and adequate milk production) stayed in the flock.

CONCLUSION

Surprisingly, SCC Group did not affect evaluated parameters of milkability except for machine stripping yield from total milk yield (%). Milk flow type and the breed had mainly effect on the parameter of milkability. Parity had a significant effect on machine stripping yield from total milk yield (%), log SCC, and solids (%). Concerning the composition of milk, fat (%) was influenced by none of the tested parameters, lactose (%) and solids (%) only by one of the tested parameters, and only solids not fat was influenced by three (SCC group, breed, and parity) of four tested factors.

ANALYSIS OF PORK ADULTERATION IN THE CORNED PRODUCTS USING FTIR ASSOCIATED WITH CHEMOMETRICS ANALYSIS

Any Guntarti, Mustofa Ahda, Aprilia Kusbandari, Faradita Natalie

ABSTRACT

Meat-based foods such as beef corned became one of the targets of counterfeiting with pork because relatively cheaper. This becomes a serious problem for Muslims, especially in Indonesia. One method that can be used to detect fat was Fourier transform infrared (FTIR) spectrophotometry. The purpose of this study was to quantitatively analyze and a group of corned beef and corned pork using FTIR spectrophotometry combined with chemometrics. Reference samples corned pork-beef made of 7 various concentration (0%, 25%, 35%, 50%, 65%, 75%, 100%) and 6 product samples purchased in the Umbulharjo, Yogyakarta. Extraction was carried out by the soxhlet apparatus using n-hexane technical solvent for 4 – 5 hours at 69 – 70 °C. Fat analyzed using FTIR spectrophotometry for generating infrared spectral data then processed with Partial least square (PLS) chemometrics for quantitative analysis and Principal component analysis (PCA) for grouping. Results of quantitative analysis chemometrics PLS, selected areas fingerprints for analysis corned pork-beef was 1180 – 730 cm^{-1} with R^2 0.9833; RMSEC 2.06%; RMSEP 1.65% and RMSECV 2.22%. The results of PCA showed groupings in different quadrants between corned pork 100% and corned beef 100%. Results showed that FTIR spectrophotometry combined with chemometrics can be used for quantitative analysis and grouping of pork corned and beef corned on the market but it can not identify pork in corned after choking process.

Keywords: corned; beef fat; FTIR; lard; PCA; PLS

INTRODUCTION

Muslims must pay attention to eat food due to it will be part of his body. Therefore, halal food is an obligation for Muslims. Halal food is defined as zero non-halal components including pork. The pork adulteration in food is used because it is cheaper than beef. This is the economic aspect reason, pork can reduce production costs **(Rohman and Che Man, 2010; Guntarti et al., 2017)**. However, we do not only consider the economic aspects. The religious aspect is an important judgment because Muslims regard pork components in processed food products is a serious problem. Islam forbade its followers to consume food products that contain pork **(Regenstein, Chaudry, and Regenstein, 2003)**.

One of the products that allow pork adulteration is beef corned. Therefore, many researchers tried to develop a halal analytical method. The triglyceride (TGA) analysis by HPLC has detection limitations because the hydrolyzed TGA can be detected by HPLC and will interfere with halal authentication **(Rohman et al., 2012[a]; Ahda, Guntari, and Kusbandari, 2016)**. FTIR spectrophotometric has been chosen because it can be combined with chemometrics to detect lard in a mixture of chicken, mutton, and veal **(Nurrulhidayah et al., 2013)**, also to detect lard in CPO and meatball product **(Ahda and Safitri, 2016; Ahda et al., 2020)** and the fat rat in beef meatballs **(Rahmawati et al., 2016)**.

The advantages of FTIR spectroscopy is an efficient analysis for detecting components in a mixture containing animal fat **(Che Man and Rohman, 2011)**. Hence, the presence of pork in processed corned beef products needs an analytical method that is accurate and precise. The use of FTIR as a halal analytical method of corned has not been reported/published. Therefore, this study was performed to determine and distinguish infrared spectra combined with chemometrics for the analysis of lard in the corned beef.

Scientific hypothesis

Lard adulteration in corned beef products can cause different vibration of the FTIR spectrum because lard contains a different TGA composition compared to beef

MATERIAL AND METHODOLOGY

Materials

Samples of pork and beef purchased at a traditional market in Yogyakarta. Spices and other additives for the manufacture of reference samples purchased in supermarkets in the District of Umbulharjo, Yogyakarta. Materials n-hexane (p.a) (Merck), n-hexane (technical) (Merck), acetone (Merck) and anhydrous Na_2SO_4.

Standard Corned Products

The corned beef was made by mixing meat, sugar, pepper, and flour. The meat was steamed for 40 minutes then packed in cans. Standard corned samples were prepared with corned beef containing 7 concentrated levels of pork in beef **(Table 1)**.

Table 1 Reference composition of Corned from beef and pork mixtures.

The concentration of corned pork (%)	Pork (grams)	Beef (grams)	Seasoning and Other Ingredients (grams)	
			Salt	Flour, Sugar, Pepper
100	90.0	0	3.0	7,0
75	67.5	22.5	3.0	7,0
65	58.5	31.5	3.0	7,0
50	45.0	45.0	3.0	7,0
35	31.5	58.5	3.0	7,0
25	22.5	67.5	3.0	7,0
0	0	90.0	3.0	7,0

Fat Extraction of Corned Products

Fat extraction was done with Soxhlet. The solvent used was n-hexane as solvent extraction. A total of 100 grams of corned beef was extracted **(Guntarti et al., 2015)**.

Fat Analysis by FTIR Spectrophotometry Method

Infrared spectra of reference samples and product samples were read by the FTIR spectrophotometer (ABB MB3000, Canada)

Data Analysis and Statistical analysis

Analysis of lard (extracted from corned beef) was carried out by spectrophotometry FTIR and processed by PLS multivariate and PCA analysis. The spectra region that showed the difference spectra of lard with other components were selected to create a model of PLS and PCA **(Miller and Miller, 2010)**.

The accuracy of the calibration models was indicated by the RMSEC and R^2 value obtained from the Horizon MB software (Philadelphia, USA). While the validation models produce RMSEP, RMSECV, and R^2 are calculated following equation below:

$$\text{RMSECV} = \sqrt{\sum_{a=1}^{n} \left(\hat{\text{Y}}\text{b} - \text{Ya}\right)^2} \Big/ \text{N} \qquad (1)$$

$$\text{RMSEP} = \sqrt{\sum_{a=1}^{n} \left(\hat{\text{Y}}\text{a} - \text{Ya}\right)^2} \Big/ \text{N} \qquad (2)$$

Where Ŷa is the actual value, Ya is the predictive value, N is the sample number, and The Ŷb is the calculated value for Ya (predictive value) based on the calibration equation with sample a **(Naes, et al., 2004)**.

RESULTS AND DISCUSSION

Design Model for Quantitative Analysis of pork in Corned

Based on the scanning, the infrared spectra showed that both pork and beef corned products contain different vibration of functional groups. The vibration C = O as the ester group was shown at wavenumber 1747 cm^{-1}. These peaks arise because the fat structure is a triglyceride consisting of the carbonyl ester group. Besides, the stretching vibration C – O group was identified at wave number 1238 cm^{-1} for beef, while pork has stretching vibration C – O group at 1234 cm^{-1}. The indication ester vibration was also illustrated at wavenumbers 1157 cm^{-1} and 1099 cm^{-1} **(Jaswir et al., 2003)**.

The vibration of the alkenes group (C = C) was illustrated at wavenumbers 3008 cm^{-1} and 1654 cm^{-1}. The different spectra produced between both pork and beef corned products showed that they have a different composition **(Figure 1)**. It can be said pork contains more unsaturated fatty acids level compared with beef. **Belitz, Grosch, and Schieberle (2009)** reported that pork contains high unsaturated fatty acids (double bonds) including oleic acid (43%) and linoleic acid (9%), while beef contains less unsaturated fatty acid than pork. Detailed vibration of all functional groups is given in **Table 2**.

However, quantitative analysis of lard in the corned products showed that the optimum difference of both pork and beef corned products was obtained at the wavenumber range of 1180 – 730 cm^{-1}. For meat discriminant, pork, beef, and mutton can be seen at 2925 cm^{-1}, 2855 cm^{-1}, and 1745 cm^{-1} with strong peaks and weak peaks at 750 cm^{-1} and 1800 cm^{-1} as fingerprint regions **(Yang et al., 2017)**. Besides, lard detection in cake formulation can be performed by FTIR at 1117 – 1097 and 990 – 950 cm^{-1} **(Syahariza et al., 2005)** and lard identification in steamed sausages and grilled sausages at wavenumbers of 1000 – 791 cm^{-1} and 1070 – 796 cm^{-1}, respectively **(Guntarti, Ahda, and Sunengsih, 2019)**. Even, lard adulteration in palm oils can be detected at 3006 and 1117 cm^{-1} **(Sim, Chai and Kimura, 2018)** or 3006 cm^{-1}, and 1120 – 1095 cm^{-1} **(Che Man, et al., 2013)** or 1481.22 – 999.05 cm^{-1} and 1793.67 – 1650.95 cm^{-1} **(Ahda and Safitri, 2016)**. Therefore, each sample type will change a marker region for lard detection. Based on the wavenumber range of 1180 – 730 cm^{-1}, the result of regression equation is y = 0.95x + 1.32, with R^2 value of 0.983 and RMSEC value of 2.055. The calibration equation is also validated using external validation and cross-validation. The results of cross-validation curve y = 0.9721x - 0.5334 with R^2 values 0.9995 and RMSECV value 2.22%. Besides, external validation has R^2 values of 0.9984, RMSEP of 1.65%, with the equation y = 0.9940x - 0.7061. the higher R^2 value and lower error (RMSEC and RMSECV) are the good indication of the obtained equation **(Rohman et al., 2012[b]; Rohman, Setyaningrum, and Riyanto, 2014; Ahda et al., 2020)**.

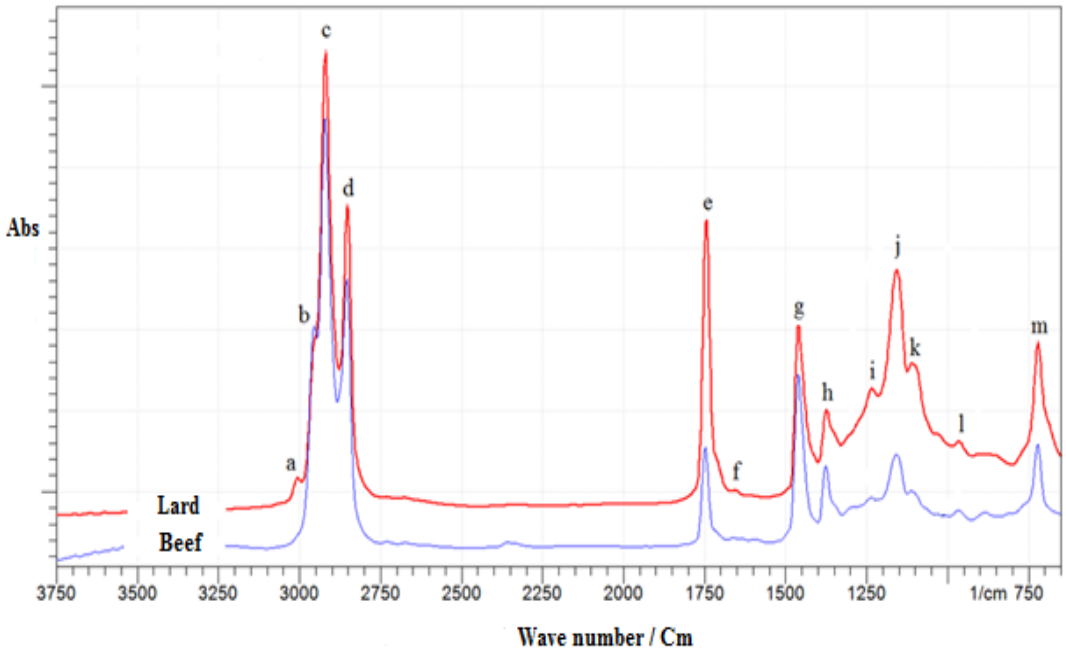

Figure 1 FTIR spectra of standard corneds from prok and beef at wave numbers 4000 – 400 cm^{-1}.

Table 2 Differences of function groups of standard corned from beef and pork.

Ribbon	Wavenumbers (cm^{-1})			Function Group	Vibration Model	Intensity
	Beef	Pork	Reference

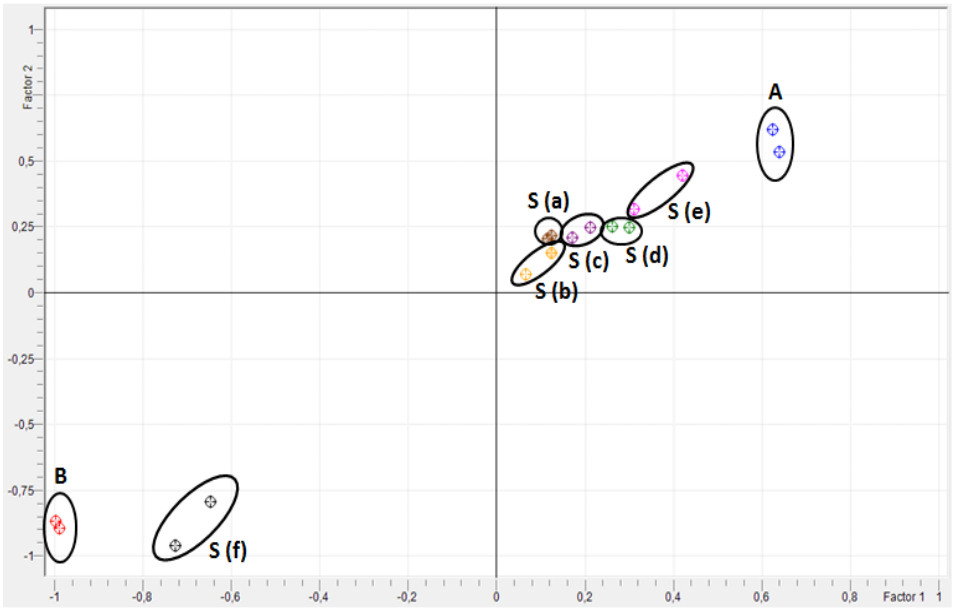

Figure 2 PCA *Score Plot* from Cornet Product Samples in the Market. Note: (A) Corned beef 100%; (B) Corned pork 100%; (S (a, b, c) Coocked commercial corned products; (S (d, e, f)) Raw commercial corned products.

Based on external validation and cross-validation were indicated that the calibration model at wave number 1180 – 730 cm^{-1} was able to give accurate results for the quantitative analysis of pork in the corned mixtures.

Analysis of Pork Adulteration in Commercial Corned Products

Analysis of pork in a food product can be performed and grouped by PCA analysis. It is an analytical technique to reduce the data when it found a correlation between the data **(Garcia, 2012)**. The PCA is unsupervised pattern recognition techniques widely used for the classification of different samples **(Nunes, 2014; Rahmania, Sudjadi and Rohman, 2015)**. PCA analysis will reduce the number of independent variables in the data to produce the new variables that are called the principal component or major components **(Che Man, Syahariza, and Rohman, 2010)**. Hence, the wavenumber regions for PCA were also optimized. Finally, the same wavenumbers used for quantitative analysis were chosen for PCA modeling due to its capability to provide good separation among the evaluated samples **(Rahayu et al., 2018; Gamperline, 2006)**.

In this study, pork analysis in the corned product is performed in optimum condition at wavenumbers of 1180-730 cm^{-1}. The discriminant analysis showed that 100% pork corned and 100% beef corned can be separated and distinguished **(Lumakso et al., 2015)**, it illustrated that both corned products have a different composition **(Figure 1)**. Therefore, analysis of pork adulteration in the commercial corned products can be performed in similar conditions **(Van der Spiegel et al., 2012)**.

In this research, we identify 3 commercial corned products and also observe the cooking effect in disrupting halal analysis. The result showed that 3 commercial corned products are not at all produced from beef. Sample (f) are grouped as pork corned, hence we can estimate that it is made from pork **(Figure 2)**. However, all samples are grouped in the beef corned product after the cooking process. It showed that the cooking process can affect the chemical properties of pork. The unsaturated fatty acids of pork may degrade during the heating process because pork corned is not separated from beef corned **(Bhaskar et al., 2012)**. Therefore, halal authentication using FTIR combined with chemometrics has a problem if the product is carried out by different process because they are possible to degrade during the process **(El-Gindy, Emara, and Mostafa, 2006)**.

CONCLUSION

FTIR spectrophotometry combined with chemometrics at wavenumbers of 1180 – 730 cm^{-1} resulted in a good correlation between the predicted value and actual value with R^2 of 0.9833, RMSEC of 2.06%, RMSEP of 1.65%, and RMSECV of 2.22%. Hence, it can be used for quantitative analysis of lard in the corned product. At wavenumbers 1180 – 730 cm^{-1}, halal authentication can be performed clearly and one of the commercial corned products was identified pork in its product. However, this method can not identify pork corned after it is cooked. Therefore, the cooking process will affect chemical compositions in commercial corned through the degradation process of unsaturated fatty acids.

ENGINEERING MANAGEMENT OF STARTER CULTURES IN STUDY OF TEMPERATURE OF FERMENTATION OF SOUR-MILK DRINK WITH APIPRODUCTS

Ivan Rogoskii, Mikhailo Mushtruk, Liudmyla Titova, Olga Snezhko, Svitlana Rogach, Oleh Blesnyuk, Yuriy Rosamaha, Tetiana Zubok, Oleksandr Yeremenko, Oleksandr Nadtochiy

ABSTRACT
The article considers the solution of problematic issues of engineering management of poly fermentation in the study of fermentation temperature of sour-milk drink with apiproducts. In the development of fermented dairy products, the components that are part of them, changes in their composition, and properties in the interconnection are considered as a technological system. The authors took into account that food technologies based on the use of the pure culture of one microorganism are limited by the capabilities of its fermentation system systems, the ultimate goal may not be achieved even by changing the conditions and parameters of cultivation. To successfully carry out fermentation processes in the technological system, a combination of cultures, associations of microorganisms with a wide range of fermentation products in contrast to one culture is promising to use. All experimental samples on a set of indicators prevailed control ones. The leader was a sample fermented with yeast with an equal ratio of cultures at a temperature of 38 – 40 °C. The authors found that the set of indicators of finished products for the production of sour-milk drinks with a complex of apiproducts, it is necessary to choose a three-strain poly fermentation product with a congruent ratio of cultures and set optimal fermentation regimes 39 ±1°C for 5.0 ±0.3 hours.

Keywords: apiproduct; sour-milk drink; fermentation temperature; technological systems

INTRODUCTION
It is known that in the development of fermented dairy products, the components that are part of raw milk, changes in their composition, and properties in the connection are considered as a technological system **(Parmjit, 2011; Palamarchuk et al., 2019)**. Its elements are independent and conditionally indivisible units that interact with each other and with the external environment **(Balduzzi and Tononi, 2008; Kozelová et al., 2011)**. The set of elements and their connections form the structure of the system, and its spatio-temporal fragments – functional subsystems **(Mda et al., 2019; Kim et al., 2015)**. The structure of the technological system for the manufacture of a sour-milk drink from apiproduct **(Grujić et al., 2011)** is presented in **Table 1**. The elements of the subsystems can function together and sequentially, in accordance with the tasks **(Giachetti, 2006; Rogovskii et al., 2019b)**. The main element of subsystem A is natural cow's milk, which provides the nutritional and biological value of the developed product **(Górska-Warsewicz et al., 2019)**. The nutritional value of milk is determined by its chemical composition, which is well studied and available in the literature **(Barłowska et al., 2011)**, is relatively stable and does not require additional research **(Rogovskii et al., 2019a)**. Milk is a structural unit of the technological system "raw milk-apiproduct-starter cultures", which is the environment of bioagents of fermentation – representatives of subsystem B **(Vieites et al., 2008)**. The result of this process is the biotransformation of components of subsystems A and B, which ensures the quality and properties of the future product **(Nikolic, 2018)**. The elements of subsystem B are lyophilized lactic acid microorganisms with known characteristics **(Table 2)** and therefore it did not require in-depth study **(Azat et al., 2016)**. In contrast to the components of subsystem B (apiproducts), which required careful examination, their characteristics may change over time **(Bishop et al., 2012)** and botanical origin **(Bober et al., 2020)**.

Scientific hypothesis
The scientific hypothesis assumes the existence of functional dependence in the fermentation process of three types of associations of lactic acid bacteria in the technological system with a complex of apiproducts and without them. The fermented milk process should be more active in the experimental media, as the hydrogen index should be lower than in the control ones.

Table 1 The structure of the technological system of sour-milk drink with apiproducts.

Subsystem	Elements of subsystems	Subsystem components
A	The components, that regulate the nutritional, biological and energy value of sour milk drink, are the living environment of biological objects	Raw milk
B	Components (growth factors) that regulate the activity and viability of biological objects	Apiproducts
C	Bioobjects that regulate fermentation	Starter cultures

Table 2 Characteristics of lactic acid bacteria.

Lactic acid bacteria	Temperature optimum, ºC	Interfacial acidity, ºT	Coagulation time, hour	Temperature range, ºC
Lactococcus lactis	25 – 30	125*	4 – 6	10 – 40
S. thermophilus	40 – 45	110 – 115	3.5 – 4	20 – 50
L. acidophilus	37 – 38	260 – 280	5 – 8	5 – 53
L. bulgaricus	40 – 45	200 – 350	4 – 6	20 – 50
B. longum	36 – 40	120 – 130	10 – 12	20 – 50

Note: * – achieved in 5 – 7 days.

MATERIAL AND METHODOLOGY

Given that food technology, based on the use of the pure culture of one microorganism, is limited by the possibilities of its enzyme systems, the ultimate goal may not be achieved even by changing the conditions and parameters of cultivation for ISO 27205:2010 **(ISO 27205:2010)**. Biological systems with a wider internal variety of signs, properties, and qualities have higher viability. For the success of fermentation processes in the technological system, it is promising to use a combination of cultures, associations of microorganisms with a wide range of enzymes in contrast to one culture.

The next series of experiments were conducted for a comparative study of technological processes in normalized milk (control technological system) and the milk environment with the complex of apiproduct (experimental technological system) with the participation of poly ferments of different bacterial composition.

First of all, two variants of associations were studied: the first consisted of three cultures – *S. thermophilus*, *L. acidophilus*, *L. bulgaricus*. The second, in addition to these, additionally contained a fourth species of microorganisms – *Lactococcus lactis* **(Table 3)**.

Table 3 Scheme of the presence of cultures in associations.

Component of the technological system	Samples			
	K1	K2	D1	D2
Prepared cow's milk	+	+	+	+
Complex of apiproducts	–	–	+	+
S. thermophilus	+	+	+	+
L. acidophilum	+	+	+	+
L. bulgaricus	+	+	+	+
Lactococcus lactis	+	–	+	–

Statistic analysis

Statistical analysis of the results of experimental studies was performed in five replicates using standard methods of research of organoleptic, physical, physicochemical, microbiological, and other indicators. The obtained results of experimental research are processed using modern analytical integrated systems Microsoft Excel 2016 and Statistica 13.3. Adequacy of decision-making was carried out according to the criteria of Fisher, Cochran, and Student.

RESULTS AND DISCUSSION

Four samples took part in the experiment: two control samples – K1 and K2, which did not contain apiproduct and two experimental samples – D1 and D2, obtained by fermentation of the technological system "raw milk-apiproduct-starter cultures". Similar studies were conducted by the authors of the following scientific papers **(Banik et al., 2003; Abdul Manan and Webb**, **2017; Montemurro et al., 2019)**. The ratio of cultures in fermentation products was congruent within each, incubation was performed at a temperature of 39 – 40 °C. In scientific works **(Ospina, Merrill and Benson, 2018; Smith et al., 2018)** incubation was performed at a temperature of 28 – 34 °C. Titrated and active acidity was determined within 6 to 12 hours every 60 minutes. In scientific works (**Shanina et al., 2019; Wijnen et al., 2020**) titrated and active acidity were determined for seven hours with an interval of 30 to 120 minutes. Samples D1 and D2 were compared with control ones **(Figure 1)**.

Studies of acid-forming activity in control and experimental environments have shown that apiproduct has a positive effect on the fermentation process, accelerating it **(Todorov et al., 2017)**. In particular, cultures grown in experimental technological systems with apiproduct overcame the stage of preparation of microorganisms for reproduction (lag phase) 2 times faster. This was more noticeable in the example of sample K2 **(Furtado et al., 2014)**. This may be due to the lower acid-forming capacity

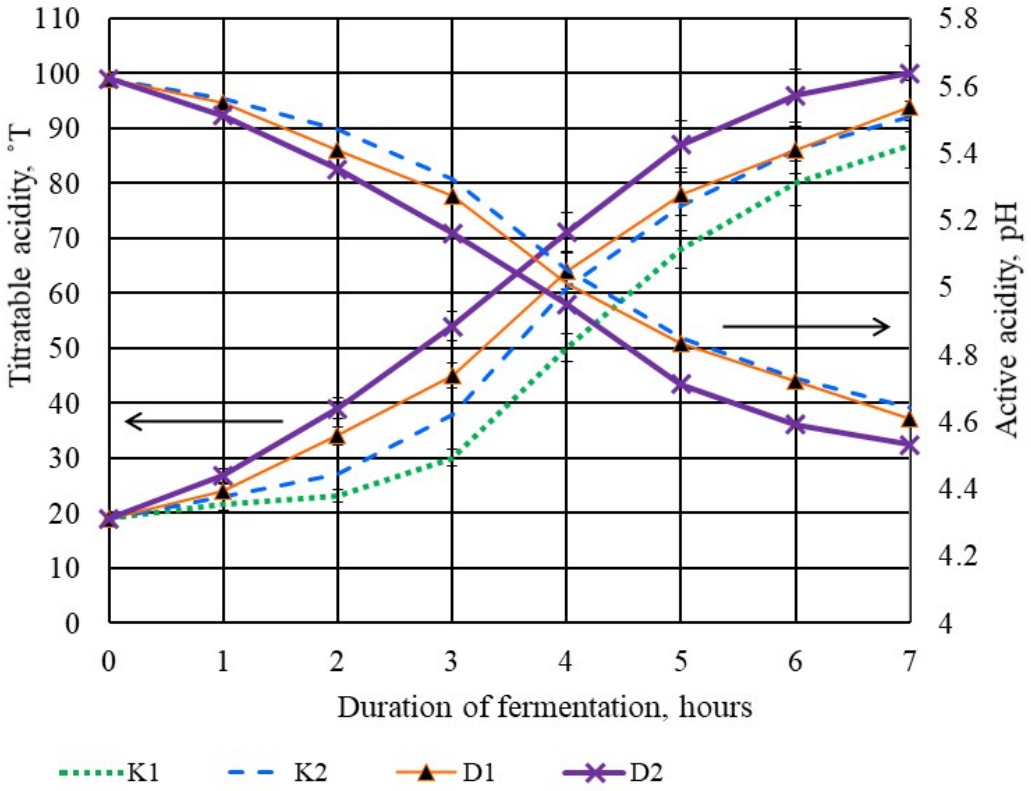

Figure 1 Dynamics of acidity of technological systems.

Table 4 Organoleptic parameters of sour-milk clots under the action of various associations of microorganisms.

Sample	Organoleptic parameters	
	consistency and color	taste and smell
K1	Moderately dense, slightly brittle and viscous	Pure, sour-milk, fresh taste
K2	Viscous, dense, homogeneous	Sour milk, moderately sour
K3	Homogeneous, viscous	Taste and smell are satisfactory
K4	The texture is viscous, slightly heterogeneous	Taste and smell are satisfactory
D1	The yellow clot is homogeneous, moderately dense	Sweet, not sour enough with a pleasant taste and smell of honey and pollen
D2	The clot of pleasant yellow color, homogeneous, dense, viscous	Harmonious sweet and sour, with a pleasant taste and smell of apiproducts
D3	Viscous sour milk gel with a yellow tint	Taste and smell are satisfactory
D4	Texture and color are satisfactory	Taste and smell are satisfactory

of *Lactococcus lactis* compared to *L. acidophilus* and *L. bulgaricus*. The reduction of the lag phase is a positive phenomenon, as it will reduce the likelihood of the development of unwanted microflora in the initial stages of fermentation of the technological system **(Sahu and Panda, 2018)**, when the acidity has not risen to a safe level yet **(Adebo et al., 2017)**.

The phase of smooth growth of biomass (log-phase) was also more productive in the technological system with the apiproduct complex for both starter cultures complex, but the association, which contained *Lactococcus lactis*, lagged behind the speed and efficiency of fermentation at all stages of microflora development **(Singh et al., 2015)**. So, the starter cultures complex, which includes *S. thermophilus, L. acidophilus, L. bulgaricus*, proved to be better in both control and experimental environments **(Glušac et al., 2015)**. To justify the choice of one of the two options for combinations of poly fermentation products **(Dafeo and Daugulis, 2013)**, an additional organoleptic evaluation was performed **(Table 4)** and the ability of the sour-milk drink to emit the moisture (syneresis) was compared.

It was found that the use of different ferments in the presence of apiproduct in milk provides products with different flavors **(Widyastuti et al., 2014)**. Thus, sour-milk drinks obtained by fermentation of the technological system "raw milk-apiproduct-starter cultures" had an appetizing appearance, pleasant color, pure sour-milk-honey smell, but the taste was not harmonious enough due to insufficient acidity. Sample D2, obtained by using three cultures (*S. thermophilus, L. acidophilus, L. bulgaricus*) had an appetizing appearance, pleasant sour-milk-honey aroma, and harmonious taste **(Spence et al., 2017)**.

The synergistic properties of sour-milk gels obtained by fermentation of the technological system "raw milk-apiproduct-starter cultures" indicate in favor of a three-strain combination of microorganisms, as sour-milk drinks, obtained by its use, better retain moisture in their structure **(Figure 2)**.

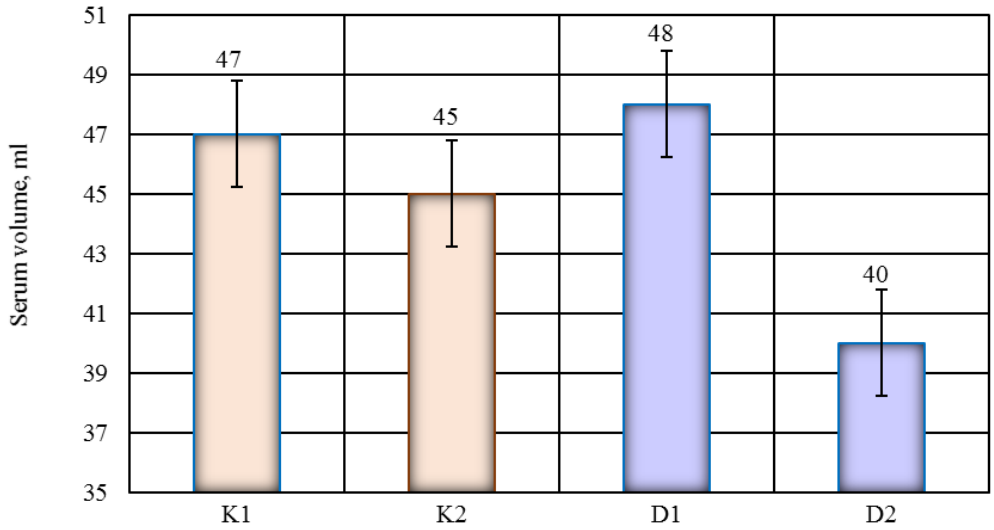

Figure 2 Synergetic properties of fermented technological systems.

Table 5 The structure of technological systems for studying the properties of associations of microorganisms.

Component of the technological system	Samples							
	control				experimental			
	K1	K2	K3	K4	D1	D2	D3	D4
Prepared cow's milk	+	+	+	+	+	+	+	+
Complex of apiproducts	–	–	–	–	+	+	+	+
2/4 *S. thermophilus*, 1/4 *L. acidophilus*, 1/4 *L. bulgaricus*	+	–	–	–	+	–	–	–
1/3 *S. thermophilus*, 1/3 *L. acidophilus*, 1/3 *L. bulgaricus*	–	+	–	–	–	+	–	–
1/4 *S. thermophilus*, 1/4 *L. acidophilus*, 2/4 *L. bulgaricus*	–	–	+	–	–	–	+	–
1/4 *S. thermophilus*, 2/4 *L. acidophilus*, 1/4 *L. bulgaricus*	–	–	–	+	–	–	–	+

After 3 hours of filtration of the 100 ml sample, less serum was released in K1 samples than in D1 by 1 ml and in K2 more than in D2 by 5 ml. The difference between samples K1 and K2 was 2 ml (4 %), and between D1 and D2 – 8 ml (16.7 %). Incubation of four-strain starter cultures complex in the medium with apiproducts led to a deterioration in the ability of the gel, formed by it, to retain moisture in the structure **(Mushtruk et al., 2020)**.

This is evidenced by a 2 % increase in the compression of the dispersion medium of sample D1 compared with K1. Thus, sour-milk gels formed by the starter cultures consisting of *S. thermophilus*, *L. acidophilus*, *L. bulgaricus*, retain moisture better than those formed by *S. thermophilus*, *L. acidophilus*, *L. bulgaricus*, *Lactococcus lactis*, the difference becomes more noticeable during the fermentation of the technological system "raw milk-apiproduct-starter cultures". This may be due to the ability of the *L. acidophilus*, *L. bulgaricus*, *Lactococcus lactis* to form a sour-milk gel with a brittle structure that displaces the dispersion medium. In contrast to lactic acid mucus-forming rods (*L. acidophilus*, *L. bulgaricus*) and thermophilic streptococcus, which form clots of viscous and creamy consistency **(Sfakianakis and Tzia, 2014)**, which provides low self-expression of serum.

A comparative evaluation of the action of two starter cultures by the set of signs of leaven, in dairy environments with a complex of apiproduct and without it, suggests that in further studies we should use the first of them. Because the combination of *S. thermophilus*, *L. acidophilus*, and *L. bulgaricus* provides the best quality in organoleptic, biochemical, technological, and others. properties of the product than poly fermentation product with the composition: *S. thermophilus*, *L. acidophilus*, *L. bulgaricus*, *Lactococcus lactis*.

Substantiation of fermentation regimes and composition of poly cultural leaven **(Kennedy and Krouse, 1999)**. The biochemical activity of microorganisms should be studied under the conditions of a set of influencing factors: the composition of the nutrient medium, the temperature of cultivation, the composition of the leaven **(Beltran et al., 2008; Bober et al., 2020)**. The influence of the first factor was investigated using two variants of media: the first – normalized milk with a mass fraction of fat of 3.2 %, pasteurized at a temperature of 87 ±2 ºC, and cooled to fermentation temperature, the second – the same milk with a complex additive. The effect of the second factor was investigated by varying the cultivation temperature **(Table 2)** from 38 °C to 42 °C in increments of 2 °C. Temperatures above 42 ºC are undesirable for the apiproduct. The influence of the third factor was studied by changing the ratio of cultures in the starter cultures. As a result of the technological system of design, eight samples of sour-milk clots were obtained **(Table 5)**: control – K1-K4 and experimental – D1-D4.

As a result of designing the technological system, eight samples of sour-milk clots were obtained, which differed in the presence of apiproduct in their composition and were fermented by different. Lactic acid bacteria (LAB) associations **(Fahrurrozi et al., 2019)**. Control and experimental samples were evaluated by coagulation time

and titrated acidity **(Marchi et al., 2009; Zheplinska et al., 2020)**. The research results are presented in **Table 6.**

Analyzing the biochemical activity of the association of lactic acid cultures in control and experimental of the technological system at a cultivation temperature of 38 – 42 ºC, we can conclude that, under these conditions, environments with apiproduct complex performed better than control ones.

The results of the study of culture activity under different cultivation conditions showed that an increase in biomass was obtained in environments with apiproducts, which is higher than in the control ones by 7.4 %. In scientific works **(Barãoa et al., 2019; Abdulgader et al., 2019)** descriptive experiments where the increase in biomass obtained in environments with a variety of products ranged only at the level of 3.5 - 4.6%.

Increasing the fermentation temperature by 2 °C causes an increase in acidity by 1 °T, a similar effect on the content of Log CFU ml^{-1} is not observed.

The number of lactic acid bacteria grown at a temperature of 3 ºC was higher than the number grown at a temperature of 40 ºC by 1.0% in the control group and 2.0% in the experimental group.

A further increase in the fermentation temperature to 42 ºC caused an inverse reaction, which resulted in a decrease in the number of viable cells, both in the control and in the experiment, by an average of 3.4 %, compared with samples cultured at 40 ºC by 2 % compared to those samples that were fermented at a temperature of 38 ºC.

As the fermentation temperature increases, the acidity of the clots increases – protein coagulation is faster by almost one hour, but under such conditions, there is a tendency to reduce the synthesis of biomass.

The time of clot formation has a directly proportional effect on the duration of the production process, and acid coagulation of milk correlates with the level of organic acids in the environment.

However, with the acceleration of coagulation, as can be seen from **Table 6**, the ability of microorganisms to

accumulate biomass decreases, and the number of viable cells decreases, both in control and in the experiment.

For example, in the control of acidity 85 °T Log CFU ml^{-1} is 8.7, and at an acidity of 88 °T – 8.5, and the time of clot formation at the specified acidity is reduced by 13 %. Similar dynamics are observed in the experimental samples, but the loss of cell concentration for every 1 °T is twice lower. It should be noted that coagulation should not be accelerated while neglecting the probiotic properties of the sour-milk drink. Therefore, the recommended fermentation regimes are 39 ±1 ° C for 5.0 ±0.3 hours of fermentation. Analyzing the results of the model associations of microorganisms, we can conclude that the best results were achieved by those who had a congruent ratio of cultures (K1, D1), both in environments with apiproduct and without them.

Studies of organoleptic, physicochemical, and rheological properties of cultures of lactic acid organisms under different cultivation conditions are presented in **Table 7**.

The data obtained indicate that with increasing fermentation temperature, there is a tendency to accelerate the decrease in the concentration of hydrogen ions and a slight increase in viscosity. A more pronounced difference was observed in the number of points scored between control and experimental samples, fermented under different conditions **(Woo et al., 2019)**. An increase in the cultivation temperature by 2 °C causes such negative phenomena as excessively sour taste, intense serum secretion, minor defects in the consistency of the sour-milk clot (flakes, etc.) and it leads to a decrease in the overall score by an average of 0.4 points for all samples.

Thus, the results of the research of organoleptic, physicochemical, and rheological properties of LAB cultures under different cultivation conditions indicate that fermentation should be carried out at a temperature of 38 – 40 ºC.

CONCLUSION

During the study of the fermentation process of three species associations of lactic acid bacteria in technological systems with a complex of apiproducts and without them, it was noted that the sour-milk process is more active in the experimental environment because the hydrogen index was lower than in control ones.

Sensory evaluation of sour-milk drinks showed that the best taste properties had experimental samples. This is because the sweet taste of honey was harmoniously combined with sour-milk, and the floral aroma of the apiproduct successfully emphasized the characteristic smell of fermented dairy products. The highest score among the experimental samples scored D1 and D2, but the relative viscosity of the sample D1 was higher by 6 % and was 83 – 85 seconds.

All experimental samples (D1 – D4) in the set of indicators prevailed control ones (K1 – K4), but the leader was the sample D2, fermented with an equal ratio of cultures at a temperature of 38 – 40 °C.

Therefore, according to the results of the study of the set of indicators of finished products for the production of sour-milk beverages with a complex of apiproducts, a three-strain poly fermentation product with a congruent ratio of cultures was selected and optimal fermentation regimes were established: 39 ±1 ºC for 5.0 ±0.3 hours.

FORMING THE SYSTEM OF FOOD SECURITY INDICATORS FOLLOWING THE CRITERIA OF THE SDGS-2030

Olena Kotykova, Mykola Babych, Irina Krylova

ABSTRACT
Effective management of any system is impossible without a clear definition of its elements, hierarchical levels, and desired performance indicators. Considering this problem in the context of food security management, the authors set out to create a system of food security indicators at different hierarchical levels. The purpose of the article is to deepen theoretical and methodological provisions and develop a system of indicators as a component of food security management at different levels, which should meet the criteria and dimensions of the SDGs-2030. The methodological basis of the research is the dialectical method and general scientific and special methods of scientific knowledge. The results obtained are of great practical importance in shaping national and regional food security policies (programs) on a sustainable development basis. Proceeding from the results of the research and the scientific and theoretical positions of the epistemological content of the category of the concept "food security", taking into account the criteria of food security of formation at different hierarchical levels and methodological aspects of its monitoring, it is proposed 54 indicators.

Keywords: food security; indicator; level; method; system

INTRODUCTION
The process of food security should be accompanied by organized monitoring of the nature of the changes, their quantitative and qualitative assessment to prepare the appropriate recommendations, and management decisions. The monitoring system is based on a combination of economic and social indicators with indicators that reflect the results of activities of state authorities in food security. According to the monitoring results, the executive authorities should decide on changes to the food basket for the main social and demographic groups of the population, and the executive authorities should make decisions on changes and approve sets of food products for the main social and demographic groups **(Verkhovna Rada of Ukraine, 2007a)**.

In the context of European integration, which involves openness of the internal and external markets of food, it is necessary to monitor the indicators of food security of the country at different hierarchical levels constantly, which will allow to react promptly to changes and to formulate corresponding state, regional and local policies.

Modern science does not provide a unified indicator system for food security monitoring. A large number of studies, devoted to this issue, indicates its relevance and the practical impossibility of the unification of indicators' system for all regions, subregions, and countries. It is obvious that the estimated indicators are not constant – they depend on the desirable criteria and specific features of a particular region, which ultimately forms the specific tasks of the state policy of each country to achieve food security grounding on sustainable development.

Ukraine does not have a methodological approach to the food security monitoring, including the all level, which should meet the criteria and dimensions of the SDGs-2030.

Scientists have made a considerable effort over the decades to create the best set of indicators for assessing food security and nutrition safety.

The overwhelming majority of scientific works on monitoring of food security is devoted to detailed research of specific aspects of the issue, for example:

(1) prevalence of micronutrient malnutrition **(Ramakrishnan, 2002)**;

(2) focus on three groups of risk factors: behavioral, environmental and occupational, and metabolic **(Forouzanfar et al., 2015)**;

(3) a comprehensive dietary analysis of low-income adults and examined differences in dietary intake between SNAP participants and nonparticipants **(Leung et al., 2012)**;

(4) examine the association between household food insecurity and the likelihood of perceived clinical malaria among 1- to 5-year-old children living in rural south Haiti **(Pérez-Escamilla et al., 2009)**;

(5) underlying mechanisms of under-and over-nutrition among children in rural China **(Zhang et al., 2016)**;

(6) summarizes the literature on the link between food insecurity and the following diet, weight gain, and chronic disease, especially among women **(Laraia, 2013)**.

These studies are local in terms of geography (a specific place of residence or region is being investigated) or have component problems (only several aspects are being investigated). The combination of all mentioned in these works (and many other) problems into a single system of indicators for monitoring food security is not meaningful, since most of them are relevant only for specific areas or groups of the population.

Some works are devoted to global research on the achieved level of food security. In particular, **Smith, Rabbitt and Coleman-Jensen (2017)** identify and examines the common determinants of food insecurity in 134 countries using cross-country comparable experiential of food insecurity.

This approach is expedient when it comes to assessing the level reached by countries, continents, or mainlands in comparison to the level of food security at the global level. **Pérez-Escamilla and Segall-Corrêa (2008)** give an overview of the advantages and disadvantages of five commonly used methods that can be used to assess food security. This study is intended to help researchers in choosing methods, taking into account their advantages and disadvantages, in monitoring food security.

Summarizing, we can conclude that the methodology of food security monitoring is based on the following basic components: problems, features, location, and methods. The indicators' system of food security monitoring should provide coverage of these components. That is why indicators of food security monitoring at the global level are inadequate in determining food security at the level of region or individual – they have different levels of problems and opportunities. So, we support the viewpoints of the scholars, **Frankenberger and McCaston (1998)** and **Gross et al. (2000)** in particular, who examine food security through the prism of hierarchical levels: global, national, households and individuals. This approach allows taking into account all the peculiarities of the formation of the food chain both of the locality (resource supply, specialization, and natural conditions) and personality (incomes, tastes, individual needs).

Global level

FAO provides information on 27 indicators of food security on the SDG-2030 **(FAO, 2019a)**; according to other criteria of the Agenda for the period until 2030, the system of indicators is under development. Therefore, an assessment of the state of food security at the global level and FAO and scientists make due to the indicators proposed by FAO in theprocessntation of the new Sustainable Development Goals (SDGs-2).

FAO is the custodian UN agency for 21 SDG indicators and is a contributing agency for a further 4. In this capacity, FAO is supporting countries' efforts in monitoring the 2030 Agenda **(FAO, 2019b)**.

Proposals of national scientists regarding the methodology for assessing food security at the global level are practically absent. Some of them are borrowed from individual indicators developed by FAO for use in the national system for monitoring food security.

National level

At the state level, the assessment of food security is carried out following the Methodology for determining the main indicators of food security, approved by the Cabinet of Ministers of Ukraine Resolution "Some issues of food security" No. 1379 dated December 5, 2007 **(Cabinet of Ministers of Ukraine, 2007) (Table 1)**.

Proposals of national scientists regarding the improvement of this Methodology for defining the main indicators of food security are different. However, some of them require a radical change of methodology for calculating the indicator, and chage the value of the margin, and deeper analysis (calculation of additional indicators) in interpreting the results. So, **Nud (2013)** "believes that the 60% threshold for the indicator of economic availability of products is too high".

Another normative document, which defines food security indicators, cannot be overlooked – The Law of Ukraine "On Food Security of Ukraine" **(Verkhovna Rada of Ukraine, 2007a)**. Currently, this document has the status of a project, and therefore official food security reports are based on the indicators contained in the Methodology for defining key indicators for food security.

We partially agree with several comments on food security indicators in the Conclusion on the draft Law of Ukraine "On Food Security of Ukraine" **(Verkhovna Rada of Ukraine, 2007b)**.

Such an indicator of food security, determined in clause 3 of Part 1 in article 7, as "provision of grain stockse food resources, defined as the ratio between the volumes of food grains in such resources and the volume of national consumption of bread and grain products in the calculation of grain". It is expedient, in our opinion, to supplement it with additional Corrective indicator – "grain production per person per year, tons". Such indicator is provided by the Methodical recommendations for calculating the level of economic security of Ukraine **(Ministry of Economic Development and Trade of Ukraine, 2013)**. Secondly, it reduces the impact on the calculation of the marginal indicator of the adequacy of grain supplies in public food resources of such factors as the level of solvent demand **(Verkhovna Rada of Ukraine, 2007a)**.

Grishova and Kryukova (2014) defined seven indicators and their corresponding normative values as the main indicators of food security. The authors also suggested a generalization of the system of indicators of the level of food security of the country using the integral coefficient.

The authors ranked the most significant integral indicators taking part in the formation of the integral index of food security level: the volume of grain production per capita, which forms the potential fund of population consumption; the level of economic availability of food; the share of food imports in the structure of consumption of the domestic market; the average wage as one of the main sources of household income.

In our opinion, this approach is appropriate in determining changes in the long-term dynamics or ranking of regions of Ukraine. The list of indicators is too large, and the method of their calculations is complicated.

Table 1 Methodology for determining the main indicators of food security.

Name of the indicator	Method of calculation	Limit (threshold) criterion
Daily energy value of a human diet	$EV = \Sigma m_i z_i$, where EV – energy value of the daily ration of a person; ia – type of food; mi – a mass of the i-th product consumed by one and the person; zi – energy value of the mass of the i-th product;	2500 kcal per day, 55% of the ration should be provided at the expense of products of animal origin
Ensuring the human diet by main types of products	$C = \frac{C_f}{C_r}$, where C – adequacy indicator consumption of certain products; Cf – actual consumption of a single product per person per year; Cr – rational norm of consumption of a separate product kg per person per year, agreed with the Ministry of Health	*
Availability of grain stocks in state resources	$G = \frac{H}{X}$, where G – indicator of grain security by food resources; H – availability of food grain in the state food reserve; X – average annual internal consumption of bread and grain products in terms of grain	17%, corresponding to 60 days of consumption
Economic availability of products	$E = \frac{B_x}{B_c}$, where E – an indicator of the economic availability of products; Bx – population expenditures for food per year; Bc – total expenditure of the population for the year	60%
Differentiation of the cost of food by social groups	$D = \frac{D_b}{D_m}$, where D – an indicator of the differentiation of the cost of food; Db – the value of consumed products in the 20 percent of households with the highest incomes; Dm – an indicator of the cost of consumed products in 20 percent of the lowest-income households	-
The capacity of the internal market of individual products	$V_i = F_i N$, where Vi – capacity of the domestic market of the i-th product; i – a type of the i-th product; Fi – annual average consumption of the i-th product; i N – average annual population	-
Food independence for a particular product	$P = \frac{I_i}{V_i}$, where P – a share of food imports of the i-th product; i – a type of i-th food product; Ii – imports of the i-th product; Vi – capacity of the domestic market of the i-th product	30%

Note: * Bread products – 101; meat and meat products – 80; milk and dairy products – 380; fish and fish products – 20; eggs (pcs.) – 290; vegetables and food crops – 161; fruits, berries and grapes (without wine processing) – 90; potatoes – 124; sugar – 38; vegetable oil of all kinds – 13. Source: **Some issues of food security (2007)**.

It is possible to avoid these errors, in our opinion, if when developing a system of food security assessment indicators, take into account the criteria for the functioning of the system.

Banakh (2016) defines five basic food security criteria and their respective indicators for statistical analysis: physical accessibility; economic availability; social accessibility; food independence; ecological factor. **Stezhko (2014)** forms a system of indicators of the state of food security, based on three criteria (although the author calls them the direction of evaluation, and as criteria defines different indicators): physical availability of food; economic availability of food; food for consumption.

It should be noted that both **Banakh (2016)** and **Stezhko (2014)** proposed to add the indicators to the system. These are soil fertility indices (environmental factor, **Banakh (2016)**) and overweight population (food security for consumption, **Stezhko (2014)**). The first indicator is one that characterizes the degree of sustainability of agricultural development – a criterion that domestic scientists practically do not take into account. At the same time, sustainable development of agriculture is an integral part of SDG2, along with food security. The second indicator is also ignored by academics since it is believed that food security is the lack of calories, and not over their daily norm, which also leads to overweight. At the same time, in other equal terms, such an indicator simply indicates the lack of economic access to food and the replacement of quality products with cheap ones, which in turn contain so-called "empty" calories, which do not allow to satisfy the need for the necessary minerals and vitamins but overload the body with carbohydrates, starch, and others.

Another important aspect for scientists is the question of the possibilities and limits of the use of food security assessment methodology in other countries. Of course, some indicators or methodologies, or methodological approaches can be borrowed, but their use in the national system for assessing food security should be justified and appropriate. Otherwise, in the end, we will have a large block of indicators, which will be difficult to interpret. There is another problem related to the methodology of collecting and processing statistical information, which has differences in each country. On January 10, 2003, Ukraine officially became the 52nd country (the first among the countries of the Commonwealth of Independent States), which joined the International Monetary Fund's Special Data Dissemination Standard. However, the list containing the IMF Special Data Dissemination Standard includes a limited list of indicators, most of which do not even indirectly reflect the state of food security. **Volchenko (2013)** introduced such indicator systems in the Russian Federation and Belarus as examples of foreign experience in the formation of the country's food security system. At

the same time, we should pay attention to the fact that the data of the systems of indicators of food security assessment of the countries are based on the criteria laid down in the approved Doctrine (RF) and the Concept (Belarus), which are aimed at achieving the goals that do not coincide with the goals that Ukraine sets itself.

We can accept may the experience of foreign researchers who propose establishing an optimal level of indicators for food security. So, **Bekenov (2003)**Error! Reference source not found.**, Ilyna and Kondratenko (2007)** determine the levels of optimality of food security indicators, but in the first and second cases it is only one indicator.

Russian explorer **Ogluzdin (2010)** proposes applying a five-point system of assessments of the state of food security. At the same time, it should be noted that it is not clear how to determine some of the proposed scientific indicators, because they sound, rather, as criteria-tasks than specific indicators. Secondly, not all indicators have limit levels defined, and therefore assign them to one of the five groups is not so easy. Thirdly, the list of indicators is too large and involves, in practice, the calculation of most of the indicators of economic, and not just food security. Instead, there are no specific indicators that determine the level of food security in the system.

We support the opinion of scientists who believe that the methodology for assessing food security indicators involves identifying their optimal, threshold and marginal levels, where the optimal level of food security indicators represents the range of values within which the most favorable conditions for reproductive processes in the national agro-industrial production are created; the threshold level is determined by the value of quantitative values, the violation of which causes unfavorable tendencies; marginal level – the limit violation of which causes threatening processes and trends in the system.

Research shows that the overwhelming majority of scientists define only the threshold levels of indicators. Some researchers' suggestions relate only to individual indicators. Thus, according to the classification proposed by **Kochetkov and Markov (2002)**, there are seven levels of food security of the population in Ukraine, which is determined by the indicator of the daily energy value of a human diet.

Kundeeva (2013) recommends to determine "the indicator of the overall physical availability of food", according to the criterion for assessing the level of food security, to assess the state of food security (levels of food security), and also, it is based on the actual state of the country's economy (unbalanced agricultural development and significant property stratification of the population) and the availability of statistical data.

The idea of evaluating food security on one indicator is attractive, but it is suitable for determining changes in the long-term dynamics or ranking of regions of Ukraine, that is, as part of a more complete monitoring of the state of food security.

Artimonova (2016) Error! Reference source not found.argues that "the goal and direction of food security are different for each level, but there are several characteristics of food security that are acceptable for assessing food security at all levels: ensuring food security; food security is ensured; unsafe food security; food disaster".

In our opinion, some of these characteristics are controversial regarding the levels of food security of the household and the individual. In particular, for the consumer, the country of production is not important if the price and quality of the product meet the requirements of the individual. The same applies to the characteristic features identified by the author as "secure food security" for a particular person, the level of consumption above the minimum necessary for physiological activity cannot be a determining indicator, since an important indicator is not the number of calories, but their quality. If consumer demand for food is met mainly through own production, this means certain restrictions for a particular person concerning her personal preferences. Every country has certain restrictions in the range of production of food products, as well as the formed food stocks, which take into account a specific list of basic products, but they do not provide the personal needs of each individual.

At the same time, we agree with the author's statement that "only the integral functioning of all levels of food security – the food security at the individual, national and international levels – will allow achieving positive qualitative changes in the provision of food products to people from all over the world, region, city and the individual person." **(Artimonova, 2016)**.

Regional level

Most scientists propose to assess food security at the regional level in the same manner as at the state level (**Error! Reference source not found.** According to the results that we substantiated, the necessity of taking into account the stability criterion of the food system of the region is determined, which requires a deeper investigation of this issue.

Piskunova and Osipova (2015) believe that "the indicator of the level and structure of per capita consumption of food can be the most informative and general indicator of the state of food security of the region."

Another group of authors **(**Error! Reference source not found.**)** propose to define an "integral indicator of food security in the regions of Ukraine": this indicator is based on the original approach, because there are less differentiation and closer interactions between the studied objects. For example, the grain stock is not taken into account, because at the regional level, the urgent transportation of grain in extreme situations is much less costly, both material and time. Consequently, only the stock of national reserves is of key importance.

Household and individual levels

The issue of food security at the household level became relevant when it was found that adequacy at the aggregated level could not ensure adequate nutrition at households or individual level. That is why the United Nations Special Committee proposed the definition of food security through the availability of food for households. Food security is provided when households have access to safe food in the amount necessary to ensure a healthy lifestyle for all its members (adequate in terms of quality, quantity, and cultural traditions) and when there is no excess risk of

loss of such access **(**Error! Reference source not found.**)**. **Error! Reference source not found.**

To establish the degree of satisfaction of personal needs through surveys, but the results will be reliable only for a certain period. On the other hand, it is fair to assert that, in other equal conditions, in the modern world, the level of income determines the level of access of a person to any material goods, including food.

Golikova (2014) believes that "food security at the household level is linked to the income of individuals." **Error! Reference source not found.**The low-income level of the population leads to the fact that price fluctuations directly affect the food situation of the poorest layers not only in the city but also in the countryside. In several countries, owners of small plots of land are frequent buyers of food, they do not provide themselves with products at the expense of their plots.

However, judging from the list of goods and services that are included in the calculations in determining the subsistence minimum, in many countries, under this term, they understood no longer the minimum need. As **Sokol (2012)** noticed, "this is no longer the subsistence minimum in its original treatment as the poverty line, but the income reflecting the minimum rates of consumption of the employee in a given period, taking into account the state of the economy." **Error! Reference source not found.**

Indicators of economic accessibility and differentiation of the cost of food by social groups become more important at the levels of the household and the individual. However, the analysis and interpretation of these indicators should be made more thoroughly according to the proposed Methodology for defining key indicators for food security. In Japan, a poor household is considered to be a family whose share of food expenditure exceeds 35% **(Nud, 2013)**. **Error! Reference source not found.**By comparing the data with such threshold values, the researcher will always have false data about the actual state of affairs. Analysis of the indicator of the differentiation of the cost of food by social groups following the Methodology for defining the main indicators of food security in the "general mass" will not allow to establish dependencies and identify the problematic aspects of household nutrition. Such an approach does not take into account the culture of food and the needs of the family, depending on their place of residence.

Scientific hypothesis

In our opinion, from a methodological point of view, the construction of a system of food security indicators should take place through the definition of the criteria for the functioning of the system. Such an approach ensures the interconnection and interdependence between the nature, objectives, and monitoring of food security at any level.

MATERIAL AND METHODOLOGY

The theoretical basis of the research is the fundamental provisions of the formation of the food security system, the modern economic theory, which defines the goals and patterns of sustainable development of the world and Ukraine, scientific works of domestic and foreign scientists on issues of food security, state administration and legislative regulation of this problem.

The methodological basis of the research is the dialectical method and general scientific and special methods of scientific knowledge. In the process of research, the following methods of economic research were used: abstract-logical (the formation of theoretical generalizations and conclusions); historical (in the study of the evolution of the formation of terminology); monographic (the study of best practices on food security issues); system analysis and synthesis (formation of a system of food security criteria based on existing problems); terminological analysis and operationalization of concepts (research of conceptual approaches to the interpretation of the concepts of "food security", "components", "criteria" and "indicators").

RESULTS AND DISCUSSION

Critical analysis of scientists' approaches to the definition of the system of food security criteria allowed to establish features of their formation in the national science (**Figure 1** – "Problem" and "Consequences"). The author's suggestions for solving these problems, including improving food security, can be summarized (**Figure 1** – "Proposals").

Therefore, when developing a system of food security indicators, we should point out the levels at which the monitoring and regulation process is conducted: global, national, and regional levels, household, and individual levels.

National level

In general, the system of indicators, approved by the Methodology for determining the main indicators of food security, meets the dimensions and criteria for food security.

At the same time, the defined system does not fully assess the criterion of implementation of effective agricultural trade policy of the state, which is the determining determinant of the national level. To ensure the objectivity of monitoring and interpretation of the obtained results, it is expedient:

(1) Include a list approved by the Methodology for defining the main indicators of food security, adding them to the system of indicators of food security assessment at the national level:

- the level of cereal stocks at the end of the period, the percentage of consumption;
- share of sales of imported food products through the trading network of enterprises, percentages;
- grain production per person per year, tons;

(2) The calculation of these new indicators should be carried out following the provisions of the Guidelines for the calculation of the level of economic security in Ukraine;

(3) Set the value of the marginal level of the indicators:

- the level of cereal stocks at the end of the period, the percentage of consumption – 100 percent;
- the share of sales of imported food products through the business network of enterprises – 25 percent;

(4) grain production per person per year – 0.8 tons **(Figure 2)**.

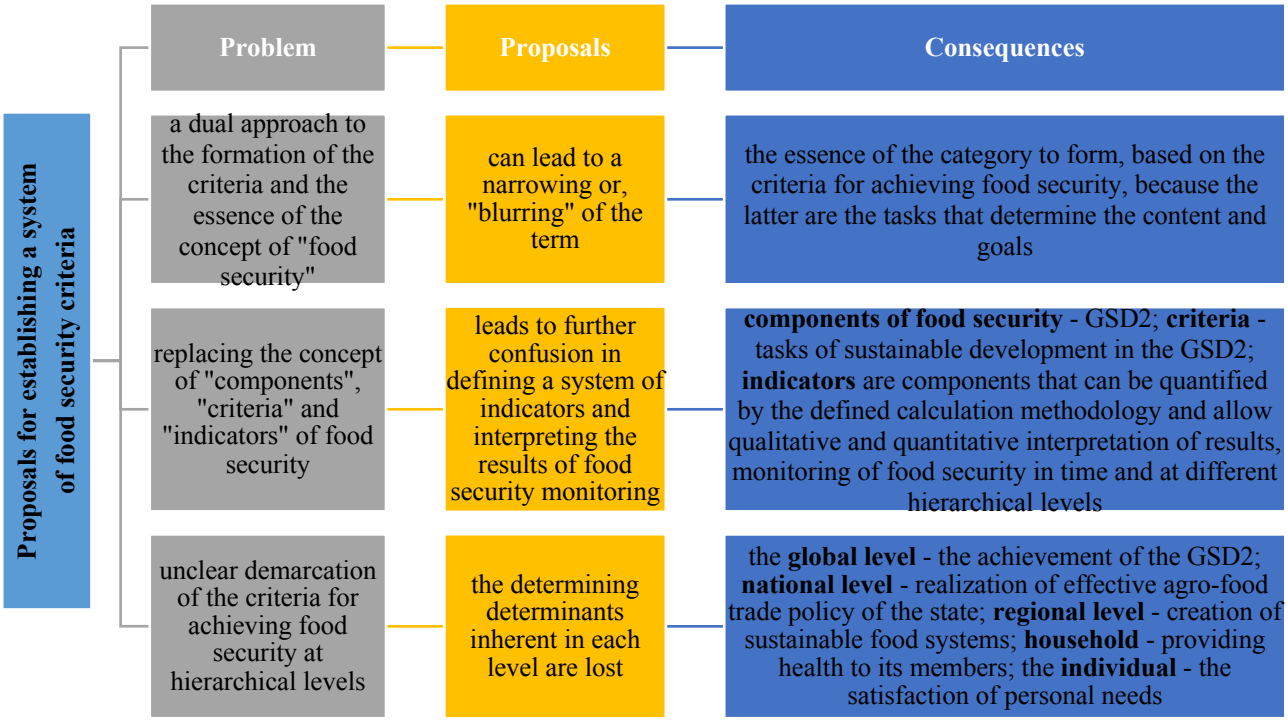

Figure 1 Proposals for establishing a system of criteria for ensuring effective food security management based on existing problems. Note: Source – Authors' work.

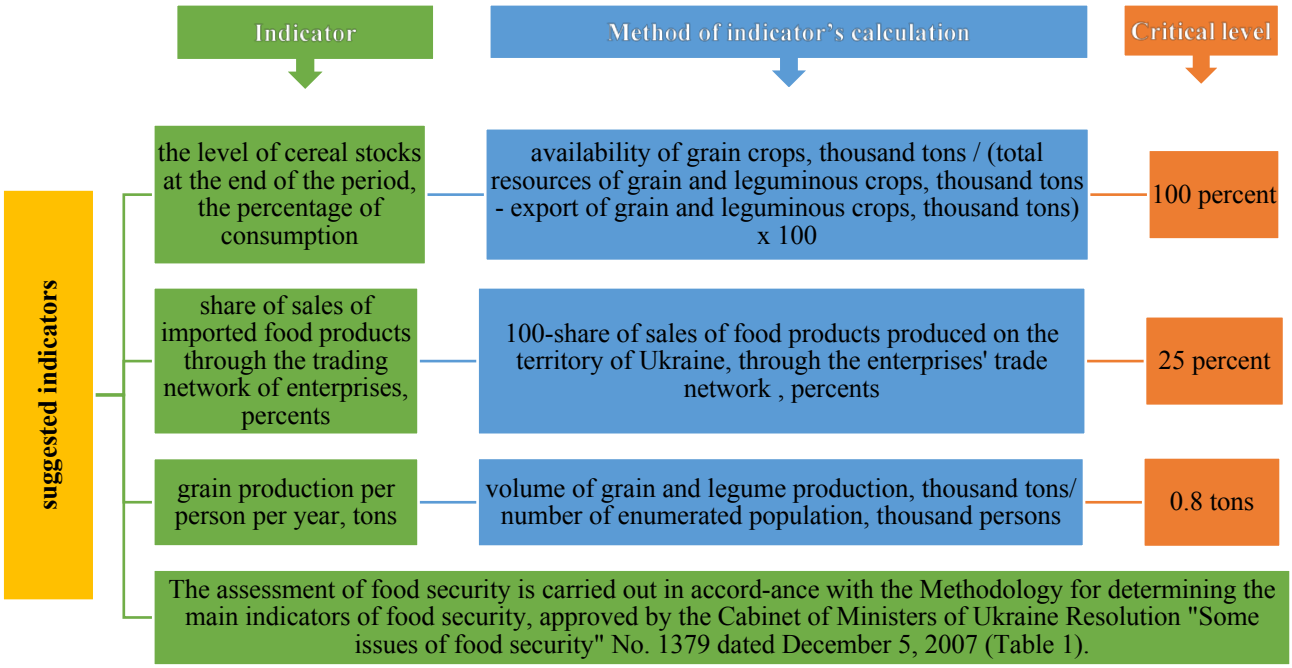

Figure 2 Proposals to improve the system of indicators to ensure effective food security management at the national level. Note: Source – Authors' work.

Regional level

Taking into account the above mentioned, there is a need for monitoring and assessment of food security at the regional level by carrying out calculations of the regional rating (ranking) of each indicator and calculating the overall rating in general for all indicatfollowingwith the Methodology for monitoring and evaluating the effectiveness of the implementation of the state regional policy (Error! Reference source not found.).

The ranking is conducted by comparing the deviation of the values of the indicators for each specific region from their best values by region for the corresponding (reporting) period and the corresponding ranking of regions from 1st to 24th place. The rating assessment is based on the calculation of relative deviations of the indicators of each region from the maximum and minimum values of such indicators of other regions by the formula:

$$R_j = \sum_{i-1}^{n} \frac{x_{maxi} - x_{ij}}{x_{maxi} - x_{mini}} + \sum_{i-1}^{n} \frac{x_{ij} - x_{mini}}{x_{maxi} - x_{mini}}, \quad (1)$$

Where: R_j – amount of the rating estimates for a particular region for each of the indicators that characterize a particular year; x_{ij} – a value of the i-th indicator in the j-th region; x_{maxi} – maximum value of the i-th indicator; x_{mini} – minimum value of the i-th indicator.

The second part of the formula is used to evaluate the indicators, which increase positively (for example, the volume of realized industrial output per capita), the first part – to assess the indicators, which increase the negative value (for example, the amount of unpaid wages).

Determination of the average arithmetic value of the sum of rating assessments of a specific region for all indicators of the annual evaluation, which characterize a separate line of activity, is carried out by the formula:

$$R_{cpj} = \frac{R_j}{n}, \qquad (2)$$

Where: R_{cpj} – an average arithmetic sum of ratings of a specific region for all indicators of a particular year; n – the number of indicators used for the calculation for a particular direction.

Due to the results of calculations, the integral rating is determined as the average arithmetic mean of the sum of rating estimates of a particular region for all years by the formula:

$$I_j = \frac{\sum_1^m R_{cpj}}{m}, \qquad (3)$$

Where: I_j – an average arithmetic sum of ratings of a specific region for all years; m – number of years for which the calculation was made.

The criterion of stability of the food system of the region is characterized by indices of production and consumption of the main types of foodstuffs, branching out of the retail chain, as well as a system for reducing, processing and subsequent use of food waste.

Official statistics do not provide information according to the latest criterion, to perform calculations of the ranking of regions with levels of food security, we propose the use of the 9 indicators **(Figure 3)**.

In general, the scheme for researching at the regional level will include six stages **(Figure 4)**.

Household and individual levels

In our opinion, it is advisable to apply the approaches proposed by Golikova K.P. **(**Error! Reference source not found.**) Error! Reference source not found.**to assess the food security at the household level, and Mostenska T.G. **(**Error! Reference source not found.**). Error! Reference source not found.**

The first approach ensures the objectivity of the analysis of the economic availability of products by comparing: the actual consumption of food with a consumer basket and rational standards; ratio and share of food costs in total costs and subsistence minimum. The second approach allows us to establish dependencies and identify the nutritional aspects of households depending on their place of residence.

In respect that neither the first nor the second approaches make it possible to characterize the health of household members as the main criterion for food security at the household level, therefore, in our opinion, to carry out a comprehensive assessment of food security at the household level, it is expedient to analyze the indicators of the expected life expectancy at birth (years) and the rate of infant mortality (deaths of children under one year per 1,000 live births). Even more problems, regarding the assessment of food security at the level of the individual, occur as follows: on the one hand, the main criterion for achieving it is the degree of satisfaction of personal needs; and on the other hand, it is necessary to comply with the principle of state administration of personal interests' subordination to the national ones, after all, eventually, only such an approach can ensure the rights and freedoms of everyone.

The hypothesis of the study is the assumption that there is a significant overproportion in the level of consumption of food products by different categories of households as well as an impact of the economic availability of products upon this misbalance. Based on this thesis, it is proposed to evaluate the level of food security of households in terms of by households' categories, based on the main indicators of food economic availability and consumption **(Figure 5)**.

There are discussions around the issue of food security indicators. In general, the proposals of domestic scientists regarding the improvement of the food security assessment system are based on the official Methodology for defining the main indicators of food security **(**Error! Reference source not found.**)** and are mainly concentrated in five areas:

(1) the formation of a system of indicators – the establishment of a list of indicators, their subordination to the criteria, the reduction or increase of their number compared with the approved Methodology for determining the main indicators of food security – were studied by **Banakh (2016)**Error! Reference source not found.**, Stezhko (2014), Ogluzdin (2010)**;

(2) improvement of the methodology for calculating the individual indicators that were proposed by the Methodology for determining the main indicators of food security, or – absolutely new indicators – were investigated by **Grishova and Kryukova (2014), Stavytsky and Prokopenko (2014)**;

(3) systematization of indicators at different hierarchical levels – was studied by **Artimonova (2016), Piskunova and Osipova (2015), Golikova (2014), Sokol (2012), Mostenska (2015)**;

(4) finding out of the optimal value of the normative (optimal, threshold and boundary) indicator level – was investigated by **Grishova and Kryukova (2014), Kochetkov and Markov (2002), Nud (2013), Kundeeva (2013)**;

(5) borrowing methodologies for assessing the food security of others (mainly post-Soviet) countries – were investigated by **Bekenov (2003), Volchenko (2013)**.

At the same time, national scientists did not agree on the construction of a unified system of indicators as part of the management of food security at different levels.

The world's scientific community also does not offer the unified indicators' system for food security monitoring at various levels, only for global one, whose indicators' system was developed by **FAO (2019a)**.

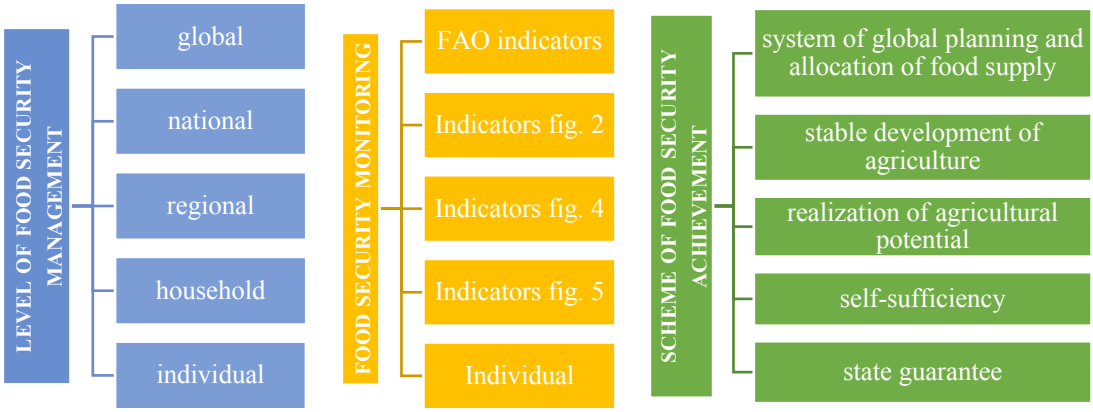

Figure 6 The place of indicators in the food security management system at different levels. Note: Source – Authors' work.

The proposed system solves a range of problems that currently exist: firstly, in the domestic monitoring system, there are developed indicators only at the national level; however, we proposed system that covers all levels; and secondly, the criteria underlying the national food security monitoring system do not meet the SDGs; instead, our proposed system of indicators is based on the need to achieve the SDGs2.

The developed system of indicators and margins of food security ensures monitoring and evaluation of the achievement of the criteria of the respective levels (global, national, regional, households, and individuals) based on the actual official information provision of the processes of food security according to the SDGs2.

The proposed system of indicators allows monitoring of food security in a systematical and integrated way, at various hierarchical levels, which enables the quality management of food security taking into account specific features and needs at each level **(Figure 6)**.

Further research will be aimed at making the strategic framework and mechanism for ensuring food security at various hierarchical levels, taking into account the monitoring results of the proposed methodology.

CONCLUSION

The formation of theoretical and methodological guidelines and methodological recommendations for the development of a system of food security indicators requires further systematic research on its content-based basis as a component of food security management at different levels in the context of the implementation of the concept of sustainable development goals 2016 – 2030.

Based on the results of the conducted research and the scientific and theoretical positions of the epistemological content of the category of the concept of "food security", taking into account the criteria of food security, formation at different hierarchical levels and methodological aspects of its monitoring, we propose:

(1) to use the FAO's system of indicators to assess global food security. It makes no sense to develop a new system that requires complex calculations in all countries of the world (because the global level has the same information – comparisons across different countries, continents, continents, etc.) when FAO outlines all indicators and reports on the state of food security in the world in open access;

(2) to assess food security at the national level, we should use the system based on the indicators of the Methodology for defining the main indicators of food security, taking into account the indicators characterizing the level of the country's agricultural and food trade policy;

(3) to use a system based on the indicators of the Methodological recommendations for assessing food security at the regional level, for calculating the level of economic security of Ukraine, taking into account indicators that characterize the stability of the food system;

(4) to assess food security at the household level, use the technique proposed by **Mostenska (2015)**, taking into account indicators that characterize the health of household members;

(5) the assessment of food security at the individual level is currently only possible through the application of a questionnaire, where attention should be focused on the analysis of indicators characterizing the degree of satisfaction of personal needs.

PATIN (*PANGASIUS HYPOPHTHALMUS)* FISH PROTEIN CONCENTRATE ALTERS INSULIN-LIKE GROWTH FACTOR (IGF)-1 AND IGF BINDING PROTEIN (IGFBP)-3 LEVEL OF SPRAGUE DAWLEY NEONATE RATS-INDUCED MALNUTRITION

Annisa Zikra Abdullah, Samnil Astuti Fitri, Muflihatul Muniroh, Tri Winarni Agustini

ABSTRACT

Malnutrition is caused by inadequate protein intake and affects growth factor. High protein from patin (*Pangasius hypophthalmus*) fish is a well-known protein source. This study aims to investigate the effect of patin fish protein concentrate (PFPC) in the IGF-1 and IGFBP-3 level of Sprague Dawley (SD) neonate rats-induced malnutrition. Thirty male SD neonate rats were divided randomly into five groups, namely normal control (K1), malnutrition control (K2), malnutrition with PFPC 13.26 mg.g^{-1} body weight (BW)/day (X1), malnutrition with PFPC 19.89 mg.g^{-1} BW/d (X2), and malnutrition with casein supplement 13.26 mg.g^{-1} BW/d (X3). K1 received a standard diet, while the others received a low 8% protein diet (L8PD) since those were born until 21 days. The standard diet was refed for all groups during the intervention (14 days). IGF-1 and IGFBP-3 levels were measured by ELISA. Normal data were analyzed by using One-way ANOVA which then was followed by post-hoc Bonferroni. Meanwhile, the others were analyzed by Kruskal Wallis and followed by Mann-Whitney U-test. Spearman test was used for correlation. PFPC contained 81.07% of protein, 4.08% of fat, 7.24% of moisture, 2.77% of ash, and 4.83% of carbohydrate. These contents had affected the growth factor. As a result, in the PFPC intervention, IGF-1, and IGFBP-3 levels (p <0.05) were decreased, while the controls were increased. The decreased values were shown in IGFBP-3 levels (p <0.05) while the increase was shown in both controls. On the other hand, the increase in body weight was shown in all groups, including control ones. A strong correlation was found between IGF-1 and IGFBP-3. PFPC has additional value on repairing malnutrition that is the best dose in effecting IGF-1 dan IGFBP3 levels is 13.26 mg.g^{-1} BW/d.

Keywords: FPC; Malnutrition; IGF-1; IGFBP-3

INTRODUCTION

Malnutrition is generally caused by restricted dietary intakes and ended with poor linear growth even in early life **(Kartini, 2019; Aheto, 2015)**. Globally, undernutrition conditions have been caused by the mortality of 30% of children **(Blossner and De Onis, 2005)**. The prevalence is still high in some developing countries in South East Asia such as Indonesia **(UNICEF, WHO, and World Bank Group, 2018)**.

Malnutrition is caused by a lack of nutrients intake, such as a protein restriction diet **(Kartini, 2019; Saunders, 2011; Gibson, 2005)**. Malnutrition, especially in the golden age, can cause growth faltering, such as stunting. Besides is also has a reciprocal relationship with infections that lead to systemic inflammation **(Bartz, 2014; Guerrant, 2008; Lunn, 2007)**. Consequently, this condition results in the disruption of the body's hormonal function, including disruption of growth hormone (GH). Furthermore, the disruption also affects the role of GH in releasing growth-related substances in the hypothalamus-pituitary-GH axis interaction. Malnutrition will also affect the mechanism in producing IGF-1 and IGFBP-3, the binding protein which is the principle binding protein of IGF-1 **(Deboer, 2017; Bartz, 2014)**.

IGF-1 and IGFBP-3 are produced in the liver. They have a function in mediating the protein metabolism and controlling the growth factors which are accumulated in somatic cells **(Guntur and Rosen, 2013; Skottner, 2012; McDonald, 2007; Laron, 2001)**. Their production is a form of GH secretion and even shows a resistant condition **(Misra, 2003; Hintz, 1978)**. Decreased IGF-1 values are shown in acute malnutrition, while IGFBP-3 in chronic one. Both of them have special functions in several metabolic conditions **(Gupta, 2011; Hoppe, 2004)**. Several studies on subjects with severe acute malnutrition, even normal, showed a decrease **(Kartini, 2019; Hoppe, 2004; Misra,**

2003). Consuming high protein intake can improve this condition especially the function of IGF-1 and IGFBP-3.

Fish protein concentrate is a product resulting from the relieving moisture and fat content. Bioactive compounds and peptide contained in fish have benefits to control growth **(Kundam, 2018)**. Patin (*Pangasius hypophthalmus*), a freshwater fish, is a tropical fish that can live in many countries in Southeast Asia such as Indonesia. Many fisheries technologies can maintain and protect the fish protein from damaged, such as by making fish protein concentrate. The fish protein intervention studies are well-known studies and affect many pre-clinical and clinical indications **(Nobile, 2016)**. With 80% protein reaches of PFPC and has greater digestibility, amino acids from patin fish, especially lysine and leucine, are more absorbed by the body than other protein sources, such as meat and poultry protein **(Pratama, 2018)**. Discussing the high protein study and its effect on linear growth and malnutrition, high protein intake has shown its effects in increasing IGF-1 in boys and increasing IGFBP-3 of premature infants **(Hoppe, 2004; Smith, 1997)**. This study aims to investigate whether the intervention of patin fish protein concentrate affects the IGF-1 and IGFBP-3 levels of Sprague Dawley (SD) neonate rats-induced malnutrition.

Scientific hypothesis

There are various doses of patin fish protein concentrate that affect insulin-like growth factor (IGF)-1 and IGF binding protein (IGFBP)-3 levels of Sprague Dawley neonate rats-induced malnutrition.

MATERIAL AND METHODOLOGY

Preparation of patin fish protein concentrate

Patin fish were bought at fishpond in the Ambarawa sub-district, Semarang Regency, Central Java Province, Indonesia. The selected patin fish as those that have a good condition as shown by fresh patin that has just been captured, weighs about 1 kilogram for one fish, has fresh flesh, has gills that are still red, the color does not change and odorless. Then the patin fish were filleted and cleaned. The filleted fish were ground using a food processor with the addition of salt (0.5%) and $NaHCO_3$ (1.5%). Next, fish pasta was steamed for 30 minutes. The steamed pasta was then pressed and extracted by 96% food-grade ethanol with a 3:1 patin ratio. The extraction was carried out twice to fully relieve the moisture and fat content. The extracted fish was then dried at a temperature of 40 ^oC and mixed until refined size (60 mesh). The PFPC was wrapped in food-grade silica gel and stored in the bottle at 4 °C **(AOAC International, 2006)**.

Table 1 Ingredient compositions (g/kg) of low 8% protein diet (L8PD) fed to malnutritiomn-induced rats.

Ingredients	L8PD (g)*
Casein purified high nitrogen	80
Corn starch	780
Cottonseed Oil	100
Salt mixture U.S.P XIV	40
Total	1000

Note: * L8PD for K2,X1,X2, and X3.

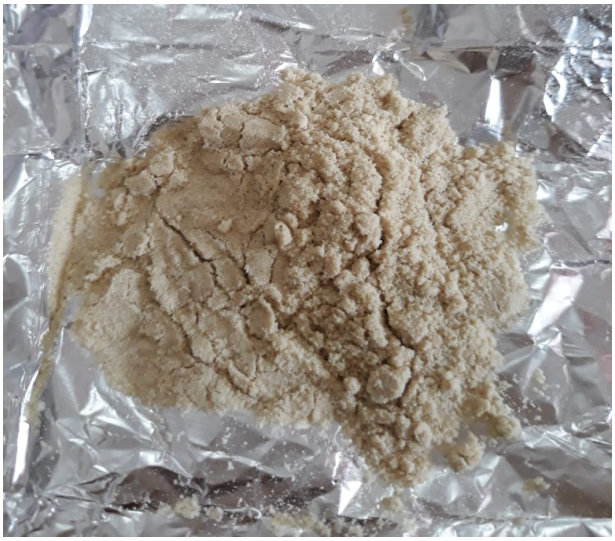

Figure 1 Patin Fish Protein Consentrate.

Proximate analysis of patin fish protein concentrate

The proximate analysis includes moisture, protein, ash, fat, and carbohydrate content (by difference) **(AOAC, 2005)**.

Research design and experimental-animals

This research was a true-experiment study with a randomized pre-post test and has a control group design. The animal used was male Sprague Dawley rats, aged 21 days induced with a low 8% protein diet (L8PD), except health control. The acclimatization was held in the laboratory of Gadjah Mada University, Yogyakarta. The rats were placed in each group and numbered. They were placed at a regulated temperature (21^oC) and a clean cage. They were given ad-libitum water during the experiment. Animal care in the laboratory was carried out in accordance with the animal Laboratory Guideline from the Central Laboratory for Food and Nutrition Studies, Gadjah Mada University, Yogyakarta.

Thirty rats were divided into five groups, namely groups of normal control (K1), malnutrition control (K2), malnutrition with PFPC 13.26 $mg.g^{-1}$ BW/day (X1), malnutrition with PFPC 19.89 $mg.g^{-1}$ BW/d (X2), and malnutrition with casein supplement 13.26 $mg.g^{-1}$ BW/d (X3) **(Wong, 2019)**. The malnutrition-condition was induced since 0 - 21 days old of neonate rat or through maternal L8PD **(Table 1)**. After 3 days of acclimatization, the IGF-1 and IGFBP-3 were examined before the intervention. The intervention group was treated with the CMC-Na suspension method for 14 days. Body weight was measured every week since the animals were born until the interventions were ended. All of the groups were fed with Comfeed II standard-diet (CSD) during the intervention period. The blood sample was taken again at the end of the intervention through the retroorbital plexus. Blood samples were collected in a centrifugation tube and centrifuged 4000 rpm in 15 minutes. IGF-1 and IGFBP-3 levels were analyzed by ELISA **(Kartini, 2019; Alishahi, 2013)**.

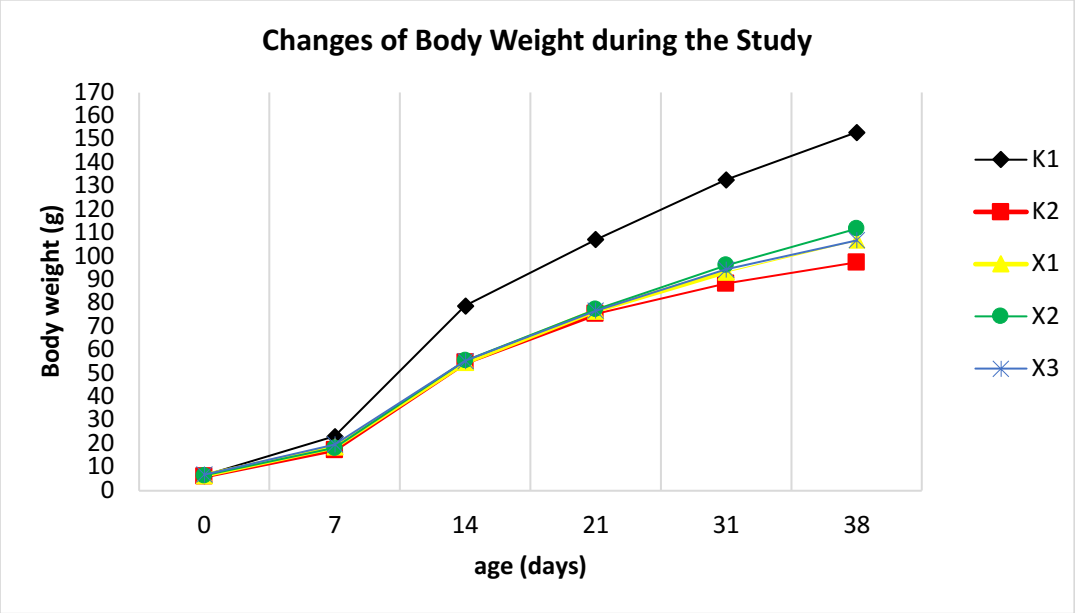

Figure 1 Changes of body weight of neonate rats during the study. Malnutrition was induced from day 0 to 21st by giving low 8% protein diet (L8PD). PFPC intervention was started from day 24th to 38th. Three days acclimatization was done from day 21st to 24th.

Ethical declaration:

This study was approved by the Health Research Ethics Commission of the Faculty of Medicine Diponegoro University Semarang through ethical clearance No. 131/EC/H/KEPK/FK-UNDIP/X/2019.

Statistical analysis

Results were expressed as mean ± SD (for normally distributed data), otherwise, it was expressed as median (min-max). Statistical difference was analyzed by using a one-way analysis of variance (ANOVA) followed by post hoc Bonferroni for normally distributed data, otherwise, the Kruskal-Wallis test followed by Mann-Whitney-U-test was used. The software used was SPSS software version 22 (SPSS Inc, Chicago, IL, USA). Spearman's correlative test was used to analyze the relationship between variables. Statistical analyses were done by the computer. The differences and correlations were considered significant at *p*-value <0.05 and 95 % confidence intervals. The strength of the correlation was determined by the *r-value*.

RESULTS AND DISCUSSION

Related data about PFPC was shown as proximate analysis **(Table 2)**. The other data about intervention processed was obtained from 30 Sprague Dawley-neonate rats, which were divided into each group consisting of 6 neonatal rats. The experimental animals used before intervention had an average body weight of 76.58 grams for the malnutrition group and 106.5 grams for the healthy control (data not shown).

Wilcoxon test carried out on the body weight before and after the intervention, showed that the intervention of PFPC increased the body weight in the all-treatment-group as shown in **Table 3** and **Table 4**. Healthy-control-K1-group has experienced a significant increase in BW ($p = 0.026$). Statistically, the difference was also found on the pre-post intervention change (Δ) of neonate rats-BW among all groups (Kruskal Wallis test; $p = 0.001$). Meanwhile Mann-Whitney U- test was also performed on two groups. The Δ-neonate rats-BW of all-intervention-malnutrition-group were higher than malnutrition-control-K2-group and this result was significant (X1 and X2 had the same *p*-value; $p = 0.004$). The Δ-neonate rats-BW of the X1-group was not different from the X3-group ($p = 0.868$). This finding demonstrated that PFPC can increase body weight which is higher in malnutrition neonate rats. Besides, this finding also showed that the ability of PFPC in dose 13.26 $mg.g^{-1}$ BW/d in increasing body weight of malnutrition neonate rats has the same ability obtained from the casein supplement. The difference in body weight obtained during the study was shown in **Figure 1**.

The IGF-1 levels decrease at the end of the intervention, and significantly different ($p = 0.028$ for X1 and X2, $p = 0.027$ for X3; **Table 4**), while K2-group experienced a significant increase IGF-1 level ($p = 0.027$). The pre-post-intervention-change (Δ) of IGF-1 levels was significantly different among five-groups (Kruskal Wallis test; $p = 0.001$). Meanwhile, the Δ-IGF-1-levels of all-intervention-malnutrition-group were different compared to malnutrition-control-K2-group (X1, X2, and X3 had the same *p*-value; Mann-Whitney U-test, $p = 0.004$). But, in suppressing of IGF-1 between all-malnutrition-treated-group, statistical analysis showed that the Δ IGF-1 in X1-group was not different from X2 ($p = 0.055$) and X3-group ($p = 0.054$). This finding indicated that the ability of PFPC in dose 13.26 $mg.g^{-1}$ BW/d was not different from the PFPC in dose 19.89 $mg.g^{-1}$ BW/d and the given of casein supplement.

Table 2 Proximate analysis of PFPC.

Nutrient Content	%

Note: [a]*p*-values were obtained by Wilcoxon test (for BW and IGF-1), paired t test (for IGFBP-3); between pre-post intervention. [b]*p*-values were obtained by Kruskal Wallis test (for BW and IGF-1), One-way ANOVA test (for IGFBP-3); pre-intervention among groups. [c]post-intervention among groups. [d] Δ among groups.

The IGFBP-3 levels experienced a decrease after the performance of the intervention. The levels were significantly different (X1, X2 and X3 had the same *p*-value; $p = 0.001$; **Table 4**), while K2-group experienced a significant increase of IGFBP-3 level ($p = 0.034$). The pre-post intervention-change (Δ) of the IGFBP-3 level was significantly different among the five groups (One-way ANOVA test; $p = 0.001$). The Δ-IGFBP-3-levels of all-intervention-malnutrition-group were different compared to malnutrition-control-K2-group (X1, X2, and X3 had the same p-value; Post Hoc Bonferroni test, $p = 0.001$).

The Spearman test on all data from all rats at the end of the study showed there was a very strong correlation that was found between the variables (IGF-1 and IGFBP-3). A very strong positive correlation was observed between IGF-1 and IGFBP-3 (r=0.861). This correlation was less weak before PFPC intervention began (data not shown).

Malnutrition can be ended with a linear growth disruption. Restriction of protein intake during the lactation period affects the disruption of long term linear growth **(Cherala, 2006; Zambrano, 2005)**. We examined that the decreasing value of IGF-1 levels in the malnutrition-treatment-group after the intervention was caused by an inflammatory response. Systemic inflammation which occurs due to protein restriction during early life has not been repaired by early re-feeding.

Inflammation is a possible indication in the intervention group which is shown through the decreasing serum IGF-1 levels in neonatal rats. Indications of inflammation are thought to occur due to the placement of each group of neonate rats in one cage. The same result was also found in other previous studies showing the effect of interleukin 6 (IL-6) inflammatory biomarkers on IGF-1 descent. The decrease of IGF-1 is related to the mitogenic function of IGF-1 thereby inducing a decrease of its concentration in cell proliferation **(Chen, 2009; Lann and LeRoith, 2008; Jenkins, 2000)**.

These indications of inflammation due to chronic malnutrition are also associated with GH resistance response, which modulates gluconeogenesis **(Hawkes and Grimberg, 2015; Fazeli and Klibanski, 2014; Difedele, 2005; Turner, 1976)**. This condition can be attributed to the increase of GH and growth hormone receptor (GHr) which modulates glucose homeostasis as indicated by an increase in body weight. However, in the mechanism of the endocrine system, the GH resistance condition causes a decrease in IGF-1 and IGFBP-3 concentrations **(Martins, 2017; Liu, 2004; Hefferman, 2001)**.

Other previous studies have assessed that serum IGF-1 levels can be assessed at four weeks of intervention. Meanwhile, this study assessed the IGF-1 in two weeks' intervention. This is also supported by the insignificant assessment of protein synthesis which ended with a disruption of metabolism especially the disruption of IGF-1 synthesis **(Caregaro, 2001)**. The disruption of synthesis of the pituitary-GH-IGF1 axis is a major factor in the decrease of serum IGF-1 levels after re-feeding. The chronic malnutrition intake which has experienced by the subject suppresses the key components of IGF-1 and indicates impaired its production in the liver **(Zamboni, 1996)**. This condition will provide IGF-1 negative feedback to the hypothalamus which results in an in increasing GH release. The decrease of IGF-1 in this study can also be related to the physiological response of IGF-1 which uses amino acids together with its pro-insulin structure, despite the subjects has been re-feed with high protein intake **(Bonefeld and Moller, 2011)**. The other inhibitor that can be related to IGF-1 activity is adjusted with the IGFBP sub-type on an individual subject and the protease of the binding protein which is modulated by the level of their affinity **(Kamycheva, 2012; Ferry, 1999)**.

Decreasing serum IGFBP-3 levels can cause disrupt IGF-1 modulation. IGFBP-3 is the principal binding protein that modulates the action of IGF-1 as a growth factor. Disturbances that are caused by protein restriction and are not properly repaired realized that the pituitary-GH-IGF axis binding protein has a reciprocal effect **(Bang, 1994)**. However, in this study, we found a negative relationship where there was a decrease in IGFBP-3 levels after the intervention. Previous studies that showed a decrease in IGFBP-3 proteolysis activity can make the binding protein of IGF-1 as a trigger of low levels of IGF-1 targets. The potential of IGFBP-3 in proteolysis depends on its post-translational modification which has a great impact on IGF-1 **(Rosen and Yakar, 2020)**. Interestingly, the proteolysis mechanism of IGFBP-3 can occur with unknown protein in the extracellular matrix besides IGF-1. This condition exactly affects the decreasing IGF-1 level **(Vorwerk, 1998; Bereket, 1995; Bang, 1994)**.

Proteolysis is the most possible mechanism in this study which has a function to reduce serum IGFBP-3 levels. Both levels of IGF-1 and IGFBP-3 which were decreased show that the mechanism most likely caused by proteolysis **(Dauncey, 1993)**. Interventions in malnutrition children by re-feeding show a decrease in proteolytic activity, but restoring energy intake in the subjects **(Zamboni, 1996)**. Decreasing the potency of proteolysis contributes to reducing the ability of IGFBP-3 to bind with IGF-1. The other reason is other competitors that can bind with IGF-1, such as IGF-1 receptors. These statements are related to IGFBP-3 which regulates IGF-1 bioactivity through non-specific proteases **(Pucilowska, 1993; Davenport, 1992)**. The action capability of this specific IGFBP-3 can even limit the bioavailability of free IGF-1 which is further regulated in the extracellular space if it is proteolysis must be done **(Rosen and Yakar, 2020)**. This research proved that IGF-1 can be modulated by one of its main binding proteins (IGFBP-3), which is supported by acid-labile sub-unit to make a binary complex.

Interestingly, other growth factors besides IGF-1 and IGFPB-3 might be involved and affected the increasing body weight of neonate rats. These growth factors show the effect of suppression on IGF-1 and IGFBP-3 but support the mechanism of other growth biomarkers which is associated with the increasing body weight **(Bereket, 1995; Bang, 1994)**. Excess of GH secretion, as the impact of its resistance condition, is stimulated by excess exactly of GHr secretion to support GH function. However, this condition reflects complete negative feedback as the result of decreasing in IGF-1 levels **(Liu, 2004; Zamboni, 1996)**. The effect of increased GHr showed in previous studies modulates the increase in somatic growth **(Liu, 2004; Hefferman, 2001)**. This hypothesis supports the results of this study. Deleting of GHr gene will affect decreasing body size **(Liu, 2004)**. In this study, malnutrition neonate rats which were re-feed with supplementation of PFPC showed a significant growth acceleration compared to the healthy control.

Malnutrition condition, which was caused by cachexia symptoms and inflicted from malignancy response, also observed a similar indication. It was shown significantly by a specific combination of high-protein intake intervention which contained leucine **(Van Norren, 2009)**. Increasing body weight is a positive effect from consuming high-protein intake which modulates the anabolism process in many cells and tissues is targeted by protein synthesis and the contribution of amino acids **(Rogers and Harper, 1965)**.

The findings in protein intervention also improve clinical symptoms due to protein restriction. Other growth factors can affect the increase in body weight of malnutrition with re-feeding **(Soliman, 1986)**. Increasing body weight can be driven by the anabolic response that is controlled by GH. The increase of GH secretion provides an alternative source of metabolism through fat mobilization and hepatic glucose production. This response has been reported in subjects without insulin resistance in basal conditions **(Smith, 1981)**.

The increase of body weight which is indicated by increased GH is also associated with carbohydrate and fat homeostasis **(Liu, 2004)**. Other studies conducted in children with marasmic and kwashiorkor showed lower serum IGF-1 levels in the marasmic group. This shows that energy intake takes the main place to process rather than the food protein process **(Underwood, 1994; Dauncey, 1990)**. Another study also observed re-feeding carried out by returning the intake of rats to the standard diet could allow that the high intake of protein would not necessarily be effectively metabolized.

Furthermore, amino acid, especially lysine and leucine which are high in PFPC products could also change weight gain. We found in this study that the PFPC contained protein amounting 80% (**Table 2**) and the PFPC in a dose of 13.26 $mg.g^{-1}$ BW/d did not have different effects from casein supplement in the same dose. These findings indicate that the ability of PFPC is no different from casein, which has purified high protein. It is expected that the PFPC has certain amino acids for gaining weight. Other studies also recognize that oral leucine supplementation stimulates muscle protein synthesis and is not dependent on insulin **(Dardevet, 2002; Anthony, 2000)**. Once again, those findings supported this study that the mechanism of decreasing IGF-1 does not affect the increase of body weight because of its function associated with amino acids

and pro-insulin **(Bonefeld and Moller, 2011; Rinderknecht and Humbel, 1978)**. Although the protein concentration in this study product was high, even exceeding the concentration of similar products from the sThe isoleucine contin PFPC is higher than white fish protein hydrolysate **(Windsor and Barlow, 1981)**. But, we did not further examine the amino acid content and their digestibility through in vitro studies.

The high protein concentration also supports the lipid and carbohydrate pool of neonate rats. Increased protein intake can affect the amount of lipids and carbohydrates stored in adipose tissue, especially white adipose tissue (WAT) **(Zhang, 2019)**. As the largest cholesterol provider, WAT can be involved in cholesterol metabolism where cholesterol can increase to high-density lipoprotein (HDL) **(Zhang, 2010)**. Besides WAT is also involved in the endocrine system which secretes protein factors, such as adipokines associated with energy regulation and inflammatory homeostasis **(Rafols, 2014; Khovidhunkit, 2004)**. From the results of this study and existing theories, they indicate that protein intake and high-fat content of PFPC products affect the function of the adiposity system and lipoprotein. This mechanism puts an end to weight gain even though there is an indication of inflammation that is shown from the decrease in IGF-1 and IGFBP-3 levels.

Limitations of this study we do not examine other growth indicators on this intervention except the body weight. Discussing another growth factor, we also do not examine another related growth factor that can relate to and support the hypothesis of this study. Inflammation is not measured in this study, as expected to exist in chronic malnutrition neonate rats. The proteolytic, which can be the most possible involved mechanism in this study is also not concerned. We did not concern about the digestible amino acid of PFPC which can be compared to other products in case of body weight gain of malnutrition rats. Other biomarkers that relate to lipid metabolism also not a concern.

CONCLUSION

The administration of patin fish protein concentrate with various doses tested, significantly increased the body weight, but decreased IGF-1 and IGFBP-3 serum level of malnutrition-induced neonatal rats. The administration of patin fish protein concentrate with dose 13,26 $mg.g^{-1}$ body weight per day is the most effective dose in increasing body weight of malnutrition-induced neonatal rats.

PHYSIOLOGICAL STATE OF PLANTS AND QUALITY OF PLUM FRUITS GRAFTED ON THE ROOTSTOCKS OF VARIOUS STRENGTH OF GROWTH DEPENDING ON THE PLANT NUTRITION MODE

Valentina Popova, Natalya Sergeeva, Olesya Yaroshenko, Anna Kuznetsova

ABSTRACT

The influence of the nutrition mode on the physiological state, productivity, and quality of the plum harvest of the Stanley variety on the rootstocks of various strengths of growth was investigated. The fertilizer system included the intra-soil application of the complex organic-mineral fertilizer based on peat and non-root dressings combined with the "Novosil" phytoregulator. The nutrition mode of plum plants was studied by the method of gross content diagnostics of elements in leaves and fruits. The significant increase of nitrogen and phosphorus content, number of functional pigments, free amino acids, and protein synthesis, especially in plants on the rootstock Best, was established during the period of the intensive shoot and ovary growth. In the early summer, the increase of calcium content and decrease of secondary metabolite one was found against the background of a decline of growth activity in plum leaves on the dwarf and medium rootstocks. The statistically reliable positive correlation between nitrogen, potassium, calcium and their content in plum fruits on the rootstock VVA 1 ($r = 0.68$, $r = 0.74$, $r = 0.52$) and rootstock Best ($r = 0.75$, $r = 0.84$, $r = 0.61$) was identified against the background of the application of fertilizers during the period of stress influence of abiotic factors in July. The green pigment content was also increased. The decline of protein content in leaves in the trees on the rootstock Best and rootstock PK SK 1 was minimal. At that time maximum losses of shared water were in plants on the rootstock cherry plum seedlings and minimum ones were on the rootstock PK SK 1. In early August the gross content of nitrogen, potassium, and calcium in the leaves of shoots increased with the application of fertilizers. In early September the excess of the sum of amino acids in plum leaves was 26,6-30,8% while the one in plum fruits was 12.5 and 23.5%; 24.2 and 11.5%; 17.3 and 19.6% on the rootstock VVA 1, rootstock Best, rootstock PK SK 1 respectively. The nutrition mode optimization promoted increasing of plant productivity on the rootstock Best and fruit weight on the rootstock VVA 1, rootstock Best, and rootstock PK SK 1.

Keywords: *Prunus domestica* plum; rootstocks; plant nutrition mode; physiological state; productivity

INTRODUCTION

Growing mainly on the rootstock cherry plum seedlings, *Prunus domestica* plum is widespread in industrial plantings of stonecrops of Krasnodar territory located in the west part of Caucasus and Ciscaucasia. The popularity of this culture is related to the precocity and the stable yield **(Eremin et al, 2000; Eremin, Prichko, Kekhaev, 2007; Eremin et al, 2010; Eremin and Brizhinov, 2011)**. The specific humid climate conditions are necessary for the successful growth and development of plum plants because the water holding capacity of tree bark and wood is unsatisfactory **(Miletić et al, 2007)**. The coefficient of water consumption to make a unit of tree mass dry matter and harvest is high, therefore, sufficient air humidity is necessary during the period of flowering and growth of shoots **(Gnezdilova and Doroshenko, 1984; Eremin, 2000; Bogdanov, 2003)**. The area is characterized by the diversity of soil and climate conditions: from temperate continental to subtropical one. There are also almost all main soils of the temperate zone that are suitable for intensive cultivation of the fruit growing industry there. Chernozem, forest, and meadow soils are the most common – Anthrosols **(IUSS Working Group WRB. 2014)**. The species composition of chernozems varies significantly changing from North to South. The main differences are in the organic matter content and the power of the humus layer, mechanical composition, soil compaction, presence of signs of salinity. Various degrees of erosion processes, the waterlogging in winter, and the formatting of verkhovodka (superficial water) are typical for foothills soils (grocerie agroseme texture-differentiated and agronomy structural-metamorphic) **(Shishov L. L et al, 2004)**. Alluvial agrohumus hydrometamorphic soils with small power of humus layer and a wide range of nutrition

elements stock that are available for plants are prevalent in the river valleys **(Simakin, 1969; Negovelov et al, 1985; Eisert, Achkanov, Durgaryan, 1987; Lipchiu and Gagai 2014)**. At the same time, the main limiting factors which interfere with the realization of the productive potential of plum are the precipitation deficit in spring and summer against the background of intensive solar insolation and the physical and chemical properties of soil. The search of special technological methods and the selection of variety-rootstocks combinations and planting structures with compact bark that keep the plum plant resistance and the formatting of economically valuable signs of fruit quality are relevant due to the regional features of soil and climate conditions **(Sergeeva, Kuznetsova, Nenko, 2015; Sergeeva, Kuznetsova, Kovalenko, 2016)**.

Early studies have identified the nutrition mode features and the yield of *Prunus domestica* plum of varieties zoned in the region on the rootstock cherry plum seedlings. The field experiments were systematic and long-lasting which allowed us to draw a conclusion about the positive effect of regular application of mineral fertilizers on the reproductive function of the crop **(Sergeeva and Yatsenko, 1999).** Further research in this area (2014 – 2017) is linked with the intensification of production, the problem of rational selection varieties and rootstocks of *Prunus domestica* plum – components that help stabilize productivity of trees in various soil and climate area conditions for new industrial plantings **(Kuznetsova et al, 2011; Kuznetsova and Romanenko, 2014)**.

Scientific hypothesis

After analysis of dynamics of *Prunus domestica* plum plant productivity in the plantings of various structures and level of agricultural equipment in chernozem leached of the central zone of Krasnodar territory the working hypothesis about the regulation function of rootstock depending on the mineral nutrition mode of the crop that contributes to the formatting of physiological resistance to the negative impact of abiotic factors repeated in summer annually was ventured. That served as the basis for conducting experimental research in production conditions of influence of the systemic application of fertilizers on the functional state, productivity, and quality of plum fruits of the Stanley variety that is quite demanding to the soil and climate conditions on the rootstocks of various strength of growth.

MATERIAL AND METHODOLOGY

The object of research 2014 – 2017 is Prunus domestica plum plants of Stanley variety on the clonal rootstocks of various strength of growth: VVA 1, Best, PK SK 1, Pixy and cherry plum seedlings **(Figure 1)**.

Figure 1 Experienced *Prunus domestica* plum Stanley variety on the rootstocks.
Note: A – *VVA 1*, cross Microcerarus tomentosa (*Thunb) Erem. et Yushev*) x (*P.cerasifera Ehrh.*); B – *Best*, *Prunus pumila L. x Prunus cerasifera Enrh*; C – *PK SK 1*, cross of hybridization *Microcerasus pumila L. x Prunus cerasifera Ehrh*; F – *Pixy*, nursling *Prunus domestica subsp. Insititia (L.)*; G –*cherry plum seedlings (Prunus cerasifera Ehrh)*.

Rootstock characteristics: *VVA 1* is the frost-resistant, but unstable to drought rootstock of domestic selection. Plum trees come into the fruiting quickly and have a crown 50% less than ones on cherry plum seedlings.

Best is the winter-hardy resistant to high temperatures medium rootstock. It has a positive influence on the precocity and the productivity of grafted trees which have an average drought tolerance.

PK SK 1 is the frost-resistant and drought-tolerant, resistant to bacterial cancer medium rootstock of domestic selection that has high productivity of the mother plants and plum trees on it.

Pixy – the easily propagated semi-dwarf rootstock of English selection that has a positive influence on the productivity and the plum tree crown compactness and gives a lot of growth in the garden. Besides, its tolerance to drought and frost-resistance is mediocre. The disadvantages of this rootstock as all seed ones are the late entry of plum trees to fruiting, the low percentage of rootstock yield from winter with low negative temperatures, and the difficulty of use in intensive gardening.

Cherry plum seedlings – the high rootstock that is high adaptative to the wide range of stress factors affecting the South of Russia. Its compatibility with all known varieties of plum is the cause of prolonged use in the North Caucasus.

The material for the study was obtained in industrial plantings of *Prunus domestica* plum of the close corporation "Plodovod" (Krasnodar) planted in 2006. Geographically, the experimental site is located in the central plains of the Krasnodar Territory. Height above sea level varies from 19 to 32 m. The climate is temperate-continental. The layout of plants is 5 x 2 m. The trees are cultivated without any support. The system for crown formatting of plum trees is spindle-shaped ensuring the greatest productivity of the variety in thickened plantings, according to several authors **(Rakićević et al, 2007)**. The forming complex pruning was carried out in the late spring on the formed ovary of fruits. Performing corrective cropping in July allowed plants to save a full ovary and realize the generative function as much as possible. The equilibrium balanced crown with fruit buds that were formed in the last summer-early autumn and had a high winter and frost resistance was created by the subsequent removal of growth points from the vegetative shoots, the thinning, and the lightening of thickened parts. The annual spring inspection of the freezing of flower buds in trees of various growth strength showed no damage from the return of cold weather and the killing frosts after the beginning of flowering. The blooming score was 4,8-5,0 in all versions of the experiment annually.

The soil of the experimental plot is the agrosem clay-illuvial low-humus heavy-duty **(Shishov L. L et al, 2004)**. The plot is aligned according to the terrain and the value of agrochemical indicators of the soil. The agrochemical study of its soil and plants was conducted using common methods and GOST standards of chemical diagnostics **(GOST standards 26204-91; 26213-91; 26951-86; Voskresenskaya, 2006; Yaroshenko and Sergeeva, 2020)**. The complex organic-mineral chlorine-free fertilizer based on peat (Organic Mineral Fertilizer from Russian abbreviation: ОМУ) was applied at a dose of 5.0 t. ha^{-1} in the garden soil in the middles at the distance 1 – 1.2 m from the trunk of the tree in optimal agrotechnical times. The effect of Organic Mineral Fertilizer was prolonged due to the content of organic-mineral complexes with humic compounds allowing to fix nitrogen and potassium in the exchange form and decrease their mobility in the soil. The phosphorus in fertilizer was presented in a form digested easily by plants. The fertilizer was granular with a mass fraction of nitrogen (in ammonium form) of 7.0%, total phosphorus (P_2O_5) of 7.0%, potassium (K_2O) of 8.2%, humic compounds of 2.5%. The non-root dressings of 0,5% solutions of special complex mineral fertilizers were applied in combination with biologically active agents thrice during the vegetative period. The fertilizers of N18P18K18Mg1S1.5 and N12P12K35Mg2S0.7 brands were used. They included Fe, Cu, Zn, Mn, B, Mo trace elements in chelated form. The non-root cultivation with fertilizer water solutions was conducted by means of the knapsack sprayer. The version with no Organic Mineral Fertilizer application and trees spraying with no addition of any fertilizers was controlled. There were 6 accounting trees in the control and experimental version. The tests were performed in four replications. The total area of the research site – 2 ga.

Laboratory tests of plants' physiological state (determining amino acids) were conducted on three analytical surfaces according to the recommended methods **(Nenko et al, 2015)**. The chlorophyll (a+b) content in the leaves was determined in dynamics using the spectral method on the spectrophotometer Unico 2800 ("United Products & Instruments", USA). The water content in leaves was analyzed by the weight method according to the M.D. Kushnirenko technique **(Kushnirenko, 1986)**. The elemental composition plants were conducted using common methods **(Voskresenskaya, 2006)**.

The metrological observations allowed us to evaluate the degree of the negative impact of abiotic factors in the summer and establish the beginning of the stressful situation for plum plants during the study.

Agrobiology accounting was carried out according to the recommended methods **(Sedov and Ogoltsova, 1999)**.

Statistical analysis

The statistical analysis was performed in accordance with the recommended method **(Volkov, 2005)**. Calculations were performed using a software package Microsoft Office 2010 ("Microsoft, Inc.", USA). The *p*-value was used ($p < 0.05$) for checking the null hypothesis to quantify the idea of statistical significance.

RESULTS AND DISCUSSION

The agrochemical indicators of the plot soil were explored before laying the experiment. The humus content of the topsoil varied between 3.05 – 3.17% (LSD ($p \leq 0.05$) = 0.14), the mobile phosphorus one – between 243 – 252 $mg.kg^{-1}$ (LSD ($p \leq 0.05$) = 7.70), the exchangeable potassium content – between 217 – 221 mg. kg^{-1} (LSD ($p \leq 005$) = 3.42). The content of the nitrate form of nitrogen in the soil layer 0-60 sm did not exceed 0.7 – 1.2 mg. kg^{-1} The chemical analysis showed a significant increase of the mineral elements forms available for plants one year after the application of mineral fertilizers. The mobile phosphorous content was 286 – 308 mg. kg^{-1}, the exchangeable potassium one was 238 – 245 mg. kg^{-1} in the mineral fertilizer application zone.

The nitrate-nitrogen content in the soil layer 0 – 40 cm increased 3 – 5 times in spring and 97 – 155% in October compared to the control version (without Organic Mineral Fertilizer application). Against that background the first non-root dressing of trees with water solutions of special fertilizers was conducted in the ratio N:Ph:P = 1:1:1. The treatment was repeated 4 – 5 weeks after flowering (the fruit size is up to 3 cm in diameter) during the stone formatting. The third dressing with water solutions of special fertilizers was conducted in the ratio N:Ph:P = 1:1:2 – 2.5 in summer (in the period of differentiation of buds). The phytoregulator "Novosil" was added in the nutrient solution composition in the ratio at the concentration of 0.02% at each treatment of plants. The changes in the seasonal nutrition mode were checked for the nutrients content in the leaves of growth shoots **(Table 1)**.

Annual systematic application of fertilizers by non-root method during the period of the intensive shoot and ovary growth (in spring) promoted increasing of the total content of nutrients in plum leaves on the rootstocks of various strength of growth. The resulting effect was also noted by several authors who have studied the influence of fertilizers on the plum nutrition mode (Miletić, et al, 2003; Fatma et al, 2018).

The significant increase was detected mainly in the nitrogen and potassium content. However, the increase in potassium content was not always confirmed statistically. Besides, the reliable increase of potassium and magnesium content was noted in the plum on the *VVA 1* dwarf rootstock during that period.

The changes in the plum nutrition mode promoted activation of physiological processes. This corresponds to the data from literature sources reporting about the positive impact of fertilizers on the stone fruit crops **(Wan Yi-zhen, Sheng Bo-biao, Du Hui-fang, 2003; Miletic et al, 2003; Cuque et al, 2011; Milosevic and Milocevic, 2012; Doroshenko, Riazanova, Maksimtsov, 2015; Fatma et al, 2018)**. The increase of several functional pigments (Chla+Chlb) in the plum leaves on rootstocks of various strength of growth was identified by the spectral analysis method in the application of fertilizers. The most significant increase of a number of the main photosynthetic pigment (Chla), an energy donor, was discovered in the leaves of plum on the rootstock *Best.* The high content of the chlorophyll b (Chlb), the activator of the biosynthetic processes, was occurred in the same version annually. The total chlorophyll content (Chla+Chlb) in the leaves exceeded stably the value in the control version by 20.1-25.4% in trees on the rootstock *PK SK 1, rootstock Pixy,* and rootstock *cherry plum seedlings*. At the same time, the lamina area of trees on those rootstocks exceeded the values in the control version by 12.7%, 7.4, and 9.1% respectively. The tendency to increase the nutrient content in the plum leaves against the background of the application of fertilizers revealed mainly in the years with the sufficient water availability on the *VVA 1* dwarf rootstock that had the

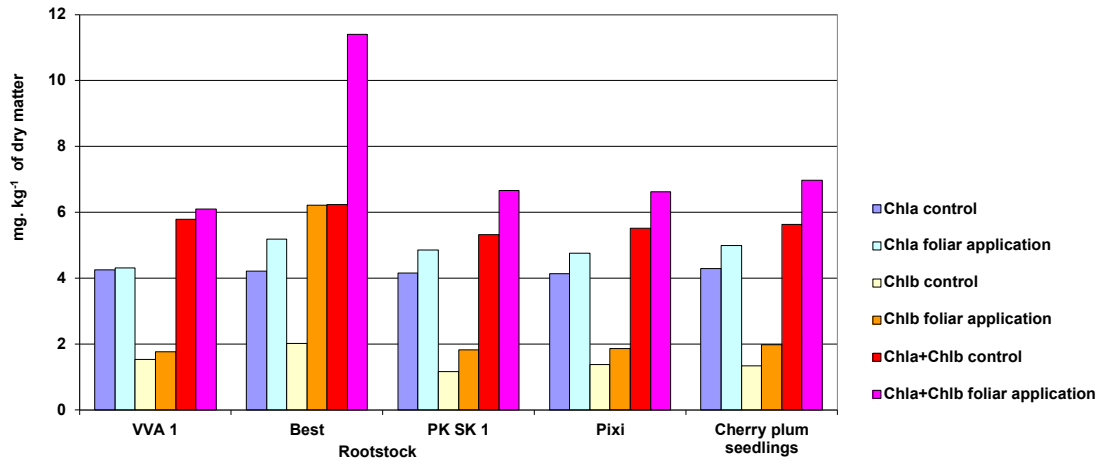

Figure 2 The content of functional pigment in plum leaves in relation to the fertilizers and variety-rootstock. combinations.

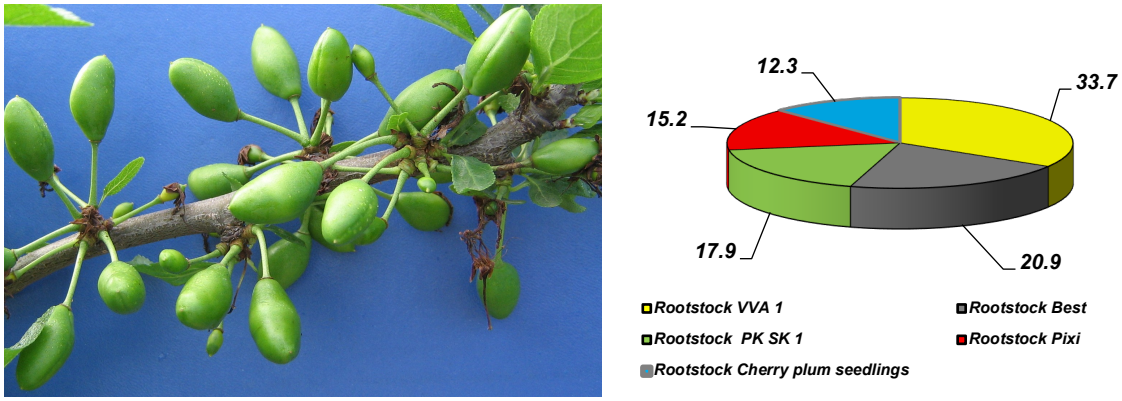

Figure 3 The excess of the number of preserved ovaries in plum plants against the background of application of fertilizers in relation to the control version (with no fertilizers) (the third decade of June),% (2014 – 2017).

surface occurrence of the main part of the root system **(Figure 2)**.

The increase of the intensity of metabolic processes that was probably associated with the activity of photosynthesis and synthetic activity of the root system was confirmed by the analysis of the free amino acid content in the leaves using the method of capillary electrophoresis.

The tendency of the predominant increase of arginine in shoot leaves was detected annually during the period of the activity of growth processes in spring when the maximum temperature was up to 28 – 32 ºC and the precipitation fell periodically. The changes in the nutrition mode promoted increasing of the arginine amount in leaves by 42.3% (*Rootstock Best*), 37.4% (*Rootstock PK SK 1*), 29.6% (*Rootstock Pixi*), 12.7% (*Rootstock VVA 1*), and 27.9% (*Rootstock cherry plum seedlings*) at that stage of seasonal plant development. More active protein synthesis was occurred in leaves on the rootstock *Best* in spring and summer annually. Its content was higher by 8-10% compared to the one in the control version (with no fertilizers). Further, the recorded annual increase in air temperature to maximum values of 30 – 35 ºC and the prolonged lack of precipitation promoted increasing of the amino acid Proline content in the leaves. Its content in leaves was 46.4% (*Rootstock PK SK 1*), 39.8% *(Rootstock Pixi*), 32.5% (*Rootstock VVA 1*), 26.2% (*Rootstock cherry plum seedlings*), and more than 80% (*Rootstock Best*) higher in the version with the application of fertilizers. The identified tendency was confirmed by our researches on other fruit crops **(Popova, Yaroshenko, Sergeeva, 2018)**.

The nutrition mode of culture changed by the end of the second decade of June against the background of the growth activity decrease of trees. The total nitrogen and phosphorous content in all versions of experiment was 2.22 – 2.24 and 0.163 – 0.168% respectively. The potassium content went up to 2.12% (*Rootstock VVA 1*) and 2.61 – 2.68% (*Rootstock Best, Rootstock PK SK1, Rootstock Pixi, Rootstock cherry plum seedlings*). Calcium in the leaves of dwarf and medium trees went up to 1.59% (*Rootstock VVA 1*) and 1.70% respectively. There were no changes in the plum on the rootstock *cherry plum seedlings*. The total magnesium content changed insignificantly. The secondary metabolite content in the plum shoot leaves decreased on the rootstocks of various strength of growth. That was probably caused by an outflow of assimilates into the growing fruits. The total number of amino acids was no more than 60.2 -89.6% of the previously established content in all versions of the experiment. In June the accountings for the degree of ovary reduction on the accounting trees showed the advantage of the version with the application of fertilizers: a number of the fully preserved ovary was higher by 12.3 – 33.7% depending on the rootstock **(Figure 3)**.

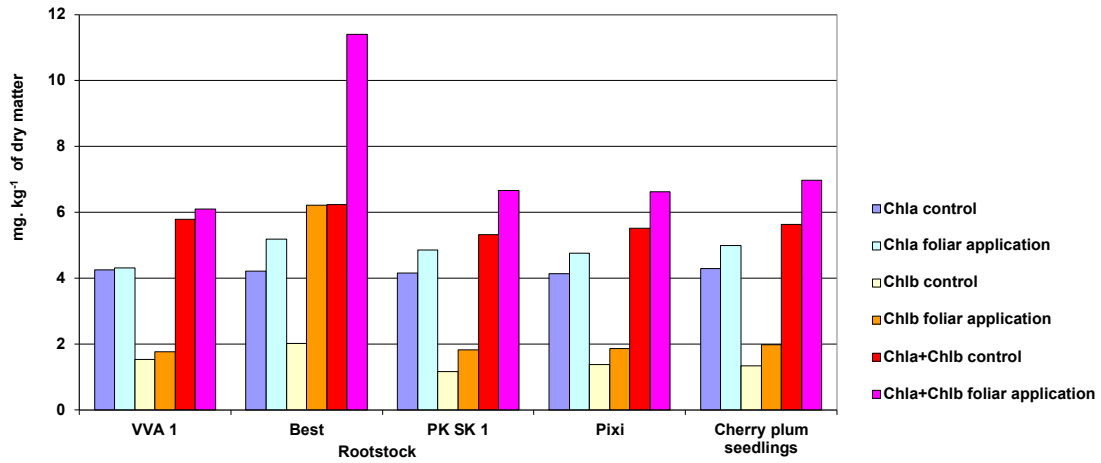

Figure 4 The most common character deformity of plum ovary development on the example of the Stanley variety on the rootstock *Best* (2014 – 2017).

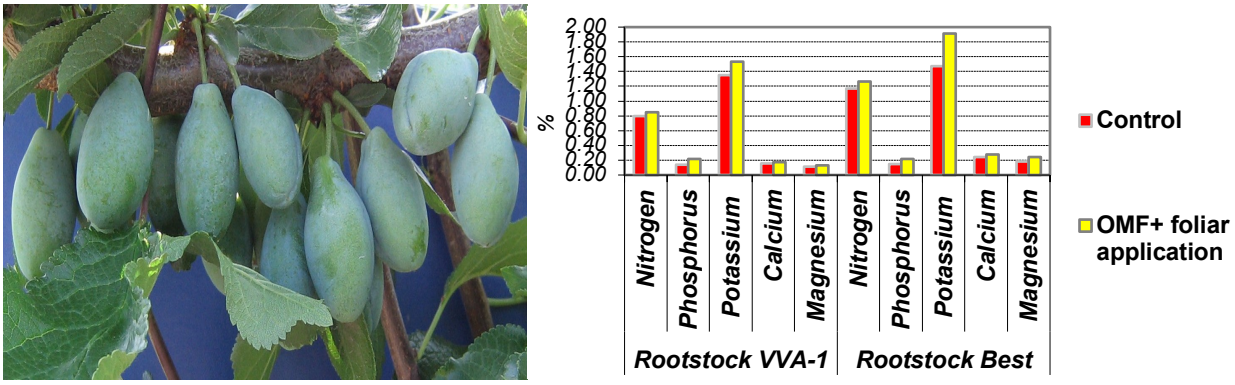

Figure 5 The chemical content of growing fruits in July (2014 – 2017).

The visual analysis and the calculation of the ovary in the control version allowed us to conclude that without the application of fertilizers, the percentage of deformed fruits, that is associated, according to **Semenov (2007)**, with the negative abiotic factors impact, is higher significantly and ranges from 3.3 to 8.7% depending on the variety-rootstock combination. The most common characteristics of ovary deformity are represented in **Figure 4**.

In July the stage of development of generative buds of plum of Stanley variety in the sinuses of side leaves of shoots was diagnosed by the method of microscopy. In the same period, the analysis of the chemical content of growing fruits was conducted with leaf diagnostics. The most significant difference between the versions was identified on the rootstock *VVA*1 and rootstock *Best* **(Figure 5)**. The closest correlation between the nitrogen, potassium, and calcium content in leaves and fruits was determined. The correlation coefficient was 0.68, 0.74, 0.52 (*Rootstock VVA 1*) and 0.75, 0.84, 0.61 (*Rootstock Best*) respectively.

The correlation analysis showed a less close relationship that did not exceed the values of 0.55 – 0.64. Several scientists **(Plich, Wójcik, 2002; Fatma et al, 2018)** pointed to changes in the quality of plum fruits and the increase of calcium content in them against the background of the application of non-root dressings.

The summer and early autumn experimental studies were accompanied by the annual accounting and the analysis of metadata because many authors pointed to the strong influence of the water stress factor on the intensity of plum growth processes **(Li Wen-hua et al, 2003)**. It is necessary to note that the longest stress situations related to hyperthermia, the lack of precipitation, and the decrease of air humidity up to 12 – 14% was observed from the second decade of July to mid-September. The data of the functional state of Prunus domestica plum plants on the rootstocks of various strength of growth was the most informative and allowing to evaluate the effectiveness of fertilizers under these conditions.

Conducted research on green pigment content in leaves identified the seasonal decrease of plant photosynthetic activity. At the same time, despite the negative effect of physical factors the level of green pigment content in plum shoot leaves was higher significantly against the background of the application of fertilizers than one in the control version. It is possibly related to the action of the phytoregulator used as a part of the nutrient solution for non-root dressings and increased the plant protective features. That fact was also pointed by in their study **(Upadysheva, Upadyshev, 2012) (Table 2)**. The difference between the experimental versions was also identified by protein content in plum leaves. The seasonal decrease of protein in shoot leaves an average of 20-24% compared to the spring and the summer period was observed in all versions of the experiment. However, when the fertilizers were applied the decrease of protein amount in leaves of plum on the rootstock *Best* and rootstock *PK SK 1* was minimal and amounted to 25.3 and 23.2 mg. kg^{-1} of dry matter respectively.

That fact characterized higher intensity of reparation processes in trees on those rootstocks.

Under the conditions of the tensity of hydrothermal factors in summer, the water content in leaves was determined depending on the application of fertilizers and the variety-rootstock combinations. Plants on the rootstock cherry plum seedlings had the most significant losses of shared water that was up to 9.3% (Organic Mineral Fertilizer + non-root dressings) and 12.7% (control, with no fertilizers). The minimal water losses were identified in leaves in plum on the rootstock *PK SK 1* that was 5.7 – 8.4% respectively.

The continuation of diagnostic studies of the functional state of the plum plant was accompanied by morphoanatomical observations of the generative buds in the first decade of August. The beginning of the differentiation of the rudimental sepals was detected in the majority of conducted buds **(Figure 6)**.

That stage of plum plant development was characterized by the next change of nutrition mode. The gross content of nitrogen, potassium, and calcium increased in shoot leaves. At the same time, the differences between the versions were significant **(Table 3)**.

According to the morphoanatomical research data, the transition to formatting of petals and stamens began in the majority of rudimental flowers of the plum plant by early September. The periodical precipitation promoted growth activity mainly in trees on the medium rootstocks. The gross content of nitrogen, phosphorous, and magnesium increased up to 18.6%, 7.7, and 29.5% respectively regardless of the version of the experiment **(Figure 7)**.

The most significant increase of amino acid content in leaves was determined in plum plants on the rootstock *Best* in the version with the application of fertilizers against that background. The excess of the sum of amino acids was 26.6 – 30.8% in some years. The correlation coefficient between the nitrogen content in leaves and the total amount of free amino acids was r = 0.56 (Rootstock *VVA 1*), r = 0.67 – 0.71 (Rootstock *PK SK 1*, Rootstock *cherry plum seedlings*), r = 0.81 – 0.83 (Rootstock *Best*).

The specified period was also the beginning of fruit ripening of plum of Stanley variety **(Figure 8),** which had an immediate influence on the post-harvest storage of fruits, according to the authors **(Manganaris, Vicente, Crisosto, 2008)**.

The significant impact of the fertilizers applying in the experiment on the content of gross forms of potassium and calcium in fruits on the rootstock *VVA 1*, rootstock *Best*, rootstock *PK SK 1* those content exceeded the amount of the element in fruits of the control version by 12.5 and 23.5%; 24.2 and 11.5%; 17.3 and 19.6% respectively.

The dynamics of plum productivity on the rootstocks of various strength of growth against the background of the application of fertilizers were analyzed depending on the protection area of tree crowns **(Table 4)**. The dimensions of plum tree crowns formed by a spindle-shaped system matched the strength of the growth of the rootstocks. The annual measurement of the protection area of tree crowns in 2014 – 2018 allowed us to establish the highest values in trees on the rootstock *cherry plum seedlings* that were amounted to 3.69 – 3.99 m^2. The smallest protection area of tree crowns was noted in the trees on the rootstock *VVA 1*

		Rootstock cherry plum seedlings		
Control	257	248	261	254
OMF+ foliar application	266	274	279	283
LSD ($p \leq 0.05$)	22.81	12.04	15.63	7.28

that was 2.02 – 2.52 m^2. The average indicators were determined on the rootstock *Best*, rootstock *PK SK 1*, and rootstock *Pixi* that are 3.07-3.13; 3.53-3.75 and 3.36-3.64 m^2 respectively. The highest stable indicators of plum productivity were identified on the dwarf rootstock *VVA 1* that matched the data of **(Provorchenko et al, 2015)**.

The applied fertilizer system promoted significant excess of reproductive function of plants. Meanwhile, the slopes of trees on the rootstock *VVA 1* caused by harvest load were observed. That indicated the need for installation of supports by using the rootstock *VVA 1*. At the same time, that crown design and the dimensions of the trees allowed us to decrease significantly the plant nutrition area without a decline of the light regime that is also pointed by **Upadysheva, 2015** in her research. The productivity of plum on the medium rootstocks was less significant, but the advantage of the version with the application of fertilizers was saved. The most significant and stable indicators of growth of productivity were received in the versions on the rootstock *Best* (*LSD* ($p \leq 0.05$) – 8.22 (2014); 5.44 (2015); 16.98 (2016); 7.52 (2017)) against the background of the application of fertilizers in those soil and climate conditions. At the same time, it is necessary to note that the values of indicators in the limits of the version were changeable significantly in trees on the rootstock *PK SK 1*, rootstock *Pixi* and rootstock *cherry plum seedlings.*

The classification of plum fruits by quality was conducted according to GOST standard 21920-76 in all versions of the experiment. Such indicators as the color of the fruit, the appearance, the presence of the damages on the surface, the turgescence, and the homogeneity were identified on the level of standard that is common for the feature of plum of European varieties **(Ionica et al, 2013).** The significant differences in the dry matter content in fruits on the rootstocks of various strength of growth were not determined that was accorded with the data of the next scientists **(Meland and Froynes, 2006)**. The sort (calibration) of fruits allowed us to identify the advantages of the version with the application of fertilizers by the criterion "the weight of fruit". The optimization of the nutrition mode of plum of Stanley variety promoted a significant increase in the fruit weight no depending on the strength of growth of the rootstock. That fact matched the data of literature sources **(Kaufmane et al, 2007, Vetrova and Roeva, 2019) (Table 5)**.

CONCLUSION

The impact of the rootstock and the systematic application of intra-soil and leaf dressings in combination with the phytoregulator on the physiological resistance of plum plants of Stanley variety to the negative effect of annually repeated abiotic factors in summer was investigated according to the criterion of functional state, productivity, and quality of fruits.

As a result of the analysis of experimental data, we identified that the application of fertilizers promoted a significant increase of total content of biologically essential elements and enhanced the synthesis of functional pigments (Chla+Chlb) in spring during the period of the intensive shoot and ovary growth in the plum tree on rootstocks of various strength of growth. The total chlorophyll content (Chla+Chlb) in the leaves exceeded stably the value in the control version by 20.1 – 25.4% in trees on the rootstock *PK SK 1*, rootstock *Pixy*, rootstock *cherry plum seedlings*. The effectiveness of the influence of the nutrition mode revealed mostly in the years with the sufficient water availability on the dwarf rootstock *VVA 1* that has the surface occurrence of the main part of the root system. The increase of the growth process activity was confirmed by the increase of the content of free amino acids that were the most active participants in metabolism in the leaves.

The conditions of mineral nutrition mode influenced the chlorophyll synthesis in plum leaves on the rootstock *VVA 1*, rootstock *Best*, rootstock *PK SK 1*and rootstock *cherry plum seedlings* in summer against the background of hyperthermia, the lack of precipitation, and the decrease of air humidity up to 12 – 14%. The specific to these conditions decline of protein content in the trees on the rootstock *Best* and rootstock *PK SK 1* was minimal. That fact characterized higher intensity of reparation processes. Plants on the rootstock *cherry plum seedlings* had the most significant losses of shared water that were up to 9.3% (Organic Mineral Fertilizer + non-root dressings) and 12.7% (control, with no fertilizers). The minimal water losses were identified in leaves in plum on the rootstock *PK SK 1* that was 5.7 – 8.4% respectively.

The periodical precipitation in early September promoted growth activity mainly in trees on the medium rootstocks. The period of growth activity was accompanied by the increase of gross content of nitrogen, phosphorous, and magnesium that was up to 18.6%, 7.7, and 29.5% respectively. The most significant increase of amino acid

content in leaves was determined in plum plants on the rootstock *Best* against the background of the application of fertilizers. The excess of the sum of amino acids was 26.6 – 30.8% in some years.

The period of the beginning of fruit ripening was characterized by the accumulation of gross forms of potassium and calcium in them. The potassium and calcium content in fruits in the version with the application of fertilizers exceeded the amount of the elements in fruits of control version by 12.5 and 23.5%; 24.2 and 11.5%; 17.3 and 19.6% on the rootstock *VVA 1*, rootstock *Best*, rootstock *PK SK 1* respectively. At the same time, the harvest accountings revealed the advantage of the versions with the application of fertilizers: there was an increase in productivity due to a decline of ovary reduction in spring and summer. The number of the fully preserved ovary was higher by 12.3-33.7% depending on the rootstock.

The commercial quality analysis by the criterion "the weight of fruit" that identified the level of economic feasibility of the adoption of optimization of culture's mineral nutrition mode showed the advantages of the version with the application of fertilizers. The largest fruits were obtained from the trees on the rootstock *VVA 1* and rootstock *Best.*

ESSENTIAL OILS AND THEIR APPLICATION IN A FOOD MODEL

Lucia Galovičová, Veronika Valková, Jana Štefániková, Miroslava Kačániová

ABSTRACT

The aim of the study was to investigate the chemical composition, antioxidant, and antimicrobial activity of essential oils (*Canarium luzonicum* CLEO, *Melaleuca leucadenron* MLEO, *Amyris balsamifera* ABEO). There was Gas chromatographic-mass spectrometric analysis used for the characteristic of the semiquantitative composition of the essential oils. The DPPH method was used to determine the antioxidant activity. Minimum inhibitory concentrations (MIC) of essential oils against *Stenotrophomonas maltophilia* were analyzed in a 96-well plate. The broth microdilution method was used for the minimal inhibitory concentration. A gas-phase antimicrobial assay was used to determine inhibitory concentrations in a food model. CLEO proved to be the best with the lowest MIC 50 and 90 of 6.67 µL.mL^{-1} respectively 6.81 µL.mL^{-1} and antioxidant activity of 33.43% among the tested essential oils. The main volatile compounds CLEO were limonene 36.38%, elemol 16.65%, α-fellandren 12.18% and elemicin 9.59%. It showed inhibition of *S. maltophilia* growth in the food model at the lowest concentrations among the essential oils.

Keywords: *Stenotrophomonas maltophilia*; *Canarium luzonicum*; *Melaleuca leucadenron*; *Amyris balsamifera*; essential oil; food model

INTRODUCTION

In recent years, natural substances have come to the fore due to their low toxicity, pharmacological effects, and economic advantage **(Dias, Urban, and Roessner, 2012)**.

Elemi (*Canarium luzonicum*) essential oil comes from an evergreen tree that reaches a height of more than 30 meters and a trunk diameter of more than 1 meter. *C. luzonicum* naturally occurs in the Philippines **(Barwick, Schans and Claudy, 2004)**.

Oleoresin is one of the aromatic components. Therefore, it has a wide range of uses in the pharmaceutical and food industries. It is also used for its rubefic, expectorant, antifungal, antibacterial and antirheumatic effects **(Nikolic et al., 2016)**.

Kajeput essential oil (*Melaleuca leucadendron*) is used for its antifungal, antiviral, antibacterial, antiseptic, and anti-inflammatory effects. The plant occurs predominantly in Indonesia **(Pujiarti, Ohtani and Ichiura, 2011)**. Many of the compounds present in this plant are considered to be bioactive substances **(Cleber et al., 2007)**.

Amyris, essential oil (*Amyris balsamifera*) comes from always green small trees and it has high flammability. It occurs in the Caribbean and near the Gulf of Mexico **(Rohmer, Schwartz and Anton, 2012)**. Amyris is rich in sesquiterpene alcohol. It has antiseptic effects **(Khan and Abourashed, 2009)**.

Stenotrophomonas maltophilia is a non-fermentative, gram-negative, aerobic bacillus. These bacteria can form biofilm structures. It is most often found in raw milk, vegetables, fruits and fish products regarding the food industry **(An and Berg, 2018)**.

We aimed to determine chemical composition, antioxidant activity, and minimal inhibitory concentrations of these essential oils against the bacterium *Stenotrophomonas maltophilia.*

Another aim was also to evaluate the inhibitory effect of essential oils against *S. maltophilia* from the surface of carrots, potatoes and apples by using a vapor phase antimicrobial test.

Scientific hypothesis

We assume the presence of biologically active substances and the antioxidant potential of essential oils. Given the available literature, we assume the inhibitory effect of essential oils on the bacteria *Stenotrophomonas maltophilia*. We believe that essential oils could also have an inhibitory effect in the vapor phase.

MATERIAL AND METHODOLOGY

Essential oil

The tested essential oils (*Canarium luzonicum* CLEO, *Melaleuca leucadenron* MLEO, *Amyris balsamifera* ABEO) were bought from the Hanus s.r.o (Slovakia).

Microorganism

Bacteria *Stenotrophomonas maltophilia* was got from the dairy industry. It was identified by 16S rRNA sequencing and MALDI-TOF MS Biotyper.

Chemical Composition of Essential Oils

There was Gas chromatographic-mass spectrometric (GC-MS, Agilent 7890B, Agilent 5977A, Agilent Technologies Inc., Palo Alto, CA, USA) and CombiPal autosampler 120 (CTC Analytics AG, Zwingen, Switzerland) parsing test of the essential oil used as well as in a previous study **(Kačániová et al., 2020)**. The results were set as the average mean and standard deviation of three repeated measurements.

Radical Scavenging Activity—DPPH Method

The activity of capturing free radicals with essential oil was determined in the same way as in the study of **Kačániová et al. (2020)** by using 2,2-diphenyl-1-picrylhydrazyl (DPPH, Sigma Aldrich, Germany) method.

Minimum Inhibitory Concentration (MIC)

The bacterial culture was cultivated in the Muller Hinton broth (MHB, Oxoid, Basingstoke, UK)) at 37 °C for 24 h. One hundred μL inoculum with a density of 0.5 McF was inoculated into each well of a 96-well microtitration plate. There was 100 μl of the essential oil with a concentration from 0.3125 μL to 10 μL per well added after inoculation. Negative control contended a mixture of MHB with essential oil, while a mix of MHB with bacterial inoculum was used as a control of maximum growth **(Hassan et al. 2011)**. The absorbance was measured and evaluated in the same way as it was in the study of **Kačániová et al. (2020)**. The experiment was carried out in three repeated measurements.

Statistical analysis

The measurements were repeated three times. Statistical variability of the data was processed with Microsoft™ Excel® software.

10-epi-γ-eudesmol		1.59 ±0.01
γ-eudesmol		0.84 ±0.01
rosifoliol		1.08 ±0.01
elemicin		9.59 ±0.11

Note: [a] mean value ±SE.

Results The MIC value (concentration causing 50% and 90% reduction in bacteria growth) was determined by logit analysis. Statistical evaluation of the antioxidant activity of the obtained data was performed using the GraphPad Prism 8.0.1 (GraphPad Software Incorporated, San Diego, California, USA). One way analysis of variance (ANOVA) followed by the Tukey test was used for statistical analysis.

RESULTS AND DISCUSSION

Chemical Composition of Essential Oils

The main volatile compounds of the analyzed essential oil CLEO based on reduced percentage were limonene 36.38%, elemol 16.65%, α-fellandren 12.18% and elemicin 9.59% **(Table 1)**. **Swift (2002)** has stated 59.4%, α-phelandrene 8.01%, and sabinene 3.35% as the main constituents of *Canarium luzonicum*.

Orchard et al. (2017) found out that the main components of the essential oil *C. luzonicum* were limonene 47.5%, elemol 18.4%, and α-phelandrene 9.2%.

Malik (2019) indicated sabinene 5.7%, α-phelandrene 17.6%, limonene 56%, and elemol 6.3% as the main components of the essential oil *C. luzonicum*. **Silva et al. (2012)** identified limonene, β-Cymene, β-fellandren, α-phellandren and β-pinene as the main components of C. luzonicum essential oil.

The main volatile compounds of the analyzed MLEO based on the reduced percentage were eucalyptol 49.23%, α-terpineol 9.92%, limonene 8.12%, and caryophyllene 5.65% **(Table 2)**. **Pujiarti et al. (2011)** in their study tested 9 varieties of *M. leucadendron* from Java and Indonesia, in which twenty-six compounds were identified.

These samples had a very similar composition. The results showed that 1,8-cineole (eucalyptol; 44.76 – 60.19%) was the main compound in these oils, followed by α-terpineol (5.93 – 12.45%), limonene (4.45 – 8.85%) and β-carophyllene (3.78 – 7.64%). **Sharifi-Rad et al. (2017)** reported *M. leucadendron* terpinen-4-ol 30%, 1,8-cyneol 15%, α-terpineol 8%, and limonene 1.5% as the main antimicrobial compounds. **Tia et al. (2013)** reported in their study terpinolene 29.21%, α-terpinene 22.55%, 2-γ-carene 8.53% and α-phelandrene 7.61% as the main components of *M. leucadenron* essential oil. **Fall et al. (2017**) identified the 1.8-Cineol, α-Terpineol and β-Citronellol as main components *M. leucadendron* .

The main volatile compounds of the analyzed ABEO based on reduced percentages were valerianol 23.24%, guaiol 16.56%, elemol 9.62%, and γ-eudesmol 7.95% **(Table 3)**.

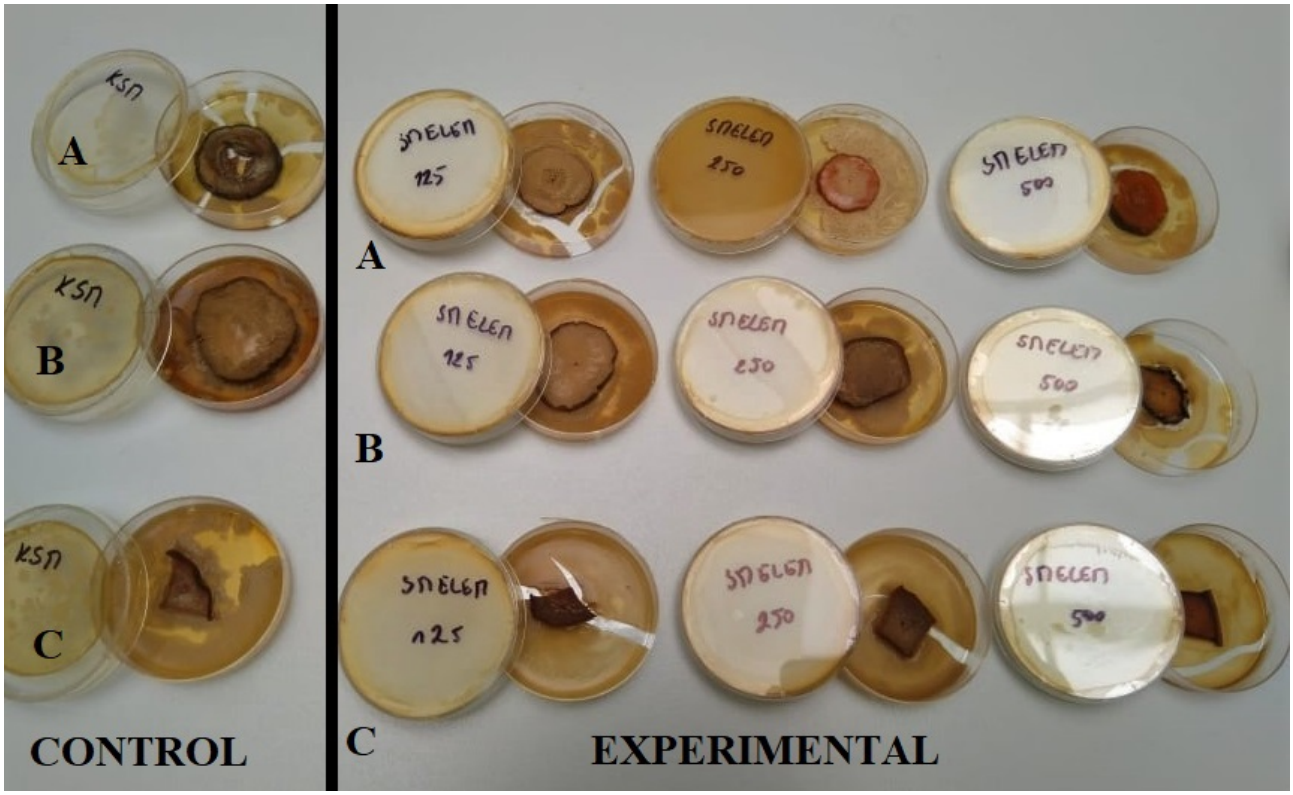

Figure 1 *In situ* antimicrobial analyses of vegetables and fruit with *S. maltophilia* in vapor phase with essential oil *C. luzonicum* (A-carrot, B-potato, C-apple).

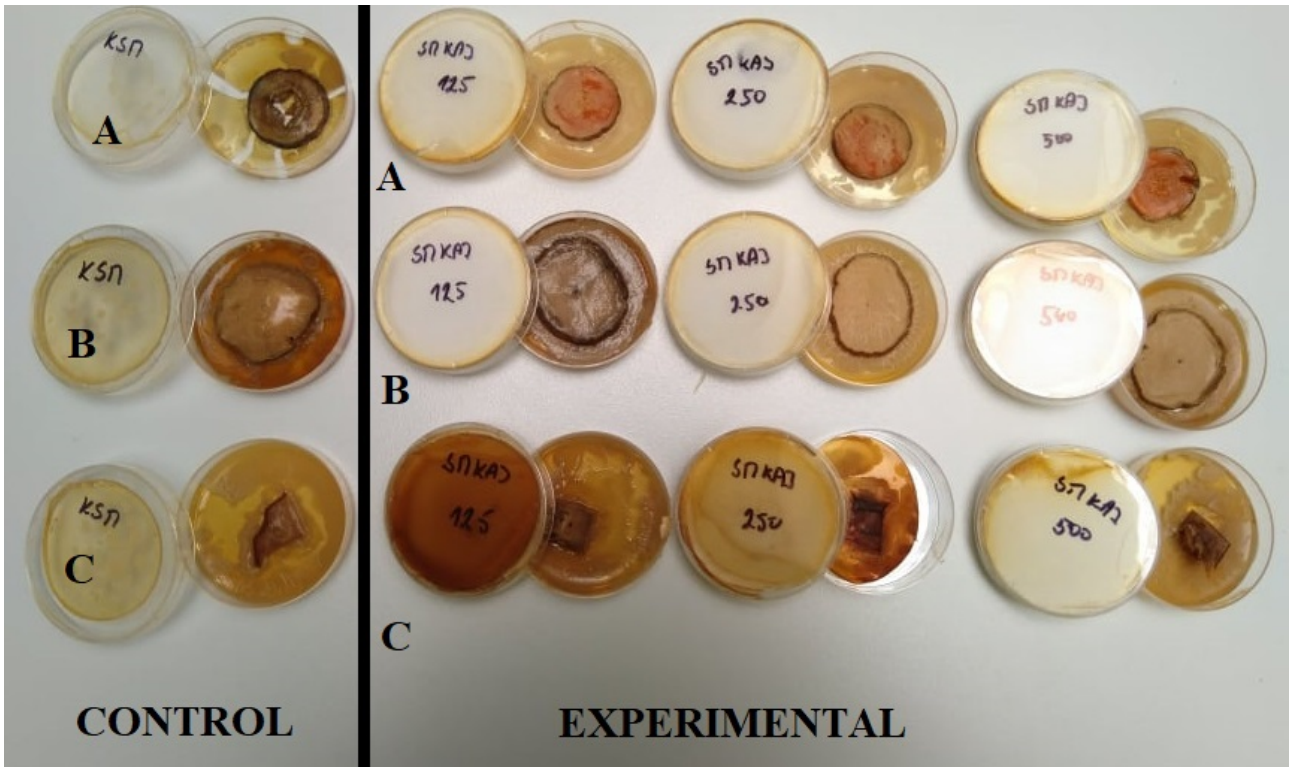

Figure 2 *In situ* antimicrobial analyses of vegetables and fruit with *S. maltophilia* in vapor phase with essential oil *M. leucadendron (*A-carrot, B-potato, C-apple).

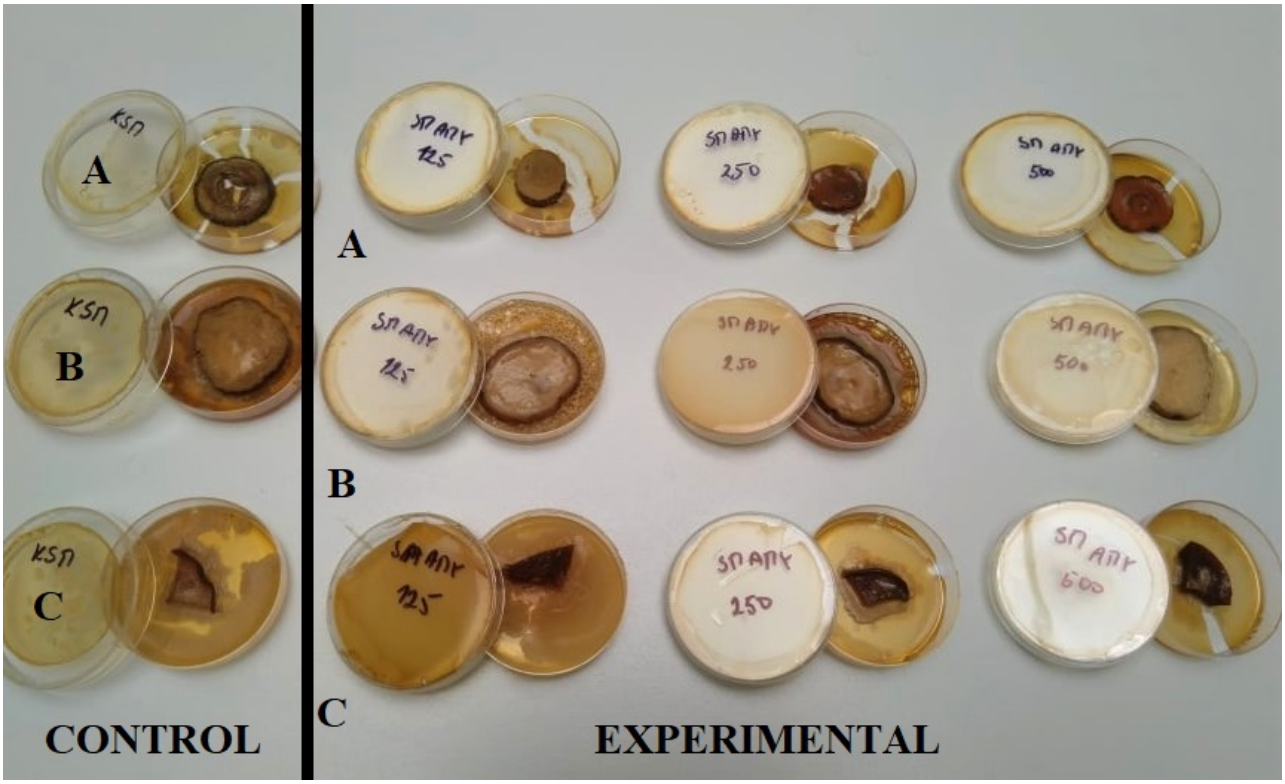

Figure 3 *In situ* antimicrobial analyses of vegetables and fruit with *S. maltophilia* in vapor phase with essential oil *A. balsamifera (*A-carrot, B-potato, C-apple).

Alves et al. (2015) analyzed the chemical composition of amyris essential oil (*Amyris balsamifera* L.) in their study. The main components are eudesmol 23.6%, elemol 14%, and valerianol 12.3%. **Uniyal et al. (2016)** studied the chemical composition of essential oils by gas chromatography and mass spectrometry. Their results show that the main components of amyris oil are β-cadinene 22.66%, (+) - calarene 23.29%, driminol 24%, and linalool oxide 8.48%. **Park and Park (2012)** reported that the major compounds of *A. balsamifera* are β-sesquiphellandrene, elemol, γ-eudesmol and valerianol. **Yun et al. (2012)** they determined chemical compounds essential oil A. balsamifera and the major constituents were elemol, γ-eudesmol and β-sesquiphellandrene.

Antioxidant Activity of essential oils

CLEO essential oil in our study had an antioxidant activity of 33.43%. **Murthy et al. (2016)** determined a DPPH radical inhibition value for the essential oil of 28%. **Lin et al. (2009)** found the antioxidant activity of *C. luzonicum* 11.38%.

MLEO inhibited the DPPH radical at 18.43%. **Pino et al. (2010)** reported that *M. leucadenron* essential oil achieved a free radical inhibition value of 19.9%. **Zhang et al. (2017)** reported antioxidant activity of *M. leucadenron* of 15.7%.

ABEO essential oil achieved an inhibition value of 9.29%. **Nikšić et al. (2018)** studied amyris essential oil in their study and recorded an antioxidant activity of 10.8%. **Dahiya and Manglik (2013)** determined the antioxidant activity of *A. balsamifera* at 19.89%.

The essential oils tested were statistically significantly different (p <0.0001).

Minimum Inhibitory Concentration (MIC)

We determined the MIC 50 and 90 CLEO for *S. maltophilia* to be 6.67 μL.mL^{-1} respectively 6.81 μL.mL^{-1} by using an agar microdilution method. **Nikolic et al. (2016)** focused on the inhibition of clinical isolates of the genus *Candida* by the influence of essential oils and found out that the MIC for *C. luzonicum* oil was 2.5 mg/ml. **Zhang et al. (2017)** reported MIC *C. luzonicum* for *E. coli* 10 μL.mL^{-1} and *P. fluorescens* 12.3 μL.mL^{-1}. **Angelini et al. (2019)** determined MIC of *C. luzonicum* for *A. tubingensis* 12.7 μL.mL^{-1} and *F. oxysporum* 3.17 μL.mL^{-1}.

There was minimum inhibitory concentration 50 and 90 MLEO for *S. maltophilia* 8.25 μL.mL^{-1} and 8.96 μL.mL^{-1}. **Siddique et al. (2020)** reported in his study for *M. leucadendron* MIC values of 4 μL.mL^{-1} for *B. spizizenii*, 8 μL.mL^{-1} *S. aureus* and resistance to *P. aeruginosa* 250 μL.mL^{-1} and *S. enterica* 250 μL.mL^{-1}. **Lieu et al. (2018)** examined the antifungal activity of *M. leucadendron* in food storage and found out MIC of 20 μL.mL^{-1} for *A. niger*. **Pintas and Quave (2019)** focused on the antifungal activity of essential oils against *Malassezia* spp. They determined a MIC of 64 μL.mL^{-1} for *M. leucadendron*. **Bautista-Silva et al. (2020)** found MIC of *M. leucadendra* for *Salmonella thiphymurium* 7.8 μL.mL^{-1} and *Pseudomonas aeruginosa* 31.2 μL.mL^{-1}.

We determined a MIC 50 and 90 of 10.31 μL.mL^{-1} respectively 10.73 μL.mL^{-1} for ABEO. **Xiao et al. (2020)** studied the essential oils and their activity against the stationary phase of *S. aureus*. They determined the MIC for the essential oil of *Amyris balsamifera* 1.5 μL.mL^{-1}. **Santiago et al. (2018)** examined the antibiofilm activity on *Xylella fastidiosa* and found out that the MIC for *Amyris balsamifera* was 125 μL.mL^{-1}.

In Situ Antimicrobial Effect on Vegetables and Fruit

The antimicrobial study of essential oils was determined by an *in situ* method. CLEO inhibited the growth of *S. maltophilia* on the surface of carrots and potatoes at a concentration of 250 mg/ml. Inhibition for apple was recorded at a concentration of 125 mg.mL^{-1} **(Figure 1)**.

MLEO showed inhibition of *S. maltophilia* growth on carrots at a concentration of 500 mg.mL^{-1}, on potato and apple surface at 250 mg.mL^{-1} **(Figure 2)**.

ABEO inhibited bacterial growth at a concentration of 125 mg.mL^{-1} per carrot, 250 mg.mL^{-1} per apple and up to 500 mg.mL^{-1} per potato **(Figure 3)**.

CONCLUSION

The results of our work demonstrated the inhibitory effect of essential oils on *S. maltophila* in a food model. CLEO proved to be the best with the lowest MIC of 6.67 µL.mL^{-1} and antioxidant activity of 33.43% among the tested essential oils. It showed inhibition of *S. maltophilia* growth in the food model at the lowest concentrations among the essential oils.

THE QUALITATIVE PARAMETERS OF POTATO TUBERS IN DEPENDENCE ON VARIETY AND DURATION OF STORAGE

Andriy Davydenko, Hryhorii Podpriatov, Sergiy Gunko, Volodymyr Voitsekhivskyi, Oksana Zavadska, Anatoliy Bober

ABSTRACT

The qualitative parameters of the potatoes tubers may be significantly changed depending on the variety, group of ripening, way, regime, and duration of storage. So, these researches aimed to define the influence of the variety characteristics and duration storage on qualitative parameters of tuber potatoes. Five potato varieties of two ripening groups were used for testing: medium-early (Satina, Red Lady, Mozart) and medium-ripe (Aroza, Sifra). The chemical properties such as dry matters (DM), starch, sugars (total and reducing), crude protein (CP), ascorbic acid (AA), and nitrates content were determined before and after 2, 4, and 6 months of storage. DM lost during the storage of potato tubers, especially during the period from 4 to 6 months. The group of ripening did not influence this index. Potato tubers of all varieties had high starch content and the duration of storage had a light effect on the level of its losses. In the medium-early group, maximum changes of starch were 1% but in the medium-ripe – 1.9%. A strong effect on the quantities of total sugars (TS) had varietal characteristics of the potato but a group of ripening had light influence. The highest content of sugars was Satin (0.65%) and the smallest Sifra (0.22%) and Mozart (0.23%). After 6 months of storage content of TS depending on the variety increased from 2 till 5 times, while the reducing sugars (RS) increased at least five times and at the end of storage were 0.4% to 0.65%. The amount of AA and its losses during storage depended on the variety. The relative losses during the total storage period were 21.9% in the medium-early group and 28.1% in the medium-ripe. Influence ripening group on level changing AA was not detected. Nitrates' content did not exceed the maximum permissible level (250 mg.kg^{-1}). Their quantities after 6 months were 47 – 61 mg.kg^{-1}.

Keywords: potato; variety; ripening group; storage; qualitative parameters.

INTRODUCTION

The biochemical composition of potato tubers is an indicator of its nutritional value and culinary properties **(Amber, Chegeni and Ferruzzi, 2018)**, which depends on variety, soil, climate, the technology of crop growing, duration and storage conditions **(Nourian, Ramaswamy and Kushalappa, 2003a; Nourian, Ramaswamy and Kushalappa, 2003b)**.

The valuable of potatoes as food is determined by the favorable biochemical composition, which is represented by DM, starch, sugars, CP, and AA. Other components that can affect its nutritional quality are present in smaller quantities in potatoes **(Amber, Chegeni and Ferruzzi, 2018)**.

The content of DM in potatoes can fluctuate within wide enough ranges of 15 – 32% and depends on both varietal characteristics and agro-climatic factors. Their quantities influence the energy value of potatoes and their culinary properties – taste, structure, consistency, and color of pulp after cooking. The quantities of DM decreasing due to physiological processes that take place in the potatoes tubers during the storage **(Zgórska and Grudzińska, 2012; Gunko and Yakovlev, 2016)**.

The basis of DM in potatoes (70 – 80%) presented by starch. Its quantity defines the nutritional value of potato tubers. The amount of starch depends primarily on variety, growing conditions, and has ranged from 9 to 24% by raw weight in the different varieties **(Liu, et al., 2007; Lu, et al., 2011; Ngobese, et al., 2017)**.

Late-ripening potato accumulates more starch substances. The storage process is accompanied by the constant transformation of starch to sugar and vice versa and as a result physiological processes that take place, their quantity was decreasing **(Mareček, et al., 2016)**.

The biological value of potatoes is determined by the content in the tubers of CP. Its biological value is superior compared to the protein of most crops because it contains all the irreplaceable amino acids that are not synthesized in

humans and has an index of valuability is 60 – 92 **(Bártováa, et al., 2009)**.

On average, potatoes contain CP about is 1.9 – 2.2% by raw weight. In the processing of potatoes, protein value is not taken into account in our time, however, in the future, they will take into account the nutritional and physiological value and pass mainly to the processing of potatoes, which are rich in protein. The process of storage is accompanied by quantitative changes in the CP: initially, its amount increases and becomes maxima in March but further storage decreases its content **(Järvan and Edesi, 2009)**.

Freshly harvested potatoes are characterized by low content of sugar: an average about is 0.7% by raw weight or 2.8% by weight of DM. More than half of them are glucose (65%), about 30% – sacharose and only 5% fructose. In the outer and inner layers of tubers the TS content is almost the same, but in the outer layers is presented sacharose and in the central part – monosaccharides. The process of storage escorted constantly transforms starch-to-glucose and vice versa **(Amjad, et al., 2019)**.

As a result, potatoes germination in their tubers may accumulate a large quantity of phosphorus esters of sugar and when there is an intense decomposition of starch to form up to 1% maltose. Increasing the number of sugars (glucose) – is undesirable, as it affects the culinary properties of potatoes, especially the quality of fried products **(Camire, Kubow and Danielle, 2009; Amjad, et al., 2019)**.

Tubers of potatoes contain different vitamins: thiamine, riboflavin, pantothenic acid, pyridoxine, nicotinic acid, carotenoids, and AA but only vitamin C which has content in the ranges from 5 till 40 mg% by raw weight has biological value. Other vitamins presented in quantities very smaller than needed for the health of a person **(Love and Pavek, 2008)**.

The highest content of AA is presented in fresh harvest potato tubers. During storage, their content decreases, especially as a result of germination **(Külen, Stushnoff and Holm, 2013)**.

Potatoes of two groups of ripening – medium-early and medium-ripe were used in the investigations. The choice of potato varieties from these two groups explained by their prevalence in the area, the increase in active temperatures in June, July, and August, low rainfall in the current period and, the need for the stable provision of large cities in the summer and autumn **(De Temmerman, Hacour and Guns, 2002; Hijmans, 2003)**.

Early planting time contributes to large and stable potato harvests in the Forest-Steppe zone of Ukraine **(Voitsehivskyi, et al., 2019)**.

This work aimed to investigate the effect of storage duration, variety characteristics, and ripeness group on changes in the biochemical composition of potato tubers.

Scientific hypothesis

Potatoes are characterized by large quantities of varieties that differ from each other, both in terms of the growing season and biochemical composition. The quality of potatoes tubers changes during storage. The magnitude of these changes depends on the characteristics of soil, climatic conditions, cultivation technology, varietals' characteristics, the activity of physiological processes, conditions, and duration of storage.

MATERIAL AND METHODOLOGY

Material

Materials of the study were potatoes tubers 5 varieties companies HZPC (Netherlands) and Solana (Germany) which apply to two groups of ripeness: medium-early (Satina – control, Red Lady, Mozart) and medium-ripe (Aroza – control, Sifra) **(Figure 1)**. Potatoes were stored in a specialized fridge chamber which equipment by ventilation. Conditions of storage: temperature + 2 to +4 ºC, air humidity 90 – 95%, ventilation – three-volume of air during one day. A sample of 25 kg of potatoes tubers each cultivar was stored in these conditions. From this sample of 1.5 – 2 kg, tubers were taken for the determination of biochemical parameters.

Methodology

Potatoes were grown during 2016 – 2018 years in the conditions of LLC Biotech LTD (Kyiv region, Boryspil district, Horodyshche village), which is located in the Forest-Steppe zone of Ukraine. The total area size of the field for potatoes cultivation is 300 m^2, the accounting area is 240 m^2, the repeatability – 3 times. The potato was cultivated by a common methodology for this crop in the Forest-Steppe zone of Ukraine.

In potato tubers, before storage and after 2, 4, and 6 months were determined DM, starch, TS, RS, CP, AA, and nitrates. The following chemical analyses were performed:

1. Content of DM was performed by the weighted method **(Skaletska, Podpryatov and Zavadska, 2014; DSTU 7804, 2015)**;
2. Content of starch was performed polarimetrically by Ewers **(Savchuk, at al., 2005)**;
3. Content of AA – to restore the Tillmans reagent, by extraction acid solution of sample potato followed by filtration of the resulting substrate titrimetric method according to the state standard of Ukraine 7803 **(DSTU 7803, 2015)**;
4. Content of TS and RS was performed by photocolorimetric method on the photo calorimeter KFK-3-01 according to the state standard of Ukraine ISO 4954 **(DSTU ISO 4954, 2008)**;
5. Content of CP was performed according to the state standard of Ukraine 7169 **(DSTU 7169, 2010)**;
6. The content of nitrates was performed by potentiometry according to the state standard of Ukraine 4948 **(DSTU 4948, 2008)**.

Statistic analysis

All experiments were carried out in triplicate and standard deviations for replication were calculated. The results were statistically analyzed using analysis of variance (ANOVA). Measurements of duplicate samples were expressed as means ± standard deviation. The level of significance associated with the statistical test was 0.05.

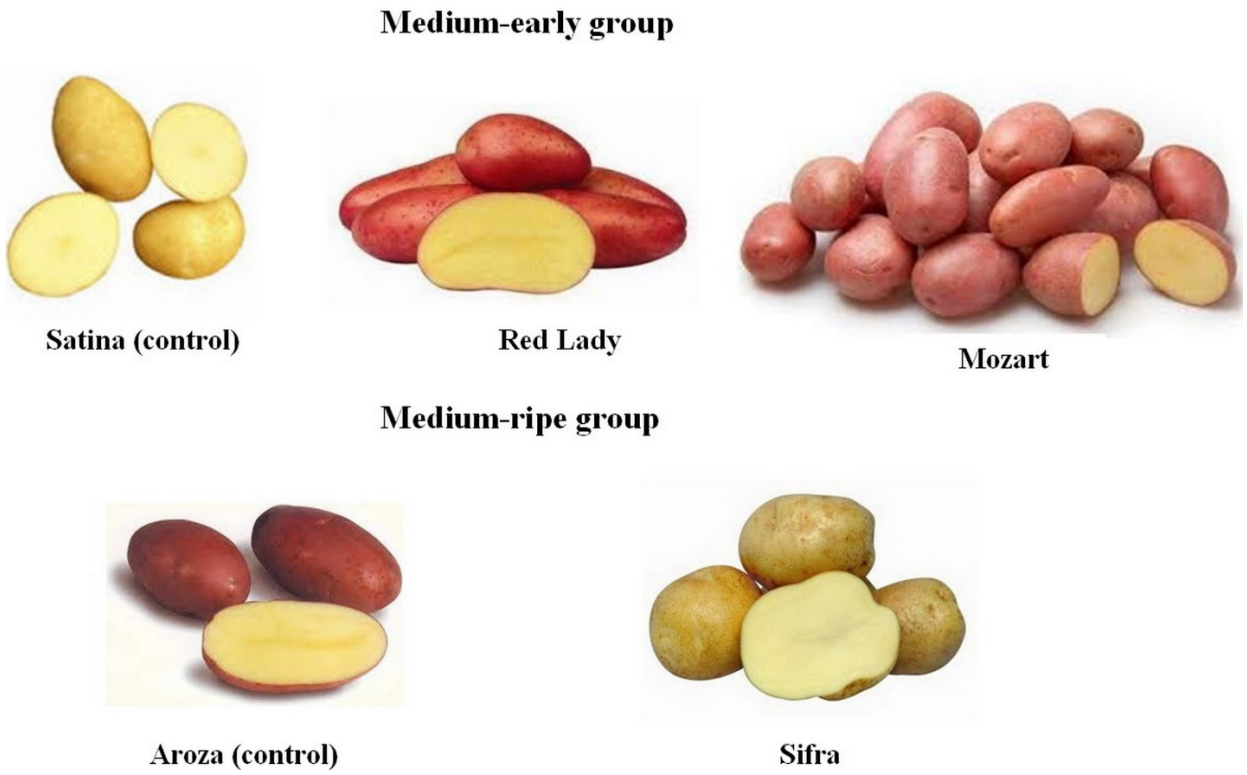

Figure 1 Pictures of potato tubers two groups of ripening.

RESULTS AND DISCUSSION

The biochemical indices of the potato tubers were determined before storage and after 2, 4 and 6 months. The dynamics changes of DM in potato tubers in the experimental varieties were presented in **Table 1**.

According to the research of L. N. Kozlova **(Kozlova, 2005)** on the level of DM accumulation in potato tubers is mainly influenced by the variety of potato (their influence is 46%**)**, the interaction of weather conditions and the place of cultivation – 29% and the combination of these factors – 12%. Other researchers indicated that the most important factors influencing the accumulation amount of dry matter in the potato tubers are varietal characteristics **(Wurr, Beanand Allen, 1978; Mareček, at al., 2015)**, fertilizers and their composition **(Kleinkopf, Westermann and Dwelle, 1981; Pobereźny and Wszelaczyńska, 2011)** and growing zone **(Dinesh, et al., 2005)**.

Our results show that during the storage of tubers potatoes of experimental varieties there was a decrease in the amount of DM, but the intensity of their change was different.

The ripeness group had a significant effect on DM accumulation. Thus, on average in the group of medium-early, at the beginning of storage, the DM content was – 23.5%, and in the group of medium-ripe – 29.3%.

At the end of storage average values of DM depend on the group were 21.1% and 25.9%, respectively. Relative losses in the two groups had averaged values from 9.8 to 11.7% over the whole period of storage. The difference in losses between the individual varieties was more significant, ranging from 2.1% (Mozart**)** to 3.6 % (Aroza).

Particularly intense was the loss of DM in the third storage period from 4 to 6 months, which can be explained by the intensification of physiological processes in potato tubers in the spring. The effect of the ripeness group on the magnitude of the loss was not established. They were affected by the initial amount of DM: than larger quantities were present before storage therefore they were more lost during the storage period.

The basis of the DM in the potato tubers presented starch **(Šimková, et al., 2013; Bhattacharjee, et al., 2014)**. Its content correlates with quantities of DM and the difference between DM and starch is about 5-9 absolute percent.

In our studies, the average content of starch in the potato tubers, depending on the ripeness group, increased from 16.5% in the medium-early to 23.7% in the medium-ripe **(Table 2)**. This indicator was more dependent on a variety.

The obtained results indicate that the index of starch in the tubers varieties which apply to medium-ripe groups sharply differ: from 21.8% (Sifra**)** to 25.5% (Aroza) **(Table 2)**. In the medium-early group, this difference was smaller – from 15.5% (Mozart**)** to 17.7% (Red Lady).

Storage for 6 months did not cause significant changes in the starch of the tubers. Thus, during three years of research an average of the relative losses were: in the medium-early group – 1% but in the group medium-ripe – 1.9%. The high starch content after 6 months of storage had the varieties of Aroza (23.3%) and Sifra (20.1%), which makes it possible to recommend these varieties for processing with obtaining starch and alcohol.

The content of CP in potato tubers was from 1.9% to 2.2% by weight and more than half of its total content was protein **(Vlasyuk, Vlasenko and Mitsko, 1979)**. The amount of protein that accumulation in potato tubers mainly depends on agro-ecological conditions of cultivation **(Bártová, et al., 2009)**, fertilizers, and their composition **(Ahmed, et al., 2009; Petropoulos, et al., 2020)**.

Table 1 Dynamics of DM in potato tubers, %.

Variety	Before storage	Duration of storage, days		
		60	120	180
		medium-early

Sifra	1.6 ±0.13*	1.6 ±0.06*	1.7 ±0.14*	1.9 ±0.11*

Note: * denotes statistically significant difference at $p < 0.05$ level.

Analysis of the content of CP indicated the low difference between these indexes between two groups of maturity **(Table 3)**.

An average during three years of research, its quantity was in the group of medium-early – 1.7% and in the group of medium-ripe – 1.8%. The highest content of CP was observed in the tubers of the 2016 harvest, which confirms its dependence on from conditions of the growing season. The obtained results are confirmed by conclusions of other researchers **(Eliseeva, 1996)**, that indicate the influence of rainfall, temperature conditions during vegetation on the accumulation of CP.

In the process of storage of tubers potato of experimental varieties, the content of CP increased and especially intensively in the period from 4 to 6 months **(Table 3)**. This result is in agreement with the results of the researches obtained by S.F. Polishchuk, which indicates that the maximum content of CP in tubers accumulates in March **(Polishchuk, 1986)**.

The sugar content of the potatoes can vary greatly depending on the variety, the technology of cultivation (fertilizers), the state of the tubers and the storage conditions **(Dogras, Siomos and Psomakelis, 1991; Ohara-Takada, et al., 2005; Galdón, et al., 2010; Muttucumaru, et al., 2013; Mareček, et al., 2013)**. Young tubers of potatoes have more sugar than ripening tubers. Tubers that have higher sucrose content than monosaccharides and have better keeping capacity **(Sowokinos, 1978; Richardson, Davies and Ross, 1990)**.

The highest importance on the ability to accumulate monosaccharides as a result of starch hydrolysis at low storage temperatures in the tubers has varietal features. Thus, the researchers recorded an increase in the sugar content in the potato tubers of the Yantarniy variety from 0.55% to 3.48% during storage at low temperatures, which made them unsuitable for industrial processing **(Gusev and Metlitsky, 1982)**.

In our investigations, the TS content an average during three years of research was 0.43% in the medium-early group and 0.4% in the medium-ripe group **(Table 4)**.

Thus, on average, during the three years of investigation, the content of TS did not differ significantly between the ripeness groups but had differences between the varieties. The highest content of sugars was contained in the potatoes of the Satina variety (0.65%) and the lowest in the Sifra (0.22%) and Mozart (0.23%) varieties. The content of RS in potatoes ranged from 0.07% to 0.28%, which makes them suitable for industrial processing **(Table 5)**.

The storage process was accompanied by an increase in the content of both total and reducing sugars.

Note: * denotes statistically significant difference at $p < 0.05$ level.

During the whole storage period, the TS content increased depends on variety from 2 to 5 times but RS increased at least five times and at the end of storage (after 6 months**)** we obtain from 0.4% to 0.65%.

That is, most varieties were characterized by an excess of optimum content of sugar 0.2 – 0.4%, which makes them unsuitable for the production of fried potatoes. However, some researchers indicate **(Metlitsky, Gusev and Tektonidi, 1972; Marquez and Añon, 1986)** that a significant deterioration in the color of potato products appears only with the content of RS is 1% and more. Some researchers **(Roe, Faulks and Belsten, 1990)** indicated the effect of fertilizers, especially nitrogen, on the darkening of potatoes during frying.

The amount of vitamin C that accumulates in potato tubers depends on many factors, the main of which are varietal characteristics, fertilizers and their doses, farming systems, zones of cultivation, soil and climatic conditions **(Hamouz, et al., 2009; Macák, Žák and Polláková, 2012)**.

Before storage, the mean content of AA in potato tubers was 9.7% in the medium-early group and 11.6% in the medium-ripe group **(Table 6)**.

The process of potatoes storage was accompanied by a decrease in the amount of AA, which negatively affected the biological value. Its relative losses during the storage

period an average set of 21.9% in the medium-early group and 28.1% in the medium-ripe group, respectively.
The lost of AA depends mainly on varietal characteristics. According to our research during the whole storage period, the greatest losses had potatoes of Aroza variety (30.6%) and the lowest – Red Lady (17.6%).

The content of nitrates in the product determines the level of its safety and is regulated according to sanitary standards. The high content of nitrates presented in the skin of the tuber and the areas of the eyes **(Ilchuk, 1993)**. As a result preparation of French fries and dried potatoes, the content of nitrates reduced by 70 – 80 % but chips by 72 – 76% **(Zabara, 2000)**. The quantity of nitrates in the potato tubers depends on different factors, the main of which are fertilizers and their doses, farming systems, and type of soil **(Yli-Halla, Viikari and Palonen, 1987; Ahmed, et al., 2009)**.

In our experiments, the nitrate content before storage was lower than allowed according to the maximum permissible level and ranged from 63 to 85 $mg.kg^{-1}$ but at the end of storage were 47 – 61 $mg.kg^{-1}$ **(Table 7)**. That is, the relative losses of nitrates during the whole storage period an average were from 25 to 28 %.

CONCLUSION

The results of the effect of storage duration, variety characteristics, and ripeness group on changes in qualitative parameters of potato tubers were established.
The potato tubers of the experimental varieties accumulated different amounts of DM. Their quantity depended on the length of the growing season, that is, the medium-early ones accumulated less (23.5%) and the medium-ripe ones more (29.3%). The process of storage of tubers was accompanied by the loss of DM, especially in the period from 4 to 6 months that explained by the intensification of physiological processes in potatoes in the spring. The effect of the ripeness group on the magnitude of the DM loss was not established.

All potato varieties had a high content of starch. Storage and group of ripening did not significantly affect the level of its losses (medium-early – 1%; medium-ripe – 1.9%). The highest starch content after 6 months of storage characterized two varieties of Aroza (23.3%) and Sifra (20.1%).

The amount of CP in the potato tubers for three years depended on the conditions of the growing season. This indicator increased during storage. Its maximum value we obtain after 6 months and the magnitude of growth over an average of three years in both maturity groups was 0.25 – 0.26%.

The amount of TS depended on the varietal characteristics of the potato: the highest content was characterized by the variety Satin (0.65%) and the lowest – Sifra (0.22%) and Mozart (0.23%). During the whole storage period, the TS content increased depending on the variety from 2 to 5 times, but RS was by 5 times and more.

The amount of AA and its loss during storage depended on the variety. During the storage period, relative losses on average were 21.9% in the medium-early group and 28.1% in the medium-ripe group. The largest losses were potatoes of Aroza (30.6%) and the smallest – Red Lady (17.6%).

Potato tubers had nitrate content less than allowed by the maximum permissible level and during storage, their relative losses were 25 to 28%.

MONITORING OF MICROSCOPIC FUNGI COMMUNITY IN SELECTED BEE PRODUCTS

Zuzana Mašková, Vladimíra Kňazovická, Veronika Mančíková, Dana Tančinová, Zuzana Barboráková

ABSTRACT

Honey is a remarkably complex food with a valued place in the human diet. An important indicator of its quality is the presence of microorganisms. This study aimed to monitor the mycological quality of 27 samples of Slovak kinds of honey and honey products with the addition of differently processed blueberries, cranberries, and red currants. Yeast and filamentous microscopic fungi were monitored using the plate dilution method. A total of 21 samples (78%) were positive for the presence of yeasts and 14 samples (52%) were positive for the filamentous microscopic fungi occurrence. In 6 samples (22%) no presence of microscopic fungi was found at all. The highest number of yeasts (3.07 log CFU.g^{-1}) was recorded in one flower honey sample and in other samples, yeast counts did not exceed 3 log CFU.g^{-1}. The highest numbers of filamentous micromycetes (2.39 and 2.44 log CFU.g^{-1}) were recorded in 2 honeydew honey samples. Overall, the following genera have been identified: *Alternaria*, *Arthrinium*, *Aspergillus* (including previously named as *Eurotium*), *Aureobasidium*, *Cladosporium*, *Mucor*, *Penicillium,* and *Stemphilium*. *Penicillium* spp. were recorded with the highest isolation frequency (41%). *Aspergillus* species were isolated from 19% of honey samples. In the honey with fruit addition, the yeasts in a range of 1.00 – 3.09 log CFU.g^{-1} and the filamentous microscopic fungi in a range of 1.00 – 1.39 log CFU.g^{-1} were found. The study showed that cranberries were the most appropriate addition from a mycological point of view. Dried and lyophilized forms of tested fruits were the most suitable. Except for honey with frozen currants and honey with fresh cranberries, all final products had a water activity below 0.610 and appeared to be stable.

Keywords: blueberry; cranberry; honey; micromycetes; red currant.

INTRODUCTION

Honey is a remarkably complex food that, contains more than 200 biologically active compounds. The main components of honey are carbohydrates and water. Some minor components present in honey are minerals, phenolic acids and flavonoids, ascorbic acid, proteins, certain enzymes, amino acids, organic acids, α-tocopherol, carotenoids, and Maillard reaction products **(Korošec et al., 2016)**.

Honey is characterized by medicinal effects and antimicrobial properties and is used in various cuisines. The application potential in bakery, confectionery, snack foods, fruit, and vegetable products and beverages is ever-increasing **(Aparna et Rajalakshmi, 1999)**. Nowadays there is an ever-increasing demand for consumer-based diversified honey products, which lead to value addition to the raw material. The honey-based spreads increase the demand for honey and provide superior products to the customers in terms of nutrition and taste **(Umesh Hebbar, Rastogi and Subramanian, 2008)**. Honey can be enriched with various additives such as nuts, well-dried herbs, spices, or fruits **(Dadant, 2019)**. According to **Krell (1996)** for the production of honey with added fruit, it is best to use soft, sun-dried fruits with the lowest possible water content. Fresh fruit can become contaminated and mildewed **(Dadant, 2019)**.

As a therapeutic product, honey has been used since ancient times. Its medical use represents support for the treatment of cold and flu, insomnia, liver and gallbladder diseases, or heartburn. Because honey contains digestive enzymes, it helps reduce excess fat in the human body **(Chaven, 2014)**. Its properties are chemically evidenced by its composition. Among features that make this product effective against microorganisms, we can quote high osmotic pressure by low water activity (average 17.2%); low pH because of the presence of organic acids (average 3.9); the presence of hydrogen peroxide generated by the action of enzyme glucose oxidase; low protein content; low

redox potential due to the presence of reducing sugars; and chemical agents present as lysozyme, phenolic acids, pinocembrin, terpenes, benzyl alcohol, and volatile substances **(Rao et al., 2016; Snowdon and Cliver, 1996)**. Despite all the honey microorganism barriers, some species of microorganisms can survive and may cause damage to honeybees or consumers **(Silva et al., 2017)**. Primary sources of microbial contamination are likely to include pollen, the digestive tracts of honey bees, the environment inside the beehive, dust, air, flowers, nectar, sources that are very difficult to control. Secondary (after-harvest) sources of contamination include air, food handlers, cross-contamination, equipment,and buildings, and these can be controlled by good manufacturing practices **(Snowdon and Cliver, 1996; Olaitan, Adeleke and Ola, 2007)**. Microbes of concern in post-harvest handling are those that are commonly found in honey (i.e., yeasts and spore-forming bacteria), those that indicate the sanitary or commercial quality of honey (i.e., coliforms and yeasts), and those that under certain conditions could cause human or honeybee illness **(Snowdon and Cliver, 1996)**.

Fungi can colonize most of the substrata on Earth. Honey is a reservoir of xerotolerant and xerophilic fungi and should be an ideal substratum for their development. Flowers and aphids could play an important role as a source of such microorganisms. However, little information has been gathered about these fungi and their relationships with honey and honey products. Honey has been studied little in terms of its fungal diversity **(Rodríguez-Andrade et al., 2019)**. Filamentous fungi and yeasts can maintain their vegetative form **(Snowdon and Cliver, 1996)**. They can remain latently in this product waiting for the moment in which the environment is suitable for their development **(Silva et al., 2017)**. They may participate in the fermentation and decay of honey. Yeast activity can cause foaming of the honey surface, smell, and taste of the fermented product **(Přídal, 2005)**. **Soni et al. (2016)** state, that the detection of yeast counts in honey is a complementary factor in determining the quality of honey. Growth of some filamentous fungi could be followed by the production of mycotoxins, which are secondary metabolites of filamentous fungi and toxic to humans and animals even in small concentrations **(Pitt, 2000)**. Among mycotoxin producers, we should highlight *Aspergillus* spp. and *Penicillium* spp. because they are the most commonly found in honey **(Foley et al., 2014; Sinacori et al., 2014)**. They are also associated with diseases in honeybees **(Silva et al., 2017)**.

It is important to know the diversity of contaminating microorganisms in honey, especially due to disseminate pathogenic microorganisms in international traded marketing **(Silva et al., 2017)**. In general, honey should be considered as a "living food" and, consequently, its "normal" mycobiota merits more extensive study **(Rodríguez-Andrade et al., 2019)**.

The aim of the present study was therefore to monitor the mycological quality of Slovak honey and selected honey products with added fruit. The fruit affects the basic Physico-chemical properties of the honey, and it may impact their stability and the development of micromycetes, so we aimed to estimate the safety of these products in terms of the yeast and filamentous microscopic fungi occurrence.

Scientific hypothesis

Honey contains various microorganisms, including microscopic fungi, which may, under certain circumstances, affect its quality and safety.

MATERIAL AND METHODOLOGY

Analyses in the present study were divided into two parts. The first were analyses of honey samples recovered from the Slovak production and the second were analyses of honey with the addition of various fruits. All analyses were focused on the detection of microscopic fungi in the monitored commodities, namely yeasts and filamentous microscopic fungi.

Honey

A total of 27 different honey samples were mycologically monitored (20 samples from the year 2018 and 7 samples from the year 2019). A list of honey samples with their characteristics is given in **Table 1**. All samples were obtained directly from beekeepers.

Each honey sample in the present study was tested for the occurrence of yeasts and filamentous microscopic fungi using a plate dilution method and appropriate culture media.

Honey with the addition of fruit

In the second part of the study, were (under laboratory conditions) prepared samples of honey with the addition of various fruits in various forms and concentrations. The fruits used in this study were blueberries (frozen, dried, and lyophilized), cranberries (fresh, dried, and lyophilized), and red currants (frozen, dried, and lyophilized). **Table 2** provides a more detailed description of the raw materials used to prepare the products. Weighed fruits were mixed with rapeseed pasted honey, particularly in the concentrations shown in **Table 3**, and have been thoroughly homogenized. Concentrations were designed according to the expected water content of the used fruit. With decreasing water concentration in fruits, the content of their addition was increased. The products were stored in glass containers in a cool and dark place. Mycological analyses were performed both on individual raw materials and final products, all variants in 3 repetitions.

Mycological analyses

Mycological analyses of honey samples, fruit samples, and honey samples with additives were aimed at determining the total counts of yeasts and filamentous microscopic fungi. A plate dilution method was used for the above analyses. The procedures were followed according to Slovak technical standards - STN ISO 21527-1 (2010) and STN ISO 21527-2 (2010). Two nutrient media were used according to the water activity of the particular sample analyzed. For samples with water activity greater than 0.95, DRBC nutrient medium (Dichloran Rose Bengal Chloramphenicol Agar; Himedia, M1881) was used.

18	10	red currants – dried	90	**10**
19	12	red currants – lyophilized	88	**12**

In the case of samples with a water activity less than or equal to 0.95, the DG18 medium (Dichloran 18% Glycerol Agar; Himedia, M1129) was used. Cultivation was performed under aerobic conditions at 25 °C for 5 – 7 days. Grown colonies were converted to colonies forming unit (CFU), using the formula (1)

$$N = \Sigma C/[(1 \times n1) + (0.1 \times n2)]d \quad (1)$$

where N = number of colonies per milliliter or gram, ΣC = sum of all colonies on all plates counted, n1 = number of plates in lower dilution counted, n2 = number of plates in next highest dilution counted, d = dilution from which the first counts were obtained.

Filamentous microscopic fungi were subsequently identified into the genera. The identification was based on the observation of macro- and micromorphological features, using respected mycological keys **(Samson et al., 2002; Pitt and Hocking, 2009; De Hoog, Guarro, and Gene, 2000)**.

Water activity (a_w) determination

The reference device, LabMaster-aw from Novasina, was used to determine the water activity of the raw materials and honey products. The measurements were performed at a constant temperature of 25 °C, in 2 replicates and the average values were taken into account.

Statistical analysis

Counts of microorganisms were reported as mean values calculated from the results of 3 replicates of mycological analyses of each sample. These were then converted to decimal logarithms, referred to as log CFU.g^{-1}.

The obtained mycological results were evaluated and expressed in isolation frequency (Fr), which is defined as the percentage of samples within which the species or genus occurred at least once. These values were calculated according to **González et al. (1996)** using the formula (2):

$$Fr\ (\%) = (ns / N) \times 100 \quad (2)$$

where ns = number of samples within a genus; N = total number of samples.

RESULTS AND DISCUSSION

Mycological analyses of honey samples

In the first part of the study, we analyzed 27 honey samples of Slovak origin. Of these, a total of 21 samples (78%) were positive for the presence of yeasts and 14 samples (52%) were positive for the filamentous microscopic fungi occurrence. In 6 samples (22%) no presence of microscopic fungi was found at all. The counts of detected micromycetes are shown in **Figure 1**. The highest number of yeasts (3.07 log CFU.g^{-1}) was recorded in flower honey sample no. 19. According to **Snowdon and Cliver (1996)**, most samples of honey contain detectable levels of yeasts. Although yeast counts in many honey samples are below 100 CFU.g^{-1}, yeasts can grow in honey to very high numbers. **Bogdanov (2011)** states that water content is an important factor for yeast development in the substrate. Honey generally contains osmophilic (sugar–tolerant) yeasts in greater or lesser amounts. If the moisture content is high enough and storage temperature is favorable, they can ferment substrate **(Subramanian, Umesh Hebbar and Rastogi, 2007)**. Fermentation is an irreversible phenomenon that can run in honey mainly during storage, causing significant economic losses. In such a case, honey presents a characteristic odor, increasing acid flavor and gas bubbles **(Perez-Perez, Rodriguez-Malaver and Vit, 2007)**. **Bogdanov (2011)** expresses the relationship between fermentation risk and water content as follows. If the water content is 17% or less - honey is safe regardless of the number of yeasts. If the water content is 17.1 – 18% - honey is safe for yeasts up to 1000 CFU.g^{-1} (3 log CFU.g^{-1}). If the water content is 18.1 – 19% - honey is safe for yeasts up to 10 CFU.g^{-1} (1 log CFU.g^{-1}). If the water content is 19.1 – 20% - honey is safe for yeasts up to 1 CFU.g^{-1} (<1 log CFU.g^{-1}). And finally, if the water content is over 20% - it is a constant risk of fermentation in honey. Similarly, **Subramanian, Umesh Hebbar and Rastogi (2007)** mention, that raw honey sample containing more than 20% moisture readily undergoes fermentation irrespective of the initial yeast count and reduction of moisture content below 17% is considered to be a safe level for retarding yeast activity. The water content in honey is one of the most important criteria of honey quality. The lower the water content, the more viscous, thick and unchanged honey is since such conditions in honey are unsuitable for the growth of osmophilic yeasts and thus prevent fermentation of honey **(Korošec et al., 2016; Čermáková, Chlebo and Husáriková, 2017)**. A previous study **(Kňazovická et al., 2020)** on the physico-chemical parameters of honey from 2018 (our first 20 samples) concluded that the water content of the honey did not exceed 20% and its average value was 17.3%.

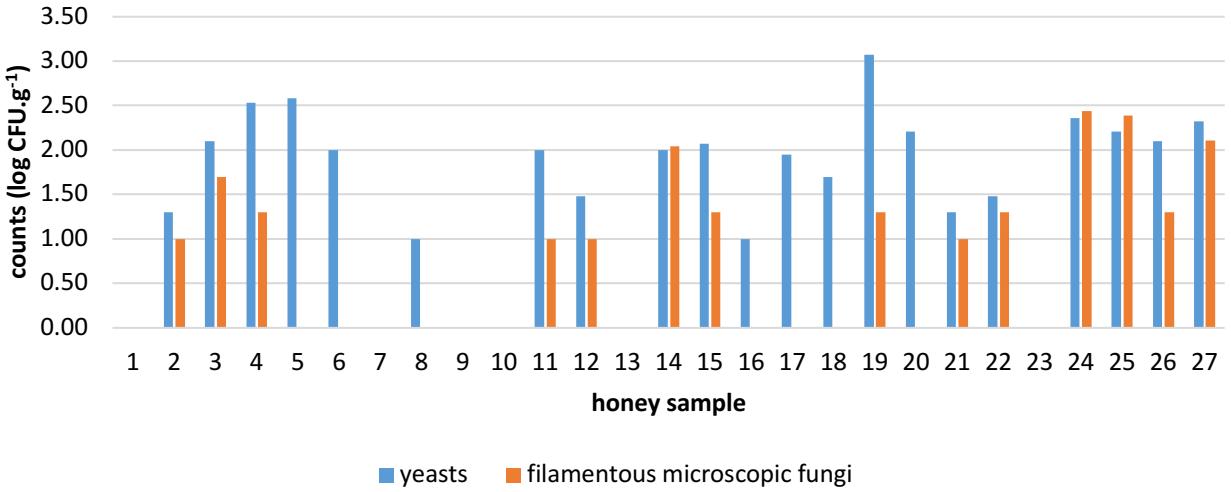

Figure 1 Counts of detected microorganisms in honey samples of Slovak origin.

From this perspective, except for the flower honey sample no. 19, we can consider our honey as safe.

In this study, we did not perform yeast genera identification, but the most common yeasts isolated from honey include for example *Schizosaccharomyces*, *Saccharomyces,* and *Zygosaccharomyces* **(Silva et al., 2017; Tančinová et al., 2017)**. Among the isolated Portuguese honey samples, *Rhodotorula mucilaginosa*, *Candida magnoliae,* and *Zygosaccharomyces mellis* were the predominant species. *Candida* spp. represented more than 45% of the honey isolates **(Carvalho et al., 2010)**. Authors **Sinacori et al. (2014)** gave information about the isolation of *Debaryomyces hansenii*, *Zygosaccharomyces rouxii*, *Zygosaccharomyces mellis*, *Aureobasidium pullulans,* and *Cryptococcus uzbekistanensis* species from honey. Among them, *Cryptococcus* species were associated with human pathogenicity. *Cryptococcus neoformans* is characterized as opportunistic human pathogen, able to infect the central nervous system **(Ashbee and Bignell, 2010)**. **Čadež et al., (2014)** isolated from bee bread and honey in Hungary five yeast strains representing a hitherto undescribed yeast species. The name *Zygosaccharomyces favi* sp. nov. is proposed for this new yeast species, which based on phenotype can be distinguished from related *Zygosaccharomyces* species by its obligate osmophilic nature.

In terms of filamentous micromycetes, the highest numbers we recorded in honeydew honey samples no. 24 and 25 (2.44 a 2.39 log CFU.g^{-1}). Honeydew kinds of honey are generally reported to contain fungal hyphae and algae when microscopically examined because bees collect honeydew, which is the product of aphids inhabiting green parts of plants. Bees along with honeydew collect additional structures, such as hyphae or spores of fungi, plant pathogens, and algae **(Escuredo, Fernández-González and Seijo, 2012)**. However, we have found that honeydew honey does not necessarily show higher numbers of viable filamentous fungi, because in 4 of the 9 honeydew honey samples we did not detect any occurrence of filamentous fungi. Moreover, no fungi (and hence yeasts) were recorded in one of them.

Considering the genera representation of filamentous fungi, we confirmed the occurrence of the following genera: *Alternaria*, *Arthrinium*, *Aspergillus* (including previously named as *Eurotium*), *Aureobasidium*, *Cladosporium*, *Mucor*, *Penicillium,* and *Stemphilium*. Isolates of the genus *Penicillium* were recorded with the highest isolation frequency (41%). For comparison, research by authors **Sinacori et al. (2014)**, performed with honey samples of different blossoming, pointed out the occurrence of different fungal species - *Alternaria alternata*, *Aspergillus niger*, *Aspergillus proliferans*, *Aspergillus spelunceus, Chaetomium globosum, Cladosporium cladosporioides, Daldinia concentrica, Emericella discophora, Emericella qinqixianii*, *Penicillium corylophilum*, *Penicillium decumbens*, *Penicillium polonicum*, and *Penicillium echinulatum*, of which *P. corylophilum* and *A. niger* were the most frequent, but in the low count, indicating that the honey is capable of containing multiplication of these fungi. **Rodríguez-Andrade et al. (2019)** have surveyed and evaluated the presence of xerotolerant and xerophilic fungi in a set of honey bee samples collected from across Spain. From 84 samples, a total of 104 fungal strains were isolated. They identified 32 species distributed across 16 genera, most of them belonging to the ascomycetous genera *Aspergillus*, *Bettsia*, *Candida*, *Eremascus*, *Monascus*, *Oidiodendron*, *Penicillium*, *Skoua*, *Talaromyces,* and *Zygosaccharomyces*. As a result of this survey, eight new taxa were proposed. Other fungi rarely found in their study were *Alternaria multiformis*, and the mucoralean *Cunninghamella bertholletiae*, *Mucor plumbeus*, and *Rhizopus oryzae*. These probably represent environmental contaminants. **Martins, Martins and Bernardo (2003)** tested 80 multi-species flower kinds of honey, commercially available in Portugal. They focused on the spores of bacteria and fungi. Yeasts and microscopic filamentous fungi were detected in 88.8% of the samples, identifying 3 filamentous fungus genera - *Aspergillus*, *Penicillium,* and *Mucor* and 2 yeast genera - *Saccharomyces* and *Candida*. *Aspergillus* spp. fungi are ubiquitous and associated with disease in many insects, plants, animals, and man. They are regarded as opportunistic pathogens that require immunocompromised hosts to establish infection.

Microbiological studies have shown a high prevalence of *Aspergillus* spp. in apiaries which occur saprophytically on hive substrates. However, the specific conditions required for pathogenicity to develop remain unknown **(Foley et al., 2014)**. The results of **Foley et al. (2014)** confirm the ubiquity of *Aspergillus* spp. in the apiary environment and highlight their potential to infect both larvae and adult bees unknown. **Bignell (2010)** reported, that food with acidic pH, low humidity, and high concentration of sugars, such as honey, are sources for growth of the fungi *Aspergillus glaucus*. In our study, *Aspergillus* species were isolated from 19% honey samples.

The analysis of filamentous microscopic fungi is now highly emphasized **(Kačániová et al., 2006)**. This is because they can produce mycotoxins that adversely affect human health and reduce the hygienic quality of food. However, the presence of fungi does not imply the presence of mycotoxin; it has necessary ideal conditions such as high water activity, the presence of sugars, and the presence of organic acids capable of reducing pH. Necessary conditions for fungal growth are not always the necessary conditions for the production of mycotoxins **(Barkai-Golan and Paster, 2008)**. Several of the fungi found in honey samples (*Aspergillus* spp. and *Penicillium* spp.) are potential producers of mycotoxins, but this does not mean that the honey may represent a risk to the health of the consumer, because (in general) the production of mycotoxins or the fungal growth is suppressed at water activities lower than 0.70, as is the case of honey (a_w of 0.60 or less) **(Rodríguez-Andrade et al., 2019)**. Despite inappropriate condition found in honey for mycotoxin production, it is important to say that the presence of the fungus can also cause disease in different ways, as induction of allergic responses and infections **(An, 2004)**.

Honey with added fruit

It is generally known that the raw materials must be of excellent quality to produce a good quality product. If poor quality raw materials with certain defective elements are used, these defects will also pass to the final product. High-quality mature honey is considered to be a food with a minimum number of microorganisms and many beneficial effects in terms of human nutrition compared to other foods and no or negligible health risks. In this part of the study, we focused at first on mycological analysis of the raw materials used for the preparation of honey with the addition of fruit. Secondly, mycological analyses of the final products were carried out. Information concerning the counts of isolated fungi **(Figure 2)** is supplemented by information on the water activity of the individual samples **(Figure 3)**, which has a significant impact on their occurrence.

Analysis of the basic raw material - rapeseed pasted honey did not show the presence of microscopic fungi. The water activity of this honey sample was 0.567. **Finola, Lasagno and Marioli (2007)** reported that the low number of filamentous micromycetes in honey is a good indicator of suitable conditions in the apiary environment.

Honey with blueberries

Regarding blueberries, only frozen fruits had a water activity value suitable for the growth of microorganisms (0.928). Yeast had the highest values in the lyophilized raw material. This is also associated with the highest yeast value in honey with lyophilized blueberries. According to **Dobiáš (2004)**, microorganisms are present in lyophilized products in the inactive state, but when added to honey, they may rehydrate and thus become active. Similarly, the highest number of filamentous fungi we detected in the lyophilized blueberries and the honey with lyophilized blueberries. Filamentous micromycetes were not present in dried blueberries and the product thereof. The water activity of the products ranged from 0.524 to 0.592 – optimal water activity in terms of long-term product stability.

The filamentous fungi most commonly identified in blueberries, were zygomycetes *Rhizopus* spp. and *Mucor* spp. The presence of *Rhizopus* spp. was also observed in honey with lyophilized blueberries. Blueberries can be perishable at high moisture content. After blueberry maturation, physiological changes and tissue softening will occur. The fruits used for the manufacture of the products must not be oppressed or rotten, must be free from infested or otherwise damaged parts **(Zambiazi et al., 2016)**.

This product may have significant nutritional properties. **Zambiazi et al. (2016)** investigated the antioxidant activity and bioactive substances in blueberries and honey products with the addition of blueberries. Honey with the addition of blueberries achieved excellent results in this experiment regarding the phytochemical content and antioxidant capacity, due to the presence of both raw materials in this product.

Honey with cranberries

In terms of the highest water activity (0.905) of raw materials, fresh cranberries appear to be the most hazardous. After the addition of fresh cranberries to honey, the water activity of the honey partially increased (0.640). According to **Woodbine (1983)**, osmophilic yeasts could be able to grow in this water activity. However, yeasts were found at relatively low values only in samples of fresh and lyophilized cranberries. They were not even present in honey with lyophilized cranberries, although they were detected in the raw material. The average number of yeasts found in honey with fresh and dried cranberries was in both cases at the limit of detection of 1 log $CFU.g^{-1}$.

The occurrence of filamentous micromycetes in raw materials can be considered as low. According to **Woodbine (1983)**, they can grow in a water activity range of 0.87 – 0.80 and the xerophilic filamentous micromycetes have a water activity range of 0.75 – 0.65. We detected representatives of *Cladosporium* and *Penicillium* genera. Within the products, filamentous fungi were found only in a sample of honey with fresh cranberries, where their number was at the limit of detection. **Tadych et al. (2015)** mentioned, that cranberry fruit is a rich source of bioactive compounds that may function as constitutive or inducible barriers against rot-inducing fungi. It is well known that it naturally contains benzoic acid, and is commonly added as a preservative to many other fruit and berry products. Higher content of benzoic acid guarantees a good shelf life of fresh and processed fruits **(Mateljan, 2017)**.

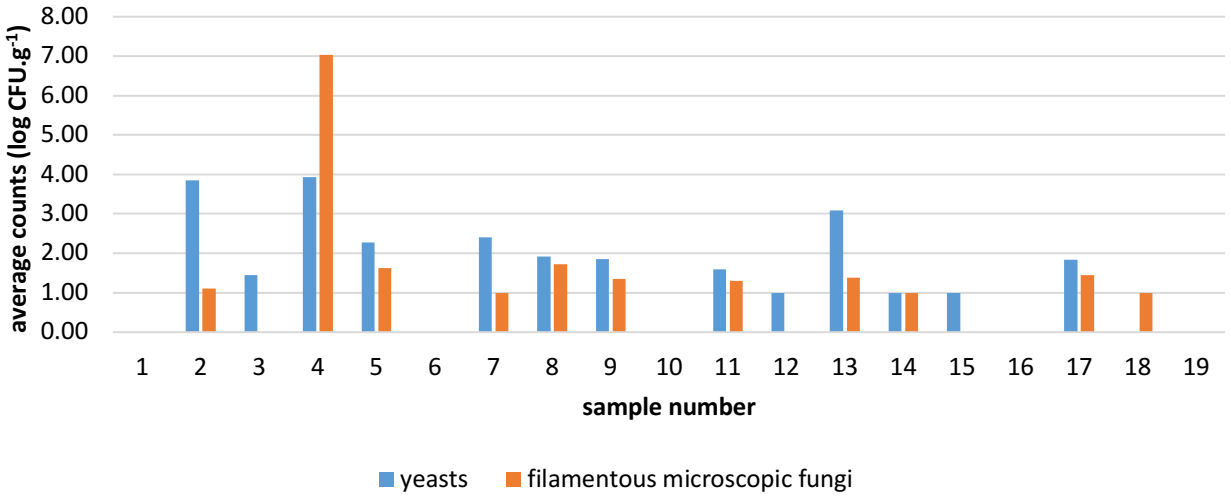

Figure 2 Mean counts of microorganisms detected in raw materials used for the production of honey with additives and in final products.
Note: (1 – honey, 2 – frozen blueberries, 3 – dried blueberries, 4 – lyophilized blueberries, 5 – fresh cranberries, 6 – dried cranberries, 7 – lyophilized cranberries, 8 – frozen red currants, 9 – dried red currants, 10 – lyophilized red currants, 11 – honey with frozen blueberries, 12 – honey with dried blueberries, 13 – honey with lyophilized blueberries, 14 – honey with fresh cranberries, 15 – honey with dried cranberries, 16 – honey with lyophilized cranberries, 17 – honey with frozen red currants, 18 – honey with dried red currants, 19 – honey with lyophilized red currants).

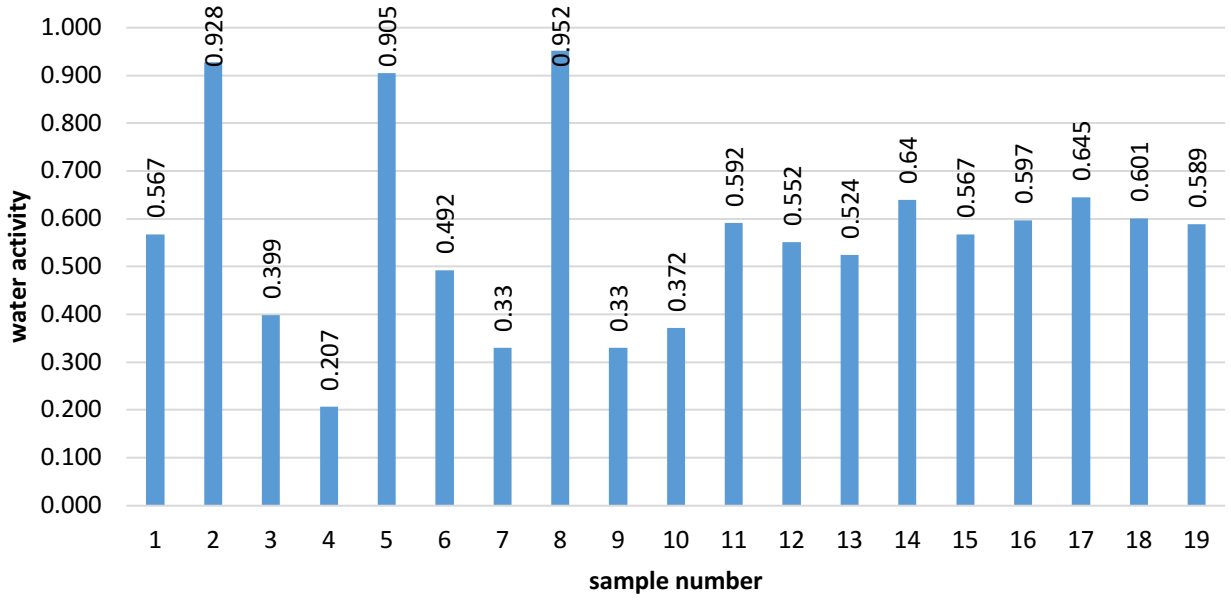

Figure 3 Water activity (a_w) of raw materials used for the production of honey with additives and of final products.
Note: (1 – honey, 2 – frozen blueberries, 3 – dried blueberries, 4 – lyophilized blueberries, 5 – fresh cranberries, 6 – dried cranberries, 7 – lyophilized cranberries, 8 – frozen red currants, 9 – dried red currants, 10 – lyophilized red currants, 11 – honey with frozen blueberries, 12 – honey with dried blueberries, 13 – honey with lyophilized blueberries, 14 – honey with fresh cranberries, 15 – honey with dried cranberries, 16 – honey with lyophilized cranberries, 17 – honey with frozen red currants, 18 – honey with dried red currants, 19 – honey with lyophilized red currants).

Honey with red currants

Red currants are a valuable component of a healthy diet because they are an excellent source of ascorbic acid, anthocyanins, and minerals **(Nour, Trandafir and Ionica, 2011)**. The water activity of frozen red currants was the highest (0.952) of all raw materials used in this study.

Woodbine (1983) reports that sporulating bacteria, gram-negative rods, or some yeasts can multiply in such processed fruits. In both dried and lyophilized currants, the water activity values were considerably lower and the growth of microorganisms would not be possible. The highest number of yeasts and filamentous fungi was recorded in frozen currants. Based on this finding, we assume their occurrence in the composite product as well, which was confirmed. Also, this product had the highest water activity (0.645). However, the yeast and filamentous fungi counts were not high (below 2.00 log CFU.g^{-1}) and some self-regulation is possible over time. The dominant fungi isolated from this raw material were *Cladosporium* spp. Yeasts or filamentous micromycetes did not occur in

lyophilized currants or honey with their addition. Yeasts were also not identified in honey with dried fruit.

CONCLUSION

Honey mycobiota can vary in qualitative and quantitative terms, depending on many factors, such as water activity, or various physico-chemical and biological parameters. For mycological diversity, which can have a significant impact on its quality and safety, it is one of the relatively few investigated commodities. Both yeast and filamentous microscopic fungi can affect honey properties. A total of 27 kinds of honey tested in this study have shown good mycological quality. For yeast occurrence, we can consider our honey samples as safe (except one flower honey sample) because they did not exceed the value 3.00 log CFU.g^{-1}. The average value in positive samples was 1.94 log CFU.g^{-1}. Similarly, the occurrence of filamentous microscopic fungi in honey samples does not present a significant risk. Their numbers did not exceed 2.50 log CFU.g^{-1} and the average number in positive samples was 1.51 log CFU.g^{-1}. Although we have observed the presence of potential mycotoxin producers, they do not have suitable conditions for production.

In the case of good physico-chemical properties of honey and in particular of sufficiently low water activity, microscopic fungi may survive, but they do not multiply and thus spoil the honey. On the other hand, in the production of various honey products, it is very important to have these properties of products under control, as these microorganisms could reproduce, cause unwanted changes and affect its safety. To produce honey with added fruit we have to use raw materials of excellent (microbiological) quality. Deficiencies in honey, blueberries, cranberries, and red berries can lead to the spoiling of the final product. It is also important to choose the appropriate combination and concentration of raw materials. The study showed that cranberries were the most appropriate addition from a mycological point of view. This may also be related to the reported benzoic acid content. In the case of cranberries and red currants, their lyophilized and dried forms were the most suitable. We have not observed the presence of yeasts or filamentous micromycetes in honey with lyophilized cranberries or currants. In the case of honey with blueberries, the dried fruit variant was the most suitable. Based on the water activity of honey with additions, all products appeared to be stable.

The use of honey in products that receive no or limited heat treatment may require additional tests. More information on the source and control of microorganisms in honey is needed to answer the concerns currently facing the industry. Moreover, it would be advisable in further research to monitor the products in storage studies.

POLLEN DIVERSITY IN HONEY OF THE CZECH REPUBLIC IN THE 2019 SEASON

Matej Pospiech, Simona Ljasovská, Dalibor Titěra, Vojtěch Kružík, Zdeňka Javůrková, Bohuslava Tremlová

ABSTRACT

Honeybees are important pollinators. As a side product of pollination, honeybees produce honey, as a natural sweetener. The source of honey depends on the hive location. In specific conditions honeybees produce monofloral honey, but more common are polyfloral kinds of honey. In this study honey from the Czech Republic in the 2019 season was evaluated by melissopalynology analysis. The common botanical taxa in the Czech Republic were determined and season impact to pollen taxa was compared for dominant pollen taxa. The taxonomic distribution of pollen in Czech honey was stable during the year. The average number of species was 11.52 taxa per sample. The dominant pollen source in Czech honey was the *Brassicaceae* family. The high pollen content in honey was confirmed also in the *Rosacea* family (fruit tree), *Ubelliferacae* family and *Myosotis* genus. During the year the pollen taxa were equally distributed in honey. Seasonal effects were confirmed only in *Salix* genus, *Ubelliferacae* family and *Phacelia* genus. Seasonal effects correspond with the blooming season and honeybee handling in the hive was also confirmed. High variability during the season and hive location was confirmed for other taxa.

Keywords: melissopalynology; botany taxa; pollen; biodiversity; adulteration

INTRODUCTION

The Czech Republic is one of the Central European countries. Its geographical position roughly in the center of the European continent means that the flora in this country includes plant species from the cold north and warm south as well as the oceanic west and continental east. The country is covered by a heterogeneous mosaic of cultural landscapes with arable fields, deciduous, mixed and coniferous forests, meadows, pastures, and human settlements. The dominant type of natural vegetation is a forest. Natural treeless vegetation includes alpine and subalpine grasslands, steep rocky slopes, steppe, peat bogs, and natural water bodies **(Kaplan, 2012)**. The flora includes 148 families of vascular plants, 925 genera, 3754 species and subspecies, and 618 hybrids. Genera with 30 or more species include *Taraxacum* (221 species), *Rubus* (127), *Carex* (85), *Hieracium* (59), *Pilosella* (59), *Veronica* (35), and *Trifolium* (34), four of which include agamospermous species, which accounts for the high diversity. Families richest in species are the *Asteraceae* (666 species), *Rosaceae* (315), *Poaceae* (273), *Fabaceae* (171), *Brassicaceae* (148), *Cyperaceae* (127), *Lamiaceae* (112), *Caryophyllaceae* (108), and *Apiaceae* or *Umbelliferae* (99) (Danihelka, 2013). Due to the human factor activity, the landscape changes and some plant species gradually disappear (Grulich, 2012), while other non-native plants are introduced into the Czech ecosystem **(Pyšek et al., 2012)**. The list of botanical species is extensive. In addition to the diversity and stability of the landscape, some taxa also participate in the honey collection of bees in the Czech Republic. The share of individual plants in the honey collection varies. It all depends on the amount of nectar and pollen produced, which is reflected in the different attractiveness of botanical species for bees. The pollen grains present in honey can be used to determine the botanical origin of it **(Von Der Ohe et al., 2004)**.

Table 1 Number of pollen grains in selected unifloral honey **(Demianowicz, 1964)**.

Type of unifloral honey	The average number of pollen grains / 10 g of honey,
Myosotis silvatica	147,456,000
Brassica napus	72,000
Taraxacum officinale	18,000
Malus domestica	18,000
Robinia pseudoacacia	1,125
Phacelia tanacaetifolia	72,000
Tilia sp.	2,250

However, when determining the botanical origin, it is necessary to consider the unlike the production of pollen by botanical taxa, which was experimentally verified in the study by Deamianowics 1964 **(Table 1)**.

At present, the pollen profile typical for Czech honey has not been described. Such data can be used not only to expand knowledge but can also play a crucial role in preventing honey adulteration. The origin of honey can be proven under certain conditions based on the pollen profile that represents the area where the honey comes from **(Aronne and de Micco, 2010; Soares et al., 2017)**. Some countries have their pollen profile of honey described. Monofloral honey is the ones characterized most commonly **(Persano Oddo and Piro, 2004; Oddo et al., 1995; Persano Oddo et al., 2004; Feás et al., 2010; Karabagias et al., 2020)**. Fewer studies have focused on the pollen profile of polyfloral honey **(Kuś et al., 2018; Čeksteryte, Kurtinaitiene, and Balžekas, 2013; Kale Sniderman et al., 2018; Puusepp and Koff, 2014; Jones and Bryant, 2014)**. For the characterization of monofloral honey, in particular, the number of pollen grains of the species as well as the amount of accompanying pollen grains must be taken into account.

This study aims to bring new knowledge about the pollen profile of Czech honey in 2019.

Scientific hypothesis

The pollen profile of honey is closely dependent on the area of collection of nectariferous and nectarless plants around the hive. Pollen profile variation during the year was verified in this study.

MATERIAL AND METHODOLOGY

Sampling Collection

The experimental material was collected from individual colonies of western honeybee *Apis mellifera carnica*. One or two sealed honeycombs from each colony were extracted using a common hand extractor. All samples were from the 2019 season. The samples were collected from May to August and classified into four groups depending on the month of their collection. The 163 samples were evaluated from 130 different areas of the Czech Republic with various geographical profiles and botanical origins. Pollen profile in posterior months is influenced by the natural handling of honey in the hive. The honey handling can cause temporal and also positional shifts according to beekeeping practice **(Vorwohl, 1972)**.

Pollen Analysis

Honey samples were prepared following the guidelines of the International Commission of Bee Botany published by von der Ohe **(Von Der Ohe et al., 2004)**. Glycerol-gelatine preparations were made in duplicate for each honey. The pollen spectrum was evaluated by Nikon Eclipse Ci-L (Nikon, JPN). The slide was automatically scanned by the motorized stage with the focus motor of Proscan III (Prior, USA). Images were captured in stag files using DFK 23U274 camera (Imaging Source, GER). The position was chosen randomly. The magnifications used were 100x and 400x.

The pollen spectrum was classified according to Stawiarich **(Stawiarz and Wróblewska, 2010)** into four groups >45% dominant, 16 – 45% secondary, 3 – 15%

important minor and <3% minor pollen. Pollen discrimination was performed according to Moar **(Moar, 1985)**. At least 300 pollen grains were counted in each preparation, where pollens were identified according to melissopalynology atlas **(El-Labban, 2020)** to the most possible exact taxon – species, genus, type of structure or family in classes >3%. Pollen not clearly identified by the evaluator was evaluated by morphometric and spectral characteristics obtained from image analysis. Referee values are shown in **Table 2**.

Statistical analysis

The data were processed statistically using the 2014.5.03 XLSTAT software (Addinsoft, USA). The normality test confirmed the not normal distribution of the data. A nonparametric Kruskal-Wallis test was used to compare the pollen profile in months and the diversity of pollen taxa during the year.

RESULTS AND DISCUSSION

Honey samples were collected during the 2019 beekeeping season, specifically from 18 May to 16 August 2019. The period was selected to include both spring and summer honey phases. Such a long period of the collection of samples enables covering botanical taxa of nectar-producing and pollen-producing plants involved in honey production in the Czech Republic. 163 honey samples were taken. Of these, 30 honey samples could be characterized as monofloral concerning their pollen spectrum. These were namely (*Brassica sp.* 8; *Prunus sp.*, *Pyrus sp.* 18; *Tilia sp.* 4). It is generally stated that if there is more than 45% of pollen grains of one species in certain honey, the honey can be described as single-species or monofloral. However, this rule does not apply to all botanical taxa. Some plants differ in their pollen-producing capacity, both in the high content of pollen grains and, conversely, due to the low content of pollen grains **(Demianowicz, 1964)**. The rule that several botanical species contribute to the composition of nectar and pollen content even in monofloral honey also applies **(Louveaux, Maurizio, and Vorwohl, 1970)**. Of the analyzed samples, 133 kinds of honey were polyfloral. The representation of individual taxa in Czech honey is summarized in **Figure 1** and these taxa are divided into four groups, namely <3% minor pollen, 3 – 15% important minor 16 – 45% secondary and >45% dominant.

The wide pollen spectrum in Czech honey is characteristic of Mediterranean areas with a high degree of urbanization and agricultural activity. Even about the large sown areas of crops in the Czech Republic, Czech honey retains in most cases the character of polyfloral honey. Differences in diversity by hive location were described in a French study **(Odoux et al., 2012)**. Here, the authors confirmed a reduction in the diversity of pollen taxa in agricultural areas. For the Czech Republic, however, there has been no similar study yet that would allow a comparison of the change in the number of pollen taxa in agricultural areas. The results of the study showed an average of 11.63 pollen taxa in pollen with a proportion of >3% occurrence of pollen grains in honey **(Figure 2)**.

Another monitored parameter was the differences in the number of pollen taxa throughout the honey season. Taxa with a frequency of presence greater than 3% pollen grains were observed **(Figure 2)**. **Figure 2** shows the number of pollen taxa during the year per sample. A shorter distance between curve points means a shorter period between sampling in a given period. The time interval between sampling at the beginning and end of the season is longer. Both the climatic conditions and the source of nectar at the given habitats affect the time interval.

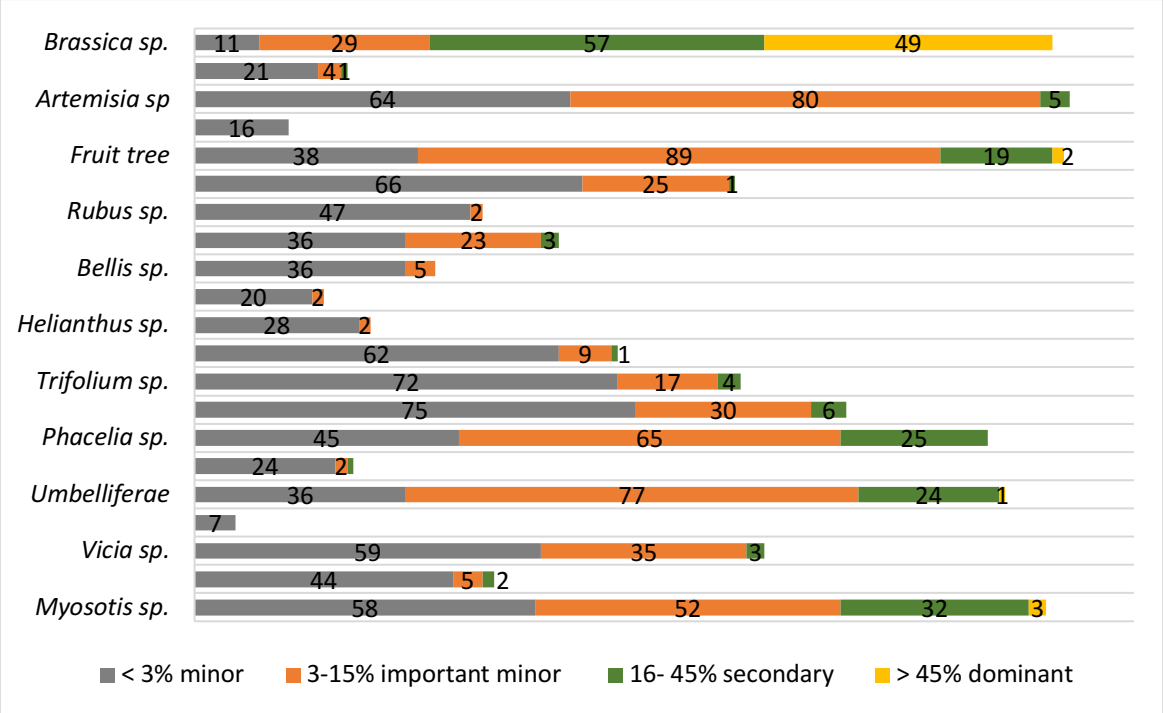

Figure 1 Absolute frequency of major pollen taxa in Czech honey in 2019.

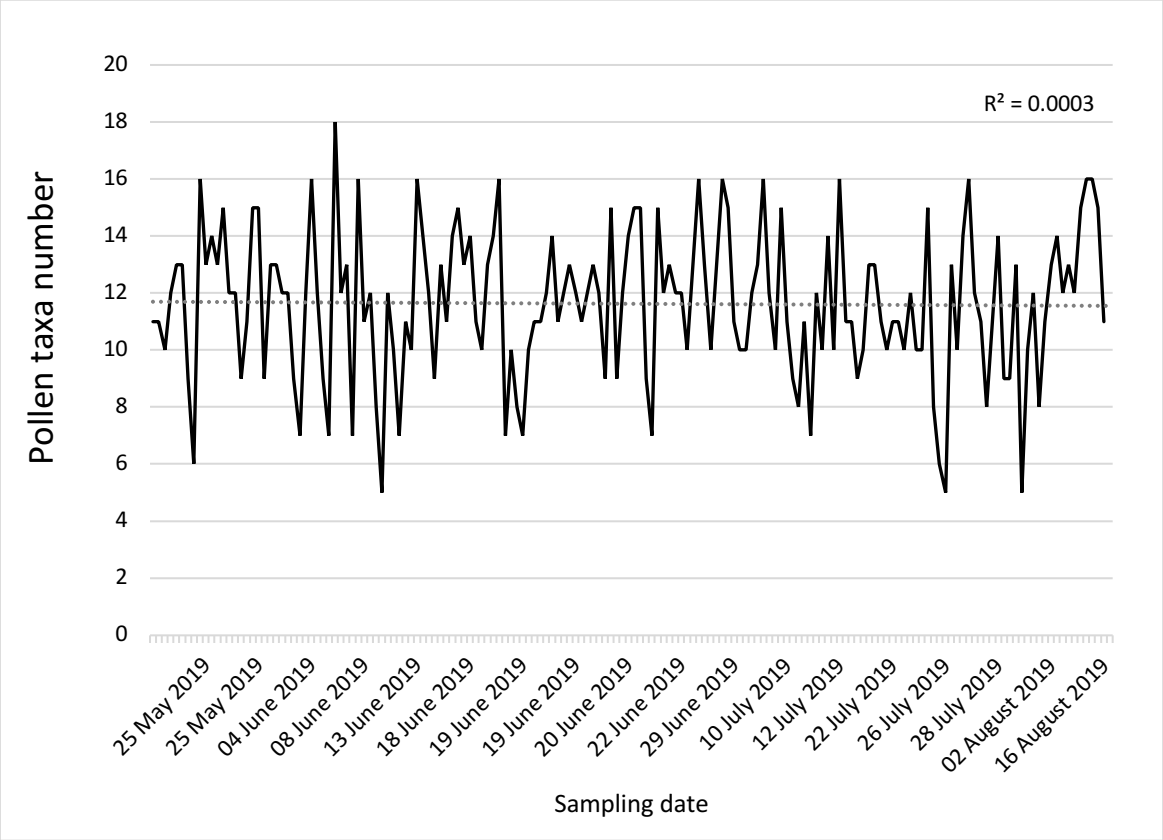

Figure 2 Taxa diversity in 2019.

For the Czech Republic, no statistically significant differences were recorded between the date of honey extraction and the diversity of pollen taxa (p >0.05). This result is also confirmed by **Figure 2** which does not confirm the change in individual months. The differences in the number of pollen taxa correspond to specific habitats, not to the time of the year. The average diversity in the spring was 12 taxa in May and 11.62 taxa in June. In summer it was 10.83 taxa in July and 11.63 taxa in August. The result is in agreement with the study **(Avni et al., 2014)** where, using chemical analysis, the authors showed that the amount of pollen in the pollen collection does not differ during the year, but is dependent on the habitat. Primarily in the spring period, pollen is responsible for the rapid development of bee colonies **(Odoux et al., 2012)** and subsequently contributes to honey yields. In the conditions of the Czech Republic, spring pollen includes primarily pollen of fruit trees. Fruit tree pollen is considered a very good source of protein for bee colonies **(Roulston and Cane, 2000)**. Due to its nutritional importance, fruit tree pollen plays an important role in bee nutrition and is associated with a high preference for bees. Even concerning lower pollen-producing capacity **(Table 1)** than in *Brassica sp.,* the pollen of fruit trees was represented in honey on average in the amount of 8.82%, in most cases, it was an important minor **(Figure 1)**. Differences between the compared months were not confirmed, but the proportion of pollen grains of fruit trees in later months, as well as other pollen sources, confirm the pollen cycle in honey within a year **(Figure 3** and **Figure 4)**. The occurrence of pollen of spring botanical species in later months is mainly due to the growth of the brood and the transport of pollen both on bees as well as by bees to their honeycombs. The influence of the pollen profile on the distance from the brood, but also the humidity in the hives was confirmed by Spanish authors (**Da Fernandez and Ortiz, 1994)**. Fruit trees include several genera and even more cultivars, but concerning their close relationship, the morphology of the pollen grain is similar, although there are differences between the pollen grains, especially in the color of the pollen **(Pospiech et al., 2019)**. For melissopalynological purposes, they are often taken as one group **(Stawiarz and Wróblewska, 2010)**. The fact that the honeybees' visits to flowers are not influenced by an exclusive species preference also makes it difficult to determine the exact species. On the other hand, the species non-specificity of the honeybee is used in orchards, where the bee is a significant pollinator **(Cunningham et al., 2016)**. Single-species honey of fruit trees is not widespread. Their occurrence has been described, for example, in Bulgaria. Due to their sensory closeness, they may be confused with other spring honey, primarily with black locust honey **(Atanassova, Yurukova, and Lazarova, 2012)**. A high proportion of pollen from *Brassicaceae* and fruit trees was also found in Polish polyfloral honey, see **Table 3** (**Stawiarz and Wróblewska, 2010)**.

Other important sources of pollen in spring honey include pollen of the *Brassicaceae* family (especially *Brassica sp.*), dandelion, hazel, and black locust **(Figure 3)**. High *Brassica sp*. pollen content is recorded primarily in honeybee colonies near the agricultural areas with these plants **(Danner et al., 2016)**. In these areas, honey can also reach the character of monofloral honey.

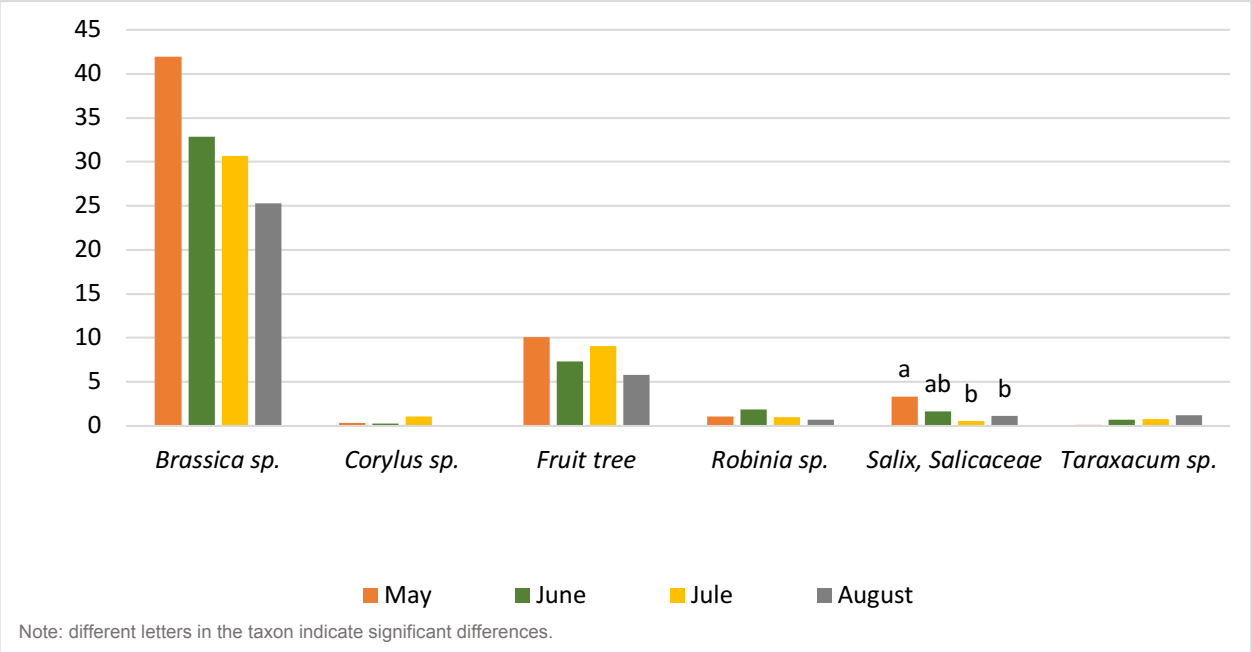

Figure 3 Average occurrence of pollen of spring botanical taxa.

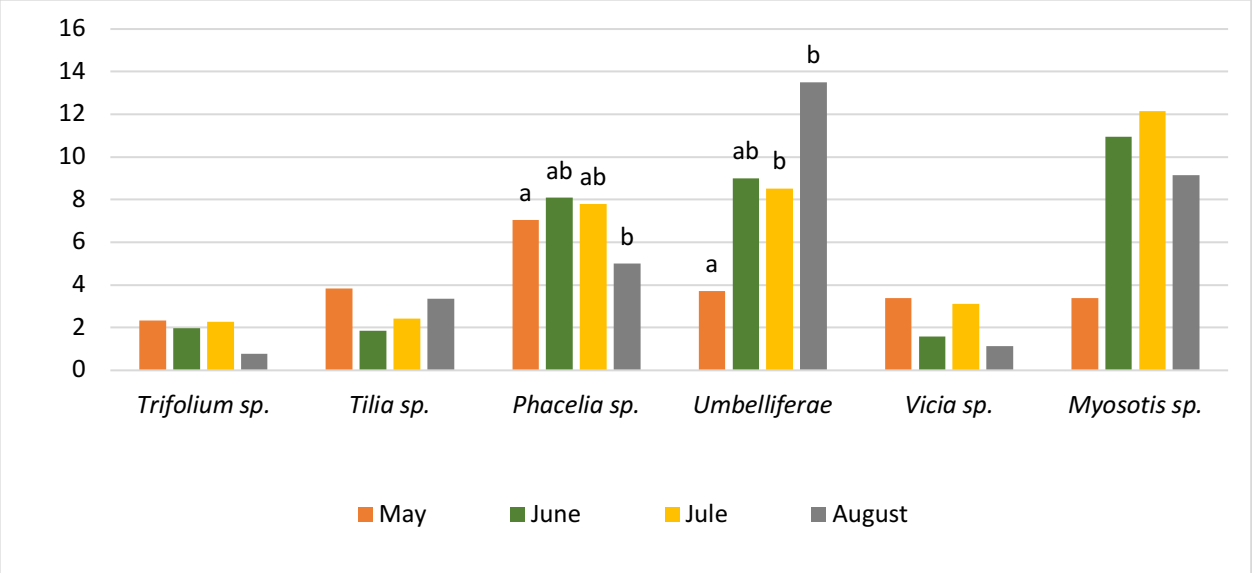

Figure 4 Average occurrence of pollen of summer botanical taxa.

Due to the high pollen-producing capacity, honey with a rapeseed pollen content of more than 80% can be considered monofloral rapeseed honey **(El-Labban, 2020)**. Of the honey analyzed in our study, 8 honey samples would meet this definition. However, high content of rapeseed pollen grains was also recorded in polyfloral honey, with more than 16% of pollen grains in 106 honey samples.

The high content of pollen grains of *Brassica sp.* is mainly due to its pollen-producing capacity **(Table 1)**. It was experimentally verified that it belongs among the most pollen-producing plants involved in spring honey collection **(Demianowicz, 1964)**. We found the average proportion of rapeseed pollen at 35.43%, in most cases it was the secondary pollen **(Figure 1)**. The high proportion of rapeseed pollen was also confirmed in Polish and Estonian honey **(Stawiarz and Wróblewska, 2010; Puusepp and Koff, 2014)**.

Salicaceae pollen is considered to be an important source of protein needed for honeybee colony development, although willow also provides some nectar. Honeybees mainly search for male flowers for their source of pollen grains **(Dötterl et al., 2014)**. The average proportion of *Salicaceae* pollen was 4.2% and in most cases, it was minor pollen. Our results showed statistically significant differences in the amount of *Salicaceae* pollen grains in May-June honey, compared to July-August honey **(Figure 3)**. The august increase shows also the temporal shift of pollen caused by handling in the hive as confirmed previously by **(Da Fernandez and Ortiz, 1994)** and **(Vorwohl, 1972)** for *Myosotis* pollen. Although monofloral *Salicaceae* honey is not described in the Czech Republic, monofloral *Salicaceae* honey can be found in Croatia, Spain, Lithuania, and New Zealand **(Jerković and Marijanović, 2010)**.

Table 3 Percentage of pollen in polyfloral honeys of selected botanical taxa.

	Czech Republic*			Portugal (Sousa et al., 2014; Feas et al., 2012)			Poland (Stawiarz and Wróblewska, 2010)			Estonia (Puusepp and Koff, 2014)

Umbelliferae	10.03	0.29	65.23	-	-	-	-	-	-	15.80	0.50	82.80

Note: * honeys with a pollen content higher than 0 are included.

Robinia pseudoacacia pollen was confirmed in honey in all monitored months. Its average representation was 2.43%. In most cases, it had a minor representation, which corresponds to the findings by other authors **(Stawiarz and Wróblewska, 2010; Čeksteryte, Kurtinaitiene, and Balžekas, 2013)**. In June, the content of *Robinia pseudoacacia* pollen was the highest and one sample contained 16.01% of this pollen. Although some authors state that >15% of *Robinia pseudoacacia* pollen indicates monofloral honey **(Oddo et al., 1995)**, more authors are inclined to the 20% limit **(El-Labban, 2020)**. The reason for the different minimum limit of pollen grains in single-species black locust honey is mainly the low pollen-producing capacity **(Table 1)** and the high nectar-producing capacity of black locust.

Monofloral dandelion honey is also characterized by a low content of pollen grains, which is usually in the range of 5 – 15% in monofloral honey as well **(Jerković et al., 2015)**. In the pollen profile of these honey, dandelion pollen is often lower than the associated species, such as *Salix* or *Cruciferae* **(Persano Oddo and Piro, 2004)**. The average proportion of dandelion pollen was 3.62% and in most samples, it was minor pollen **(Figure 1)**. According to the pollen profile, one sample would meet the 15% condition. The accompanying pollen was *Myosotis sp.* pollen (23.33%), *Phacelia sp.* pollen (11.03%,) and fruit tree pollen (10.26%). Various concomitant pollens (*Salix sp.* 33% and *Brassica sp.* 16%) were also confirmed in the study **(Jerković et al., 2015)**. The lowest proportion offspring-flowering trees in Czech honey was represented by hazel pollen, **Figure 3**. The average amount reached 2.96% and in most cases,s it was minor pollen. Hazel is one of the spring pollen-producing plants. The reason for its low incidence might be climatic conditions or the use of pollen exclusively for the development of honeybee colonies **(Odoux et al., 2012)**. The presence of hazel pollen in honey has also been confirmed in Estonia **(Puusepp and Koff, 2014)**, Germany, Australia **(Bibi, Husain, and Naseem, 2008)**, and Lithuania **(Čeksteryte, Kurtinaitiene, and Balžekas, 2013)**.

The representation of the main summer pollen taxa is summarized in **Figure 4**. *Myosotis sp.* pollen had the highest proportion in honey (10.99%), but even so, it had a minor or important minor representation in most samples **(Figure 1)**. Forget-me-not is one of the plants with the highest pollen-producing capacity **(Table 1)** and for a honey to be classified as monofloral honey, the forget-me-not pollen content must be more than 90% **(van der Ham, Kaas, and Kerkvliet, 1999)**. However, monofloral forget-me-not honey is rare in Europe **(Persano Oddo et al., 2004)**. The occurrence of *Myosotis sp* pollen in honey has been confirmed by several authors, with a varying frequency and amount of this pollen in honey **(Stawiarz and Wróblewska, 2010; Gençay Çelemli et al., 2017; Downey et al., 2005)**. The second most abundant pollen was pollen of the *Umbelliferae* family (10.03%), similarly to *Myosotis* pollen, and in this case, the amount of pollen in honey varies, as reported by individual authors. Some authors consider it minor pollen **(Lieux, 1981)**, some consider it dominant pollen **(Marco et al., 2012)**. In Europe, some species of this family are also found in single-species honey (*Daucus Carota, Coriandrum sativum*) **(Persano Oddo et al., 2004)**. The percentage of pollen of the *Umbelliferae* family in the May-June period differed significantly from the July-August period. The differences are due to the blooming period of this family, which is mostly summer and autumn, primarily for taxa important from the beekeeping perspective **(Abou-Shaara, 2015)**.

The *Phacelia sp.* is an agricultural crop with a short growing season well-known to the beekeepers. It can therefore be used as a source of nectar and pollen **(Sprague et al., 2016)** by beekeepers themselves, or it is used in intensive agriculture for green manure **(Titov and Mamonov, 2013)**. *Phacelia sp.* pollen was confirmed in honey from the Czech Republic and the average content in honey was (8.68%), but in most cases, it had a minor representation **(Figure 1)**. The *Phacelia sp.* pollen occurred mostly in honey from the May-July period, in August honey this pollen was represented less. A statistical difference was demonstrated between May and July. Due to the high pollen-producing capacity, honey with a *Phacelia* pollen

content >90 % is considered monofloral *Phacelia* honey **(van der Ham, Kaas, and Kerkvliet, 1999)**. A more recent Polish study also admits a lower proportion of pollen grains (from 68%) in the case of corresponding physico-chemical and sensory parameters **(Kuś et al., 2018)**.

The most well-known summer nectar-producing tree is considered to be the linden (*Tilia sp.*). Linden has a high nectar content but a low pollen content. Therefore, a low proportion of pollen grains (>20%) is permissible for monofloral linden honey **(van der Ham, Kaas, and Kerkvliet, 1999)**. The average content of pollen grains in the Czech Republic was 3.52% and in most honey, it represented minor pollen in honey. This finding is in line with Polish and Bulgarian polyfloral honey **(Stawiarz and Wróblewska, 2010; Dobre et al., 2013)**. In three honey samples, the pollen content was higher than 20%, which may indicate monofloral honey. The secondary pollen in these samples was rapeseed pollen (1.21 – 19.86%), *Phacelia sp*. pollen (15.05 – 21.75%), and *Umbelliferae* pollen (2.69 – 18.88%).

As reported by several authors **(Lieux, 1981; Kale Sniderman et al., 2018)**, *Vicia sp*. pollen is an important taxon in polyfloral honey, however, according to the study **(Stawiarz and Wróblewska, 2010)**, it is considered a minority representative. In the Czech Republic, its average content of pollen grains was 3.62% and in most cases, it was minor pollen (<3%) **(Figure 1)**. *Trifolium sp.* pollen was represented in Czech honey on average in the amount of 3.47%. It was minor pollen **(Figure 1)** in most honey. The percentage found is lower than described in other countries **(Jones and Bryant, 2014; Stawiarz and Wróblewska, 2010)**. Varying content of pollen grains of Trifolium sp., however, was also observed in various localities in Lithuania, wherein some localities the content of Trifolium sp. pollen was even lower **(Čeksteryte, Kurtinaitiene, and Balžekas, 2013)**.

A comparison of the pollen profile of the Czech Republic in 2019 with foreign studies is summarized in **Table 3**. The selection of taxa is limited concerning the availability of information on the pollen profile of honey from abroad. Botanical taxa for which a comparative study is not available are excluded from the table.

CONCLUSION

In most cases, Czech honey has the nature of polyfloral honey. In 2019, the predominantly represented pollen was of *Brassica sp*. Fruit tree, *Umbelliferae*, and *Myosotis sp.* had a higher percentage as well. The amounts of dominant pollen taxa in Czech honey do not differ significantly during the year. Confirmed botanical taxa were present in honey in all monitored months. Differences between months were confirmed only for pollens of *Salixaceae*, *Umbelliferae* family, *Phacelia sp.* and they are in accordance with the blooming time of these botanical species. The occurrence of pollen taxa in the months out of the main blooming season is caused by physiological handling in the hive, which results in the transfer of honey and pollen cells in the honey flow season. The bee handling management of honey and pollen is also affected by climate conditions and the availability of pollen and nectar sources each year. For this reason, the study will be extended to the following years in order to confirm or possibly exclude the conclusions found in the 2019 season.

VITAMIN C AND NITRATES CONTENTS IN FRUIT AND VEGETABLES FROM FARMERS' MARKETS AND SUPERMARKETS

Monika Sabolová, Lenka Kouřimská

ABSTRACT

Fruits and vegetables are the best food sources of vitamin C. However, fruits and vegetables can be also sources of potentially harmful substances to the human body, nitrates being one of these. The aim of this study was to compare vitamin C and nitrates contents in selected fruits and vegetables from supermarkets and local farmers' markets. Samples of plums, strawberries, apples, spinach, red peppers and tomatoes were chosen for analysis. Content of vitamin C and nitrates was analyzed by HPLC/DAD. The hypothesis was that local market fruits and vegetables contain more vitamin C and fewer nitrates than samples bought in supermarkets. Laboratory analyses showed that there were differences in vitamin C in the case of strawberries, tomatoes and red peppers. The highest level of ascorbic acid was in red pepper samples (141 $mg.100g^{-1}$). In the case of fruit, the highest content was in strawberries (70 $mg.100g^{-1}$). As far as nitrates content is concerned, in three cases out of six, the fruit and vegetables we tested from farmers' markets contained lower concentrations of nitrates than those purchased at supermarkets and the hypothesis was accepted in these cases. There was no significant difference between the nitrate content of the local market and supermarket strawberries and red peppers. Tomatoes had significantly higher nitrate content when purchased at farmers' markets than at supermarkets. Leafy vegetables are considered to be the major source of nitrates, and this was confirmed by this study. The highest content of nitrates was in the spinach sample (2969 $mg.kg^{-1}$). Among all fruit samples, strawberries had the highest nitrates levels (maximum 131 $mg.kg^{-1}$). The results of this work showed that the content of ascorbic acid and nitrates differs significantly depending on the type of fruit or vegetables.

Keywords: ascorbic acid; nitrate; fruit; vegetable; farmers' market

INTRODUCTION

Fruit and vegetables are an important part of human nutrition and their adequate daily consumption can help prevent serious diseases **(WHO, 2003)**. The **WHO (2004)** recommended at least 400 g of fruit and vegetables daily to prevent chronic diseases such as heart and cancer, type 2 diabetes mellitus and obesity, as well as to prevent and reduce micronutrient deficiencies, particularly in less developed countries **(WHO, 2003)**.

Vitamin C is the most important vitamin in fruits and vegetables. Except for humans and other primates, most phylogenetically lower animals can synthesize this vitamin **(Rekha et al., 2012)**. More than 90% of vitamin C in the human diet comes from fruit and vegetables. The highest amounts of this vitamin occur in blackcurrants, citrus fruits, spinach, tomatoes, red peppers **(Lewin, 1976; Lee and Kader, 2000; Saxholt et al., 2008; Rekha et al., 2012)**.

Vitamin C improves immune system function, acts as an antioxidant, and reacts with oxygen and other molecules **(Rekha et al., 2012; Soni et al., 2017)**. According to **EFSA (2017)**, the reference intake of vitamin C for a healthy adult should be 90 mg per day. Vitamin C content in vegetables and fruits depends on several factors, such as variety, habitat, growing year, storage and processing **(Mařáková, 2008; Matějková and Petříková, 2010; Oyetade et al., 2012; Combs, 2017)**.

Vitamin C is a very unstable compound. It is rapidly oxidized with oxidizing agents, especially iron, copper, various enzymes (e.g. ascorbase, peroxidase, cytochrome oxidase) and air/oxygen **(Jeney-Nagymate and Fodor, 2008)**. Moreover, the stability of vitamin C decreases with increasing temperature, pH **(Jeney-Nagymate and Fodor, 2008)** and light access **(Nováková, Solich and Solichová, 2008)**. During processing, the stability of vitamin C is higher in fruit than in vegetables due to their lower pH **(Mařáková, 2008)**.

Nitrates are created in fruits and vegetables mainly via the nitrification of ammonia nitrogen. They play an important role in plant nutrition, growth and development. Higher nitrates concentrations accumulate in leaves, while lower

concentrations are present in roots, tubers, seeds and fruits. For this reason, leafy vegetables (spinach, lettuce, etc.) are the most important source of nitrates and may contain more than 2000 $mg.kg^{-1}$ **(Maynard et al., 1976; Santamaria, 2006)**.

Nitrates themselves are relatively nontoxic, but their metabolites (nitroso compounds), which could be formed in the human body, can cause several health problems **(Santamaria, 2006)**. Consumption of vegetables with high nitrate content may increase the risk of methemoglobinemia or gastrointestinal cancer **(Du, Zhang and Lin, 2007)**. **Bevc et al. (2012)** reported an association between nitrates and cancer of the bladder, ovary, stomach and liver. According to **EFSA (2008)**, the acceptable daily intake for nitrates (ADI) is 3.7 mg per kg of body weight per day. **Temme et al. (2011)** reported a real average daily nitrate intake of 1.38 mg per kg of body weight per day. The main sources of nitrates are vegetables (mainly lettuce) and drinking water. Due to the undesirable effect of nitrates on human health, their content in certain kinds of vegetables is regulated by **Commission Regulation (EC) No 1881/2006**.

On the other hand, intake of small amounts of nitrates can also have a positive effect on the gastrointestinal tract **(Duncan et al., 1999)** and the cardiovascular system **(Webb et al., 2008; Sobko et al., 2010; Lundberg et al., 2011)**. The negative effect of nitrates on human health can be significantly limited by the simultaneous presence of vitamin C **(Kopec, 2010; Shehata, 2010)**.

The accumulation of nitrates in fruit and vegetables depends on many factors - mainly their type or genotype, variety, maturity, climatic conditions (light intensity, air temperature and carbon dioxide concentration), agronomic factors (e.g. timing and form of nitrogen application), soil type and harvest time **(Sorensen, Johansen, and Poulsen, 1994; Colla et al., 2018)** and also by heat treatment (i.e., frying, baking, cooking), storage or preservation **(Prasad and Chetty, 2008; Temme et al., 2011)**.

Farmers' markets are a form of selling agricultural and food goods to the general public, with the aim of a) supporting small and medium-sized agricultural growers, breeders and food producers; b) supplying citizens with fresh agricultural crops and food of mainly national and regional origin; c) creating new social space which, in addition to the sale of agricultural goods, serves to get people together and to bring the urban population closer to the agricultural season and natural cycles; d) revitalizing selected urban areas and improving their ambience. Farmers' markets usually take place in the open air. Only seasonal and local goods should be sold at farmers' markets **(Bohatec, 2011; Sedláček, 2015)**.

The most common products at farmers' markets include fruit and vegetables **(Brůčková, 2012)**. Unlike organic food, there is no legal or generally accepted definition for local food. Many authors describe it as "local food" such foods that were produced within 100 km of the consumer. Other authors argue that local foods are those produced in a certain region or country.

Another positive factor for buying local food is its freshness. At farmer's markets, we find fresh fruits and vegetables that were picked just before the sale, while in supermarkets we can come across food that has traveled to the counters for several days and matured on the way. This also relates to the carbon footprint; the production of local food is significantly more energy-efficient and thus more environmentally friendly **(Brůčková, 2012; Kukla 2012)**.

For most consumers, fruits and vegetables that come from farmers' markets are considered healthier than usual "conventional" supermarket products. However, it is not clear whether these farm products contain more nutrients and/or less harmful substances **(Wunderlich et al., 2009)**. Therefore, this work aimed to compare the content of vitamin C and nitrate in selected fruit and vegetables purchased at farmers' markets and in supermarkets.

Scientific hypothesis

Fruits and vegetables from farmers' markets will have a higher vitamin C content and a lower nitrate content than those from supermarkets.

MATERIAL AND METHODOLOGY

Vitamin C and nitrates levels were monitored in three different kinds of fruit (apples, plums and strawberries) and three different kinds of vegetables (spinach, red peppers and tomatoes). The Jonagold apple variety was used for analysis. For other analyzed fruit and vegetables the variety was not declared by supermarkets and farmer´s markets. Fruit and vegetables (except spinach) were purchased in the period September-November (spinach in the period October-November) in four different supermarkets and four different farmers' markets in the same locality. The same kind of fruit or vegetables were always bought at the same time in the supermarket and the farmers' market.

Samples preparation

All fruit and vegetable samples were cleaned before analysis. Parts that are not consumed were removed. The edible parts were homogenized for 1 minute in a kitchen blender (Zepter, Italy). In the case of ascorbic acid determination, 2.5 g of the sample plus 15 mL of 3% metaphosphoric acid (Honeywell, Germany) were mixed. The sample was filtered through filter paper to a 25 mL volumetric flask, filled up to the mark with the extraction solvent, filtered through a PTFE membrane 0.45 µm filter, and directly injected into the HPLC 20 µL Rheodyne 7725i loop (Rheodyne, USA).

In the case of nitrates determination, 5 g of homogenized sample was placed into a 150 mL beaker with 60 mL of demineralized water and left in an ultrasonic bath for 10 minutes. After that, it was filtered through filter paper to a 100 mL volumetric flask, filled up to the mark with extraction solvent, filtered through a membrane filter, and injected into the HPLC system as mentioned above. Each sample was measured in triplicate.

Instrumental analysis

A high-performance liquid chromatographic (HPLC) method was used to determine ascorbic acid and nitrates contents. The HPLC system (P680 HPLC pump, Thermostatted Column Compartment TCC–100, and DAD detector UVD340U (Dionex, USA set at 254 nm) consisted of a C18 guard column (10 x 10 mm) and a Luna® 5 µm C18 analytical column (250 x 4.6 mm; Phenomenex, Germany) heated at 25 °C. The mobile phase was 5% methanol (Lach-Ner, Czech Republic) adjusted to pH 3 by o-phosphoric acid (Lachema, Czech Republic) with

a flow rate of 0.8 mL.min^{-1}. The calibration curve was determined using standard solutions of ascorbic acid p. a. (Lach-Ner, Czech Republic) at concentrations of 5, 10, 20, 60 and 100 mg.L^{-1}. The correlation coefficient of the calibration curve (R^2) was 0.9992.

The same HPLC instrumentation was used for the determination of nitrates content. The detector was set at 214 nm and KH_2PO_4 solution (c = 10 g.L^{-1}, pH 3, Lach-Ner, Czech Republic) was used as a mobile phase with a flow rate of 1 mL.min^{-1}. The calibration curve was determined using standard solutions of sodium nitrate p. a. (Sigma, Japan) at concentrations of 10, 30, 50 and 100 mg.L^{-1}. The correlation coefficient of the calibration curve (R^2) was 0.9957.

Statistical analysis

Linear regression equations, regression coefficients (R^2) as well as other results (means and standard deviations) were calculated from the data using Microsoft Office16 Excel. The differences between samples were evaluated using a one-way analysis of variance (ANOVA). Scheffe's test was used to calculate statistically significant differences between samples using statistical software Statistica 12 (StatSoft Inc.). For all statistical tests, a 5% level of significance was used.

RESULTS

Ascorbic acid content

The data from the analysis of ascorbic acid in fruit and vegetable samples are in Table 1. Concerning the fruit samples, the values of vitamin C content in plums did not vary much and was around 5 mg.100g^{-1} of the sample (from 4.24 to 6.38 mg.100g^{-1}). There was no statistical difference in vitamin C content between plums from farmers' markets and those from supermarkets. Similarly, in apple samples, the vitamin C content was less the same, ranging from 3.56 to 5.86 mg.100g^{-1} of sample and there was no difference between samples from local producers and those from supermarkets. In contrast, all strawberry samples from farmers' markets had a significantly higher vitamin C content than supermarket samples (the maximum of all analyzed samples was 70.53 mg.100g^{-1}, the minimum was 39.98 mg.100g^{-1}).

Considering vegetables, the vitamin C content in the spinach samples (ranging from 23.98 to 42.46 mg.100g^{-1}) was around an average of 30 mg.100g^{-1} and there were no differences between the market sources. There were differences in the case of tomatoes (18.00 to 32.54 mg.100g^{-1}) or red peppers samples (58.57 – 141.26 mg.100g^{-1}) from farmers' markets and supermarkets. Samples of red peppers from the supermarket had significantly higher vitamin C contents than red peppers from farmers' markets, but the opposite was true for tomatoes. In farmers' tomatoes, the average content of ascorbic acid was by 6 mg.100g^{-1} higher than in tomatoes from supermarkets. In the overall comparison of fruit and vegetables, the highest content of vitamin C was found in red pepper and the lowest in apples and plums. The major determinant of vitamin C content is the species of plant (p <0.0001) rather than where the fruit or vegetable is purchased (p = 0.9140).

Nitrates content

The levels of nitrates in samples are seen in Table 2. In the case of fruit samples, the plum samples contained from 1.80 mg.kg^{-1} to 5.00 mg.kg^{-1} of nitrates. One sample from the supermarket contained up to twice as many nitrates as the sample from the farmers' markets. The nitrates content of plum samples from supermarkets varied quite a lot from 3.25 to 5.00 mg.kg^{-1}. Similarly, apple samples from farmers' markets had significantly fewer nitrates than samples from supermarkets. The highest nitrate content was measured in a sample from the supermarket (13.02 mg.kg^{-1}), while the lowest nitrate content was measured in one sample from the farmers' market (6.36 mg.kg^{-1}). In contrast, there was no difference in nitrates content (110.17 – 131.90 mg.kg^{-1}) between strawberry samples from farmers' markets and supermarkets.

Comparing the monitored vegetable samples, there was a significant difference between spinach samples from farmers' markets and supermarket samples. The nitrate content of samples from farmers' markets was less variable (1332 – 1509 mg.kg^{-1}) than their content in samples from supermarkets (from 1084 to 2969 mg.kg^{-1}). The same was observed in the case of tomatoes (the values ranged from 37 to 53 mg.kg^{-1}) where the average measured nitrate content in samples from supermarkets was significantly higher (by 10 mg.kg^{-1}) compared to samples from local producers. On the contrary, red peppers did not show any difference between the sources where they were purchased. The nitrates contents were quite similar (around 35 mg.kg^{-1}), except for one sample from the farmer's market (71 mg.kg^{-1}).

The levels of nitrates differed significantly among all analyzed samples from supermarkets and farmers´ markets (p = 0.0349) and also among the assayed kinds of fruit and

Table 1 Ascorbic acid content in fruit and vegetables from supermarkets and farmers' markets.

Fruit or vegetable	Ascorbic acid content		
	Supermarkets (mg.100g^{-1} ±*SD*)	Farmers' markets (mg.100g^{-1} ±*SD*)	*p*-value
Apple	4.86 ±1.00	5.58 ±0.16	0.0613
Plum	5.32 ±0.95	5.25 ±0.50	0.8664

vegetables (p <0.0001). The highest amount was in spinach, the least in plums.

DISCUSSION

Many factors are affecting the level of vitamin C in fruit and vegetables and, therefore, its content can vary a lot. From this point of view, our experimentally measured values are generally in line with literature data. Of the assayed samples, the highest content of vitamin C was in red peppers. Its average contents were 78.9 mg.100g^{-1} (from farmers' markets) and 105.5 mg.100g^{-1} (from supermarkets). This is less than observed in other studies. **McCance and Widdowson (2014)** reported an average content of 120 mg.100g^{-1} of vitamin C in red peppers in their study; **Lee and Kader (2000) and Saxholt et al. (2008)** reported values up to 151 mg.100g^{-1}. Strawberries had the second-highest average vitamin C content of 52 mg.100g^{-1} (supermarket) and 66 mg.100g^{-1} (farmers' markets). Similar results were obtained by **Lewin (1976)**, **Lee and Kader (2000),** and **Saxholt et al. (2008)**, who reported vitamin C levels in strawberries ranging from 35 to 60 mg.100g^{-1}. Vitamin C levels in strawberries are comparable to those in citrus fruits (40 – 50 mg.100g^{-1}) **(Lee and Kader, 2000)**.

Spinach is a vegetable with a high content of vitamins and minerals. Our value for vitamin C content was similar to values observed by **Bureau et al. (2015)** (23.7 mg.100g^{-1}). The vitamin C content we found in tomatoes is following literature values, 30 – 35 mg.100g^{-1} **(Lewin, 1976)**. According to **George, Kaur, Khurdiya, et al. (2004)**, however, the vitamin C content of tomato pulp may be 84 to 324 mg.100g^{-1}. The deviations of some of our results for the content of vitamin C from the data in the literature may have been affected by analyzing samples purchased in the autumn and the way of their storage **(Matějková and Petříková, 2010)**.

Our results indicated that only in the case of strawberries, tomatoes, and peppers from farmers' markets and supermarkets were significant differences in vitamin C content found. The biggest difference was in strawberry samples. Strawberries from farmers' markets contained 27.4% more vitamin C than strawberries from supermarkets. In contrast, the content of vitamin C in plums from farmers' markets and supermarkets was almost identical. There is not much information in the literature comparing products from farmers and supermarkets. Studies are usually focused on the differences between organic and conventional fruit and vegetables and their findings are often controversial **(Silva et al., 2018; Andrade et al., 2017)**. **Andrade et al. (2017)** tested the quality of strawberries grown in organic and conventional systems. The content of vitamin C in organic strawberries was (49.07 mg.100g^{-1}) and in conventional strawberries (52.32 mg.100g^{-1}). According to these authors, the content of vitamin C in strawberries does not differ significantly between the conventional and organic systems. The authors state that vitamin C content depends on many factors, including variety, ripeness, growing conditions and harvest time. These factors could then lead to significant variations in results, both between studies and within studies.

Esch et al. (2010) looked for differences in vitamin C content between organic and conventional fruits.

The tested fruits were oranges, mangoes, kiwi, lemons, gala apples and red apples. Of these six fruits, the only lemon showed a significant difference between organically (higher content) and conventionally grown samples. This study confirmed that the content of vitamin C depends on several factors, not just the way of cultivation. **Wunderlich et al. (2009)** reported that pre- and post-harvest conditions have a major effect on vitamin C levels in vegetables.

Based on our results, the hypothesis that fruit and vegetables from farmers' markets have a higher vitamin C content can, therefore, neither be accepted.

Fruit and vegetables also contain substances that could have a negative impact on human health. For this reason, the second half of this work was focused on nitrate content in fruits and vegetables from farmers' markets and supermarkets. It can be stated that there were significant differences in the nitrates content among the assayed kinds of fruits and vegetables.

According to **Prugar (2008)** and **Colla et al. (2018)**, fruit and vegetables can be divided into four categories according to nitrates content. The highest nitrate content is in leafy vegetables such as spinach. **Maynard et al. (1976)** and **Santamaria (2006)** reported that nitrates accumulate primarily in leaves, while lower nitrate concentrations are present in roots, tubers, seeds and fruits. For this reason, leafy vegetables (spinach, lettuce, parsley, etc.) are considered the most important source of nitrates. Tomatoes and peppers belong to the group with nitrates content of less than 250 mg.kg^{-1} **(Colla et al., 2018)**.

Maximum levels for nitrates content are given by **Commission Regulation (EC) No 1881/2006** only for salad and spinach. The maximum limit for spinach is set in two categories, i.e. 3500 mg NO_3.kg^{-1} for the harvest from 1 October to 31 March and 2500 mg NO_3.kg^{-1} for the harvest from 1 April to 30 September. The highest measured nitrates content in the spinach sample in our case was

2969 mg.kg^{-1}. As the purchase of the samples took place in October, it can be assumed that the maximum limit for nitrate content was not exceeded.

Prugar (2008) and **Colla et al. (2018)** classified spinach into the "very high nitrates category", i.e. more than 2000 mg.kg^{-1}. In this study, the results of spinach from farmers' markets with average nitrates content of 1391 mg.kg^{-1}, would fit to the "high nitrates category" (i.e. 1000 – 2000 mg.kg^{-1}). Supermarket spinach contained 47.5% more nitrates than spinach from farmers' markets. This difference was most likely due to different growing conditions. Fruit and vegetables from wholesalers come very often from greenhouses.

The main factors contributing to the increased nitrate concentration are temperature, lack of light and strong fertilizer concentration. In contrast, products from farmers' markets are usually grown in the open air in fields with enough light. Moreover, it is best to buy vegetables from the afternoon harvest. In the morning, the nitrate content in fruits and vegetables is higher than in the evening. It is therefore recommended to harvest agricultural products in the afternoon **(Sorensen, Johansen and Poulsen, 1994; Colla et al., 2018)**.

Muramoto (1999) conducted a similar study with iceberg lettuce, Roman lettuce and spinach from supermarkets (conventional cultivation) and farmers' markets (organic cultivation). This author concluded that samples of spinach from the supermarket (average nitrates content 2540 mg.kg^{-1}) had a significantly higher nitrates concentration than samples from farmers' markets (average nitrates content 1810 mg.kg^{-1}). **Muramoto (1999)** also suggested that the use of nitrogen fertilizers may be the main cause of this difference. In other studies, **Barker (1975)** and **Stopes et al. (1989)** reported a positive correlation between the number of nitrogen fertilizers and nitrates accumulation in spinach.

Compared to vegetables, the fruit samples had much lower nitrates content. **Bahadoran et al. (2016)** reported an average of 27 mg nitrates per 100 g plums in their study. The highest nitrates content of our fruit samples was found in strawberries, which belong (together with bananas) to a "higher nitrates category". **Walker (1990)** reported up to 150 mg of nitrates in 1 kg of strawberries in his study. We observed average nitrates content of strawberries from 116.63 mg.kg^{-1} (from farmers' markets) to 122.39 mg.kg^{-1} (from supermarkets). The explanation for the high nitrate content could be the presence of a thin, porous layer on the surface of strawberries, their frequent fertilization, or the way of growing in greenhouses where the lack of light causes the accumulation of nitrates.

In the case of our samples, no significant difference was found between strawberries from supermarkets and farmers' markets. This observation is consistent with the study of **Bordeleau et al. (2002)**, who also examined the difference in nitrates content of strawberries from farmers' markets and supermarkets. Other samples – plums, red pepper, tomatoes, and apples contained less than 250 mg of nitrates per kg, thus belonging to the low nitrate fruit and vegetable category according to the nitrates content classification **(Prugar, 2008; Colla et al., 2018)**.

In three cases out of six, the fruit and vegetables tested by us from farmers' markets contained statistically lower nitrates concentrations than those purchased in supermarkets. In these cases, the hypothesis that fruits and vegetables from farmers' markets have lower nitrates content than fruits and vegetables from the supermarket can, therefore, be accepted. On the other hand, there was no significant difference between the nitrates contents of strawberries and red peppers from farmers' markets or supermarkets, whereas tomatoes had significantly higher nitrates content when bought from farmers' markets.

Studies that have found significantly lower levels of nitrates in products from farmers' markets generally explain this by a lower fertilization rate. **Bordeleau et al. (2002)** stated that mineral fertilizers have a greater effect on nitrates levels than livestock fertilizers or humus. Other important factors influencing nitrates content are weather and light conditions.

CONCLUSION

The results of this work showed that the content of ascorbic acid and nitrates differs significantly depending on the type of fruit and vegetables. The most important source of vitamin C from the assayed fruits and vegetables was red pepper. One hundred grams of it would sufficiently cover the recommended daily dose of 90 mg. Comparing the different kinds of fruit and vegetables, significant differences in vitamin C content between samples from farmers' markets and samples from supermarkets were found in strawberries, red peppers and tomatoes.

Analyses of nitrates content showed significantly lower nitrates content in spinach, apples and plums from farmers' markets than from supermarkets. The most important source of nitrates was spinach, but the content did not exceed the limit set by legislation. Compared to vegetables, the fruit samples had much lower nitrates contents. Strawberries had the highest nitrates content of the fruit samples examined.

Overall, there were significant differences in nitrate content in fruit and vegetables from supermarkets and farmer´s markets. On the other hand, differences in vitamin C content were not found.

Since the majority of studies compare the quality of organic and conventional products rather than comparing the nitrates and vitamin C contents of fruit and vegetables from farmers' and supermarkets, it would be better to focus on this area in the future. Our findings suggest that farm products may not always be a better choice in terms of vitamin C and nitrates content than fruit and vegetables purchased in supermarkets.

INFLUENCE OF DIFFERENT STORAGE CONDITIONS ON THE OCCURRENCE OF ENTEROCOCCI IN SMEAR RIPENED CHEESES

Olga Cwiková, Gabriela Franke

ABSTRACT

The number of enterococci was monitored in smear-ripened cheeses stored under different temperature regimes. Sampling and subsequent analyses were performed on the day of manufacture (A/0 = B/0 = C/0), at the end of BBD (A/35, B/35, C/35), two weeks after BBD (A/49, B/49), and eight weeks after BBD (C/91). No statistical difference (p >0.05) was found in the numbers of enterococci in cheeses stored under different temperature regimes until the Best-Before date or at the end of monitoring after 49 and 91 days respectively. At the beginning of storage (A/0, B/0, C/0), the numbers of enterococci in cheeses were 2.3 log CFU.g^{-1}. The highest number of enterococci was recorded after 49 days of storage at 6 °C at 5.4 log CFU.g^{-1}. During storage, there was an increase (p <0.05) in the numbers of enterococci in all types of temperature regimes. Enterococci content was influenced (p <0.05) by both the storage period and storage method (temperature regime).

Keywords: *Enterococcus* spp.; smear-ripened cheese; storage period and temperature

INTRODUCTION

Enterococcus sp. is a gram-positive bacterium found in various places: it is a commensal living in the digestive tract of animals, insects and humans **(Li et al., 2017)**, often found in fermented foods such as fermented dairy and meat products, in soil, water and plants **(Lebreton et al., 2014; Fuka et al., 2017)**. Enterococci are found in large quantities in traditional products made from raw milk, particularly in cheeses. Enterococci are associated with traditional European cheeses manufactured in Mediterranean countries, such as Greece, Italy, Spain and Portugal, from raw or pasteurized goats', ewes', water-buffalos', or bovine milk **(Moreno et al., 2006)**. Although their presence is generally considered to be due to inadequate hygiene conditions during processing **(Gelsomino et al., 2002)**, they can act as natural starter cultures in the production of various types of cheeses **(Giraffa, 2003)**. These are artisan cheeses produced in Southern Europe, e.g. Venaco cheese **(Casalta and Zennaro, 1997)**. Enterococci are found in cheeses made from both raw and pasteurized milk because they survive the pasteurization temperature **(İspirli et al., 2017)**. The resistance of enterococci to pasteurization temperatures and their ability to adapt to different substrates and different growth conditions not only leads to their discovery in foods made from raw materials (milk, meat) but also in foods obtained by the thermal process. They are therefore able to survive the conditions of food production. They can also contaminate finished products **(Hanchi et al., 2018)**. However, their incidence in traditional cheeses made from raw cow's milk of high microbiological quality is low **(Garabal et al., 2008)**, which is likely to result in the loss of some taste attributes.

In terms of pathogenicity and antibiotic resistance, as well as biogenic amine production, enterococci in food, of course, are not desirable microorganisms.

However, some enterococci are used in the industry **(Ogier and Serror, 2008)** because of their biochemical properties suitable for technological applications **(Centeno and Carballo, 2015)**. Some strains have been designed as complementary starting microbiota **(Franz et al., 2001; Moreno et al., 2003)**, *E. durans, E. faecalis* and *E. faecium* are also marketed as probiotic cultures **(Centeno and Carballo, 2015)**, show antimicrobial effects against alimentary pathogens, which is related to the presence of genes encoding enterotoxin production **(İspirli et al., 2017)**. For this reason, *Enterococcus* sp. is one of the most controversial genera belonging to lactic acid bacteria **(Lebreton et al., 2014)**. Enterococci can adapt to adverse environmental conditions. They are also known for their antibiotic resistance. The most important enterococcal diseases include urinary tract infections, nosocomial infections and superinfections, meningitis, bacterial endocarditis and bacteraemia **(Gardini et al., 2001; Arias and Murray, 2008)**.

Scientific hypotheses

Hypothesis 1: Enterococci survive the freezing process and their number does not change significantly during the freezing of cheeses.

Hypothesis 2: The duration of the storage of cheeses affects their safety in terms of enterococcal content.

MATERIAL AND METHODOLOGY

The smear ripening cheese for testing was delivered as small rounds (diameter 45 mm, height 10 mm), where a 100 g package contained 5 pieces of these round portions. Before shipment, the cheeses ripened for 7 days, while the best before date (BBD) on the package was 28 days. A total of 5 batches of the product were analyzed. Each batch of the samples was made from different pasteurized milk. Analyzed smear-ripened cheese is produced from fat-free sour curd. To the curd was added water, neutralization salts and *Candida valida* and bacteria *B. linens*. After the formation of cheese by a drying process, which allows for the reproduction of oxidizing yeasts *Torulopsis* spp. and *Candida* spp., which creates a suitable environment for the onset of action of proteolytic bacteria *B. linens* that during maturation forms on the surface of cheeses which are golden yellow to orange sebum in color.

The samples were supplied by the cheese manufacturer and were divided into three groups designated as (A), (B) and (C) then stored in different temperature regimes. Sampling and subsequent analyses were performed on the day of manufacture (A/0 = B/0 = C/0), at the end of BBD (A/35, B/35, C/35), two weeks after BBD (A/49, B/49), and eight weeks after BBD (C/91).

Samples in the temperature regime (A) were stored at 6 °C after production for the entire BBD (7 days before and 28 days after shipment), i.e. 35 days. These cheeses were then stored for 14 days after the BBD expired at 6 °C, i.e. 49 days in total (6 °C/35 days → 6 °C /14 days). Samples in the temperature regime (B) were stored at 6 °C after production for 28 days (7 days before and 21 days after shipment), i.e. 28 days, then they were frozen and stored at -18 °C for 7 days. Subsequently, after BBD (35 days), the cheeses were stored at 6 °C for 14 days, i.e. 49 days in total (6 °C/28 days → -18 °C/7 days → 6 °C/ 14 days). Samples in the temperature regime (C) were stored at 6 °C after production for the entire BBD (7 days before and 28 days after shipment), i.e. 35 days. They were then frozen and stored for 49 days (7 weeks) at -18 °C. After 49 days of freezing, the cheeses were stored at 6 °C for 7 days, i.e. 91 days in total (6 °C/35 days → -18 °C/ 49 days → 6 °C/7 days).

The analyses were carried out in the laboratory of the Institute of Food Technology, Faculty of AgriSciences of Mendel University in Brno according to **STN EN ISO 7218:2007 (2008)**. For one analysis, 3 consumer packages were always used. 10 g of each 100 g package of cheese was taken with a sterile scalpel by cutting a section through the sample through all the wheels; the sample contained the center and the edge of the cheese **(Figure1)**.

Figure 1 Sample preparation (smear ripened cheese).

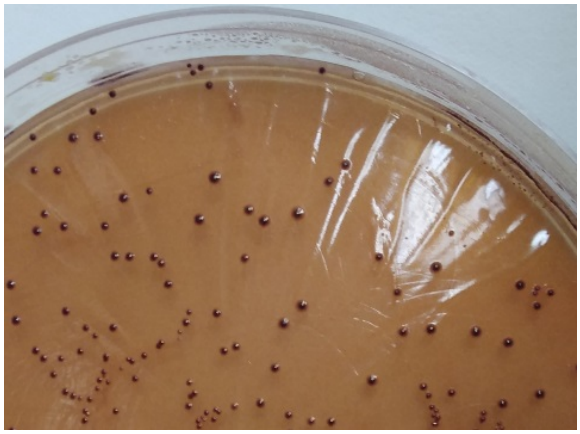

Figure 2 *Enterococcus* spp. in Slanetz-Bartley agar (isolated from smear ripened cheese).

Enterococci were determined on the Slanetz-Bartley agar (soil composition according to **STN EN ISO 7899-2 (2001)**, aerobically grown at 37 °C for 48 h **(Figure 2)**. Confirmation was made by growth on bile esculin agar (composition according to **STN EN ISO 7899-2 (2001)**; incubation at 44 °C for 24 h) and the catalase test (negative).

Statistical evaluation was performed in the Statistica Statsoft program (version 12) and Microsoft Excel 2010. Basic statistical characteristics, such as mean and standard deviation of the mean were calculated.

To compare the *Enterococcus* spp. content during the storage period within the given temperature regime, a simple scattering analysis method (ANOVA) including the Duncan post-hoc test was used. Normality was tested by the Shapiro-Wilk test.

The proportion of factors (temperature and storage period including interactions) on the total variability of BA content in cheese was calculated using the general linear model (two-way ANOVA with interactions).

RESULTS AND DISCUSSION

Influence of storage temperature on the number of enterococci

No statistical difference (p >0.05) was found in the number of enterococci in cheeses stored under different temperature regimes until the Best-Before date or at the end of monitoring after 49 and 91 days **(Figure 3)** respectively. Enterococcal counts were 4.7 log CFU.g^{-1} when stored under the regime (A) until BB date after 35 days of ripening, 4.8 log CFU.g^{-1} when stored under temperature regime (B) and 4.7 log CFU.g^{-1} under the regime (C). At the end of monitoring, 5.4 log CFU.g^{-1} of enterococci was detected in cheeses after storage for 49 days under the temperature regime (A), 5.2 log CFU.g^{-1} when stored under the regime (B) and 5.0 log CFU.g^{-1} under the regime (C) after 91 days.

Enterococci are highly resistant to environmental conditions, grow over a wide temperature range (25 to 45 °C), tolerate pH from 4.8 to 11.0, the salt content of

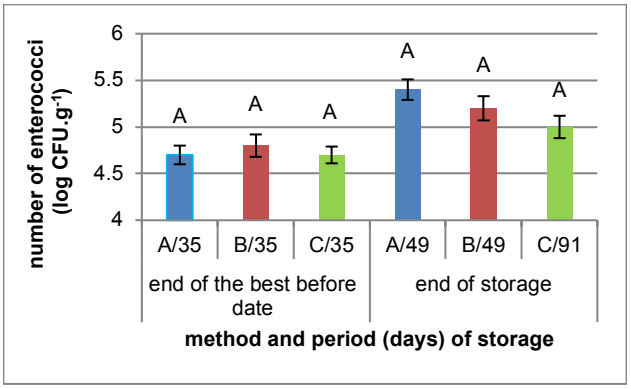

Figure 3 Comparison of the the number of enterococci (log CFU.g^{-1}) in smear ripened cheeses stored in different temperature regimes (A, B, C) and analysed at the end of the best before date after 35 days of ripening and at the end of storage after 49 or 91 days of ripening. Note: A/35: storage at 6 °C/35 days, B/35: Storage at 6 °C/28 days and at -18 °C/7 days, C/35: storage at 6 °C/35 days) (A: storage at 6 °C/35 days and at 6 °C/14 days, B: storage at 6 °C/28 days and at -18 °C/7 days and at 6 °C/14 days, C: storage at 6 °C/35 days and at -18 °C/49 days and at 6 °C/7 days; n = 15.

6.5 percent, bile presence of 40 percent and survive at 60 °C for 30 minutes **(Domig, Mayer and Kneifel, 2003)**. **López-Díaz et al. (2000)** indicated a wider range of growth temperatures from as low as 10 °C.

Due to their high resistance, they survive and tolerate temperature changes well, as shown in **Figure 3**. **Bockelmann et al. (2005)** reported that the usual number of enterococci on the surface of smear-ripened cheeses is <6 log CFU. cm^{-2}. Higher counts of enterococci compared to our study, >8 log CFU. cm^{-2}, were also detected by **Amato et al. (2012)** for fully ripe smear-ripened cheeses when stored at 4 to 8 °C. **Komprda et al. (2012)** also recorded higher counts compared to our study (depending on the season) until the Best Before date (42 days after production) when stored at 5 °C, namely 6 to 7 log CFU.g^{-1}, and 5.2 to 6.4 log CFU.g^{-1} after 66 days after production, wherein the lower value corresponds to the counts of enterococci that we found in our experiment at the end of the monitoring under the regimes (A/49), (B/49) and (C/91). Also, **Fontana et al. (2010)** reported higher counts of enterococci in smear-ripened cheese compared to our study, namely 7.2 log CFU.cm^{-2}. According to **Schneller, Good and Jenny (1997)**, the distribution of enterococci in cheese may be inhomogeneous.

Freezing is not the cause of the devitalization of all cells **(Görner and Valík, 2004)**. As reported by **Kadlec, Melzoch and Voldřich (2012)**, during freezing enzymatic reactions proceed slowly. Because they are mesophilic bacteria, according to **Šilhánková (2008)**, when the temperature falls below the optimal growth level, the rate of propagation drops sharply and eventually stops, although the sensitivity to cold shock varies among different bacteria. The devitalizing effects of low temperatures are, according to **Drdák et al. (1996)**, more efficient in repeated freezing and thawing, but this is not the case with bacterial spores that may survive under these conditions.

Possible sources of contamination of cheeses with enterococci are the raw material (milk), production workers, production equipment, water taps, saline solutions, tanks; however, their origin in cheeses is sometimes unclear **(İspirli et al., 2017)**. **Greifová et al. (2003)** reported that the decisive enterococci contamination of milk comes from the milking equipment and plant feed. In raw milk, enterococci are clear indicators of inadequate decontamination of equipment and machinery. As thermoresistant bacteria, some species of enterococci survive required pasteurization temperature, therefore they are a normal part of pasteurized milk.

Influence of the storage period on the number of enterococci

At the beginning of storage (A/0, B/0, C/0), the numbers of enterococci in cheeses were 2.3 log CFU.g^{-1}. At the end of storage, 5.4 log CFU.g^{-1} of enterococci was detected in cheeses under (A) temperature regime, 5.2 log CFU.g^{-1} when stored under (B) regime and 5.0 log CFU.g^{-1} when stored under (C) regime conditions. During storage, there was an increase (p <0.05) in the number of enterococci in all types of temperature regimes **(Figure 4)**.

Increasing enterococcal numbers during ripening was described by **Novella-Rodríguez et al. (2004)** for goat cheeses made from raw milk, **Roig-Sagués et al. (2002)** for Spanish cheeses, **Maher and Murphy (2000)**, **Macedo et al. (2004)** and **Martuscelli et al. (2005)** for smear-ripened cheeses. Counts of enterococci increased during 60 days of ripening of cheeses made from pasteurized milk in an experiment by **Martuscelli et al. (2005)** from 3.3 ±0.2 to 8.8 ±0.3 log CFU.g^{-1}, which are much higher values compared to our study. According to **Komprda et al. (2012)**, at 5 °C enterococci counts did not change significantly in smear-ripened cheeses (p >0.05); at

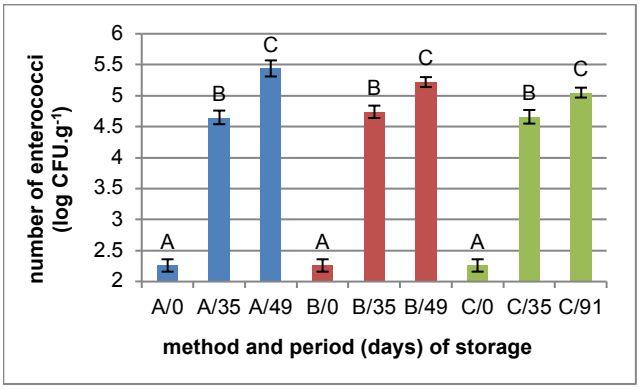

Figure 4 Comparison of the the number of enterococci (log CFU.g^{-1}) in smear ripened cheeses stored in different temperature regimes (A, B, C) and analysed on production day (0), at the end of the best before date after 35 days of ripening. Note: A/35: storage at 6 °C/35 days, B/35: storage at 6 °C/28 days and at -18 °C /7 days, C/35: storage at 6 °C/35 days and at the end of storage after 49 or 91 days of ripening: A: storage at 6 °C/35 days and 6 °C/14 days, B: storage at 6 °C/28 days and at -18 °C/ 7 days and 6 °C/14 days, C: storage at 6 °C/35 days and at -18 °C/49 days and at 6 C/7 days. Averages marked with different letters are statistically different within a given factor (storage period) (p <0.05); n = 15.

the end of ripening, the counts of enterococci were 6.1 log CFU.g^{-1}, which is more than 1 log higher than our study recorded. Although the number of enterococci in cheeses may be 1 log CFU.g^{-1}, values reaching up to 7 log CFU.g^{-1} have been found **(Pircher et al., 2007)**. Based on the experiment, **Rea et al. (2004)** concluded that the increase in enterococcal numbers in the first 6 hours (from 5 log to 7 log CFU.g^{-1}) is due to the water loss during cheese processing, which appears to be the cause of the apparent increase in enterococcal numbers. The survival of enterococci in cheese during ripening is due to a wide range of growth temperatures, tolerance to high temperatures, salt and acid concentrations **(Šilhánková, 2008)**. In contrast to enterobacteria, enterococci show a higher resistance to antagonist bacteria, which are represented by starter microorganisms **(Macedo et al., 2004)**. An increase in the number of enterococci during the ripening of smear-ripened cheeses was also described by **Calasso et al. (2016)**; after 30 days of ripening their number increased to 4.5 ±0.2 log CFU.g^{-1}, which is comparable to our experiment. Also **Schneller, Good and Jenny (1997)** noted an increase in the number of enterococci during cheese ripening. Levels of enterococci in different cheese curds range from 10^4 to 10^6 CFU g^{-1} and in the fully ripened cheeses from 10^5 to 10^7 CFU g^{-1} **(Moreno et al., 2006)**.

Enterococci are widespread in nature and get into raw milk and dairy products during production, especially from the equipment and also from the water where basic hygiene conditions are not observed **(Ogier and Serror, 2008; Li et al., 2017)**. Enterococci are commonly found in raw milk with different microbiota reported in different countries, reflecting local practices and levels of hygiene **(Čanigová et al., 2016)**. We are, however, not able to fully explain the origin of enterococci in cheeses, as the cheeses were made from pasteurized milk. Thus, enterococci originating from the gastrointestinal tract of a dairy cow should be devitalized by heat treatment. The same conclusions were reached by **Gelsomino et al. (2002)**, who found that dairy cow manure is not a source of enterococci, even though the same enterococcal strains were found in milk, cheese and dairy equipment as in dairy cow manure. On the contrary, **Görner and Valík (2004)** reported that Kielwein did not find a link between the species composition of enterococci in dairy cow manure and the milking equipment in 1997 and concluded that enterococci cannot be considered as indicators of faecal contamination but as indicators of inadequate sanitation.

This study also evaluated the contribution of the method and time of storage to the variability in the number of enterococci. Analyses carried out (two-way ANOVA with interactions) show that both the storage period and the storage method (temperature regime; **Table 1**) influenced the enterococcal content.

Table 1 Influence of individual factors (storage method, storage period) on the enterococci content (initial measured values in log CFU.g^{-1}) in cheeses.

Indicator	% explained variability			
	Storage method	Storage period	Interaction	Error
Enterococci	7*	82*	7*	4

Note: * p <0.05.

According to **Giraffa (2003)**, it is difficult to answer the question of whether the presence of enterococci in food is safe. It is necessary to carry out a more detailed identification of the individual strains present in cheeses and to evaluate the pathogenicity of these strains **(Franz, Holzapfel and Stiles, 1999)**. Due to the variety of *Enterococcus* species and their importance in food, the detection and enumeration of enterococci have become an important concern in current research activities **(Hamad, Selim and Yassin, 2019)**.

CONCLUSION

The hypothesis that enterococci survive the freezing process and their numbers do not change significantly can be confirmed. No statistical difference (p >0.05) was found in the numbers of enterococci in cheeses stored under different temperature regimes until the Best-Before date or at the end of monitoring after 49 and 91 days, respectively.

The hypothesis that the duration of the storage of cheeses affects them in terms of enterococcal content can be confirmed. During storage, their numbers increased (p <0.05). However, it should be noted that the view of enterococci is not unambiguous. On the one hand, they are used as cheese-making cultures in some countries, and on the other hand, they can cause health problems in immunocompromised individuals.

From the viewpoint of pathogenicity and resistance to antibiotics, as well as the production of biogenic amines, enterococci in foods are not desirable microorganisms.

DETERMINATION OF SELECTED TERPENIC SUBSTANCES IN GRAPES AND WINE OF THE CULTIVAR PÁLAVA

Marcela Cehula, Michal Kumsta, Radek Sotolar, Lenka Sochorova, Tunde Jurikova, Jiri Mlcek, Mojmir Baron, Jiri Sochor

ABSTRACT

The presented study is focused on the determination of the content of terpenic substances in grapes and subsequently produced a wine of Czech variety Pálava (the Czech Republic, wine region Morava), which is a protected landscape with long-term tradition and culture. The aim of this study was the analysis of the aromatic profile of the cultivar Pálava, which was fermented by the original yeast strains from the Moravian wine region. Larger amounts of flavoring substances occur in grapes as bound flavoring substances, most often in the form of glycosides. One of the basic groups of aromatic substances is monoterpenes. The content of twelve free and bound terpenic substances was measured by the GC-MS method, namely linalool, ho-trineol, α-terpeniol, β-citronellol, nerol, geraniol, furan linalool oxide 1, furan linalool oxide 2, nerol oxide, epoxylinalol 1, epoxylinalol 2 and 2,6-dimethyl-3,7-octadiene-2,6-diol. The results were statistically compared by using a simple descriptive statistical method and ANOVA method. We noted a difference between the content of free and bound terpenes was very significant ($p \leq 0.05$). We found that using uncommercial yeasts could have an effect on the content of the volatile and terpenic compounds in wines. An important finding was that in fresh berry extracts there was a higher proportion of bound terpenes than free terpenes. The results have shown that the production technology of wine and the fermentation process has a clear impact on the content of the substances.

Keywords: terpens; grape; wine; GC-MS

INTRODUCTION

Pálava is a Moravian wine grape cultivar, named after the Protected Landscape Area of Pálava, which was created by crossing the cultivars Traminer Red and Müller Thurgau. The cultivar was bred by Ing. Josef Veverka, who started this breeding in 1953 at the Breeding Station in Velké Pavlovice and later continued in Perná. The cultivar has been entered in the State Variety Book in 1977 **(Kuneš et al., 2015)**.

The Pálava Protected Landscape Area (PLA) means a rich natural and cultural heritage. The vineyards cover approximately 16% of the total size of PLA **(Miklín and Smolková, 2011)**.

Despite the busy tourism in the area, wine and viticulture are an important phenomenon and the most important wine-growing area in the Czech Republic **(Miklín, 2012)**. Shrubs are moderately lush with dense leaves. The leaves are medium-sized, usually shallow-lobed. There is dense hair on the back, the blade surface is indefinitely wavy and leathery. The flowers are two-sexed, self-dusting, and five-flowered. The fringes are medium-sized, 100 – 160 mm long, conical, and sometimes winged **(Hakl et al., 2007)**.

The berries are light red with a gray tinge and have an oval shape with an average length of 14 mm. The skin is firm and the flesh is juicy, aromatic, with a spicy flavor. The average weight of the bunch is 169 g, the average weight of the berries is 1.1 g. It is moderately resistant to winter frosts and less resistant to spring frosts due to early budding. It is prone to attack by insects because it has very thick shrubs due to pecks. Resistance to other fungal diseases is average **(Kraus et al., 2005)**.

By **Butnariu and Butu (2019)** wine is one of the best selling agricultural products and by **Kong et al. (2019)** grapes (*Vitis vinifera* L.) are economically important fruit crops worldwide. The most important factors affecting the aroma in Muscat and non-Muscat cultivars are terpenic and aliphatic alcohols **(Matujašević et al., 2019)**.

Among the attributes that affect the marketability of wine, there are the production method and technological processes, such as the fermentation of fresh grapes, the application of the quantity and type of yeast, etc.

The study is focused on the analysis of the aromatic profile of the cultivar Pálava, which was fermented by the original yeast strains from the Moravian wine region. Using gas

chromatography with mass detection (GC-MS) 12 terpenic substances were determined, which are important for shaping the character of the wine.

Scientific hypothesis

The difference between the results of the determination of free and bound terpenes in berries will be significant.

The content of the individual terpenes will be higher for the bound terpenes than for the free terpenes.

The content of terpenic substances is higher in fresh berries than in samples of the wine.

MATERIAL AND METHODOLOGY

The measured contents in grapes and wine were determined by extraction with methyl t-butyl ether. The weight of one sample was 100 grams of the cultivar Pálava. Samples of berries and wines were taken from the wine region of Moravia. Wine sampling was carried out one month before the end of the fermentation. At the same, we used a control sample which contained the only methyl t-butyl ether.

To fulfill the objectives of this study, there were used technology Shimadzu GC-17A, Autosampler: AOC – 5000, Detector: QP-5050A.

The results have been processed by using the software GC solution. Program LabSolutions, GC MS. Version 1.20. The separation conditions have been set as follow: Column: DB-WAX 30 m x 0.25 mm; 0.25 µm stationary phase (polyethylene glycol).

An injection volume of sample: 1 µL split ratio 1:5.

Carrier gas flow rate He: 1 mL.min^{-1} (linear gas velocity 36 cm.sec^{-1}).

The injection chamber temperature was set at 200 °C.

The initial temperature of the 45 °C column was maintained for 3.5 minutes, followed by a temperature gradient: up to 90 °C by 15 °C.min^{-1}, up to 135 °C by 6 °C.min^{-1}, up to 207 °C by 9 °C.min^{-1}, up to 252 °C by 15 °C.min^{-1}.

The final temperature was held for 5 min. The total analysis time was 30 minutes. The detector operated in SCAN mode with an interval of 0.25 s in the range of 14 – 264. Detector voltage at 1.5 kV.

Substances were identified based on mass spectrum and retention time. Quantification was performed by comparing the sample peak area and the external standard with the correction for the internal standard.

The used analytical method, gas chromatography-mass spectrometry (GC/MS) was similar to the scientific study by **Pedersen et al. (2003)** and **Dziadas and Jeleń (2010)**.

Basic measured parameters of analyzed grapes were: weight 50 berries (76 g); red. sugar (22.8 °NM); pH (3.27); titric acids (7.6 g.L^{-1}).

The basic measured parameters of the analyzed wine were: red. sugar (0.1 g.L^{-1}), content of alcohol (11.7%); pH (3.5), titr. acids (7.94 g.L^{-1}).

Statistical analysis

After measuring terpene content in the samples, the results were statistically evaluated using simple descriptive statistics and the ANOVA method- one-factor method (without repetition). For statistical analysis, we used statistical software MS Excel (v.16.0, Microsoft-Windows).

RESULTS AND DISCUSSION

In the study, **González-Rodríguez et al. (2011)** three new commercial fungicides have been applied to wines according to GAP, which due to the aromatic structure of white wines. In the presence of fungicidal residues, the scent manifestation of geraniol was significantly reduced, thereby significantly reducing the floral nuance. However, it has not been shown that these fungicides have affected the formation of 1-hexanol and cis-3-hexen-1-ol formed during the fermentation processes, including harvesting, transport, crushing, and pressing.

Aim of the study **Zeleňáková et al. (2011)** was to examine of factors (manufacturer, temperature and storage time) influencing the variability of yeast amount and pH changes in bottled white wines. They discovered that storage time did not significantly impact the amount of yeast in wine (p = 0.5507).

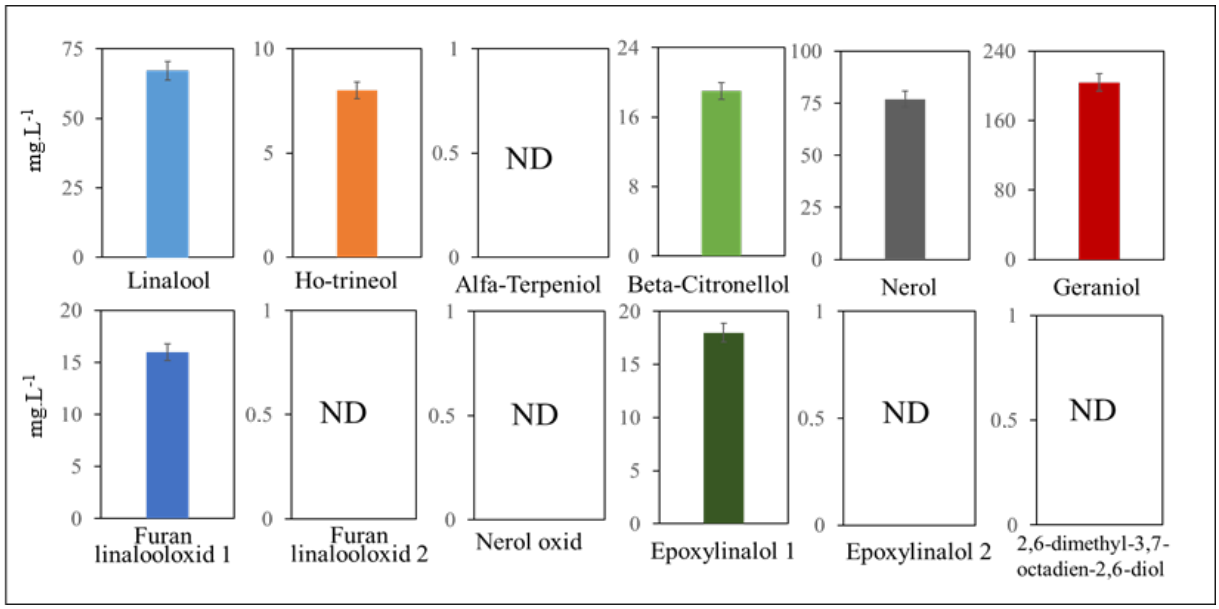

Figure 1 Values of the content of free terpenic substances in berries of the cultivar Pálava.

According to **Synos, Reynolds, and Bowen (2015)**, the use of various yeasts affects the content of ethyl isobutyrate, isoamyl acetate, 3-octanone, hexanoic acid, nerol, phenylethanol, and vitispiran. This claim was based in particular on the formation of various volatile substances found in wine. Using commercial yeast, the type of wine, berry processing, and fermentation is a factor for increasing the incidence of terpenes. **Lengyel and Panaitescu (2017)** studied the accumulation of free volatile terpene flavors (FVT) and bound precursor terpene flavors (BPT) under the action of 12 selected wine yeast strains. The 12 strains used in the alcoholic fermentation resulted in the determination of considerable amounts of terpene flavor compounds, between 370 $\mu g.L^{-1}$ and 1100 $\mu g.L^{-1}$, which recommends their use in making quality wines. By **Kačániová et al. (2019)** the wine grape berries share a complex microbial ecology including filamentous fungi, yeasts and bacteria. The study **Holešinský et al. (2020)** focused on the isolation of a consortium of microorganisms from spontaneously fermenting that naturally contain lactic acid bacteria, non-saccharomyces yeasts, and saccharomyces yeasts. The smallest amount of ethanol was formed from the isolates containing *Hanseniaspora uvarum*, while *Candida sake* isolate produced the lowest amount of hydrogen sulfide and *Zygosaccharomyces bailii* produced the highest. The killer proteins of *Pichia* spp. on the wine spoilage yeasts, studied by **Błaszczyk, Satora and Sroka (2015)**, are known for their broad spectrum of antifungal activity including pathogens such as *Candida albicans*. In this study, there was stated that the killer toxins could be used in the food industry as selective tools to control infections during the fermentation of wine. We agreed with this opinion. There are a lot of studies that determined the presence of microorganisms in wine and grape berries, namely e. g. **Drożdż et al. (2015)**; **Snopek et al. (2019)**; **Felšöciová, Kačániová and Vrábel (2020)**; **Kunová et al. (2020)**.

Yang et al. (2019) demonstrated that seventeen terpene glycosides were quantified in grapes and wines as pentosyl-glucopyranoside, the content of which ranged from 804 to 836 $\mu g.kg^{-1}$, and from 155 to 192 $\mu g.L^{-1}$. Eight free terpenes were present in wines with their content ranging from 40.1 to 59.7 $\mu g.L^{-1}$.

Compared to the above studies, it was noted that linalool (it has a floral aroma with a touch of lemon and spices) content was significantly higher for bound terpenic substances compared to free terpenic substances in berries ($p \leq 0.05$). Similar results were also observed in the determination of ho-trienol, α-terpeniol, geraniol, furan linalooloxid 1 and 2, nerol oxide, epoxylinalol 1, and 2, and ultimately 2,6-dimethyl-3,7-octadien-2,6-diol were not detected (Figure 1 and 2). To compare and obtain more accurate data, we measured each sample in three repetitions.

A statistically significant relationship between the individual measured attributes in the samples was demonstrated ($p \leq 0.05$).

Kostrz and Satora (2018) stated that the most common terpenes in wines are nerol (associated with citrus, magnolia aroma), citronellol (rose aroma), geraniol (with pleasant rose, geranium aroma), limonene (orange, citrus aroma), linalool (associated with floral, herbal, lavender), citral (with the smell of citrus) and β-ionone (with pleasant seaweed, violet, flower, raspberry).

By **Somkuwar et al. (2019)** among the studied varieties, Nielluccio wine recorded the highest concentration of total volatile compounds (191.53 $mg.L^{-1}$) while, it was least in Caladoc wines (15.45 $mg.L^{-1}$).

Comparing the measured terpene contents with the study **Matujašević et al. (2019)** the total relative content of terpenes in the control sample from 4.80% (Banat Muscat) to 24.78% (Radmilovac Muscat), in the sample with a lower dose of the enzyme (0.3 $g.kg^{-1}$) from 8.05% (Italia Muscat) up to 50.85% (Early Muscat) and in the sample with the higher dose of the enzyme (0.7 $g.kg^{-1}$) from 11.07% (Italia Muscat) to 34.78% (Radmilovac Muscat). The content of terpenic substances increased by an application of enzymes.

From this aspect, it can be deduced that in this way an increase in volatile and terpenic substances can be

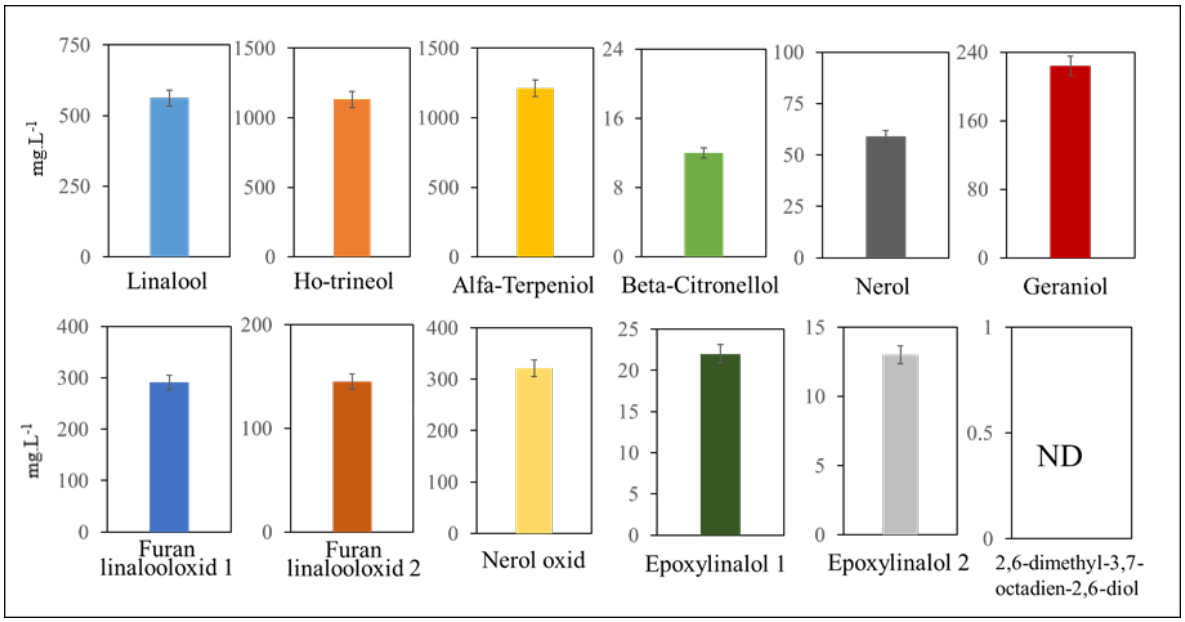

Figure 2 Values of content of bound terpenic substances in berries of cultivar Pálava.

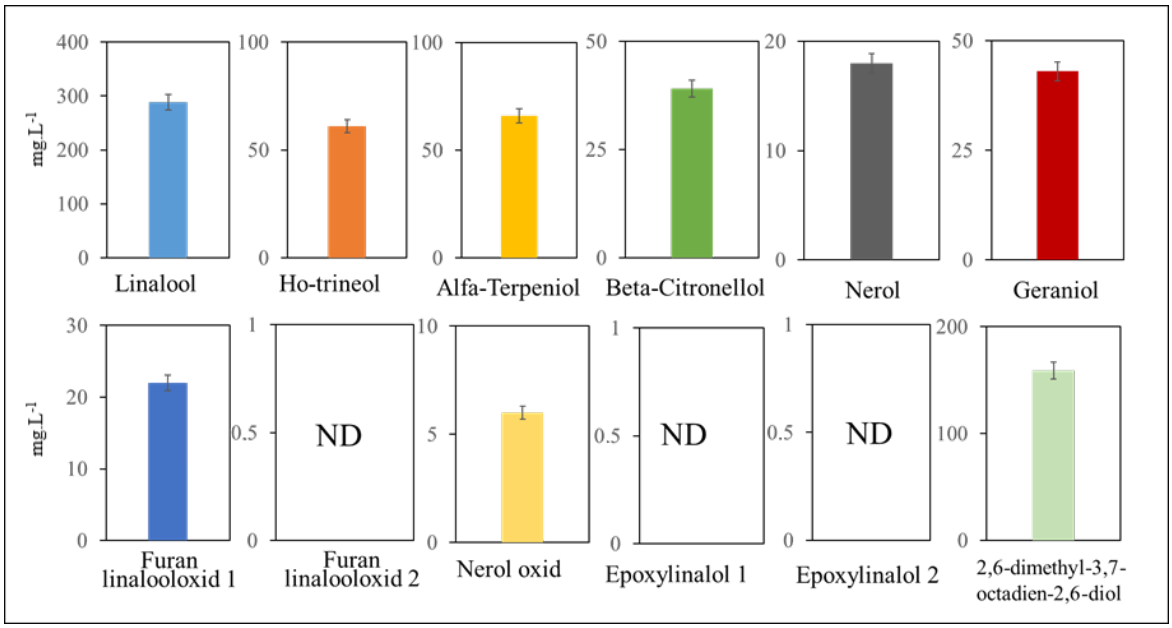

Figure 3 Values of total terpenic substances in wine of the cultivar ´Pálava´.

achieved.

By comparing results which are shown in Figure 3, we noted that despite β-citronellol, the content of terpenic substances was very low. 2-6-dimethyl-3,7-octadien-2,6-diol were measured only in wine samples wherein the samples of fresh berries were not detected.

We demonstrated a statistically significant meaning between the measured values of terpene compounds in the wine ($p \leq 0.05$).

Baron et al. (2017) deal with the determination of the content of both free and bound terpenes in berries and wine. They declared that the terpene content in wine increased gradually with the period of maceration. The highest and the lowest amounts of terpenes were recorded after 24 hours of maceration and no maceration, respectively. We agreed with this opinion because the length of maceration affects the content of terpens in wine. Otherwise, in the study **Blagoeva et al. (2020**) there was noted it is necessary to regulate the temperature of alcoholic fermentation to values of 14 – 16 °C to obtain a high-quality organoleptic profile.

Wang et al. (2020a) detected free terpenes by using solid-phase microextraction-gas chromatography-mass spectrometry (SPME-GC–MS). Their findings indicate that the matrix effect of phenolic acids can effectively control the release and modulate the global feature of wine aromas. In another similar study **Song et al. (2020)** the determination of the total concentrations of terpene glycosides were 7.32, 3.50, and 81.27 mg.kg^{-1} in Ecolly, Cabernet Gernischet (CG), and Muscat Hamburg (MH) grapes, respectively. **Haygarov, Yoncheva and Dimitrov (2016)** determined the content of terpenes in selected grape varieties Rubin and Storgozia. The presence of terpenes was less marked and there was no significant difference in the quantity and quality of aromatic components. **Cehula et al. (2020)** presented in their study that wines with superior sensory properties did not contain higher levels of antioxidants or higher antioxidant activity. The formation of 13 volatile compounds was studied by **Lakatošová et al. (2013)**. Authentication of particular aromatic substances in typical Slovak wines and its saving in newly founded database can help to prevent wine falsification. They registered significant differences in the production of isoamyl acetate, 1-hexanol and 1-heptanol ($p \leq 0.05$).

Liu et al. (2017) noted that the major aroma components in grapes and wine include free volatile compounds and glycosidic nonvolatile compounds. Glycosidic aroma precursors are important reserves of grape and wine aroma components. Investigations concerning the chemical structures. The most used sulfur dioxide in winemaking owing to its antioxidant and antimicrobial properties. **Wang et al. (2020b)** studied to reveal the varietal characteristics of terpene glycosides (TGs) in ripe Meili grapes. They found that 49 of TGs were detected by UPLC–Q-TOF-MS. Monoterpenol pentosyl-glucosides were the main TGs, especially $C_{10}H_{18}O_2$ pentosyl-glucoside, which constituted 51.94 – 52.72% of the total concentration. **Shih et al. (2019)** found a novel application of terpene compound α-pinene for the alternative use of sulfur dioxide. They showed that α-pinene possessed an excellent antibacterial ability and could be a viable alternative for SO_2 in winemaking.

CONCLUSION

In this study, we demonstrated huge differences between measured results of content of terpenic substances in extracts of fresh berries of grape (*Vitis vinifera*) and extracts of wine. In both types of samples, we selected the typical Czech cultivar Pálava. We found significant relationships between total terpenic content *($p \leq 0.05$)*. Using uncommercial yeast could have a possible effect on the content of bioactive substances. We increased in wine volatile and terpenic substances by the used method and the results can be achieved. Also, we have once again justified the importance of wine production technology regarding fermentation.

MILK CONSUMPTION IN CHILDHOOD AND ADULTHOOD AND ITS EFFECT ON BODY COMPOSITION

Kristína Jančichová, Martina Gažarová, Marta Habánová, Jana Kopčeková, Jana Mrázová, Petra Lenártová

ABSTRACT

Throughout their life, people are exposed to many different types of milk. First, it is breast milk if infants are breastfed or special formula based on cow milk with modified composition if they are not breastfed. Later in life, it is recommended that humans consume the milk of other mammals as a source of highly valuable protein, calcium, and phosphorus. This work aimed to evaluate the effects of methods and duration of feeding in infancy and consumption of milk or milk alternatives in adulthood on body composition. We used a questionnaire of 21 specific questions to obtain information on breastfeeding and milk consumption. All 84 participants (18 men, 66 women; age 23.26 ±1.36) underwent measurement of body composition, using BIA methods (InBody 720). A comparison of the information from the questionnaire with the information from the body composition measurement was made. Significant differences were observed in visceral fat area (p = 0.048) and waist-to-hip ratio (p = 0.022) according to duration of breastfeeding. Participants who were fed formula for a shorter time than 1 year (until 12 months of age) showed a higher percentage of body fat (p = 0.047). The fat percentage of milk was a significant factor for the waist-to-hip ratio (p = 0.026). Participants consuming plant-based milk alternatives showed significant differences in waist-to-hip ratio (p = 0.031) and body mass index (p = 0.015) and highly significant differences in weight (p <0.001) and fat-free mass (p <0.001). In conclusion, results show that the duration of breastfeeding may prevent the development of overweight and eventually obesity. Usage of infant formulas as an alternative to breast milk should be limited to those who are unable to breastfeed. The current consumption of milk indicates the benefits of whole milk in the diet but also shows increasing interest in the advantages of plant-based milk.

Keywords: milk; breastfeeding; plant-based milk; body composition; milk fat percentage

INTRODUCTION

From the very first day of their life, humans are introduced to milk. They are exposed to breast milk or formula as the only sustenance until 6 months of age. Breastfeeding should then continue up to 2 years of age and beyond, but children should also begin to eat adequate complementary foods as recommended by the WHO **(WHO, 2011)**. Human milk composition is dynamic and varies daily, during a feeding, based on the lactation stage, between mothers and populations. The mean macronutrient composition of mature milk is estimated to be approximately 0.9 to 1.5 g of protein, 3.2 to 3.6 g of fat, and 6.7 to 7.8 g of carbohydrates, mainly lactose (6.5g) in 100 ml. Energy is estimated to range from 65 to 70 kcal (270 to 295 kJ) in 100 ml and is highly correlated with the fat content of human milk. Macronutrient composition differs; preterm milk tending to be higher in protein and fat **(Ballard and Morrow, 2013)**. Mineral content is approximately 0.2g, represented by calcium, phosphorus, sodium, potassium, magnesium, and iron. Vitamins present in the milk include A, D, E, C, and B vitamins, but human milk is deficient in vitamin K **(Bernier, Adrian, and Vidon, 1988)**. Breastfeeding provides many positives for both infants and mothers: decreased postpartum bleeding and faster uterine involution caused by increased concentrations of oxytocin, decreased menstrual blood loss and increased child spacing attributable to lactational amenorrhea, earlier return to pre-pregnancy weight, decreased risk of breast cancer, decreased risk of ovarian cancer, and possible decreased risk of hip fractures and osteoporosis in the postmenopausal period **(American Academy of Pediatrics, 2005)**. Known effects in infants include a decrease in child morbidity and mortality; protection against diarrhea, respiratory infections, and otitis media; and a possible 68% reduction of malocclusion in children **(Victora et al., 2016)**. There are also positive effects on cognitive skills, which determine educational outcomes, and on knowledge and skill accumulation during both childhood and adult life. Longer breastfeeding duration is also associated with decreased autistic traits and decreases the risk of overweight and obesity in adulthood **(Victora et al., 2016; Boucher et al., 2017)**. However, breastfeeding for longer than 12 months or during the night increases the risk of dental caries in

deciduous teeth **(Tham et al., 2015)**. Despite all the positive effects, many infants and children do not receive optimal feeding. WHO reports that only about 44% of infants aged 0 – 6 months worldwide were exclusively breastfed throughout 2015 – 2020 **(WHO, 2020)**. Unfortunately, some mothers are not able to breastfeed. Known alternatives include human milk provided by milk banks or infant formulas. The main ingredient of an infant formula is usually cow milk, which must be modified because of its different composition than human milk **(Blanchard, Zhu and Schuck, 2013)**. The composition of infant formula is defined by The European Union Commission Directive (2006) concerning infant formula that applies to all member states **(European Commission, 2006)**. Nevertheless, formula-fed infants face a higher risk of diseases due to a lack of specific and innate immune factors present in human milk **(Stuebe, 2009)**. Later in life, it is recommended that people continue to have milk intake, most frequently cow milk, because it contains several essential nutrients **(Haas et al., 2019)**. Cow milk is proposed as a useful eatable, mainly during childhood and adolescence, when its content of calcium (125 mg per 100 ml), the protein of high biological value (3.5 g per 100 ml), phosphorus (100 mg per 100 ml), and other micronutrients promotes skeletal, muscular, and neurological development **(Blanchard, Zhu and Schuck, 2013; Visioli and Strata, 2014)**. However, its relatively high-fat content (approximately 70% SFAs; myristic and palmitic acids combined account for ~50%, the remainder are mostly short- and medium-chain FAs and oleic acid) has marked it as potentially detrimental food, especially in connection to cardiovascular health **(Visioli and Strata, 2014; Juráček et al., 2020)**. Furthermore, due to widespread health issues linked to milk consumption, such as lactose intolerance or milk allergies, and lifestyle changes, an alternative market for plant-based milk is emerging **(Chalupa-Krebzdak, Long and Bohrer, 2018)**. Plant-based milk alternatives are fluids made from ground plant matter (cereals, pseudo-cereals, legumes, oilseeds, nuts) extracted in water. Further homogenization is necessary and results in particle size distribution in the range of 5–20 μm, which imitates cow milk appearance and consistency **(Sethi, Tyagi and Anurag, 2016)**.

Scientific hypothesis

Many studies confirm and highlight the beneficial effects of breastfeeding on health in later life. This study aimed to determine whether breastfeeding in childhood affects the development of body composition and to observe differences between breastfed and formula-fed participants. We also try to refute the stigma that consuming whole milk is not suitable for maintaining optimal body weight and body fat.

MATERIAL AND METHODOLOGY

We examined the relationship between breastfeeding in childhood, milk and milk alternatives consumption, and body composition in adulthood. A questionnaire method was used to obtain information on breastfeeding in infancy and the current consumption of milk and milk alternatives. Each participant completed the questionnaire alone and anonymously. The survey involved 84 participants, 18 men (21%), and 66 women (79%). The average age of the participants was 23.26 ±1.36. The questionnaire consisted of questions on gender, age, educational level, health status, and certain anthropometric parameters, and 21 specific questions on milk consumption. Body composition data were obtained using InBody 720 (Biospace Co. Ltd., Seoul, Republic of Korea), a multi-frequency bioelectrical impedance analyzer (BIA). Measured parameters included body weight (kg), FM (fat mass, kg), FFM (fat-free mass, kg), percentage of body fat (%), VFA (visceral fat area, cm^2), WHR (waist-to-hip ratio), and BMI (body mass index). We compared the information from the questionnaire with the information from the body composition measurements. Participants undergoing measurements using BIA were healthy, without a pacemaker. None of the women were pregnant. All participants provided written consent to the bioelectrical impedance measurement.

Statistical analysis

Statistical analysis was carried out using MS Excel 2010 (Los Angeles, CA, USA) and STATISTICA Cz version 10 (**TIBCO Software Inc., Palo Alto, California, USA**). Data were expressed in **Figure 1** and **Figure 2** as a mean ± standard deviation (SD), minimum, maximum, median, and mode were calculated. Statistical comparisons between groups were made utilizing a one-way analysis of variance (ANOVA) followed by Tukey's post hoc test. Significance levels were determined as p <0.05 (*), p <0.01 (**), and p <0.001 (***).

Table 1 Mean values of selected anthropometric parameters according to the duration of breastfeeding

Duration of breastfeeding	Anthropometric parameter						
	Weight [kg]	FFM [kg]	FM [kg]	Percentage of body fat [%]	VFA [cm^2]	WHR -	BMI [kg/m^2]
<4 months	70.66	49.94	20.72	27.46	78.60[1]	0.87[1]	24.35
4 – 6 months	65.34	49.85	18.49	23.86	62.80	0.85	22.80
6 – 12 months	67.40	50.82	16.58	24.56	67.26	0.85	23.13
>12 months	59.75	46.52	13.23	21.92	52.12[1]	0.82[1]	20.99

Note: [1]p <0.05 was considered statistically significant.

RESULTS AND DISCUSSION

Breastfeeding

We compared the participants who were breastfed as infants with those not breastfed and investigated the potential effect of breastfeeding on body composition. The differences were not significant, which could be due to the uneven distribution of participants, breastfed (n = 80), and non-breastfed (n = 4). However, breastfeeding may have a small but consistent protective effect on obesity prevention, as indicated by a meta-analysis of 9 studies with more than 69,000 subjects, concluding that breastfeeding significantly reduces the risk of developing obesity in adult humans (Arenz et al., 2004). Some studies suggest that breastfed infants tend to have lower FM when compared with formula-fed infants. When we examined the FM to weight and FM to lean body mass ratio, breastfed infants showed lower values. Formula-fed infants tend to have a lower lean body mass to body weight ratio (Pludowski et al., 2009). Breastfeeding directly from the breast appears to be the safest way for children to receive breast milk. It protects against obesity, as these children have the least chance of being overfed. In infants fed breast milk from a bottle, the risk is higher but still low, as breast milk helps to create an intestinal microbiome that is likely to help prevent obesity **(Azad et al., 2018)**. Breastfeeding protects against overweight and obesity in children by inducing lower plasma insulin levels, thereby reducing fat storage and preventing excessive early adipocyte development **(Oddy, 2012)**. Significant differences in body composition depending on the duration of breastfeeding in childhood were observed for VFA (p = 0.048; **Figure 1**) and WHR (p = 0.022). In both cases, there was a significant difference between participants breastfed for less than 4 months and those breastfed for more than 12 months. Higher mean values of VFA and WHR were present in participants breastfed for less than 4 months **(Table 1)** and therefore did not meet the WHO recommendations of min. 6 months of breastfeeding **(WHO, 2011)**. This finding agrees with the claim that infants breastfed longer (6 months or longer) have a reduced risk of developing overweight and obesity **(Victora et al., 2016)**. Long-term breastfeeding is directly related to a decreased risk of obesity **(Yan et al., 2014)**. The recorded changes in other measured parameters were not significant, but they were visible in the graphic display. Participants who were not breastfed were fed formula, which replaced breast milk. The use of infant formula increases the risk of childhood obesity due to overfeeding, and childhood obesity is often carried into adulthood **(Azad et al., 2018)**. We observed significant differences in the percentage of body fat in the group of formula-fed participants. Participants fed for only 1 year (until 12 months of age) showed higher values when compared to participants fed for 1.5 years (until 18 months of age) (26.02% to 19.16 %, respectively; p = 0.47). Exclusive breastfeeding prevents improper dietary practices, such as the early introduction of complementary foods, which could lead to unhealthy weight gain. Protein and total energy intake are higher in formula-fed infants compared to breastfed infants, which is positively associated with the development of obesity later in childhood **(WHO, 2014)**, leading to an increase in total cholesterol in adulthood **(Owen et al., 2008)**. Unfortunately, infant formula, which should be considered a specialized food that is vital for children who cannot be breastfed, is becoming a regular meal for children due to promotion and marketing **(McFadden et al., 2016)**.

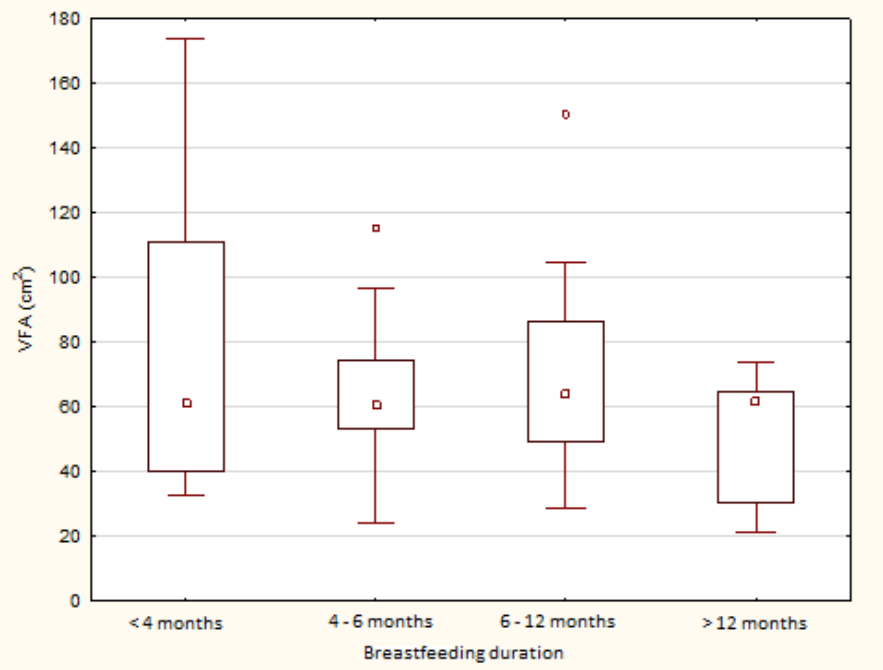

Figure 1 Differences in VFA according to duration of breastfeeding in infancy.

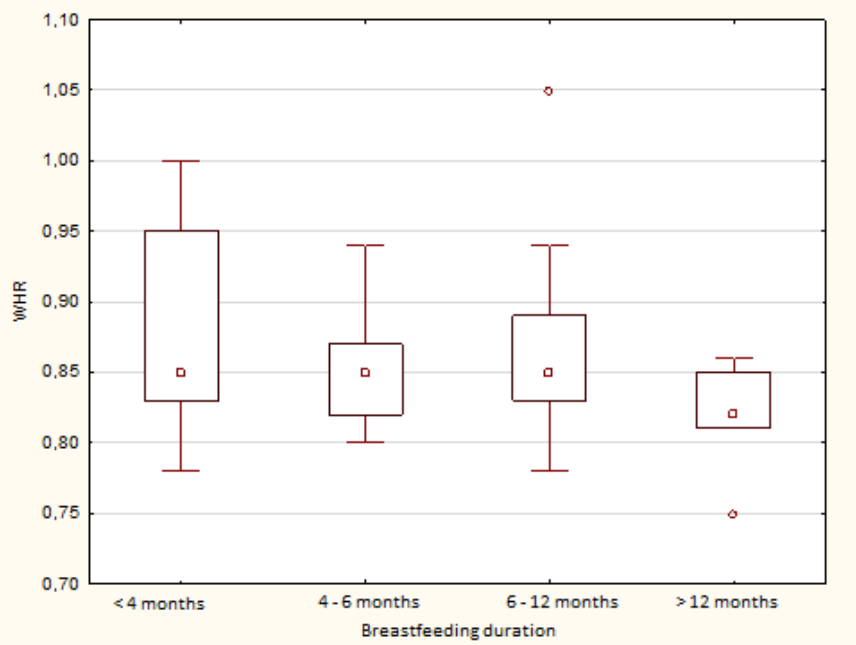

Figure 2 Differences in WHR according to duration of breastfeeding in infancy.

Current milk consumption

We investigated the effects of current milk consumption in participants on body composition. Participants were divided into 2 groups, consumers, and non-consumers of milk. We did not find any significant differences; in fact, the values of anthropometric parameters were very similar **(Table 2)**. Available scientific evidence suggests that consumption of milk and dairy products does not adversely affect body weight or body composition **(Spence, Cifelli and Miller 2011; Schwingshackl et al., 2016)**. Most of the cross-sectional and prospective studies suggest a favorable relationship between milk consumption, body weight, and body composition in children and adolescents. Also, milk is an important source of calcium, vitamin D, phosphorus, and potassium in the diet of children aged 2 to 18 **(Spence, Cifelli, and Miller 2011)**. Following the milk consumption analysis, we paid separate attention to the fat percentage in milk, according to the possibilities available on the market (fat content 0.5%; 1.5%; 3.5%). We observed a significant difference in WHR between the groups consuming milk with a fat content of 1.5% and 3.5% (0.86 and 0.83, respectively; $p = 0.026$; **Figure 2**). A higher percentage of fat in milk is inversely related to weight gain and thus is not a factor for the development of overweight and obesity **(Rautiainen et al., 2016)**. Today, many people succumb to the phenomenon of plant-based milk because of health or other reasons. Therefore, we also monitored the effect of these beverages on body composition and its parameters. The mean values of anthropometric parameters according to the consumption of plant-based milk are shown in **Table 3**. We observed statistically significant differences in the parameters of

Table 2 Mean values of selected anthropometric parameters according to current consumption of milk.

Participants	Anthropometric parameters						
	Weight [kg]	**FFM [kg]**	**FM [kg]**	**Percentage of body fat [%]**	**VFA [cm^2]**	**WHR -**	**BMI [kg/m^2]**
Consumers	67.15	50.26	16.90	24.62	67.01	0.86	23.11
Non-consumers	64.37	48.83	15.54	24.3	62.71	0.85	22.79

Table 3 Mean values of selected anthropometric parameters according to current consumption of plant-based milk.

Participants	Anthropometric parameters						
	Weight [kg]	**FFM [kg]**	**FM [kg]**	**Percentage of body fat [%]**	**VFA [cm^2]**	**WHR -**	**BMI [kg/m^2]**
Consumers	59.51[2]	44.49[2]	15.2	24.74	60.55	0.84[1]	21.86[1]
Non-consumers	77.98[2]	61.00[2]	16.98	22.3	68.75	0.89[1]	25.38[1]

Note: [1]differences at $p < 0.05$ were considered significant, [2]differences at $p < 0.001$ were considered highly significant.

weight and FFM. Mean body weight in participants consuming plant-based milk alternatives was 59.5 kg and those who did not consume plant-based milk 77.98 kg (p <0.001). Similarly, the mean FFM of consumers was 44.49 kg and of non-consumers 61.00 kg (p <0.001). Significant differences were also noted for WHR (0.84 to 0.89 respectively; p = 0.031) and BMI (21.86 vs. 25.38, respectively; p = 0.015). These differences may be due to the different nutritional composition of plant alternatives to milk, in particular their lower energy content. It is not recommended to use these beverages as substitutes for cow milk **(Singhal, Baker and Baker, 2017; Vanga and Raghavan, 2018)**, even though calcium-fortified soy beverage is comparable to cow milk in its macronutrient content **(Silva, Silva and Ribeiro, 2020)**.

CONCLUSION

We did not observe significant differences between breastfed and non-breastfed participants, but in those who were breastfed as infants, the duration of this period played a significant role. Significant differences were detected in VFA (p = 0.048) and WHR (p = 0.022) between participants breastfed for less than 4 months and breastfed for more than 12 months. This finding is consistent with the WHO recommendations and the benefits of breastfeeding. Participants that were formula-fed as infants showed a higher percentage of body fat (p = 0.047) when fed for less than 1 year (12 months). Consumption of milk did not cause significant differences in body composition. However, the fat percentage of milk was a significant factor for WHR (p = 0.026), refuting claims that whole milk is a detrimental food. Participants consuming plant-based milk alternatives showed significant differences in WHR (p = 0.031) and BMI (p = 0.015) and highly significant differences in weight (p <0.001) and FFM (p <0.001). Those differences are most likely due to the lower energy content of these beverages and various protein and fat compositions based on the raw materials used for production.

ADHESION OF MARZIPAN PASTES BASED ON DRY DEMINERALIZED WHEY

Igor Stadnyk, Volodymyr Piddubnuy, Mykhail Kravchenko, Larysa Rybchuk, Olena Kolomiiets, Svitlana Danylo

ABSTRACT

The results of researches of rheological and adhesion characteristics of marzipan pastes with dry demineralized whey (DDW) and glycerin are given. The positive effect of dry demineralized whey and glycerin on the characteristics of model compositions of marzipan pastes has been established. The component compatibility of DDW and almonds has been confirmed. It has been experimentally established that DDW and glycerin lead to changes in the structural state of marzipan pastes, changing the quantitative values of rheological characteristics. It is confirmed that with increasing DDW concentration, the indicators of deformation and plasticity increase. The indicators of elasticity and resilience of marzipan paste decrease, which in general leads to an increase in molding ability. The surface effect on the properties of marzipan pastes with dry demineralized whey and glycerin was carried out. The technological expediency of using glycerin in the composition of marzipan pastes with DDW to increase their plasticity and pliability while maintaining high molding properties is substantiated. The rational content of glycerin is established, which allows regulating the adhesion properties within the set limits for paste-like finishing semi-finished products from marzipan masses. The rational content of DDW and glycerin in the composition of marzipan pastes while ensuring high functional and technological properties in the application of confectionery flour on the surface is substantiated. Mathematical modeling of adhesion behavior of marzipan pastes is carried out. The adhesive properties of the pastes are mathematically substantiated and their ability to have flexibility under the action of the applied shear stress is confirmed within the established limits. Its currents are considered and substantiated. A study of moisture absorption by flour confectionery when covered with marzipan paste is provided. The wetting angle is considered and the work of adhesion is determined. Based on researches the directions of use of the developed marzipan pastes in confectionery production as finishing semi-finished products for a covering and as a layer for flour confectionery products and modeling of figured products are offered.

Keywords: marzipan paste; adhesion; whey powder; glycerin; rheological properties; modeling

INTRODUCTION

Confectionery production is an art, so there is a fleeting fashion. The quality of products significantly depends on how receptive the manufacturer is to the latest trends in the product market, how he/she knows the tastes of consumers, and their solvency. With the country's entry into a new level of market relations, the assortment policy of the food industry in general and confectionery, in particular, has changed. In the conditions of market competition more and more attention is paid to the level of aesthetics of confectionery products. The range of confectionery and semi-finished products produced in our country is diverse, constantly changing, and has about 5,000 items. Stricter consumer requirements for the taste of confectionery products with a limited raw material base and reduced quality of raw materials encourage scientists to create a new direction in the confectionery industry which is the development of compound foods based on raw materials in certain regions.

Improving technological processes is one of the main directions in the food industry. It involves the study of changes in physicochemical properties when using various methods of influencing natural raw materials used for human nutrition. Extensive opportunities in this direction open up when creating such process conditions that provide a comprehensive impact on raw materials. Therefore, the main technological directions in the development of new types of confectionery and semi-finished products are to improve the range of products for baby and dietary nutrition, increase the amount of protein, reduce carbohydrates, and especially sugar. To solve this goal, the addition of various fillers to the composition of sugar masses, which enrich the product with biologically active substances, has recently become widely used.

Modern semi-finished products for confectionery products are represented by a wide range of various creams, chocolate, marzipan, sugar, paints, toppings, cast caramel decorations, etc. A special place among the finishing confectionery semi-finished products is occupied

by marzipan mass of a mixture of raw almond kernels, apricots, or nuts. Due to the exclusivity of organoleptic properties and versatility of use in various areas of confectionery production **(Tamova, Shchikarev, and Basyuk, 2015)**, the paste has the necessary set of substances for the human body. Due to the high level of import dependence **(Dmitrieva and Makarova, 2016)**, the production of marzipan in Ukraine is limited, because 80% of the almond kernel consumed in Ukraine is of foreign production. This necessitates the search for new ingredients of domestic production, which will reduce the share of imports of dependent raw materials in the recipes of marzipan masses and reduce the cost of finished products. At the same time, it is important to preserve the typical marzipan taste, aroma, and structure of the product, as well as to increase its biological and nutritional value. Such improvement of existing technologies of marzipan pastes should be based on the use of non-traditional vegetable raw materials aimed at increasing the biological value, reducing energy consumption, improving flavor and functional and technological properties.

Analysis of model approximations of medium types

Most confectionery consists of sugar or other sweet substances (honey, xylitol, sorbitol), as well as molasses, various fruits and berries, milk, butter, cocoa beans, nut kernels, flour and other components. These are mainly sweet products that have a pleasant taste and aroma, good appearance, high nutritional value, calories and good digestibility.

In the work of **Tamova, Shchikarev and Basyuk (2015)** and **Kozlova (2014)** it is noted that the choice of process parameters involves comprehensive research to identify the nature of changes in the structure and properties of both individual components of raw materials and raw materials as a complex. Therefore, the participation of scientists in the implementation of technology is to deepen the understanding of the importance of nutrition in human life, taking into account national traditions, transformations of individual food components in the body structure, their impact on organs and systems. Preservation of valuable nutrients and BAS, the formation of habitual consumer characteristics, high bioavailability and product safety is based on the development of production technologies with the necessary physiological properties by improving recipes, methods and modes of processing raw materials, technological parameters of production.

Developed technologies of marzipan pastes **(Apet and Pashuk, 2004; Pat. No. 2015152421, 2017)** the authors aim to find and study the physiological and technological properties of non-traditional raw materials, which in terms of biologically active substances (BAS) can be attributed to the so-called functional ingredients, studying their influence on the course of preparation and formation of product quality. The recipe mainly included walnuts, hazelnuts, cashews, pecans, peanuts, chestnuts, cherry stones, apricots and pumpkin seeds. Replacement of almonds with peach or apricot pits **(Chorrna et al., 2015)** was accompanied by the name of the made persipan paste. In the works **(Chorrna et al., 2015; Tamova et al., 2015)** it is noted that the optimal quality of marzipan mass can be obtained from sweet almonds with the addition of 1 – 2% bitter. Its limitation is due to the danger of the formation of hydrocyanic acid from amygdalin.

In works (**Apet and Pashuk, 2004; Pat. No. 2015152421 (2017)** the ways of strengthening of taste and aromatic indicators of marzipan pastes are noted. Their prescription composition may include a variety of non-traditional raw materials, such as coffee meal, chicory powder, bunduk seeds. This approach gives marzipan pastes the smell of coffee and the taste of hot chocolate. At the same time, other works **(Apet, 2004; Pat. No. 20150211, 2016)** noted that the use of pear and amaranth seed powders not only enhances the taste and aromatic qualities of marzipan pastes but also improves rheological characteristics due to the high oil content. This creates the conditions for increased viscosity and adhesion stress, which improves the formation of these confectionery masses.

Reducing the caloric and glycemic content of finishing semi-finished products in their production happens by using different technological properties, origin, composition, caloric content and sweetness of sugar substitutes and sweeteners. Technologies of marzipan paste with low sugar content **(Pat. No. 20150141, 2016; Pat. No. 2016127117, 2017)** are represented by model compositions of sodium or potassium acesulfame, aspartame. The use of synthetic sweeteners indicates the lack of such compositions. Studies by the authors **(Fernandez and Santos, 2018; Zeynep and Sifa, 2014)** confirm their negative impact on human health.

The use of natural sweeteners in the technology of marzipan pastes, namely: agave syrup, erythrol, stevioside, palatinosis can significantly reduce the high caloric content **(Pat. No 20150211, 2016)**. Known technologies of marzipan masses **(Pat. No. 20150211, 2016; Pat. No. 20150141, 2016)** in which various types of flax, barley, buckwheat, corn, lentil, rice are used as fillers as well as pea flour, increase the internal forces of adhesion of the components of marzipan masses. Such fillers bind moisture better and promote the formation of a more homogeneous and plastic structure of the mixture during molding. However, despite the positive attitude, these compositions reduce the organoleptic characteristics due to the presence of a sharp cereal taste and aroma. Baby foods that are part of the diet of children need special care as objects of enrichment. Their bodies are more sensitive to non-traditional ingredients because children's metabolic systems are not yet sufficiently formed and are not able to withstand high loads, to respond adequately to them.

Dried chokeberry berries and medlar leaf powder are used as a functional additive in marzipan paste technologies. This allows not only to increase the nutritional and biological value but also to achieve the maximum possible preventive effect with a relatively small content of marzipan pastes. As an antioxidant use the drug "Cyclorar". This biologically active substance improves the nutritional value of marzipan masses and improves its molding properties.

The main disadvantage of marzipan pastes with these additives is reduced sensory characteristics. The use of additives to enrich the nutritional composition has a significant effect on changes in the color and taste of this product. As a result, there are problems with the toning of

marzipan paste and obtaining the appropriate color scheme. This makes this type of finishing semi-finished product unsuitable for confectionery coating and modeling of figured finishing semi-finished products. The raw material for the production of marzipan pastes due to biological, physical, and mechanical factors changes its properties and acquires characteristic of this type of paste. The process of production of pastes can be considered as a set of processes of change of rheological characteristics of the formed semi-finished product according to a compounding under the influence of biological, physical, and mechanical factors. On the other hand, changes in rheological characteristics affect the choice of design and modes of operation of equipment. Therefore, the complex of rheological (structural and mechanical) properties of marzipan pastes are the most important, which predict their state in a variety of technological processes and characterize the physical state, dispersion, structure, structure, and type of interaction.

It is established that methods and means of determining the rheological characteristics of different types of deformation affect product quality **(Stadnyk et al., 2019)**. In our opinion, the works by **Kravchenko et al. (2019)** give some examples of calculations of technological processes and equipment aimed at studying the physical and mechanical properties of the environment. This approach allows to improve and intensify the technological process, to develop scientifically sound methods for calculating the technology of forming marzipan pastes.

Developed technologies of marzipan and praline masses **(Sirohman and Lozova, 2008; Pat. No 2008121837, 2009)** in the prescription composition of which included milk powder, in our opinion allowed to improve consumer properties and reduce production costs. It is known that DDW is used in the manufacture of confectionery as a substitute for condensed or powdered milk in the production of creamy caramel, iris, fondant, icing, chocolate **(Kravchenko et al., 2020)**.

As a result of the analysis of literature and patent sources, the wide use of glycerin in the prescription composition of paste-like finishing semi-finished products was revealed. Glycerin in the technology of sugar pastes is used to reduce the stickiness (adhesion) of the food system, it gives softness to the pastes, improves the molding properties, makes them more pliable in the manufacturing process of finishing semi-finished products **(Gulenko, Sibileva, and Zhyvotkevych, 2013)**. This determines the relevance of research on the feasibility of using glycerin in the technology of marzipan pastes with DDW.

The creation of a new technology of marzipan pastes with DDW, the feasibility of using glycerin in their composition requires in-depth studies of rheological and sensory characteristics of finished products to justify rational technological processes, which largely determine the consumer and functional properties of marzipan pastes. The relevance of the search for new recipe ingredients for marzipan masses in the partial replacement of almond flour, the use of which can simultaneously solve several technical problems to ensure the specified organoleptic and rheological properties, is quite high.

When calculating the recipe, the main difficulties arise due to the instability of the movement of the paste, and, accordingly, shear deformations, the impact of quality indicators. At the same time, the improvement of the technological process requires the establishment of a relationship between the characteristics of the components that affect marzipan pastes in the formation of products.

Therefore, the main approach to the choice of marzipan paste formulation is to establish rheological connections, which are the most realistic for solving the problem in the formation of semi-finished products and products. Accordingly, the study of the developed marzipan pastes requires in-depth knowledge of all the intricacies of the process, its mathematical description.

Scientific hypothesis

Creation and determination in the prescription composition of marzipan pastes of rational concentration of glycerol with dry demineralized whey to ensure the specified (desired) rheological, surface characteristics, which will help to some extent in ensuring the technological feasibility of use.

MATERIAL AND METHODOLOGY

Materials

Dry demineralized whey made from cottage cheese with 90% level of demineralization under TU U 15.5-00413890-089:2014 **(Table 1)**; marzipan paste, made by traditional technology; model systems of marzipan paste with the addition of DDW in concentrations of 10 – 40% **(Table 2)**, and food glycerin TU U 10.8-40570177-001:2016: 1 – 6% **(Table 3)** of the total mass of dry components of marzipan mass (almond kernel and powdered sugar).

Table 1 Physical and chemical and organoleptic parameters of DDW.

Name of indicator	Characteristics and norm
Taste and smell	Sweet, without foreign tastes and odors
Appearance and consistency	Fine powder
Colour	Light cream
Mass fraction of dry matter, %	97.00
Mass fraction of ash, %	2.63
Mass fraction of lactose, %	75.92
Mass fraction of fat, %	1.0
Mass fraction of protein, %	15.45
The acidity is titrated	4.7
Acidity is active	5.825
Solubility index	Complete solubility

Table 2 Prescription composition of model systems of marzipan pastes, per 100 g.

Name of raw materials	Control	Samples with addition DDW, %			
		10	20	30	40
Powdered sugar	43.0	38.0	33.0	28.0	23.0

Research methods

Sensory properties of model systems of marzipan pastes were determined according to the developed scales of organoleptic descriptors. Marzipan pastes with DDW were differentiated depending on sensory features of a consistence: marzipan pastes for a covering of confectionery; as a layer for flour and confectionery (LFC); marzipan pastes for making candies, bars, tiles; for modeling of figured products (MFP).

The study of the rheological properties of control and experimental samples was carried out using a plane-parallel plastomer of the Tolstoy modification, which is based on determining the shear deformation related to the thickness of the sample at constant stress **(Figure 1)**.

During the study of the rheological characteristics of the model systems, a fixed load was selected for all variants (65 g), provided the same temperature (+6 °C) and sample height (7 mm).

The study of the surface characteristics of the control and test samples was performed on a dynamometer connected to the MIG-1.3 measuring instrument. It allows characterizing the degree of adhesion of materials of a different structure at their surface contact. The adhesion strength was determined by the method of normal separation of the steel plate from the structured body (marzipan paste). The search for the obtained data of the results of the experimental array of the optimal mass fraction of DDW and glycerin in marzipan pastes was carried out according to known methods and methods of statistical processing using the known method of correlation and regression analysis of experimental results using differential operators qualitatively and quantitatively evaluate the characteristics in the selection of matrix ingredients**.**

Statistical analysis

This work is aimed at creating and studying the prospects of using marzipan paste based on a rational concentration of glycerol with dry demineralized whey. Estimation of the basic regularity of change of compounding structure and properties of marzipan paste is based on optimum parameters and modes at its rheological properties. The prescription composition establishes the probability of the obtained results of structure formation, necessary for the description of consumer properties. Features of the effect of glycerin and whey dry demineralized in the formation of the structure of marzipan paste and the conditions for achieving rational rheological parameters, it is possible to predict the adhesion of the paste.

A whole complex of rheological studies was carried out during the development of the prescription composition of marzipan pastes. To clarify the role of glycerol and dry

demineralized whey, the planning and formulation of computational experiments were performed to obtain the appropriate regression equations. The dependence of the structural and mechanical properties of the pastes on the content of DDW and glycerin were constructed by the method of an arbitrary experimental design.

According to the results of rheological studies, it is not recommended to increase the concentration of glycerin by over 5%. These results are confirmed by the results of sensory analysis. The zones of rational concentrations of DDW and glycerin in the composition of marzipan pastes were determined by the method of compromise solutions. Accordingly, the variables, optimization criteria, as well as the area of the definition of factors were identified.

The determined mathematical dependences of the main structural and mechanical parameters of marzipan pastes on the content of glycerin and DDW have the form:

1. by strength index:

$$Y_{1MFV}=-2.35x_1^2-1.25x_2^2-3.14x_3^2+0.13x_1x_2-$$
$$-1.52x_1x_3+0.89x_2x_3+7.27x_1+4.81x_2-6.73x_3+21.07$$

2. by extensibility index:

$$Y_{1MFV}=-1.08x_1^2-0.48x_2^2-0.26x_3^2+0.09x_1x_2-$$
$$-0.87x_1x_3+1.02x_2x_3+5.48x_1+3.48x_2-4.27x_3+7.12$$
$$Y_{2MFV}=18.6x_1^2-1.08x_2^2-0.67x_3^2+3.44x_1x_2-$$
$$-1.04x_1x_3+0.78x_2x_3+4.41x_1+5.48x_2-6.12x_3+122.12$$

3. by the ability to form index:

$$Y_{3MFV}=-0.18x_1^2-0.73x_2^2-2.61x_3^2+0.04x_1x_2-$$
$$-2.94x_1x_3+7.45x_2x_3+2.45x_1-3.57x_2+1.54x_3+2.8$$
$$Y_{3MFV}=-0.15x_1^2-0.46x_2^2-3.07x_3^2+2.01x_1x_2+$$
$$+2.01x_1x_3+6.37x_2x_3+1.76x_1-2.31x_2+1.04x_3+3.9$$

Where:

Y_{1MFV} is strength of marzipan paste *MFV*, points; Y_{2MFV} is extensibility of marzipan paste *MFV*, points; $Y_{3\ MFV}$ is ability to form, points; X1 is content of MJ and CP,%; X2 is content of glycerin,%; X3 is MSDS content,%.

By integration, the functions were obtained and the areas of optimal parameters of glycerol and DDW content in marzipan pastes were determined **(Table 4)**.

The optimal values are selected by rounding the optimized values within the compromise areas, to facilitate the dosing of the components of the formulation of marzipan pastes in the production environment.

Thus, the results of rheological and sensory studies confirmed the possibility of adding DDW to the prescription composition of marzipan pastes at a concentration of 10 – 20%, which allows the improvement of their sensory, technological, and functional properties.

RESULTS AND DISCUSSION

Meeting the needs for high-quality food is one of the main social and economic problems of today. Quality issues **(The European Commission, 2005; DSTU 3355-96, 1996; DSTU ISO 9001, 2015)** in particular the development of new products at domestic food companies, are now receiving increasing attention. Consumption or maintenance of a balanced and nutritious diet is ensured by the implementation of national programs to improve food quality and an integrated food safety system. That is why the problems of ensuring the safety and quality of products are becoming increasingly important for the food industry of Ukraine. This is facilitated by the country's transition to new political and economic relations with the European Union.

An in-depth analysis of rheological and sensory studies of newly developed formulations allows for their further use. Therefore, based on our determined optimal values of marzipan paste LFC, we analyze the effect on the strength of adhesion. The theoretical estimate of adhesion is currently very approximate, due not only to the imperfection of the equations used to calculate the strength of intermolecular bonds but also to the fact that it is impossible to estimate the actual number of bonds per unit area. Also, it is difficult to estimate the true contact area, which is always much larger during visual observation, due to the presence of roughness in the surface layer.

The study of the application of marzipan pastes on confectionery semi-finished products allows us to determine and justify their rationale prescription composition. Adhesion according to **(Adamson, 1976; Rydil, 1936)** as a surface phenomenon is associated with rheological parameters and characterizes the volumetric properties of marzipan pastes. It occurs at the boundary between two phases of heterogeneous condensed bodies: marzipan paste is one phase, the contact surface is the second phase, which causes adhesion.

The volumetric properties of the paste determine the area of contact of the two bodies, which affects the amount of adhesion and its consequence, which characterizes the state of the surface after removal of the adhering mass of the paste.

Adhesion has concomitant phenomena that characterize the bulk properties of food masses and significantly affect the adhesion interaction of the components of marzipan pastes **(Kravchenko et al., 2019)**. The influence of volumetric characteristics of food masses on surface properties can be traced by considering the ratio of adhesion and cohesion **(Stadnyk et al., 2019)**. In the case of adhesion, there is a limit of phase distribution, for cohesion such a limit is absent **(Wake, 1976)**. Cohesion is the body's resistance to destruction associated with overcoming the forces of interaction between atoms and molecules at the interface and means bonding within marzipan pastes, ie within a single phase.

Table 4 The range of optimal parameters of glycerol and MSDS content in marzipan pastes.

Model compositions of marzipan pastes	X_1(glycerin), %			X_2(DDW) %		
	$X_{1\ min}$	$X_{1\ min}$	Optimal value	$X_{2\ min}$	$X_{2\ max}$	Optimal value
Marzipan paste (LFC)	4.8	5.3	5.0	27.0	33.7	30.0
Marzipan paste (MFP)	4.4	4.5	5.0	18.2	22.4	20.0

In the process of applying effort to the marzipan paste when applied to the workpiece is the fractional interaction of their surfaces. The nature of the mass flow of marzipan paste in the form of different profiles is determined by the structural and mechanical properties and the strength of interaction (sticking) with the contact surfaces. Therefore, the amount of adhesion, in this case, is characterized by the force of separation, the specific work of separation relative to the unit area, the contact time to change the bonding conditions between the substrate and the adhesive under load. Therefore, the maximum increase in the forces of interaction of the paste with the contact area of the workpiece is characteristic. Violation of these relationships leads to the production of low-quality products and reduces the efficiency of the process. The phenomenon of the interaction of the above-mentioned bodies is rather little studied, and the nature of adhesion requires research. In works (**Zimon, 1974)** the nature of adhesion is often explained by diffusion and electrical theory. Adhesion is always the result of the intermolecular interaction of surfaces different in nature **(Deryagin, 1978; Zimon, 1974)**.

In the food industry, there are many processes in which the forces of friction and adhesion interact simultaneously. These phenomena occur when the relative displacement of the contact surfaces of the two bodies. In researches by (**Deryagin 1978),** simultaneous interaction of force of friction and adhesion is considered and their connection is established. The law expresses the proportionality of friction forces to a normal load. Some researchers as (**Souheng, 1982; Lee, 1979)** believe that the only cause of external friction is the forces of attraction between the surfaces of bodies. Chemical adhesion may occur during the adhesion of liquid and elastic and plastic food masses **(Berlin and Basik, 1974)**.

In our process, a liquid meniscus appears between the contacting phase parts. In this case, it seems to tighten the particle and the surface. The amount of adhesion will be determined by capillary force:

$$F_k = 4\pi\sigma_T r \quad (1)$$

Where:
σpn is the surface tension of the liquid condensed between the contacting bodies.

According to (**Vakula and Prytinin, 1984)** there is a spreading of a thin layer of liquid that is on a body surface.

If the “adhesion” or “adhesion force” is evaluated by the dependence of M. Stefan and Gorbatov, then such a process takes place in time, ie adhesion is evaluated as a process that must be performed to separate the samples **(Adamson and Gast, 1997; Rydil, 1936)**. Distance differences can characterize the phenomenon of cohesion. In this case, the pressing of the two bodies is a capillary interaction:

$$P = 2\alpha F \cos\beta / h = 2\alpha F_k / h \quad (2)$$

Where:

α is the coefficient of surface tension, N.m^{-1}; $cos\beta$ characterizes surface wetting; α 'is the coefficient of surface tension at full wetting, N.m^{-1}; h is the thickness of the layer of marzipan paste, m.

Assuming that the force applied from the outside to the paste increases linearly with time:

$$P = \omega c * \tau,$$

Where:
ωc is the rate of increase of force, N.s^{-1}; τ is an hour, s.

Assuming that the contact area also varies according to the linear law, we obtain:

$$S = S_0 \cdot C\tau \quad (3)$$

Where:
C is the coefficient of proportionality, which depends on the properties of the product and characterizes the rate of decrease in the area; *S0* is the current value of the area of actual contact, m2.

Substituting (2 and 3) into the dependence of M. Stefan and Gorbatov, taking into account that at the moment of separation his time is obtained:

$$P_0 = \frac{2\alpha}{h} \cdot \frac{\omega_c}{\omega_c + \frac{2\alpha \cdot C}{h}} \quad (4)$$

For convenience, the equation is represented as (5)

$$\frac{1}{P_0} = \frac{h}{2\alpha} \cdot \frac{C}{\omega_c} \quad (5)$$

Since it is assumed that the increase in force and the change in the contact area are linearly dependent on time, we can assume that $C/\omega c$ is a constant value of A, ie:

$$\frac{1}{P_0} = \frac{h}{2\alpha} + A \quad (6)$$

The amount of adhesion is directly proportional to the tension surface of the marzipan paste and inversely proportional to the thickness of its layer. This dependence (6) can occur at a small thickness of the product layer.

Using such thermodynamic concepts as free surface energy and surface tension, we can describe some stages of the adhesive interaction of the process of applying marzipan paste on the surface of the flour confectionery, **Figure 2** (wetting the adhesive surface of the substrate). Despite the extreme importance, the processes of wetting and adhesion are still not clear enough, their study continues in all developed countries. Researchers are now particularly interested in the kinetics of wetting, nonequilibrium wetting, and other aspects of wetting processes.

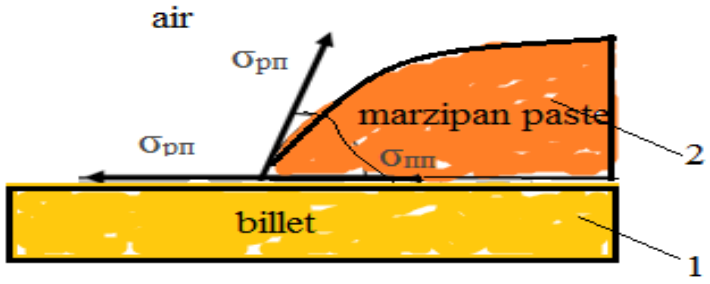

Figure 2 Equilibrium of forces affecting the angle of contact of marzipan paste 2 with the surface of the workpiece 1.

We consider the nature of their interaction as a process that occurs on the verge of contact of three phases. Wetting is also a manifestation of molecular forces, a manifestation of the affinity of the adhesive to the substrate **(Adamson and Gast, 1997; Rydil, 1936)**.

The paper by **(Shanina et al. 2019)** used the method of studying the surface tension at the interface between the phases, which allowed us to obtain very reliable research data. The study of wetting of different substrates is of interest in that it allows to identify the affinity of the adhesive to the substrate, to compare the molecular forces acting in different systems of adhesive which is the substrate.

All known methods and devices for determining surface tension are considered and analyzed in the works by **(Souheng 1982); Lee 1979); Adamson 1976); Rydil 1936)**. Moreover, in the work of the authors **(Fisher, 1979)** the technical means that allow automating the measurement process are described.

When applying marzipan paste on a hard surface of the workpiece, as noted earlier, there is a process of involuntary increase in the contact area, there is wetting. A layer of paste applied to the surface of a solid confectionery is a special physical object, the shape and structure of which is determined by the prescription composition.

In the work by **(Berlin and Basik, 1974)** it is noted that the application of a viscous liquid with its fluidity depends on the environmental conditions and the properties of the surface on which it is applied. Our offered marzipan pastes should ensure their smooth application (wetting) of the substrate surface, as well as interfacial contact between the adhesive and the substrate and interfacial or adsorption interaction at the interface of the two phases. To achieve a good application of the paste (wetting) with good adhesion, it is necessary that the surface tension of the adhesive was greater than the surface tension of the substrate. The wetting phenomenon is associated with the ratio of surface tensions (σ) of the adhesive and the substrate.

Conditions for applying a paste (wetting) of a hard surface

If before the collision with the surface the paste layer had a surface *Sk*, and the surface of the solid workpiece was *St*, then in equilibrium, when the paste layer forms a drop of a certain shape on the body surface, the surface area of their collision will be *Sc*, and the paste surface area *Sp*. The total free surface energy at the initial moment is:

$$E = S_k\sigma_n + S_T\sigma_T \qquad (7)$$

Finally, after reaching equilibrium, the total free surface energy will be:

$$E_2 = S_n\sigma_n + S_{TP}\sigma_{TP}$$

It is known that a necessary condition for the spontaneous process of applying the paste is that there is a decline in free surface energy **(Berlin and Basik, 1974)**. In our case, when stopping the application (the action of shear stress), the decline occurs quite quickly:

$$\Delta E = (E_1 - E_2) \prec 0 \qquad (8)$$

For this condition of applying the paste, the inequality is valid:

$$\frac{\sigma_T - \sigma_{Tn}}{\sigma_n} \succ \frac{S_n - S_к}{S_{тп}} \qquad (9)$$

It follows that at σт> σтп there is an increase in the surface contact of the paste with the medium (Sp> Sk). Thus, the application (wetting) is thermodynamically possible under the condition σт> σтп.

The equilibrium of the paste layer on the surface of a solid body (excluding the surface roughness and the action of gravity) is subject to the Jung equation from which it follows:

$$\sigma_T = \sigma_{nT} + \sigma_n cos\theta$$

Where:

Θ is the edge angle or wetting angle. From which it follows:

$$\cos\Theta = \frac{\sigma_T - \sigma_{Tп}}{\sigma_п}$$

Analysis of the state of equilibrium in the ternary system (solid-liquid – gas (air)) leads to the dependence of the form:

$$\sigma_T = \sigma_п \quad (10) \quad \sigma_т = \sigma_п \frac{1+\cos\theta}{1-\cos\theta} \frac{\sigma_T - \sigma_{Tn}}{\sigma_n} \succ \frac{S_n - S_к}{S_{тп}} \qquad (10)$$

Interfacial surface tension for two media is determined by Antonov's rule, according to which the surface tension is equal to the difference of surface tensions of each of the phases separately **(Adamson and Gast, 1997; Rydil, 1936)**.

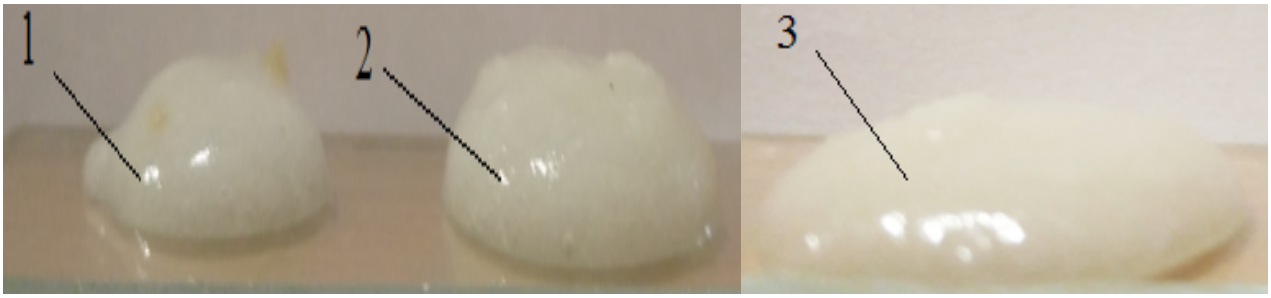

Figure 3 Blurring of marzipan paste.
Note: 1 – beginning of application, 2 – aging time 3 minutes; 3 – standing time 7 minutes.

Assuming this assumption for solid-liquid systems, we can write

$$\sigma_{тп} = |\sigma_т - \sigma_п| = |\sigma_п - \sigma_т|$$

Then, using Jung's rule **(Adamson and Gast, 1997; Rydil, 1936)** it is possible to receive a simple expression for the value of surface energy of a firm body:

$$\sigma_T = |\sigma_n - \sigma_T| + \sigma_n cos\theta \quad (11)$$

$$\sigma_T + \sigma_T = \sigma_n + \sigma_n cos\theta \quad (12)$$

$$2\sigma_T = \sigma_n(1 + cos\theta) \quad (13)$$

$$\sigma_T = \frac{1}{2}\sigma_n(1 + cos\theta) \quad (14)$$

It follows that the determination of the magnitude of the surface energy of a solid is possible by measuring the marginal wetting angle, ie the layer of paste **(Figure 3)**.

Determination of wetting angle of marzipan pastes

The study of the contact angle θ was determined by the method of dynamic measurement, provided that the phase boundary moves and there is a change in the contact angle over time is the method of changing the volume of the drop **(Figure 3)**. Among these processes, sorption and dissolution in the boundary layer of the two contacting phases promotes the diffusion of atoms (molecules) through the layer of confectionery and paste to desorb and release moisture.

The method of operative determination of the wetting angle was used to calculate the values of the derivative at the point of contact of the marzipan paste with the solid surface of the sponge blank. The surface of the marzipan paste is not described by simple analytical expressions. For an analytical description of the profile line of such a surface, you can use an approximation polynomial of the form:

$$y = a_0 + a_1 x + a_2 x^2 + a_3 x^3$$

Where:

x and y are, respectively, the vertical and horizontal coordinates of the point on the surface of the marzipan paste;

$a_0, a_1, a_2 i a_3$ are polynomial coefficients.

The value of the angle, in this case, can be found by determining the derivative at the point of three-phase contact:

$$y' = tg\theta = a_1 + 2a_2 x + 3a_3 x^2$$

Obviously, at $\sigma_т < \sigma_{тп}$ and $\cos\Theta < 0$, ie when the marzipan paste does not stick (wet) to the surface, the edge angle Θ must be less than 90 °. If the wetting angle is more than 90 °, partial wetting occurs. At Θ = 0, when the edge angle is not formed, there is a complete wetting, or spreading, which in our conditions does not occur.

$$\sigma_т > \sigma_п + \sigma_{тп}. \quad (15)$$

Thus, the wetting edge angle Θ or cos Θ is a measure of the application of marzipan paste. In the manifestation of physicochemical hysteresis, the wetting angles of the marzipan paste depend on the contact time of the phases during application to the surface of the workpiece. The surface of the workpiece marzipan paste covers completely, without the formation of voids. Therefore, the shape of the drop corresponds to a minimum of free energy. In our case we use the formula:

$$\theta_z = |arctg(a_1 + 2a_2 x + 3a_3 x^2)|$$

According to our research and data processing, the contact equation of applying the paste at an angle will be:

$$y' = -0.677 + 1.641x + 0.013x^2 + 2.454 \cdot 10^{-3} x^3$$

The equation for determining the angle will be:

$$\theta_z = |arctg(1.641 + 0.013x + 2.454 \cdot 10^{-4} x^2)|$$

Therefore, to achieve high adhesion, the surface tension of the paste must be of great importance.

It is also necessary that the surface tension of the solid confectionery was greater than the surface tension of the paste in contact with it.

Under such conditions, the application of adhesive on the surface of the substrate will be provided:

$$\Sigma \text{ substrate} > \sigma \text{ adhesive} \quad (16)$$

High-quality application of marzipan paste on flour confectionery allows moisture to penetrate some of its layers.

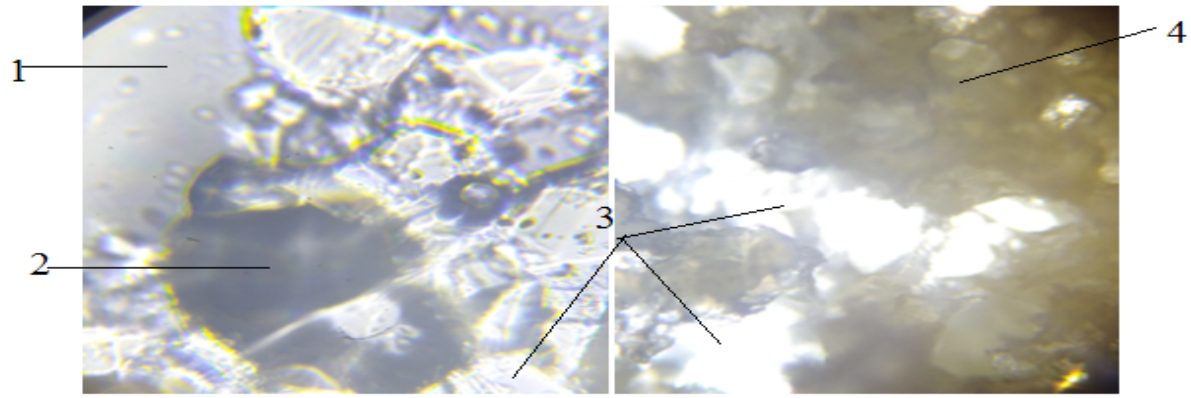

Figure 4 Photos of penetration of moisture of marzipan paste into a firm surface of flour preparation.
Note: 1 – marzipan; 2 – workpiece; 3 – air cavities in the workpiece; 4 – moisture penetration of the paste.

We made a section of applying the paste before and after 30 s of its contact. Photographs of the section under the microscope are presented in **Figure 4**.

According to the developed recipe, to determine the rate of penetration of moisture of marzipan pastes into the surface of the confectionery was used by weight method of research at a temperature of 25 °C.

The amount of moisture that penetrated through the surface of the confectionery was periodically weighed with an error of not more than 0.001 g. The change in the mass of the workpiece determines the amount of moisture that has penetrated through the test material. The experimentally established dependences of the change in the mass of the experimental samples in the time measured in min are shown in **Figure 5**.

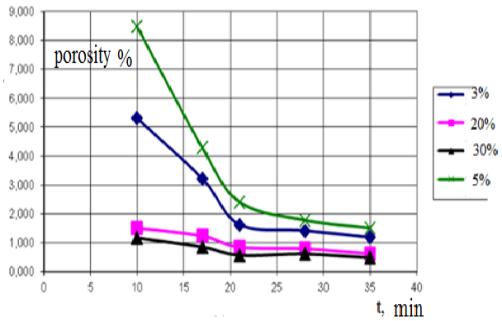

Figure 5 The rate of moisture permeability of marzipan pastes in the workpiece surface.

From the graphs shown in **Figure 5**, it follows that the absorbency of the sample coated with marzipan paste with a content of 20% and 30% DDW remained stable for 15 – 20 min from the beginning of the experiment. The less-dense molecular structure of marzipan paste with glycerin causes a greater ability to pass moisture into the workpiece. It may be desirable for the active application and coating of confectionery semi-finished products.

Calculation of the process

The effectiveness of this modification can be assessed by calculating the work of adhesion (Wa), which is determined **(Zimon, 1974)** by the ratio of surface energies of the adhesive, substrate, as well as interfacial energy:

$$W_a = \sigma_{ng} + \sigma_{Tg} - \sigma_{Tn} \quad (17)$$

Where:

σ_{ng} is the surface tension of the paste (adhesive) on the border with gas (Air), MJ.m^{-2}; σ_{Tg} is the surface tension of solid body (substrate) at the boundary with gas (air), MJ.m^{-2}; σ_{Tn} is interphase surface tension, MJ.m^{-2}.

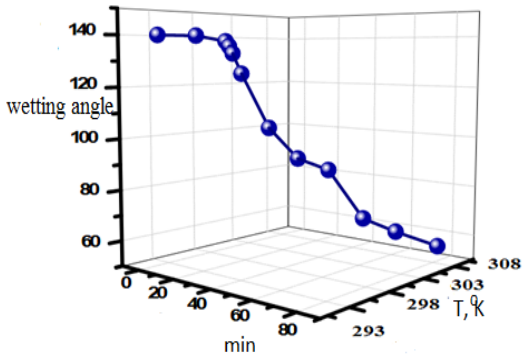

Figure 6 Dependences of the wetting angle on the ambient temperature and holding time for the pasta-confectionery system.

Temperature and time dependences of wetting are investigated. **Figure 6** presents the results of the experiments. It is shown that in the temperature range 293 – 308 the conditions for wetting the workpiece surface (θ >90 deg) are not created. The dependence of the wetting angle in the system of marzipan paste (sponge cake) on the temperature is nonlinear, which may indicate a chemical interaction. The calculation of temperature changes showed that the probability of such a process significantly depends on the temperature of the experiment. The process of flow at the adhesion boundaries at the contact of the paste with the workpiece is best at temperatures that are present in the production premises: 20 – 250 °C, which is an improvement in wetting in the system.

σ_{ng} is the surface tension of the paste (adhesive) on the border with gas (Air), MJ.m^{-2}; σ_{Tg} is the surface tension of solid body (substrate) at the boundary with gas (air), MJ.m^{-2}; σ_{Tn} is interphase surface tension, MJ.m^{-2}.

Taking into account Young's equation, the work of adhesion can be determined by the formula, which uses the values available for experimental determination:

$$W_a = \sigma_{ng}(1 + cos\theta) \quad (18)$$

Taking into account the interfacial interaction, a more accurate value of the adhesion can be determined by the formula:

$$W_a = \sigma_{ng}(2 + b \cdot \sigma_{kr}) - b \cdot \sigma_{kr}^2 \quad (19)$$

Where:

b is the coefficient of proportionality equal to the tangent of the angle of inclination, depending on cosθ = f (σn) to the abscissa.

Σkr is the critical value of the surface tension of the adhesive, which provides complete wetting, MJ.m^{-2} (equal to the value of the surface tension of the substrate).

Dependence (19) is the equation of the parabola, the vertex of which is at the following value of the surface tension of the adhesive:

$$\sigma_{ng} = \frac{1}{b} + 0.5\sigma_{kr} \quad (20)$$

The maximum adhesion work is determined by the dependence of the type:

$$W_{a\max} = \frac{1}{b} + \sigma_{kr} + 0.25b\sigma_{kr}^2 \quad (21)$$

Figure 7 shows the dependence of the adhesion on the surface tension of marzipan paste with different compositions.

The performed calculations and constructed graphical dependences testify to an increase of work of adhesion and

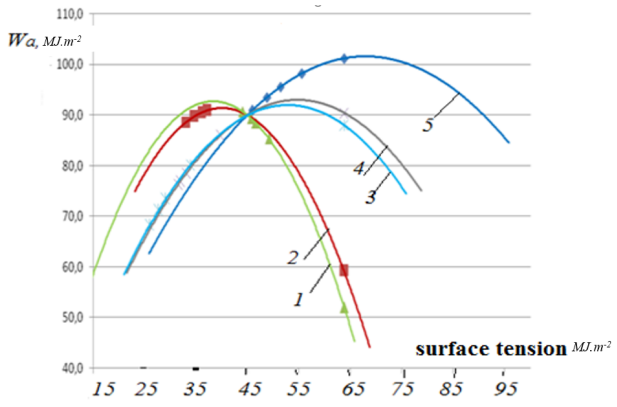

Figure 7 The dependence of the adhesion on the surface tension of marzipan paste according to the recipe.
Note: 1,2 – glycerol 3% and MSDS 20%, 3,4 – glycerin 4% and DDW 25%, 5 – glycerin 5% and DDW 30%.

the use of paste with DDW of 20% and 30% and glycerin to 5%. The most effective indicators of marzipan **pastes (Figure 7 item 5)** with 30% DDW and 5% glycerin. Therefore, this recipe has the most significant effect compared to other recipes. This is due to the quality distribution of marzipan paste and its adhesive properties. Partial replacement of almond flour with DDW in the prescription composition of marzipan pastes leads to changes in the structural state and quantitative values of rheological and sensory characteristics.

Indicators of the total deformation with increasing concentration of glycerol do not increase in direct proportion and depend on the mass fraction of DDW in the composition of marzipan pastes. Accordingly, at a concentration of DDW of 20%, the indicators of total deformation increase depending on the glycerol content in 1.0 – 1.2 times, at a concentration of DDW of 30% increase in 1.0 – 1.3 times, respectively. Irreversible deformation at a concentration of DDW of 20% is constant and does not depend on the concentration of glycerol. At a concentration of DDW of 30% with increasing concentration of glycerol, the reverse deformation increases by 1.5 times. The inverse deformation increases in direct proportion to the total deformation

CONCLUSION

The current direction of improving the preparation of marzipan pastes is and remains the search for promising sources of raw materials and the establishment of rational methods of their introduction, which will create optimal conditions with given biotechnological properties and establish mechanisms and factors of their formation. From the given mathematical analysis the compounding and selection of parameters of preparation of marzipan pastes are substantiated. Thus, in the process of formation, an increase in the strength of adhesion with an increase in the concentration of DDW, which is confirmed by sensory studies, a significant increase in stickiness. The surface properties of the pastes depending on the time of contact with the adhesive and air confirmed the fact of lengthening the working time, which is a very important factor in the modeling of shaped finishing semi-finished products made by hand. Based on the carried out sensory and rheological characteristics the directions of technological use of marzipan pastes which basis is based on structural properties are offered. Marzipan paste PKV is intended for a covering and as a layer for flour and confectionery products as the main indicator of consistency is extensibility. The best indicators were found at the concentration of DDW of 25% and glycerol of 4.5%. For marzipan paste, LFC used for the manufacture of candies, bars, tiles, as well as modeling of shaped products, the main criterion for the characteristics of the consistency is the forming ability of the paste. The best indicators are established at a concentration of DDW of 30%.

AROMA MARKETING AS A TOOL TO INCREASE TURNOVER IN A CHOSEN BUSINESS ENTITY

Jakub Berčík, Roderik Virágh, Zdenka Kádeková, Tatiana Duchoňová

ABSTRACT

The paper deals with the evaluation of the effectiveness of the application of aroma marketing describing a few possibilities of using aromatization in practice. Nowadays, many sophisticated tools are used in marketing and consumer behavior, such as sensory marketing and sensory perception. The following is the term of marketing communication and its division into the above-the-line and below-the-line communication, sales promotion, and in-store communication. The paper also focused on the new trends in the place of sale and aroma marketing. The subject of the practical part is the use of the aroma in the food store. An important part consists of a characteristic of the alliance, questionnaire survey, comparison of achieved sales volume and sales before placing the aroma diffuser, and while it was placed in the grocery store. The article aims to find out how the coffee aroma in the store influenced consumer decision-making and stimulated them to impulsive purchase and consequent influence on the company turnover. Concerning the results of our observation and questionnaire survey, we formulate suggestions and recommendations for the business operation and practice. The whole research was made in the grocery store "Môj obchod".

Keywords: aroma; aroma marketing; marketing communication; Môj obchod; sensory marketing

INTRODUCTION

The use of scent in retail and sales, in general, is astonishing. Scent's main role is to make the customer feel comfortable, happy and put them at ease so they will spend more time in the store, spend more money and ultimately make them more likely to return. The type of scent that is used depends on what is being sold, who it is being sold to etc **(American Marketing Association, 2020)**.

Nowadays consumer behavior has an increasing role in launching products on the market **(Džupina, Hodinková and Kiková, 2016)**. Although the brand has a huge impact on the consumer's purchasing decision, it is closely related to the product placement in the stores because the final purchase decision by the consumer is made in the store or point of sale **(Košičiarová, 2013)**. The fact is that the environment is the most powerful influence when making the final purchase decision **(Doric, Primorac and Kozina, 2016)**.

Aroma marketing dynamically increases commercial results, creates the setting for a pleasant stay in private and public areas, and enhances consumer response, loyalty, and trust in the brand **(E2 Aroma, 2020)**.

The human senses act as an extraordinary source of information processing and generating **(Krishna and Schwarz, 2014)**. They must be perceived to help understand consumer processes, in which individual behavior and decision-making are important factors. Sensory marketing is an innovative marketing strategy to stimulate the customer's relationship with the brand, which promotes a lasting emotional connection that optimizes brand loyalty **(Hussain, 2019)**.

Appealing to customers' sense of smell creates sales opportunities by putting them in the buying mood **(Abassi, 2016)**. According to **Pajonk and Plevová (2015)**, aroma marketing is a series of events in which aromas can encourage customers to buy goods and services and increase the activity of employees. Several authors deal with the placement of products in the store and their impact on the customer **(Zajác et al., 2015; Kozelová et al., 2013)**.

The set up of the store is perceived by the consumer through all his sense organs. This form of perception can be defined as the process by which customers organize, obtain, and select the necessary information from the environment **(Berčík et al., 2016)**.

People constantly use the senses to create and renew impressions of the stimuli around them, and these impressions are stored and processed, leading to the creation of the meaning of the stimuli. This can further help them to make decisions. It is considered important to understand the behavior of the senses during consumer decision making **(Krishna and Schwarz, 2014)**. The challenge for marketers is to explore, understand and

stimulate all five senses of consumers, which can lead to a shift in the behavior of consumers who have a direct impact on turnover, profits, and market share **(Hussain, 2019)**.

The senses help to understand the things going on around us by recalling the information from the memories. Our sensor systems constantly encode, acquire, and reconstruct information. Our social background and cultural differences affect the way our senses connect with our memories. This type of information is important for organizations in developing their marketing strategies for sensory challenges in brand communication **(Nghiêm-Phú, 2017)**.

Erdil explained the application mechanism of sensory marketing: it creates stimulation based on external environmental factors that can appeal to the senses of consumers. These external environmental factors affect not only the emotions of consumers, but also the evaluation of products or brands, so these factors may ultimately affect the intentions and behavior of customers when shopping **(Erdil, 2015)**.

When selling, as well as when buying, all 5 senses are needed – sight, hearing, smell, taste, and touch **(Krishna and Schwarz, 2014)**.

Colors have also a meaning, but in any country or culture, it can have an opposite meaning. Some countries can be very sensitive to the color chosen from a marketing point of view, so it is necessary to choose the color according to the country of operation **(Horská, Palúchová and Gálová, 2018)**.

Zachar (2011) emphasizes that hearing is one of the most used senses, although its potential in marketing communication is not so much used. Approximately 12% of the human perception of the environment is occupied by hearing, another 50% are unknowingly accepted.

Over time, fragrances become among the basic elements of the image of the work environment. Nowadays, it is not considered exceptional that companies or various institutions have a specific scent that makes them recognizable. Fragrances, in addition to inducing a feeling of freshness and purity, also perform another function and that is to induce a feeling of holidays, customs, and traditions **(Pajonk and Plevová, 2015)**.

Although the receptors sensitive to a particular chemical are scattered haphazardly in the nose, their axons find their way to the same target cells in the olfactory bulb, in a way that chemicals of similar smell excite neighboring areas, and chemicals of different smell excite more separated areas **(Uchida et al., 2000)**.

The olfactory bulb sends axons to the olfactory area of the cerebral cortex. A complex substance, such as food, activates a scattered population of cells **(Lin, Shea and Katz, 2006; Rennaker et al., 2007)**.

Hultén, Broweus and van Dijk (2009) consider taste to be one of the most obvious senses that one perceives. On the tongue and even in the throat, a person has taste buds, which are otherwise called taste receptors, through which we can recognize individual tastes. The combination of taste and other senses creates a taste experience, such as smell and taste, sound, and taste.

Lišková (2014) in her publication states that touch is the oldest of all five senses. It is unique in the fact that unlike other human senses, which have a specific place on the human body – eyes, ears, mouth, nose, only the touch is perceived by the skin all over the human body. The hands and tongue are the most sensitive to touch, the other parts prove a different degree of sensitivity. For a trader to choose a business environment, it is necessary also to think about the touch, because both are closely related. In our opinion, smell is the most important sense that affects the customer when buying and therefore we pay more attention to it in the submitted paper.

Erenkol and Merve (2015) emphasize that almost 75% of the feelings that occur during a day are regulated by odors. Aroma directly affects the limbic system, which controls feelings and memory segments in the brain. The odor is of emotional significance to humans, on average one can recognize up to 10,000 scents, and 65% of the fragrances that man has felt in the past are stored in the brain for up to one year **(Krishna, 2010)**.

The pleasant smell released into the air keeps the buyer in the store longer, besides it has a positive effect on his desire for a product or service and at the same time increases his willingness to invest more money when buying **(Paluchová, Berčík and Neomániová, 2016)**.

Smells and odors characterize products, determine their specificity and uniqueness. The products usually have their characteristic odor, based on which they can be distinguished from others. According to different scents, an image is created not only of individual products but also of employees, for example. Managers or traders often suffer from the appropriate choice of perfumes, which they consider to be part of their expression and overall image **(Pajonk and Plevová, 2015)**.

According to **Štibinger (2012)**, each person also interprets the aroma in their unique way. It is proven that two people will never feel the same, even though it is the same chemical substance. It is also remarkable that 80% of what we perceive as taste passes through the olfactory sense.

The use of aromas can be included in the basic communication functions of the seller – customer **(Vysekalová, 2012; Abe, 2005)**.

According to **Lindström (2009)**, it can be said that in the connection between research and the use of aroma to improve the economic situation, a new division was born, which we classify under sensory marketing and even higher under neuromarketing creating a new term "Scent marketing" **(Štefániková et al., 2020)**.

Jurášková and Horňák (2012) define that scent marketing is perceived as a form of sensory marketing that focuses on activating one particular sense, which is the smell. To have a positive effect, it uses aromatizers or diffusers (which release odors into the environment) to its advantage. The meaning of this marketing is considered not only to spray a pleasant scent into the sales area but also to achieve the best possible results by choosing the right essence, which is applied at the right time to the right place.

Aroma marketing can also be included in the field of digital technologies, as they are used in aroma diffuser units **(Frey, 2017)**.

Scientific hypothesis

We have set the following research assumptions for our research:

Assumption 1: We assume that the customers will perceive individual factors differently before using the aroma diffuser.

Assumption 2: We assume that the feelings of the store atmosphere before and after using the aroma diffuser are different.
Assumption 3: We assume there is a difference between the impression of smell in the store before and after using the aroma diffuser.
Assumption 4: We assume that the significance of the smell after using the aroma diffuser is more important.
Hypotheses H_0 and H_1 were created for each assumption, which was verified by using the statistical tests. Hypothesis H_0 states that there is no difference between the indicators, hypothesis H_1 states that there is a difference between the indicators. The results of the hypotheses are given in the results of the work.

MATERIAL AND METHODOLOGY

Before researching real conditions, the influence of selected coffee aromas was tested in laboratory conditions using electroencephalography (16-channel mobile device from Emotiv EPOC). The subject of the test was four coffee aromas, the aim of which was to determine their effect on the emotional response (valence) (Table 1).

We decided to test the difference in emotions (valence) also by the statistical test which proved the significant differences in the emotions of participants tested the aroma of "Coffee" flavor and "Coffee House", "Cappuccino" as well as "Coffee and Cake". Conversely, differences have not been confirmed between the aromas of "Coffee House", "Cappuccino" and "Coffee and Cake", which may be since these are sweeter aromas (Table 2).

The subject of the testing were aromas: "Coffee House", "Cappucino", "Coffee and Cake"and "Coffe" for which we assumed the best influence on the sale of "TO GO" goods. Conscious evaluations were performed on a scale of 1 to 10, (where 10 meant the best evaluation) immediately after smelling the given sample.

METRO Cash & Carry offers marketing cooperation, which is based on a unified identity for small sellers with mixed goods, through the store chain called "Môj obchod". This project was established in 2012 and already in September 2013, the number of participating stores climbed to 100. There are currently up to 530 established "Môj obchod" stores in Slovakia and a network of stores operating abroad, in the Czech Republic under the name "Můj obchod" and in Poland under the name "Odido".More than 70 independent owners manage these stores and provide food and miscellaneous goods throughout the Slovak Republic. Behind this success is the fact that doing business in the alliance benefits suppliers, customers, and also consumers.

For our research was chosen the store "Môj obchod", located in the small village of Červeník on Hollého Street since 2014. The premises of this store are located in a relatively new apartment building on the ground floor, with a barrier-free entrance. The village Červeník has about 1700 inhabitants and there are two food stores situated relatively close to each other. "Môj obchod" store is mostly visited by the inhabitants of the village, which is dominated by regular customers who make their regular purchases here.

Table 1 Effect of Four Coffee Aromas on Emotional Response.

	Coffee House	Cappucino	Coffee and Cake	Coffe (pure)
Valence (polarity of emotions)	0.015	0.014	0.021	-0.01
Conscious evaluation	8.09	7.61	8.79	7.5

Note: Source: Results of the research.

Table 2 Wilcoxon Paired Test – Comparison of the Valence of Individual Aromas.

	Coffee House	Cappucino	Coffe and Cake	Coffee
Coffee	H_1	H_1	H_1	
Coffe and Cake	H_0	H_0		
Cappucino	H_0			
Cappucino				

Note: H0 – they are the same = there is no difference; H1 – they are different = there is a difference; Level of significance $\alpha = 0.01$. Source: Results of the research.

At the entrance to the store, there is a large cold counter with a selection of fresh meat products and cheeses, the store also offers bakery products, sweets, fruits, vegetables, various dairy products, soft drinks, drugstore, alcoholic beverages, and tobacco products. Customers can also buy draft wines or fresh desserts here. In this store, the assortment is different and according to the owner, tobacco products are sold the most. The owner strives to keep these foods attractive and encourages the people to shop mainly because of the proven quality. The store has been reconstructed several times since its inception and has undergone various changes.

Our research took place in the store "Môj obchod – Potraviny u Línajov".

Figure 1 shows an overview of the annual turnovers of the chosen "Môj obchod" store within the years 2016 to 2019. In 2016, the "Môj obchod" store was in operation for the third year with an annual turnover of 505,428 €. The store profits every year and its sales almost always grow significantly. In 2017, they rose to 571,222 €, but the owner had higher aims, so in 2018 introduced the sale of fresh meat to the store with a trained butcher. That year, sales rose rapidly to 635,165 €. Despite higher sales, this meat sale lasted only seven months and the owner decided to cancel these services from the store due to the high costs. The year 2019 showed lower sales due to the abolition of the butcher's shop, but the store continues to profit with a turnover of 609,987 €.

We researched in this store in two phases. The first phase without using the aroma diffuser; the second phase with its use. During both phases, a questionnaire survey was realized

We researched in the two phases in the store "Môj obchod – Potraviny u Línajov" The first phase without using the aroma diffuser; the second phase with its use. During both phases, a questionnaire survey was realized. The first phase – a questionnaire survey took place two weeks from March 1, 2020, to March 14, 2020. We placed 30 questionnaires in the store, which the salesmen offered to customers who had already made their purchase in this store. We contacted another 30 respondents again directly in the store after making the purchase and provided them with a tablet for filling in the form electronically using Google forms. In these weeks we managed to reach all 60 respondents. The questionnaire consisted of five classification questions (gender, age, monthly income, residence, and economic activity) and twelve factual questions, which were mostly related to the aroma of marketing and shopping feelings. In the questions, we asked the respondents how often they visit the store and how much time they spent in it, what influences them as much as possible when shopping and whether they are used to buying "TO GO" goods.

In the second phase – the questionnaire survey took place in a selected store using the aroma diffuser. We chose the "Cappuccino" aroma since it is most related to the types of coffee sold in the store and we assumed that it can evoke in the customers the feeling and wish to taste this product.

A survey with "Cappuccino" canned coffee – the aroma was held within the two weeks from March 15, 2020, to March 28, 2020. This phase of the survey was carried out in the same way as it was without the use of aroma with the help of shop assistants, who were given 30 pieces of printed questionnaires and by using the tablet, we obtained another 30 completed forms from the addressed respondents directly in the store. The questionnaire was identical to the one provided in the first two weeks. Together, we received the full number of responses from respondents in 60 forms.

Then we made several comparisons:

1) Comparison of sales volume and turnover of canned coffee. At this stage, we focused on whether there were changes before and during using the aroma in the store and we compared the individual periods by using a graphic representation and the table. We assume that the results we achieved in our research are largely influenced by the occurrence of Covid-19. People do not feel as comfortable in the store as under normal circumstances and also have to wear face masks, which reduce the intensity of the aroma.

2) Comparison of sales volume and turnover of selected confectionery. In selected periods before and during using the aroma in the store, we focused on observing changes in this segment of food, because the used aroma may also affect the sales of these products. We have shown these changes graphically and also in a table.

3) Monitoring the average values of purchases in the period when the aroma diffuser was not installed in the store and comparing them with the average values in the second stage of testing when the coffee aroma was used in the store. We focused on whether the application of the aroma caused changes in the final values of customer purchases. The receipts provided to us by our customers after their purchase also helped us in this evaluation.

The aroma diffuser "Aroma Streamer 650" was used to carry out the research. This device works with the principle of nebulization. A smooth and micro-fine nebulization of exclusive perfume compositions provides a quick aromatization of areas up to 100 m². It contains the integrated multi-function timer, which allowed us to set its operation every single day of testing.

"Cappuccino" aroma was sprayed into the air every four minutes for only 60 seconds. Of the three possible levels of setting the device, it was set to the second level.

The device was set from Monday to Saturday every day in the following time intervals – first mood: from 09:00 am to 11:00 am second mood: from 2:00 pm to 4:00 pm, third mood: from 5:00 pm to 7:00 pm.

On Sunday, we changed the device a bit because customers are in the store mostly from 9:30 am to 3:00 pm. The device was set as follows – first mood: from 9:00 am to 11:30 am second mood: from 12:30 pm to 2:00 pm, third mood: from 3:00 pm to 5:00 pm.

Used device: Aroma Streamer 650

Used software: MS Excell 2016

Statistical analysis

We used the following statistical methods to process the obtained data: Mann Whitney test, also called the Wilcoxon two-sample test – we compare the medians of two samples independent of each other. This test gives us the answer to the question of whether the difference between the medians (order of averages) of the two groups is statistically significant or only random. If the difference is significant (p <0.05), it means that there is a relationship between the sequence variable and the binary variable (group). The values of the characteristics can be calculated using the following relations (1, 2):

$$U_1 = m * n + \frac{m(m+1)}{2} - T_1 \quad (1)$$

$$U_2 = m * n + \frac{n(n+1)}{2} - T_2 \quad (2)$$

The relation (3) applies here:

$$U_1 + U_2 = m * n \quad (3)$$

which is used to control the calculation.

We reject the null hypothesis at the level of significance α in the case if $U_0 \leq U_\alpha$, where U_α are critical values of the Wilcoxon two-sample test.

If the possibility m >30 and n >20 occurs, then the test value will have the following form (4):

$$U = \frac{U_1 - \frac{1}{2}m*n}{\sqrt{\frac{m*n}{12}(m+n+1)}} \quad (4)$$

The alternative hypothesis is accepted if $|U| \geq u_\alpha$.

Friedman's test is a non-parametric alternative to repeated measures of ANOVA, where the assumption of normality is not acceptable. It is most often used in the case of an ordinally dependent variable. With this test, we verified whether the level of the specified character depends or does not depend on the change of conditions. It has the following form (5):

$$F = ((\frac{12}{nk(k+1)}\sum_{j=1}^{k} Rj2_{)-3n(k+1)} \quad (5)$$

Where:
n – number of respondents;
k – number of responses;
Rj – order of individual sample files.
H_0: The values have the same level and there are no statistically significant differences.
H_1 : The values do not have the same level and there are statistically significant differences.
We reject the hypothesis if F >x^2.

Nemenyi method – is based on the Kruskal-Wallis method on the one-way classification. The critical value is calculated by using the formula (6):

$$r_{\alpha,K,N\approx q\alpha,K\sqrt{\frac{K(K+1)}{6N}}} \quad (6)$$

Test of agreement of two differences (7,8)
H_0: $\pi 1=\pi 2$
H_1: $\pi 1\neq \pi 2$

π average – average proportion ; δ (π1 + π2) - selection error of the share difference ; has an N (0,1) distribution.

π average = (n1 * p1 + n2 * p2) / n1 + n2

$$\sigma_{(\pi 1+\pi 2)}=\sqrt{p*(1-p)*(\frac{1}{n1}*\frac{1}{n2})} \quad (7)$$

$$TCH=\frac{\pi 1-\pi 2}{\sigma} \quad (8)$$

KH = NORMSINV(1-ALFA)
TCH <KH : H_0 is accepted
TCH >KH : H_0 is rejected

RESULTS AND DISCUSSION

A survey of customer behavior before using the aroma diffuser in the chosen store

The survey involved 60 respondents, of which 35 were women and 25 men. According to the provided data, we can state that the selected store is mostly visited by women, up to 58% and 42% of visitors are men. After an interview with the employees of the store, we found out, that mainly women go to the store to buy the food for the entire family.

The differences between the individual age categories are not significant, i.e., all age categories over 18 years of age go to the store, approximately evenly. Total 16 respondents (27%) were from 26 to 33 years of age,14 respondents (23%) from 42 to 59 years and 13 respondents (20%) over 60 years old followed by 10 respondents (17%) aged from 34 to 41 years. The smallest group of respondents was created by 8people (13%) from18 to 25 years of age.

According to economic activity, the largest share of the respondents is employed -up to 22 people (37%). The second-largest group of respondents (13) were pensioners (22%). Furthermore, there are two groups with the same number of participants (6)representing a 10% share, namely students and mothers on maternity leave. The following smaller group consisted of 5 entrepreneurs (8%) Two groups with the same number of respondents, three working in the state sphere, and three unemployed with a 5% share. In the last place are 2 self-employed persons with a share of 3%.

Regarding the monthly income, the largest group of 26 respondents (44%), have a monthly income of up to 580 €. The second-largest group of 15 respondents (25%), had a monthly income from 581 € to 1,000 €. 11 respondents (18%) declared their monthly income between 1,001 € and 1,500 €. The last smallest group of 8 respondents (13%) had a monthly income of more than 1,501 €.

The chosen store is located on the ground floor of a block of flats in the countryside, which means that the majority of respondents (total 53, representing 88% share) come from the countryside. The other 7 respondents (12%) stated they live in the city and had to travel to visit the store. The majority of respondents visit the store several times a week (total 38, representing 63% share). As a result, people who get used to shopping in this store like to come back and make their regular smaller purchases here. Another group of customers visits the store several times a month (total of 15 respondents, representing 25% share). 6 respondents visit the store occasionally, which represents a 10% share. Only 1 person visits the store every day (1.7%)

When asked how much time they spend in the store, 36 respondents (60%) answered in the range of from 9 to 15 minutes. The second group consists of 21 respondents who spend less time in the store for up to 8 minutes. These respondents have a 35% share. The smallest group of respondents who spend more than 16 minutes in the store is 5% and consists of 3 people out of 60 respondents.

On average, customers stay in the store for a short time to buy and do not stay there arbitrarily. This may be because nothing in the store attracts them enough to spend there more time. The shop without any better experience for which they would stay in the store longer, which could be managed through implementing a certain level of marketing in the store.

Subsequently, the respondents had to determine the feelings of the atmosphere in the store on a five-point scale. The store was rated neutral by 20% of the surveyed customers and the largest percentage received a pleasant rating, up to 46.7%.

30% of respondents indicated the possibility of "very pleasant" feelings from the store, which may well affect our final research with the introduction of flavoring.

Anderson (2014) and **Vlahos (2007)** argue that the term "aroma marketing" can be used to set the mood, promote products or brand position **(Meng-Hsien, Cross and Childers, 2018)**.

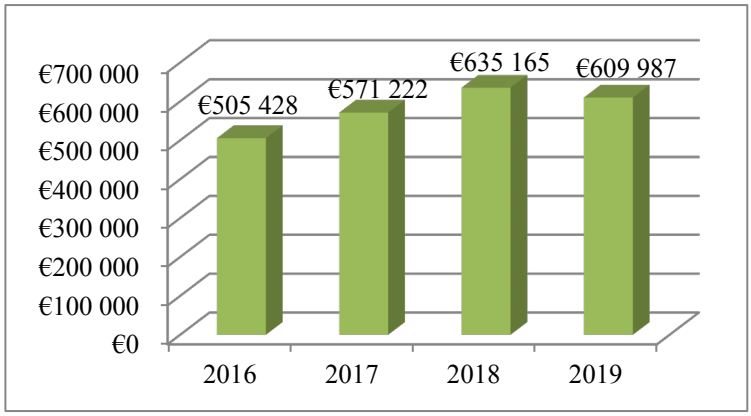

Figure 1 Overview of the Annual Turnover of the Chosen "Môj obchod" Store within the years 2016 to 2019 (in €). Note: Source: **Finstat, 2020**.

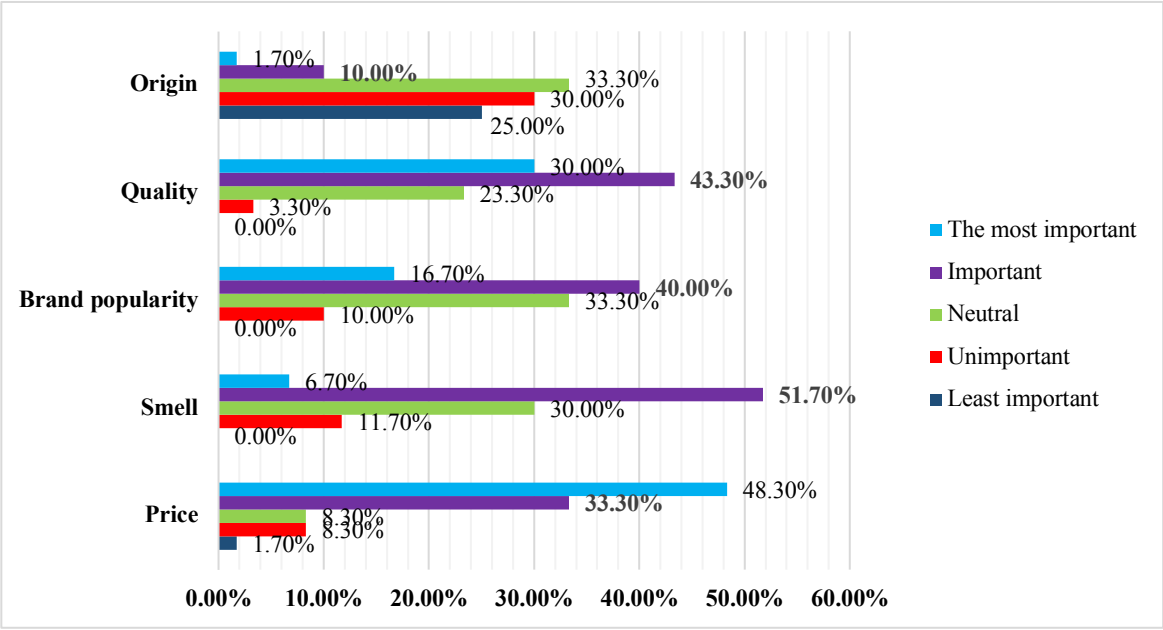

Figure 2 Factors Influencing the Purchase of Canned Coffee According to Importance. Note: Source: Results of the research.

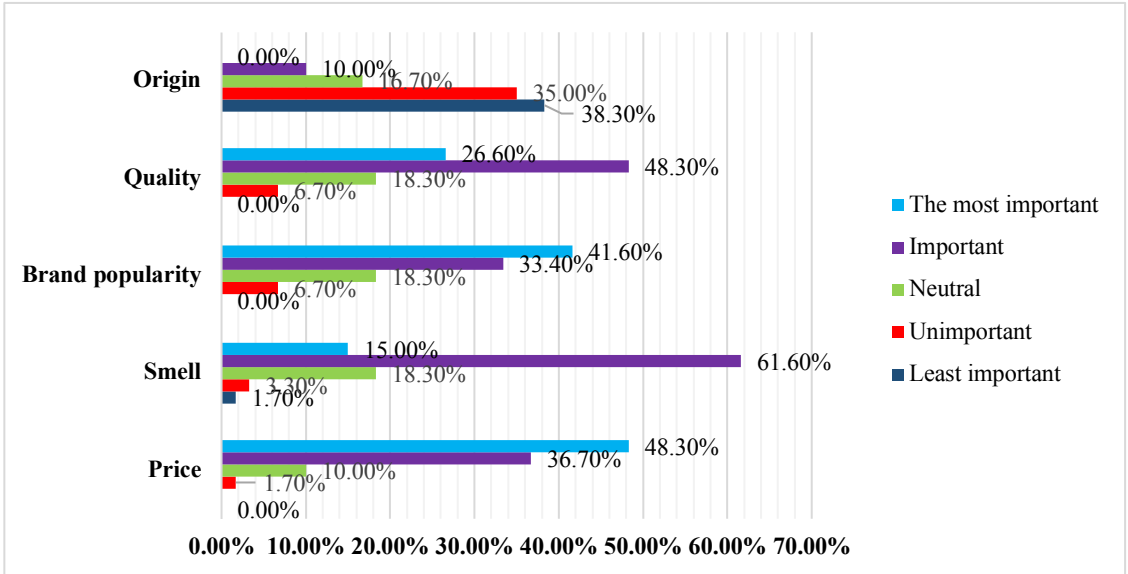

Figure 3 Factors Influencing the Purchase of Canned Coffee According to Importance after Using Aroma Diffuser. Note: Source: Results of the research.

For the research of the increase in turnover, it was subsequently necessary to identify what average price is the customer willing to pay at the local store. As it is a smaller store, people usually make smaller purchases for households, and the obtained values are also related to this fact. 22 respondents (36.7%) buy their goods in the amount of 11 € to 20 €. The second most common group of purchases is up to 10 €, as stated by 20 respondents (33.3%). Furthermore, the purchase from 21 € to 50 € proved 18 respondents (30%). Customers state that their regular purchases in this store are usually not above the level of 50 €. We can assume that customers are willing to spend more when shopping in larger supermarkets, where they have a wider choice of goods in larger quantities and go to the selected store earlier for the goods they consume daily and replenish it.

Even before using the aroma diffuser, there is a certain smell in the store, e.g. the smell of fresh-baked pastries.

To choose the correct aroma is not always as easy as it may seem at first glance. If we want to support sales of confectionery, it is not enough to add a chocolate aroma **(Vysekalová, 2014)**.

According to **Gobe (2010)**, the smell of a product creates a characteristic feature and can be easily identified by the customer. If the product is "pleasant-smelling", it looks positive and provides a space for a favorable identity. Every single smell plays a different role. For example, peppermint and lemon can boost alertness and energy; cedar and lavender can reduce tension.

Thus, the largest group of respondents (total 32, representing 53.3%) stated that they felt a "pleasant smell" at the entrance. 21 respondents (35%) stated that they consider the smell to be "very pleasant". Another 7 (11.7%) respondents felt a "neutral smell" at the grade. We can state that customers chose the most "pleasant" smell most often due to the natural scents that were carried by the store.

We also asked about other aromas to which the seller should appeal the most, which is sales support for both sales and sales staff **(Přikrylová and Jahodová, 2010)**.

Respondents could mark several answers to a given question. Based on the obtained data, the seller should pay the most attention to the visual side of the store and goods. The sense of sight was marked by up to 43 respondents (71.7%), the second sense that should be pointed out was the smell, which was marked 39 times (65%). Taste and hearing took 20% share and customers pay the least attention to the tactile sense (only 3.3%). The visual side of the store is the most important when the customer moves around the store and searches for the selected goods. If we add the aroma to this and combine these two investigated quantities, it is more likely that the customer will buy the goods.

Subsequently, we focused on "TO GO" goods. Respondents buy "TO GO" goods to a large extent, most of them chose to buy them "a few times a week", up to 32 respondents (53%). The possibility "sometimes" was indicated by 25 respondents (42%) and 3 respondents (5%) buy "TO GO" goods every day. We assume that these goods are bought by people mainly due to the hectic time in which we live. For example, if they buy canned coffee, they save time for making coffee at home. Some people may have become accustomed to this way of life, so they are buying such goods more and more often. It's also a good way to enjoy shopping by choosing such a small, not very expensive item.

As all 60 respondents stated that they buy all these goods. The largest number of respondents 37 (61.7%) stated that they buy sweets. The second most purchased is canned coffee, which was marked by 29 respondents (48.30%). Furthermore, the chips were marked by 24 respondents (40%), sandwiches by 14 respondents (23.3%) and the least purchased are energy drinks with 10 marks (16.7%).

Then we focused only on the canned coffee and which factors influence customers when buying it. Respondents could assign degrees of importance to individual factors. All factors available to them for selection are listed in Figure 2.

The most important factor that would affect them when buying was the price, which was indicated by up to 48.3% of respondents. They consider quality to be the second most important factor with 30% a share. This is followed by the popularity of the brand 16.7%, then the smell of 6.7%, and the origin was indicated by only 1.7% of respondents. In the least important area, there was an origin with a significant value of 25%. From the above data, we can say that people are most affected by price, product quality, brand popularity, and smell. The least important factor for customers has become the origin of the product.

We then focused only on canned coffee and which factors influence customers when buying it. Respondents could assign degrees of importance to individual factors. All factors available to them for selection are listed in Figure 2. The most important factor that would affect them when buying was the price, which was indicated by up to 48.3% of respondents. They consider quality to be the second most important factor with a 30% share. This is followed by the popularity of the brand 16.7%, then the smell 6.7%, and the origin was indicated by only 1.7% of respondents. In the least important area, there was an origin with a significant value of 25%. From the above data can be concluded that people are most affected by price, product quality, brand popularity, and smell. The least important factor for customers has become the origin of the product.

For verification, we also used research assumption 1, where we assumed that before using the aroma diffuser, the customers will perceive individual factors differently. To verify this assumption, we used the Friedman test with Nemenyi pairwise comparison method. We verified the assumption of a selected sample of respondents. The value of the test characteristic (0.05) is higher than the critical value (0.001), therefore we can state that the customers rated the individual factors differently before using the aroma diffuser. However, up to 78% of customers said they did not buy canned coffee.

A survey of customer behavior after using the aroma diffuser in the chosen store

At this stage of the survey, the chosen store is visited mostly by the customers aged 42 to 59 (total 19 respondents, 32%), followed by the second group of 15 respondents (25%) from 26 to 33 years. Furthermore, there are 12 respondents (20%) over the age of 60 and 9 respondents (15%) from a group of 34 to 41 years old. The smallest group of 5 respondents (8%) are people aged from 18 to 25 years. There are only small differences in this study compared to the first stage of the survey.

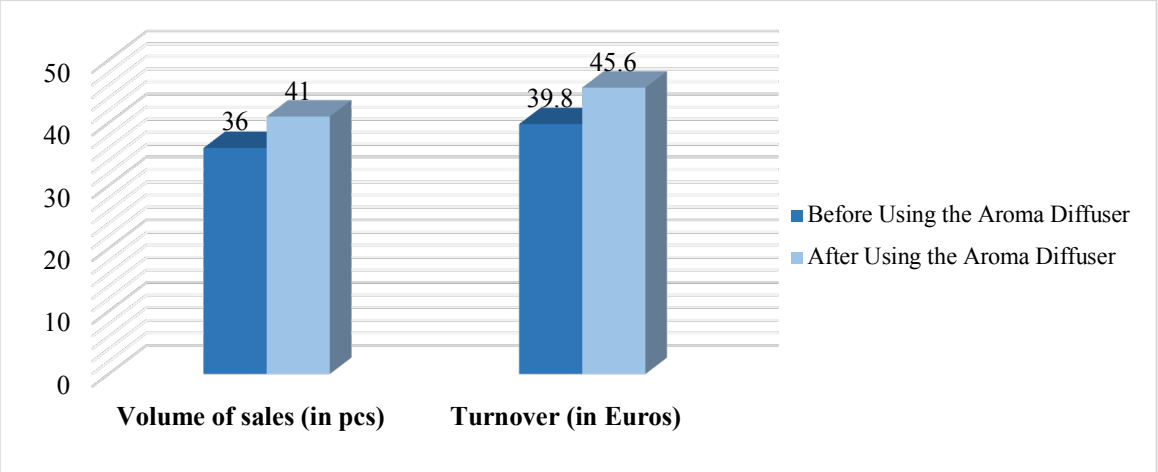

Figure 4 Volume of Sales and Turnover of Canned Coffee Before and After Using the Aroma Diffuser (in €). Note: Source: Results of the research.

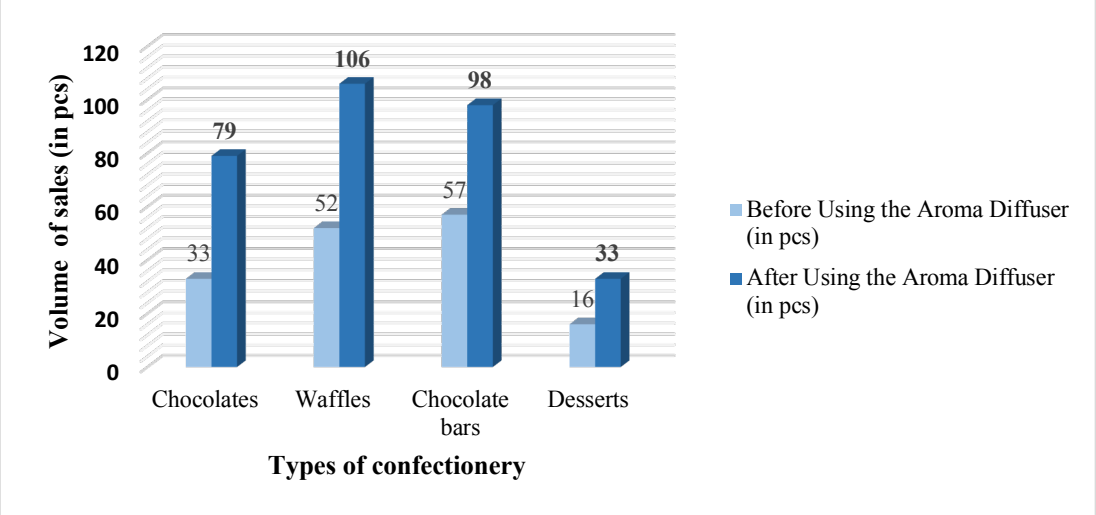

Figure 5 Volume of Sales of Confectionery Before and After Using the Aroma Diffuser (in pcs). Note: Source: Results of the research.

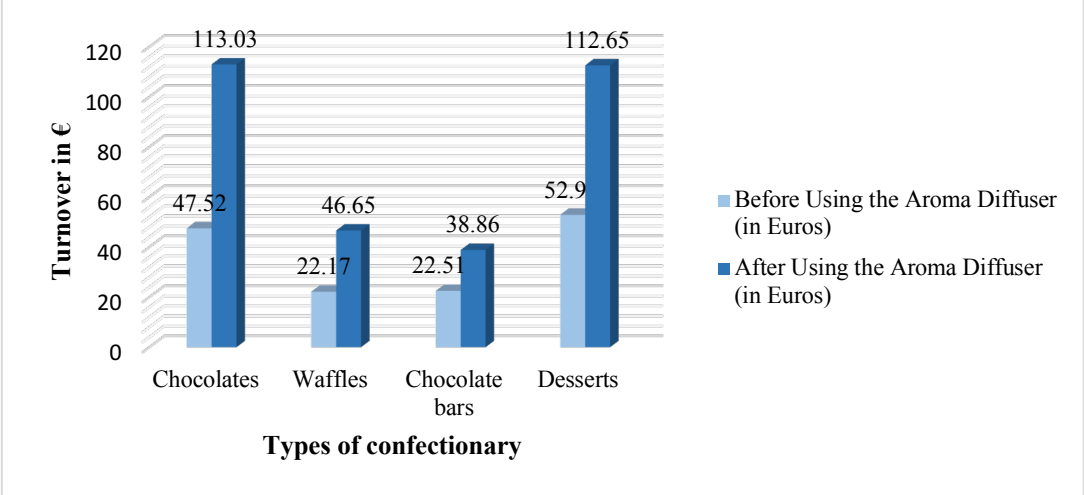

Figure 6 Turnover of Confectionery Before and After Using the Aroma Diffuser (in €). Note: Source: Results of the research.

As many as 26 respondents (43%) were from the group of employed people, which is almost half of the respondents, and compared to the previous stage of the survey, this number has increased by 6%. The second-largest group with 13 (22%) are pensioners. Groups ranging from 8% to 5% are students, mothers on maternity leave, entrepreneurs, self-employed and unemployed people.

A total of 23 respondents (38%) stated that their monthly income ranges from 581 € to 1,000 €, the increase is 13%, compared to the first stage of the survey. 22 respondents (37%) stated their monthly income is up to 580 €. Furthermore, 11 respondents (18%) reported their income is from 1,001 € to 1,500 € and the remaining 4 respondents (7%) have an income higher than 1,501 € per month.

Most customers visit the store several times a week (total 38, representing 63%). 13 customers (22%) visit the store several times a month, which is 7% more than in the first stage of the survey. Daily visit to the store was marked by 5 respondents (8%), this number also increased by 6%. Only 4 surveyed customers (7%) visit the store occasionally.

Regarding the time spent in the store, more than 38 respondents (63%) said they would stay in the store from 9 to 15 minutes. A total of 12 respondents (20%) stated that they spend more than 16 minutes on their purchase, which is 15% more than in the first stage of the survey. Due to the situation with the Covid-19 virus, people decided to visit the store with the intention of larger one-time purchases, which last significantly longer than usual. The last group consists of customers who visit the store in the interval from 1 to 8 minutes and there were 10 of them (17%).

Fragrances or aromas thus support the customer's stay in the store **(Madzharov, Block and Morrin, 2015)**.

The change in the evaluation of the feelings from the atmosphere of the store occurred with the possibility of "unpleasant", which was marked by 2 respondents (3%). We believe that due to the smell of cleaning and disinfecting detergents, which were used more in the store on the given days. A total of 7 respondents (12%) had "neutral" feelings about the atmosphere. The second largest group consisted of the surveyed customers who marked a "pleasant atmosphere" (Total 23, representing 38%). The most marked was "very pleasant" atmosphere in the store, by up to 28 respondents (47%), which is 14% more than before using the aroma diffuser in the store. We can assume that the used aroma had a positive effect on the senses of customers.

We also verified this factor by using Mann Whitney – a one-sided test, based on Assumption 2. We assumed that the feelings of the store atmosphere before and after using the aroma diffuser are different. The critical value was higher (0.09) than the test characteristic (0.05), which means there is no difference between the evaluation of the customer feelings before and after using the aroma diffuser in the store.

As many as 31 (52%) customers stated that they usually spend between 11 € and 20 € on their purchases, there is an increase compared to the first stage of the survey, by up to 15%. On the contrary, purchases up to 10 € fell by 2% and this answer was marked by 17 respondents (28%). Average purchase from 21 € to 50 € was marked by 11 respondents (18%) and more than 51€ spent just 1 respondent (2%). Because the Covid-19 pandemic broke out much more intensively in the second stage of testing, we can assume that people were responsible and went to the store only for things that they needed for everyday life. This could mean that the number of their purchases could rise to 20 €, which can hold food without which households cannot function normally.

The smell in the store was marked as "unpleasant" by up to 4 respondents (7%) and we can assume that it was again caused by disinfectants and cleaning detergents, which were used excessively these days. A total of 3 respondents (5%) consider the "neutral" smell in the store. The "pleasant" smell in the store was for 18 respondents (30%) and the highest share was achieved by a "very pleasant" smell, which was marked by up to 35 respondents (58%), which represents an increase of 23%. It very much depended on when the questionnaire was filled in and when the aroma was activated in the store. In the evening, the store was cleaned more intensively.

In assumption 3 was assumed there is a difference between the impression of smell in the store before and after using the aroma diffuser.

We have used again the Mann Whitney – a one-sided test. The value of the test characteristic is higher (0.05) than the critical value (0.02), therefore can be stated, that customers felt the difference after applying the aroma to the store. According to the obtained data, the seller should pay attention to the sight and visual side of the store, as up to 48 respondents (80%) marked this answer, which is 37% more than in the first stage of the survey. The second one is the smell with 31 answers (52%), marked by 13% fewer people. The taste was marked by 16 respondents (27%) and hearing by 5 respondents (8%).

The largest share among the answers which smell in the store attracted the customer the most, was the smell of fresh-baked pastries", which was marked by up to 31 respondents (51%), this group increased by 9%. The second-largest group was created by the answers that the respondents could complete themselves. This group of responses has undergone the most significant change. The most common response is the "smell of chocolate", which occurs up to 16 times (27%). Furthermore, it is "disinfectant or cleaning products", which was mentioned by 5 respondents (8%) and 1 respondent (2%) stated the smell of "cappuccino".

Aroma has a remarkable ability to make customers look around the store longer, spend more money, and return to the store more often. Emotions and memory are affected by the power of scents in very close ties. Find the right scent and you can get around rational thoughts. In-store testing shows that aroma can be the holy grail. It has the power to encourage the customer to join a new brand and remain loyal **(Calvo-Porral, Ruiz-Vega, and Lévy-Mangin, 2018)**.

The most marked answer when buying "TO GO" goods were that the respondents buy these goods a few times a week (total of 38 respondents, representing 64%), compared to the first stage there is an increase of 11%.

14 respondents (23%) indicated that they buy these goods only sometimes, which caused a decrease of 19%. "TO GO" goods are bought daily by 8 respondents (13%), compared to the first stage there is an increase of 8%.

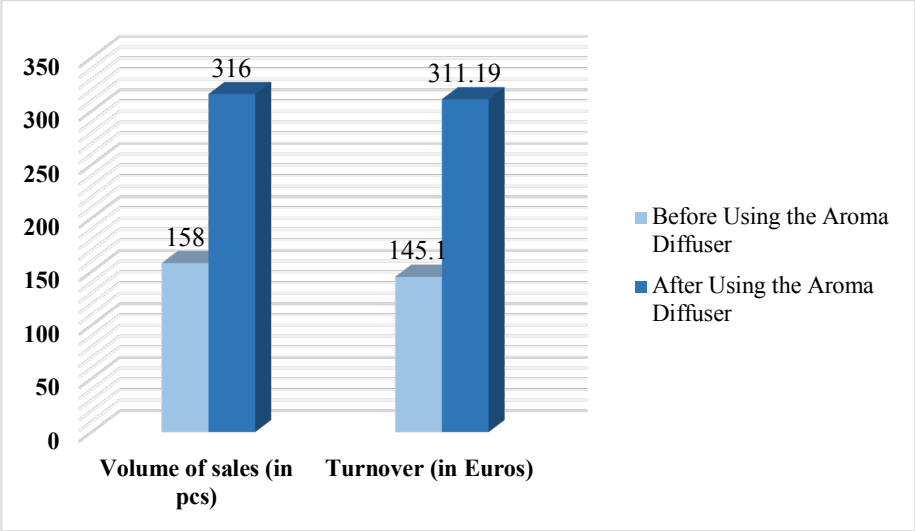

Figure 7 The Total volume of Sales and Turnover from Confectionery Before and After Using the Aroma Diffuser. Note: Source: Results of the research.

Table 3 Types of Selected Canned Coffees – Their Quantity (in pcs) and Turnover in €.

	Quantity in pieces		Difference	Turnover in Euros		Difference
	Before	After		Before	After	
Nescafé	12	14	**2**	15	17.5	**2.5**
Energy coffee	8	11	**3**	8.8	12.1	**3.3**
Ice coffee Landessa	16	16	**0**	16	16	**0**

Note: Source: Results of the research.

As many as 45 respondents (75%) said they prefer to buy sweets. This percentage increased by 38% compared to the first stage of testing, which is more than half. We can assume that they were influenced by the sweet aroma they felt when shopping. Canned coffee and chips have a relatively equal proportion of 25 (42%) and 26 (43%) respondents. The sandwiches and baguettes were mentioned by 13 respondents (22%), and the least marked item was energy drinks, which were mentioned by 6 respondents (10%).

As in the first stage of the survey, respondents had the opportunity to assess the importance of the factors that would make them buy canned coffee in the selected store. That is the factor that would motivate them the most to buy. Respondents had the opportunity to assign degrees of importance to individual factors. Most respondents stated that they consider the price to be the most important factor, up to 48.3%, and the second one is the brand popularity. The smell was marked as important by up to 61.6%, which represents a 10% increase. People consider the origin of the product to be the least important (38.3%) and the insignificant factor (35%), compared to the first survey, these percentages increased by 13% and 5%. With a value of 18.3%, the respondents described the quality, the brand popularity, and the smell as neutral. We can state that customers consider the price, brand popularity, quality, and smell to be a really important factor. These results are shown in Figure 3.

Assumption 4: We assume that the significance of the smell after using the aroma diffuser is more important.

We have used the Mann Whitney again – a one-sided test. Where we got a critical value of 0.01, which is less than the test characteristic of 0.05, which proved that customers found the smell more important after using the aroma diffuser in the store.

After using the aroma diffuser in the store, we find that sales of canned coffee increased slightly. 19 respondents (32%) stated that canned coffee is in their shopping cart and this number has increased by 10%. A total of 41 respondents (68%) stated that they did not buy canned coffee, which is 10% less than before applying the aroma.

The total volume of canned coffee sales and turnover before and after using the aroma diffuser is shown in Figure 4. The sales volume before applying the aroma was 36 pieces, while after applying the aroma it was 41 cans, which means a small increase in sales and also in the comparison of turnover. Sales increased by 5 pieces together from all selected types of coffee. Before using the aroma diffuser, the turnover was 39.8 € and after using the aroma diffuser, the turnover of these goods was 45.6 €, which is an increase of 5.8 €.

We can assume that used aroma had a positive effect on sales, but not very significant. Finally, the customers combined the aroma we used with sweets. In Table 3, we described the specific types of canned coffee that were observed, namely Nescafé coffee, Energy coffee, and Ice coffee Landessa.

"TO GO" goods also include confectionery, which is why we deal with them in the submitted paper.

In the chosen two periods, we observed the volume of sales and turnover of a certain segment of goods concerning the placement of the aroma diffuser directly in the store. Based on the recording of individual items, we were able to observe changes in the volume of sales and turnover, to find out where was the largest increase in sold items.

Figure 5 shows the volume of sales of the chosen confectionery before and after using the aroma diffuser. All available and obtained data show us that the sales volume of goods on which we focused, increased during the period of applying the aroma in the store. Of all examined items, the sales of waffles increased the most, by 54 pieces, while the original sale was 52 pieces. Another big increase was the chocolates from the original 33 sold pieces to 79 pieces. Chocolate bars increased from 57 pieces to 98 pieces. Desserts also increased the volume of sales from 16 to 33 desserts. Based on the data obtained in practice, we can state that for selected types of confectionery, the aroma has a positive effect on the shopping behavior of consumers and thus helps to increase the volume of purchases

Figure 5 shows the volume of sales of the chosen confectionery before and after using the aroma diffuser. All available and obtained data show us that the sales volume of goods on which we focused, increased during the period of applying the aroma in the store. Of all examined items, the sales of waffles increased the most, by 54 pieces, while the original sale was 52 pieces. Another big increase was the chocolates from the original 33 sold pieces to 79 pieces. Chocolate bars increased from 57 pieces to 98 pieces. Desserts also increased the volume of sales from 16 to 33 desserts. Based on the data obtained in practice, we can state that for selected types of confectionery, the aroma has a positive effect on the shopping behavior of consumers and thus helps to increase the volume of purchases.

Due to the increase in the volume of sales, the turnover from confectionery also increased. This is clearly shown in Figure 6. Turnover from sold chocolate increased the most, by up to 65.51 € and this difference is higher than the turnover from chocolate before applying aroma. The second-largest increase was in desserts, where the store earned 59.75 € more than in the first stage of our survey, followed by the waffles which turnover increased from 22.17 € to 46.65 €. The lowest increase was noticed in chocolate bars, in which turnover increased by 16.35 €.

Table 4 lists all the items on which we examined the volume of their sales and turnover. During applying the aroma, Mila waffles were sold the most, where the difference was 26 pieces. In the chocolate segment, we recorded a large increase of up to 17 pieces of Milka milk chocolate. Regarding the turnover, we recorded the most significant difference by 25 € in Milk Metro Premium chocolate. Another important item was the Tatiana chocolate candies box with an increase of 19.25 €. In short, we can say that our research has yielded positive results and the use of such marketing tools is beneficial for the store.

Figure 7 shows the total volume of sales and turnover from confectionery before and after using the aroma diffuser. Without the used aroma 158 pieces of selected confectionery were sold, and during the use of the aroma, the volume of sales increased to 316 pieces. Before aromatization was turnover of confectionery 145.1 € while applying the aroma was recorded an increase of turnover to 311.19 €. Through this research, we concluded that the aroma of the store has a positive effect on the volume of sales and turnover of confectionery in this store. The volume of sales of confectionery increased by exactly half, by 158 pieces, and the turnover increased by 166.09 €.

Table 4 Types of Selected Confectionery– Their Quantity (in pcs) and Turnover (in €).

	Quantity in pieces			Turnover in Euros		
	Before	**After**	**Difference**	**Before**	**After**	**Difference**

Note: Source: Results of the research.

During the survey, we also found out the average values of purchases from customers. In Figure 8 we can see the average value of the purchase before and after using the aroma diffuser. Before applying the aroma, the average value of the purchase was 11.48 €. After applying the aroma in the second stage of the survey, this average purchase value increased by 3.83 € to 15.31 €. After comparing the found values, we can state that the aroma led customers to buy the items that attracted them due to their sensory perception, and the value of the average purchase increased slightly. We can state that aroma is one of the factors that have a positive effect on shopping behavior.

Based on the results of the research, we can state that using the aroma diffuser in the store brought a clear benefit in increasing sales of either canned coffee or confectionery. However, it is necessary to handle the aroma diffuser unit wisely, because when multiple aromas are mixed, it can also bring the opposite effect. To place the aroma diffuser in the store could also be beneficial for such products that cannot produce their natural scent, for example, due to packaging, and thus increase their attractiveness to the customer. Another reason for applying the aroma is to focus on products that are selling less and thus support their sale.

Merchants are increasingly using the surrounding aroma as a strategic tool to differentiate themselves from the competition, attract customers, stimulate sales, influence moods and create an overall pleasant and unforgettable shopping experience **(Madzharov, Block and Morrin, 2015)**.

The use of aromas is a new generation of communication tool that measures the impact on the consumer and the impact that is created on the customer and interactivity in the store **(Labská, 2012; Rimkute, Moraes and Ferreira, 2016)**.

Aroma marketing, or so-called Scent marketing, can be used in two areas. The first is ambient scenting, this term means filling the space with a suitable type of scent and the other area is scent branding, which can be used to create a specific scent. It identifies a brand, product, institution, company, or environment. The scent should be selected and

deployed to match and perfectly adapt to the environment and context **(Naščáková and Danková, 2017; Minsky, Fahey and Fabrigas, 2018)**.

There also exist the products that represent a characteristic feature of a particular product and the main reason for buying such a product is mainly the smell **(Krishna, 2013)**.

It is important to search for and use new forms of marketing, as we are increasingly oversaturated with advertising and this has made the customers more immune to traditional marketing **(Berčík, 2017)**.

CONCLUSION

The environment in which the customer is located during his purchase has an intensive effect on him and also affects sales. One of the modern tools used in commercial operations to make the products visible and also to support their sales is aroma marketing. This type of marketing deals with how aromas can stimulate human senses and emotions and purposefully change the customer's behavior and improve the shopping experience.

The important thing is the representation of the senses when shopping, and the human brain often does not realize that the smell released in the store can keep the customer in the store for longer, or to cause the desire to buy the product that was not originally planned to buy.

To examine consumer behavior a questionnaire survey was conducted directly in the store where the aroma diffuser was used. Thanks to this survey, we wanted to find out to what extent customers will be affected by the aroma released into the store and whether it will affect their shopping behavior. There were no significant differences in the number of store visits and the time spent in the store during the purchase before and after using the aroma diffuser. The only change was that a few customers spent more than 16 minutes in the store applying the aroma, which was usually up to 15 minutes before using the aroma diffuser in the store. Customers stated that during applying the aroma, in addition to the staff, they were also more affected by the smell in the store. When evaluating the feelings from the atmosphere of the store before and after using the aroma diffuser, we assumed that the feelings will be evaluated differently. In addition to the questionnaire survey, we also used the Mann Whitney test. However, this test showed us that the customers did not notice the difference between the periods and perceive the atmosphere in the same way. However, we noticed that two respondents described the feelings about the store as unpleasant and we believe that this is due to excessive disinfection of the store in the evening due to the occurrence of Covid-19 and strict hygiene regulations of the Slovak government. This fact is followed by the fact that the smell in the store was described by 4 respondents as unpleasant and we think that it is also due to disinfectants. Nevertheless, customers perceive the smell in the store better after using the aroma diffuser, and this was also confirmed by the statistical Mann Whitney test. According to the obtained results, customers believe that the seller should appeal to sight, followed by smell and taste when organizing the store.

When choosing the aroma, we tried to make it as similar as possible to the aroma of cappuccino. Nevertheless, during the second stage of the survey, customers in the store smelled the most the fresh-baked pastries also the smell of chocolate. This refuted our assumption of an increase in coffee sales. We were also interested in whether customers buy "TO GO" goods. The largest group of respondents buys such goods a few times a week, mostly sweets, canned coffee, and chips. We were interested in which factor customers consider most important when buying the canned coffee. By statistical testing using the Friedman test with the Nemmenyi method, we confirmed the fact that after using the aroma diffuser in the store, the respondents consider the smell as important and significant. The survey showed us that they consider the origin of the product to be the least important factor. By using the pairwise comparison test we found that using the aroma diffuser did not affect the sales of canned coffee. This refuted our assumption that the aroma we applied to the air would mainly affect the sales of canned coffee.

The highest increase in the volume of sales of confectionery during aromatization was shown in waffles, chocolates, chocolate bars, and desserts. From the obtained data, we can state that the aroma was one of the factors that strengthened sales and thus contributed favorably to the increase in sales of these food products which more than doubled. We dare to say that aroma as a marketing tool appears to be a positive tool and can bring economic prosperity in the future. We also focused our attention on whether the average value of purchases by customers has increased. According to the respondents, we concluded that the average value of the purchase increased from the original 11.48 € to 15.31 €, which may also be caused by the fact, that customers added to the cart, for example, sweets, because they were affected by used aroma in the store. We can state that customers increased the value of their purchases also due to the situation with the Covid-19 virus and increased their food stocks in households. Through aroma marketing, it is possible to build a positive relationship of an individual to a brand, product, or service. It is likely that based on the smell, the customers will keep this relationship in mind and will return to the purchase.

CHEMICAL PROPERTIES AND ACCEPTANCE IN THE BISCUIT FORMULA OF BELITUNG TARO (*XANTHOSOMA SAGITTIFOLIUM)* WITH ADDITION OF ANT NEST TUBERS (*HYDNOPHYTUM FORMICARUM)* PLANT

Anjar Briliannita, La Supu

ABSTRACT
This study was aimed to analyze the nutrients content, antioxidant activity, and acceptance of the biscuit formula of Belitung taro (X*anthosoma sagittifolium*) with various parts of ant nest tubers (*Hydnophytum formicarum*) plant. Antioxidant activity was found by the DPPH method, nutrient content by the AOAC method, and sensory evaluation analysis by 30 untrained panelists. The results of this study found out that each biscuit formula (35.25 grams/73.60% antioxidant activity) contained 130 kcal of energy, carbohydrates of 59.08 ±0.16%, the protein of 4.13 ±0.06%, fat of 22.17 ±0.19% so that it was able to compensate for 5.97 – 6.57% of total energy requirements based on the Nutrition Adequacy Rate for the Elderly per day. The overall preference level in the biscuit formula by untrained panelists was 4.10 ±0.72 (rather like-like). The addition of 7.5% ant nest tuber powder in the biscuit formula had an antioxidant activity (DPPH) of 73.60 ±0.36%. The most preferred biscuit formula was the C013 biscuit formula (addition of 6% ant nest tuber powder per gram biscuits), with the higher antioxidant activity, and its nutrient content to compensate for the nutrition adequacy rate for the elderly per day.

Keywords: biscuits; Belitung taro; ant nests tuber; antioxidant activity; organoleptic test

INTRODUCTION
Belitung taro or kimpul *(Xanthosoma sagittifolium*) is a tropical plant derived from *Araceae* family, containing high starch ranging between 22% to 40%, and because of that, Belitung taro or kimpul is a good source of carbohydrate **(Pérez, Schultz and de Delahaye, 2005**). Small starch granules from Belitung or taro *(Xanthosoma sagittifolium*), from the aspect of digestibility, starch with a small granule size was easier to digest. Other significant nutritional content in Belitung or kimpul taro *(Xanthosoma sagittifolium*) was protein one level higher than sweet potato and cassava (every 100 grams of taro or Belitung *(Xanthosoma sagittifolium*) contains 1.9 g of protein while cassava contains 1.2 g and sweet potato 1.8 g. Belitung taro tubers contain 0.32 g total phenolics per 100 grams of material; 0.26 g flavonoids per 100 grams of material and activity *scavenging* better using DPPH testing (78.22 ±0.56%), *hydroxyl radical* (69.11 ±0.21%), superoxide radicals (83.27 ±0.08%), and ABTS *radical cations* (76.11±0.07%) **(Nishanthini and Mohan, 2012)**.

Meanwhile, *Hydnophytum formicarum* or ant nests tuber plant from West Papua were used in research as a source of antioxidants. This plant was hereditarily consumed in the form of boiled tuber powder and was used to cure diseases such as cancer, tumors, gout, migraine, periodontitis, coronary heart disease, tuberculosis, and leukemia, but it was also used to treat diabetes mellitus. Significantly, the ethyl acetate extract *Hydnophytum formicarum* was also the most potent antioxidant, showing 83.31% of radical scavenging activity with IC_{50} 8.40 $\mu g.mL^{-1}$ in the DPPH assay. The other extracts display weak to moderate antioxidative activities, ranging from 28.60 – 56.80% radical scavenging. The SOD assay shows that methanol extract exhibits the highest activity (74.19% inhibition of superoxide radical). The dichloromethane and ethyl acetate extracts display comparable SOD activity. The promising bioactivities of the crude ethyl acetate extract guided the first isolation of bioactive flavonoid and phenolic compounds: isoliquiritigenin, protocatechualdehyde, butin, and butein from this species, we propose that *Hydnophytum formicarum* Jack. can serve as a new source enriched with potent antioxidative and antimicrobial agents **(Prachayasittikul et al., 2008)**.

Based on another study *H. formicarum* tuber from Setiu wetland and Muara Rupit showed very good potency as antibacterial and antioxidant agents**.** All samples showed high DPPH free radical scavenging activity (IC50 less than 10 $\mu g.mL^{-1}$). Via MTS assay, no cytotoxic activity of all samples was observed against HeLa cells. Only a fraction from Setiu Wetland showed very strong cytotoxic activity against MCF-7 cells (IC50 = 2 $\mu g.mL^{-1}$) and its morphological features stained by Annexin-V/PI and DAPI

Figure 1 *Hydnophytum formicarum* and ant nest tuber powder
Note: a) ant nest tuber plant (*Hydnophytum formicarum*) raw; b) ant nest tuber plant (*Hydnophytum formicarum*) dry; c) ant nest tuber powder plant (*Hydnophytum formicarum*).

showed that the cell death was mediated by apoptosis. **(Andriani et al., 2017)**.

Studies were conducted on the structure and rheological properties of three cocoyam varieties *Xanthosoma sagittifolium* (red-flesh), *Xanthosonia sagittifolium* (white-flesh) and *Colocasia esculenta* starches and raphides in an attempt to characterize them. No distinct variation was observed in starch granule sizes of the two *Xanthosoma* species. Starch granules sizes in the ranges of 0.74 – 1.19 and 0.74 – 1.10 μm were obtained for the *Xanthosoma* species (red tubers) and *Xanthosoma* species (white tubers), respectively. Significantly smaller sizes (0.05 – 0.08 μm) of starch granules were observed for *Colocasia esculenta*. Peak viscosity was highest in the *X. sagittifolium* (red-flesh) variety while the white-flesh variety showed the least tendency to retrogradation **(Sefa-Dedeh and Kofi-Agyir Sackey, 2002)**. Based its study *X. sagittifolium* species white tubers have a low glycemic index because of their high amylose starches. The glycemic index has been categorized by Miller as low GI is pounds

a b

Figure 2 Beiltung taro and flour.
Note: a) Belitung taro *xanthosoma sagittifolium* raw; b) Belitung taro *xanthosoma sagittifolium* flour.

Figure 3 Biscuits made with addition of Beiltung taro flour and ant nest tuber flour.

55, moderate GI is between 56 – 69 and high GI is ≥70. Glycemic index (GI) has been widely used in the management of blood sugar levels among diabetes, however; in the South Pacific, very little information regarding the GI of local foods is made available. Other research was to determine the glycemic index and the glycemic load of 5 South Pacific foods (Plantain (*Musa AAB*), tannia (*Xanthosoma sagittifolium*), roti or chappati, homemade pancake, and Lees cabin crackers) have moderate GI values ranging from 59 to 68. The Glycemic Load (GL) for cabin biscuit was the highest **(Lako et al., 2004)**. Based on sensory test the best treatment was obtained from the proportion of *Xanthosoma sagittifolium* flour: black soybean flour at 70:30 with 2% agar was liked by panelists **(Kasih and Murtini, 2017)**. Biscuits are an instant food that is consumed mostly because of the appetizing, ready to be consumed, the cost is also cheap and the availability of short time and biscuits can make a significant contribution to the daily intake of cereals. However, in an era of increasing functional food popularity, new demands have been set for various categories of snacks including biscuits that can maintain the traditional

nutritional aspects of food and show additional health benefits **(Vujić, Vitali Čepo and Vedrina Dragojević, 2015; Briliannita and Mustika Matto, 2020)**.

Scientific hypothesis

Hypothesis: biscuits with the addition of ants nest tuber and Belitung taro are significantly different in the sensory properties, nutritional value, and antioxidant activity of a variety of biscuits compared to biscuits without addition.

MATERIAL AND METHODOLOGY

Main Material

The main material used in this study was Belitung taro (*Xanthosoma sagittifolium*) and ant nest tubers (*Hydnophytum formicarum*) from the distributor in Sorong City in West Papua, Indonesia (Figure 1 and Figure 2).

Another material was tropicana slim sugar, salt, Max Crimer, Blue Bland Cookies in Mega Mall, The West Papua Indonesia.

Chemical material used in this study was (1) nutritional analysis: protein katalis, H_2SO_4, aquades, borat, BCG asam-MR, NaOH, Na2S2O3, HCl 0.02 N, petroleum ether, buffer HCl-(KC1) bisa pH 4.5, asam acetate pH 1, methanol-PA (2): DPPH analysis: 0.5 mM, methanol, dan vitamin C, vitamin E in Chemix Pratama Yogyakarta.

Chemical analyses of the Biscuits

The chemical composition of fresh biscuits (as prepared on the day of baking) was determined according to the methods of the Association of Official Analytical Chemists International **(AOAC, 2006)**: the total protein content by the Kjeldahl procedure with nitrogen to a protein conversion factor of 5.7; fat content by the Soxhlet method and ash content by carbonization. The total carbohydrate content was calculated by subtracting the sum of moisture, protein, fat, and ash percentages from 100%.

Preparation of dough and baking of the biscuits

The preparation of dough and baking of the biscuits was based on the study of **Krystyjan et al. (2015)**. Dry ingredients were mixed and then combined with others according to the recipe presented in Table 1. The dough was mixed for 10 min to obtain a homogeneous consistency and then placed into the fridge at ±6 °C for 30 min. The dough was then rolled out and 5 mm thick biscuits with a 60 mm diameter were formed and baked at 200 °C for 12 min. (Figure 3). The biscuits with the ant nest bulb powder addition in amounts of 6% and 7.5% concerning the wheat flour were prepared in the same way as the control sample (biscuits without ant nest tuber powder). The results of all the experiments are given as the average of replicates. Each replicate (biscuit) was obtained from separately prepared batches of dough.

Analysis of antioxidant activity (DPPH Method)

Antioxidant activity by DPPH method was based on **(Sompong et al., 2011; Briliannita, 2017** and **Hetharia et al., 2020)** with modification. DPPH 0.1 M was prepared by diluted 0.0039 g DPPH with ethanol 96% until 100 mL. DPPH solution (1 mL) was mixed with 200 µL aliquot and the absorbance was measured at 515 nm after 30 min incubation. The data was served as mg of vitamin C equivalent (VCE) per L with the help of the vitamin C standard curve (0 – 40 $mg.L^{-1}$).

Sensory analysis of the biscuits

For sensory analyses, the laboratory was equipped with special boxes and fulfilled all the basic requirements stated by SNI 01-2346-2006 (Indonesia National Standard, Organoleptic or sensory testing instructions) and sensory analysis was carried out according to **(BSN, 2006; Pauline et al., 2017)** with modification. The evaluation was performed by an untrained panel of 27 women and 3 men that were between the ages of 18 and 25 from students of the Nutrition Department Of the Polytechnic Of Ministry Of Health Of Sorong. For each sample, and for the same panelist, four repetitions were done. The evaluation was done on a Five-point hedonic scale. The scale and categories were as follows: good = 5, fair = 3 and poor = 1. Evaluated characteristics were color, aroma, taste, texture, and overall acceptance.

Statistical analysis

This study used Statistical Product dan Service Solution (SPSS) version 15.0 (Stat Soft, USA). Results were expressed by average ± standard deviation. The effect of the results was performed using the Kruskal-Wallis test (α = 0.05). The samples of individual varieties were evaluated to each other. Furthermore, all samples of individual varieties of biscuits were evaluated against common biscuit (C001).

RESULTS AND DISCUSSION

Chemical composition of the biscuits

Table 2 shows the content of essential nutrients in biscuits. After analyzing the data obtained it was found that the addition of ant nest tuber powder did not affect the carbohydrates content in biscuits – the amount of which oscillated around 60.55%. There was, however, a small but statistically significant increase in ash and water content and a significant decrease in protein and fat content in those biscuits that had additional ant nest tuber powder at 6% and 7.5%. Such a decrease can come from the fact that the ant nest tuber powder contains three times more protein and four times more ash than the Belitung taro flour that was used for baking.

Significant increase of water content for this study, because one to two water populations are identified for Belitung taro flour and are highly dependent on the temperature and concentration rather than the, showed higher retrogradation tendency. An increase in relaxation times at 75 – 80 °C is observed for flours and starches corresponding well to the amylograph pasting temperatures revealed using the Rapid Visco Analyzer **(Boakye et al., 2019)**. The results of other research show that *Xanthosoma sagittifolium* powder proportion, mixing time, and water addition, significantly affect water holding capacity, oil holding capacity, texture, and protein solubility of TVP (p <0.05). The effect of XSP addition on water holding capacity increase when added to 20% **(Lindriati, Herlina, and Arbiantara, 2018)**.

Table 1 Components used for the preparation of biscuit dough (35.25 g).

Material	C001	C013	C014
Wheat Flour (g)	17.6	17.6	17.6
Taro flour (g)	13.2	13.2	13.2
Ant nests tuber (g)	0	1.06	2.64
Vegetable Crimer (g)	0.39	0.39	0.39
Chiken eggs (g)	1.67	1.67	1.67
Margarine (g)	1.49	1.49	1.49
Baking Powder (g)	0.04	0.04	0.04
Sugar of *Tropica Slim* (g)	0.84	0.84	0.84
salt (g)	0.02	0.02	0.02

Note: C001 – without ant nest tuber powder (0%), C013 – 6% ant nest tuber powder, C014 – 7.5% ant nest tuber powder.

Table 2 Content of nutrient raw, and biscuits.

Nutrient Composition	Belitung Taro Raw	Ant Nest Tubers Raw	C001 without ant nest tuber powder	C013 with 6% ant nest tuber powder	C014 with 7.5% ant nest tuber powder
Water (%wb)	8.18 ±0.00^{a}	13.35 ±0.38^{b}	7.35 ±0.12^{a}	9.24 ±0.07^{c}	9.80 ±0.12^{c}
Ash (%db)	14.18 ±0.11^{a}	4.35 ±0.28^{b}	2.82 ±0.21^{c}	5.36 ±0.16^{d}	6.15 ±0.19^{d}

Table 3 Sensory evaluation results.

Characteristic	Biscuits		
	C001 without ant nest tuber powder	C013 with 6% ant nest tuber powder	C014 with 7.5% ant nest tuber powder
Colour	3.50 ±0.90^{a}	3.57 ±0.72^{b}	3.26 ±0.83^{a}
Aroma	3.86 ±0.77^{a}	3.60 ±0.96^{a}	3.30±0.95^{b}
Taste	3.90 ±0.71^{a}	4.20 ±0.96^{a}	3.30 ±1.11^{b}
Textur	3.57 ±0.77^{a}	3.83 ±0.74^{b}	3.33 ±0.92^{a}
Overall	3.80 ±0.71^{a}	4.10 ±0.72^{b}	3.53 ±0.82^{a}

Note: (a, b) The values with the same letters in the same row are not significantly different (p <0.05).

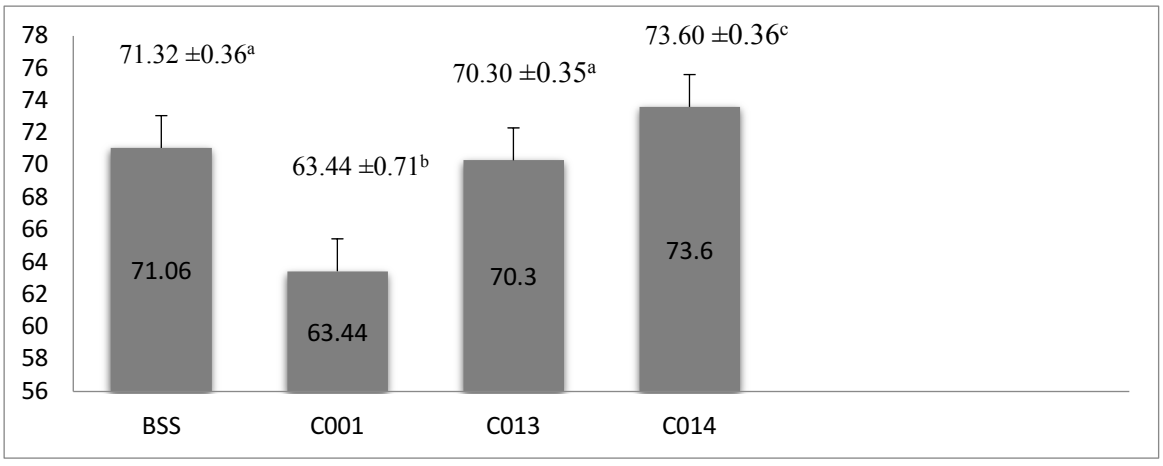

Figure 4 Ability to inhibit free radical by ant nest tuber powder (%) (DPPH Assay).

Based on the research of physicochemical properties of starches of five cocoyam cultivars where starch granule sizes varied significantly in length and width, while amylose content ranged from 11.55% (NCe002) to 33.77% (NXs001). Also, water absorption capacity (21 – 36%), pH (4.8 – 5.3), gelling point (60.5 – 69.5 °C), foam capacity (4.46 – 18.28%), bulk density (0.14 – 1.15 g.mL^{-1}) and swelling power (2.31 – 10.09) varied significantly (p <0.05) among the cultivars. Water content on our research increased **(Falade and Okafor, 2013)**. A significant increase of ash content was not caused by an interaction between Belitung taro flour with ant nest tuber powder. Product ash levels experienced an increase with increasing portions of flour (Belitung taro flour and ant nest tuber powder). This could be because of the high ash content in both materials. Another factor allegedly due to immersion with salt in the preliminary treatment Belitung taro flour. Salt contains minerals including sodium, chloride, and iodine that can be calculated in measuring ash content. Such as in the results of others our research showed that the different sections of *Xanthosoma sagittifolium* cormels were significantly different (p <0.05) in chemical composition. The apical section of all the species had high protein content while the distal section had high levels of ash, fibre, and minerals. Potassium was the most abundant mineral (763 – 1451 µg.100 g^{-1}) with appreciable amounts noted for zinc (17 – 51.1 µg.100 g^{-1}), magnesium (46.7 – 85.0 µg.100 g^{-1}), and phosphorus (41.6 – 63.1 µg.100 g^{-1}) **(Sefa-Dedeh and Kofi Agyir-Sackey, 2004)**.

Antioxidant activity

DPPH Assay

The highest antioxidant activity determined by the DPPH method was biscuit C014 (with 7.5% ant nest tuber powder) 73.60 ±0.36,(p <0.05). The lowest antioxidant activity was determined in biscuit C001 (without ant nest tuber powder) 63.44 ±0.71, p <0.05). Biscuits showed statistically significant differences p <0.05, except sample BSS and biscuit C013, due to their content of ant nest tuber powder difference (Figure 4). Significantly, the ethyl acetate extract was also the most potent antioxidant, showing 83.31% of radical scavenging activity with IC50 8.40 µg.mL^{-1} in the DPPH assay. The other extracts display weak to moderate antioxidative activities, ranging from 28.60 – 56.80% of radical scavenging, α-tocopherol, a positive control, shows antioxidative activity with IC50 6.67 µg.mL^{-1} **(Prachayasittikul et al., 2008)**. Antioxidant activity values ranged from 63.44 ±0.71 to 73.60 ±0.36 in four samples. The other research showed that extracts *Hydnophytum formicarum* could increase lymphocyte proliferation by increasing concentration. There was no chemical content difference observed on extracts *Hydnophytum formicarum*. These extracts contained flavonoids, phenolic, aldehyde/ketone, terpenoids, and tannin **(Darwis, Hertiani and Samito, 2014)**. *Hydnophytum formicarum* showed oxidant activity with IC50 = 7.03 µg.mL^{-1}. *Hydnophytum papuanum* showed oxidant activity with IC50 = 6.19 µg.mL^{-1} **(Makaba, 2017)**.

Sensory evaluation analysis

The sensory evaluation analysis is shown in Table 3. According to the data, biscuits supplemented with 6% ant nest tuber powder obtained a higher total score (4.10 ±0.82) in the sample C013 and the same as in the sample C001 (total score 3.80 ±0.71). The overall assessment allowed the classification of the product to be acceptable (3.53 ±0.82) in the case of the maximum additive (sample C014). When comparing particular sensory characteristics of four biscuits directly, significant differences (p <0.05) were observed between the sample C001 and the sample C014. On this basis, it can be concluded that the applied fortification of biscuits with ant nest tuber powder was possible and gave the desired results, at a level of 6%. Slight differences were noticed between the sample C001 and the sample C014 with a 0% and 7.5% supplementation of ant nest tuber powder. In particular, such characteristics as taste, color, aroma, and texture deteriorated. One of the main factors, as regards the deterioration of the taste of biscuits, was ant nest tuber powder; when used in significant quantities, the biscuits were leaving a crumb biscuit on the tongue. Besides, the color of the product depends on the chemical composition of ant nest tuber powder, which in turn depends on the plant species and environmental conditions **(Agatonovic-Kustrin et al., 2018)**. Thus, the flavonoid, vitamin E, phenolic, aldehyde/ketone, terpenoids, and tannins as well as the reducing sugars introduced to the product with ant nest tuber powder affected its color. Curiously, the darkening of color caused by the addition of ant nest tuber powder was not observed by the assessors.

CONCLUSION

The addition of ant nest tuber powder (7.5%) in the biscuit had an antioxidant activity (DPPH) of 73.60 ±0.36%. According to the sensory evaluation of the biscuits, they were acceptable in characteristics of the color, aroma, taste, texture, and overall. The obtained results have shown that it was statistically significant that panelists will be likely to accept the produced biscuit (p <0.05). The higher the addition of ant nest tuber powder, the higher the antioxidant activity in biscuits and lower the biscuit protein content (p <0.05).

THE INFLUENCE OF CHOSEN ORGANIC FERTILIZERS ON QUALITATIVE PARAMETERS OF THREE *DAUCUS CAROTA* L. VARIETIES

Marcel Golian, Lucia Hlavačková, Adriána Maťová, Ivana Mezeyová, Miroslav Šlosár, Alžbeta Hegedűsová, Samuel Adamec

ABSTRACT
In rational nutrition, vegetables play an important role due to their high biological and low energy value. The most widespread vegetables in our country belong to root vegetables. They are grown mainly for bulbs, corms, rhizomes, fleshy roots, and hypocotyl tubers. Root vegetables can be eaten raw or cooked. Carrot (*Daucus carota* L.) is a basic representative of root vegetables. For the most valuable components counts beta-carotene – the major component of total carotenoids. This paper evaluates changes in total carotenoids, refractometric dry matter, and gravimetric dry matter in three varieties of carrot (Kamaran F1, Komarno F1, Romosa) grown in soil and climatic conditions ex-situ in Nitra. We have evaluated roots grown in non-fertilized soil, soil after application of manure, horticultural compost, and their combinations. The results show that the variants fertilized with compost and a mixture of compost and manure had the most considerable influence on the synthesis and content of total carotenoids as well as the content of dry matter and refractometric dry matter.

Keywords: total carotenoids; antioxidant; fertilizer; vegetable; quality

INTRODUCTION
Cultural plants are an essential part of civilization. Many of them had originally been harvested as wild plants, later on, cultivated and consciously bred. Vegetables generally represent the juicy parts of plants. They can be grown on arable land, but in the tropics and subtropics, some of the vegetables can be collected from the wild (eg. roots, leaves, etc.). In rational nutrition, vegetables play an important role because of their high biological and low energy value **(Vargová, 2003)**. Vegetables are of great importance for health, especially in terms of the content of vitamins that affect normal metabolism. The beneficial effect of the contained minerals on the acid-base balance in the human body is also significant. Due to their low calorific value, vegetables can be extensively used in a weight-reduction diet. Vegetables, especially when fresh constitute a rich source of vitamins, primarily vitamins A and C. Consumption of vegetables provide many health benefits, such as reducing the risk of heart disease, including heart attack, obesity, diabetes, and stroke. It protects against certain types of cancer and can also reduce the risk of developing kidney stones **(Seljåsen et al., 2012)**. Carrots ranks among the 10 most important vegetable species in terms of cultivated areas' size and production volume indicated in tons **(Simon and Goldman, 2007)**. Carrots produce strong roots with high nutritional value. It contains valuable components such as carotene, thiamine, and riboflavin. It is also a source of carbohydrates, proteins, fat, minerals, vitamin C, and calories **(Yawalker, 1985)**. **Ergun and Süslüoğlu (2018)** state that carrots are primarily valued because of their high beta-carotene contents. In addition to that, the root contains various bioactive compounds including other forms of carotenoids, phenol compounds, and vitamins. Beta-carotene is known as provitamin A and it is known as a strong antioxidant. According to **Oberbeil and Lentz (2003)**, carrots also have a high content of selenium, D, E, and K vitamins, essential oils, lecithin, potassium, calcium, magnesium, iron, copper, phosphorus, iodine, cobalt, and sugars. Among the sugars, the most commonly occurred are sucrose (about 50%), glucose, and fructose **(Šapiro and Raab, 1988)**. Terpenoids are responsible for astringency and bitterness **(Kopec et al., 2010)**. The characteristic taste of carrots is given by their intense sweetness and minimal bitterness **(Simon, 1982)**. Significant amounts of fiber are to be found in the roots. The acid content is low, with malic acid, citric acid, and oxalic acid being the most prominent of the variety of acids contained **(Šapiro and Raab, 1988)**. At present, the total annual yield of carrots in Slovakia has a decreasing tendency compared to the past decade. In 2007 the total annual yield of carrots was 31,817 t per 2,568 ha. Between 2007 and 2008, the yields lightly increased, reaching 37,155 t per 2,562 ha. Afterward, between 2008 and 2010, the total annual yield of carrot mildly lessened up to 34,879 t per 2,454 ha in 2010. However, between 2010 and 2012 total annual crops decreased dramatically to as little as 6,685 t per 250 ha.

Proceeding to 2012 – 2014, the total annual crop of carrots was relatively stable, reaching 6,502 t per 232 ha in 2014. Between 2014 to 2015 though, we were experiencing a slight increase in total annual yield which resulted in 10096 t per 312 ha in 2015. Between 2015 and 2017, the total annual yield decreased again, in 2017 it decreased to 5, 730 t per 185 ha. Average hectare yields in Slovakia in the last decade reached 16 t **(FAOSTAT, 2020)**.

Scientific hypothesis

The concentration of total carotenoids depends on the variety.

More intense usage of fertilizers can support the synthesis of carotenoids, refractometric dry matter, and total dry matter.

MATERIAL AND METHODOLOGY

Characteristics of the research area

The research was carried out in the form of a small-plot experiment under the conditions of the vegetable sampler of the Department of Vegetable Production in the area of Botanical Garden at the Slovak University of Agriculture in Nitra. We used four soil variants, the size of each was 6 x 7 m (42 m²). Monitored varieties are shown in Figure 1 and Figure 2.

Variants

1. variant with the application of livestock manure in the amount of 44 $t.ha^{-1}$ and compost applied in the amount of 44 $t.ha^{-1}$ (MH K).
2. variant with the application of livestock manure in the amount of 44 $t.ha^{-1}$ (MH).
3. variant with the application of mature compost in the amount of 44 $t.ha^{-1}$ (K).
4. variant with non-fertilized soil (control variant) (KON).

By each variant, three experimental trials were carried out.

Characteristics of monitored varieties

***Daucus carota* ´Romosa´ (Rom.)**

A profitable late Berlicum variety is characterized by exceptional external and internal root coloring. The roots are of high quality, cylindrical and 16 – 19 cm long. The flesh is juicy and delicious. This carrot variety reaches a vegetation period of 127 days from sowing to reaping. This variety is recommended for storage. It is suitable not only for storage but also for industrial processing. When densely sown, it is also suited for direct consumption **(Bejo, 2016)**.

Figure 1 Examined carrot varieties, sorted by variety and variant.
Note: left: Kamaran F1, Komarno F1 and Romosa.

Figure 2 Examined carrot varieties.
Note: from the left – Kamaran F1, Romosa and Komarno F1.

***Daucus carota* ´Kamaran F1´ (Cam.)**

This is a late and highly productive hybrid of the Berlicum and Flakkee variety. It forms dull-ended roots up to 26 cm long. It has excellent external and internal coloring. The roots weigh 300 – 500 grams and have a diameter of 2.5 – 4.5 cm. Carrots of this variety are suitable for long-term storage. The vegetation period of Kamaran F1 variety in our climatic conditions reaches 135 days. It can accumulate less nitrate and is suitable for industrial processing and storage **(Bejo, 2016)**.

***Daucus carota* "Komarno F1" (Kom.)**

This variety of carrots is a late and very fruitful Flakkee type variety foremost suited for industrial processing. Komarno F1 variety is typical with high yields and high dry matter content. Its typical smooth conical roots with strong and healthy leaves of dark green color are very resistant to fungal and bacterial diseases. The roots have intense dark red coloring and weigh 200 to 500 grams. Vegetation time for this variety of carrots in our conditions is 161 days. This variety is excellent for freezing, production of carrot juice, and wherever an intense dark color of the final product is required. The variety is also suitable for storage **(Bejo, 2016)**.

Measurement methods of selected qualitative materials

Total carotenoid content

The extraction of samples has been done at the Laboratory of Beverages, AgroBioTechResearch Center of SUA in Nitra. The measurement of total carotenoid content was realized in the laboratory of the Department of Vegetable Production of SUA (Slovak University of Agriculture) in Nitra. The content of total carotenoids was assessed by spectrophotometric measurement of substance absorbance in petroleum ether extract on Spectroquant® Spectrophotometer Pharo 100 at 445 nm wavelengths **(Hegedűsová et al., 2015)**. Calibration was not performed due to the calculation of the total carotenoid content, which was performed according to the average specific absorbance ε. The measurement was taken three times. Total carotenoid content was recalculated according to the relationship reported by **Biehler et al. (2010)**.

Determination of refractometric dry matter

The refractometric dry matter was measured in triplicate by using a refractometer (type CRUESS DR201-95).

Determination of dry matter

The dry matter content was determined by using a gravimetric weighing method. The analyzed plant material was dried at 105 °C up until the weight became stable.

Statistical analysis

Statistical analysis was performed by using Statgraphic Centurion XVII (StatPoint Inc. USA). The obtained results were evaluated by analysis of variance (ANOVA) and the average values were tested by LSD test at the significance level of 95%.

RESULTS AND DISCUSSION

Total carotenoid content

Carotenoids are an important group of biologically active compounds attributed to a wide range of health benefits. These are natural pigments that occur mainly in vegetables but also in other natural resources such as fungi, algae, microorganisms, crustaceans, fish, birds but also mammals **(Kulczyński a Gramza-Michałowska, 2019)**.

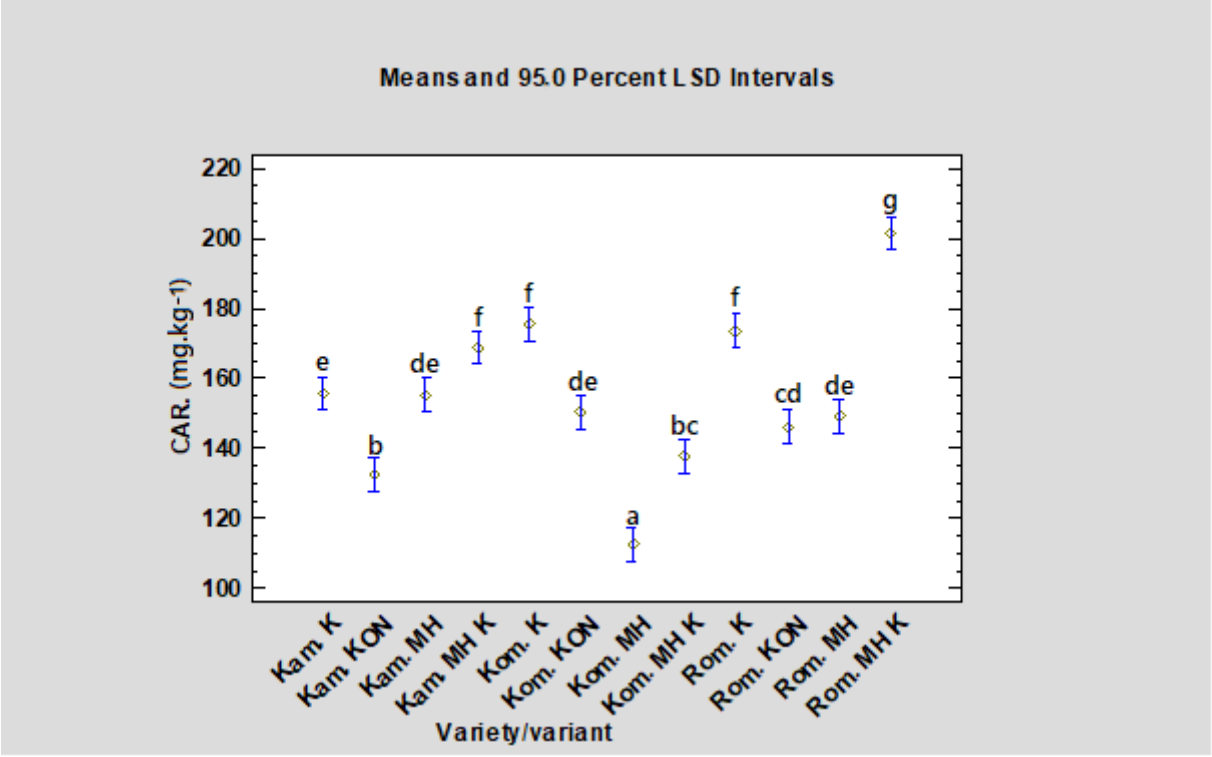

Figure 3 Total carotenoids content (mg.kg^{-1}) in varieties Kamaran F1, Komarno F1 and Romosa according to the variants. Note:The values in the columns with different letters are significantly different from each other.

Based on our results (Figure 3), it is possible to find the highest content of carotenoids in the Romosa variety, namely in the Rom variant MH K (201.32 mg.kg^{-1}). Subsequently, a decreasing trend was observed in the following order: Rom. K by 14% (173.62 mg.kg^{-1}), Rom. MH by 26% (148.96 mg.kg^{-1}) and Rom. KON by 27% (146.03 mg.kg^{-1}). The same findings concerning the variety's particularities were detected in the Kamaran F1 variety. The highest content of carotenoids was recorded in variant Kam. MH K (168.91 mg.kg^{-1}). As for other variants from the Kamaran F1 variety, a decreasing trend can be observed in the following order: K by 7% (155.84 mg.kg^{-1}), Kam. MH by 8% (155.38 mg.kg^{-1}) and Kam. KON by 21% (132.66 mg.kg^{-1}) in terms of carotenoid content determination. Different findings were noted for the Komarno F1 variety. The highest content of total carotenoids in this variety was recorded in the variant Kom K (175.64 mg.kg^{-1}). In other variations of Komarno F1 variety was detected a lower content of total carotenoids decreasing in the following order: Kom. KON by 14% (150.18 mg.kg^{-1}), Kom. MH K by 22% (138.08 mg.kg^{-1}) and Kom. MH 36% (112.62 mg.kg^{-1}). Miękus et al. (2019) and **Amorim-Carrilho et al. (2014)** report that the total carotenoid content of carrots is generally 160-380 mg.kg^{-1} of fresh matter. **Fikselová et al. (2008)** report that the carotenoid content of most varieties ranges from 60 – 120 mg.kg^{-1} of fresh matter, but some varieties have a carotenoid content of up to 300 mg.kg^{-1} of fresh matter. The varieties examined in our study can certainly not be evaluated as highly above average regarding their content of carotenoids. **Kaur and Sogi (2016)** report a total carotenoid content of 324 mg.kg^{-1} while **Saha et al. (2016)** in their experiments set the highest content at 144 mg.kg^{-1}. **Kiraci and Padem (2016)** observed purple varieties of carrots and found out that the content of beta-carotene (the main constituent of carotenoids in carrots) is 117 – 149 mg.kg^{-1}. A study by **Santos and Simon (2006)** confirms that the content of carotenoids is genetically determined for individual varieties**. Smoleń and Sady (2009)** revealed no significant effect of N-fertilization on carotenoid concentration in carrots. Our research has refuted this claim. However, obtained results confirm the findings of **Evers (1989)**, who claims in his study that variants treated with P and K or NPK fertilizers were characterized by a higher carotene content in the roots.

Hochmuth, Brecht, and Bassett (1999) studied the total carrot root yield and the content of total carotenoids and sugars. They found the levels of N fertilization maximizing carrot root yield (in tonnes) also maximized carrot quality in terms of sugar and carotenoid levels. **Kovács et al., (2012)** verified the use of compost, mineral fertilization, and bacterial fertilization in carrot cultivation. The highest content of total carotenoids in the roots was detected in variants with compost. Recent studies have shown that the content of total carotenoids in carrot roots can change completely when the roots are exposed to light. Illuminated roots have chloroplasts with high lutein levels instead of beta-carotene-rich chromoplasts found in roots below the ground **(Rodríguez-Concepción and Stange, 2013)**. From carrot production with an emphasis on the production of the high content of beta-carotene, it is important to choose the appropriate agrotechnical.

Dry matter content

The results (Figure 4) show that the highest dry matter content was determined in the Kamaran F1 variety, namely in the Kam. K (14.16%) variant.

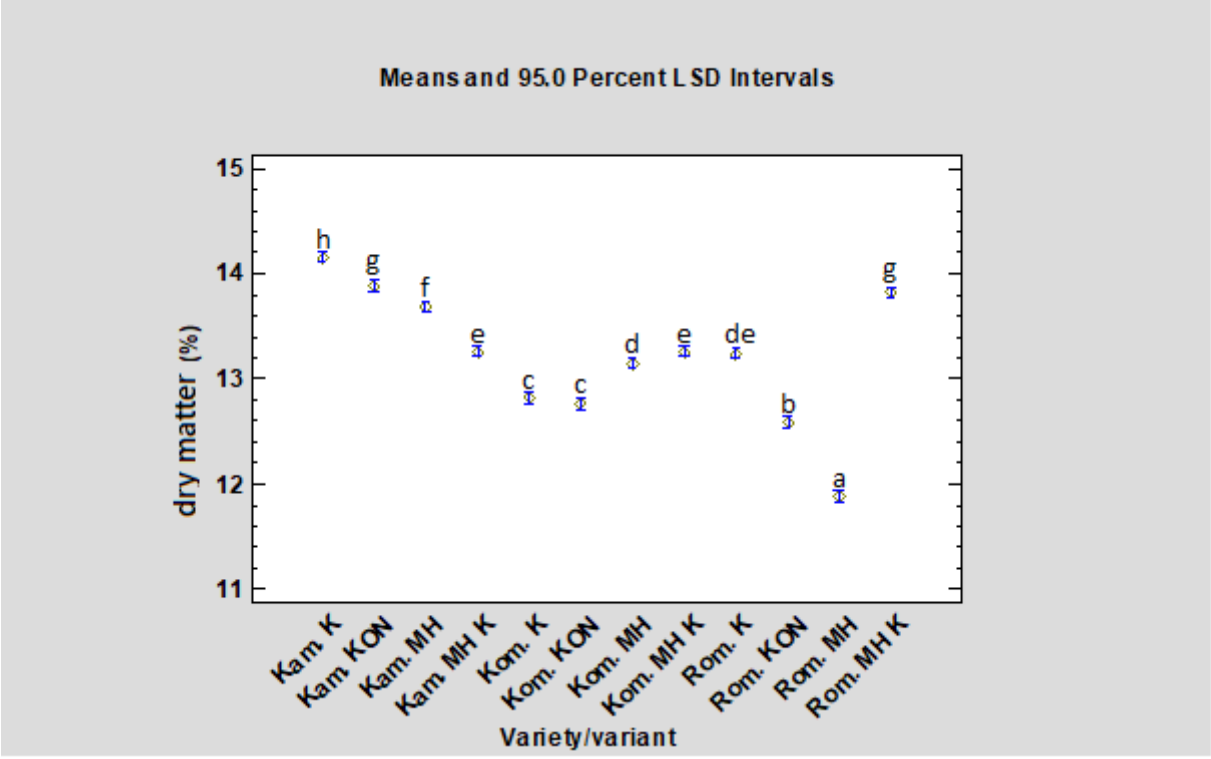

Figure 4 The dry matter content in (%) in varieties Kamaran F1, Komarno F1 a Romos aaccording to the. Note: The values in the columns with different letters are significantly different from each other.

In the case of the other variants (Kamaran F1 variety), the decreasing trend in the order of Kam. KON by 2% (13.88%), Kam. MH by 3.3% (13.69%) and Kam. MH K 6.4% (13.26%) can be noted in the dry matter contents. In the Romosa variety, other findings were detected in terms of variation effects. The highest dry matter content was determined in the Rom. MH K (13.82%) variant. In the case of the other variants (Romosa variety), the decreasing trend in the order of Rom. K by 4.2% (13.24%), Rom. KON by 8.9% (12.59%) and Rom. MH by 13.97% (11.89%) can be observed in the dry matter contents. The highest dry matter content of Komarno F1 was determined in the variant Kom. MH K (13.26%). In the case of other variants (Komarno F1 variety), the decreasing trend in the order of Kom. MH by 0.83% (13.15%), Kom. K by 3.3% (12.82%) and Kom. KON by 3,7% (12,77%) can be stated in the dry matter content. Variants fertilized with compost and a mixture of compost and livestock manure had the highest impact on the dry matter content. **Bach et al. (2015)** reported that the dry matter content of most varieties varied from 11.1 to 13.7 $g.100^{-1}$ g of fresh weight. However, the authors add that in 2009, the dry matter content was significantly higher ($p \leq 0.05$) than in 2007 and 2008. In comparison with Bach, a relatively high average dry matter content was found in our study. **Dhillon et al. (2016)** reported that the dry matter content of the carrot varieties studied ranged from 6.68% to 8.70% (average 7.66%). Compared to Dhillon, we again detected a significantly higher percentage of dry matter. However, the varieties examined by us cannot be assessed as highly above average concerning their dry matter content. **Gopalan, Rama Sastry, and Balasubramanian (1991)**, **Longvah et al. (2017)**, and **Fanlégué et al. (2018)** agree with us that the moisture content of carrots varies between 86 and 89%. **Kaur and Sogi (2016)** determined a 10% dry matter.

Refractometric dry matter

The highest refractometric dry matter content was determined in the Kamaran F1 variety (Figure 5), namely in the Kam. variant K (11.98 °Brix). We observed a decreasing trend in the contents of the refractometric dry matter in other variants of Kamaran F1 variety with KON declining by 5.1% (11.37 °Brix), Kam. MH by 6.5% (11.2 °Brix) and Kam. MH K by 10.02% (10.78 °Brix). Different findings emerged from the measurements of the Romosa variety.

The highest refractometric dry matter content was determined in the Rom. variant MH K (11.22 °Brix). Other variants of the Romosa variety showed a decreasing trend in the following order: KON by 3.48% (10.83 °Brix), Rom. K by 4.46% (10.72 °Brix) and Rom. MH by 12.84% (9.78 °Brix). Slightly different conclusions can be drawn from researching the Komarno F1 variety. The highest content of refractometric dry matter was determined in variant Kom. MH K (10.63 °Brix). In the case of other variants (Komarno F1 variety) a similar decreasing trend was recorded in the refractometric dry matter content which declined in the following order: MH by 0.28% (10.6 °Brix), Kom. KON by 6.21% (9.97 °Brix) and Kom. K by 7.06% (9.88 °Brix). Variants fertilized with compost and a mixture of compost and manure had the highest impact on the refractometric dry matter content. **Valšíková et al. (2013)** report that the average refractometric dry matter content of fresh carrot roots was 7.6 °Brix. Authors also recorded that after 14 days of package-free storage in a laboratory the refractometric dry mater values increased to 14.8 °Brix. In comparison with Valšíková, we detected higher average values of refractometric dry matter contents in our research. **Seljåsen et al. (2013)** state that the refractometric dry matter content values in carrots varied from 45 – 72 $mg.g^{-1}$ of fresh matter (60%) depending on the variety.

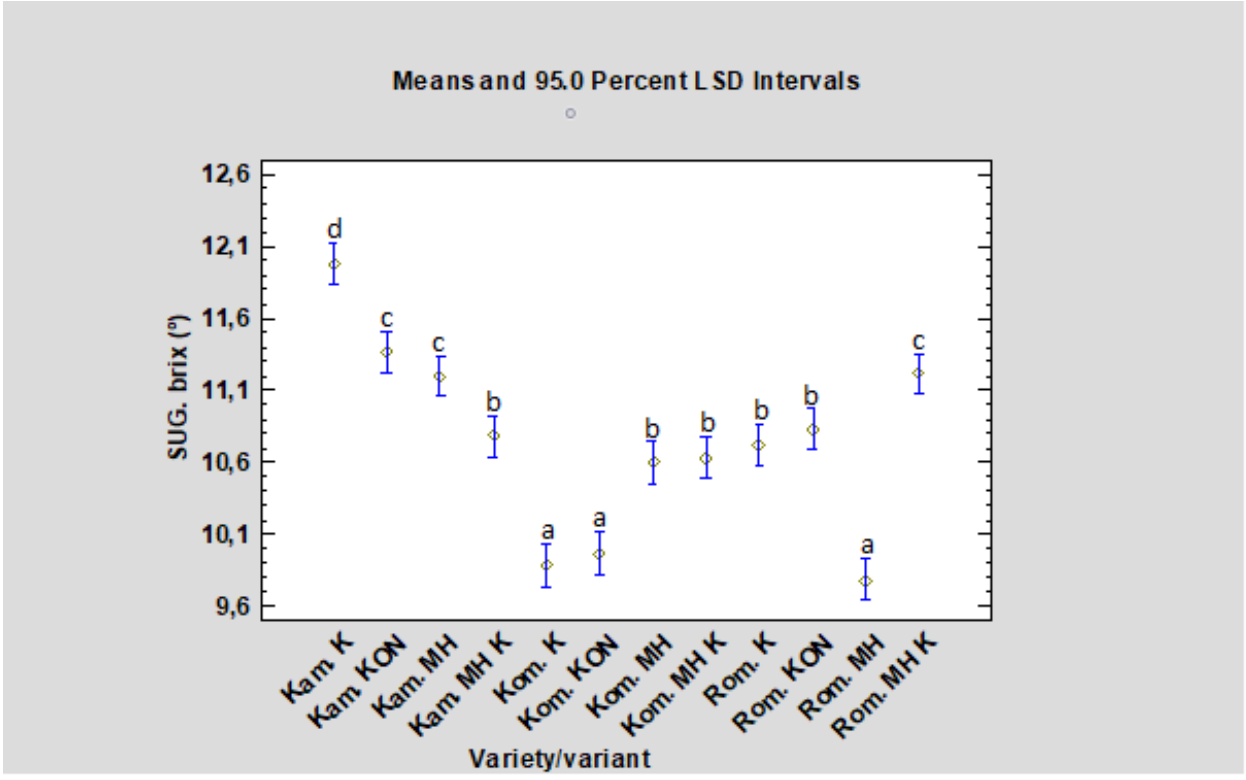

Figure 5 Refractometric dry matter content in Brix (°) in varieties Kamaran F1, Komarno F1 a Romosa according to the variants. Note: The values in the columns with different letters are significantly different from each other.

Machewad et al. (2003) claim that carrot root is considered one of the tastiest and juiciest roots and the total soluble solids content mean value reaches approximately 12 °Brix. **Saha et al. (2016)** detected results stretching from 6.7 to 10.48 °Brix. Similar findings (6 – 8 °Brix) were published by **Jabbar et al. (2015)**; **Gills et al. (1999)** reported values ranging 8.6 – 10 °Brix; **Holley et al. (2007)** 7 – 10.5 °Brix; **Nadulski et al. (2014)** 8.2 °Brix; **Evrendilek and Ozdemir (2019)** reported values ranging from 7.2 to 9 °Brix; and **Santana-Gálvez et al. (2019)** came with the resulting values of 8.1 °Brix. Comparing these to the results of our research, we detected lower values of carrots' refractometric dry matter. **Smoleń and Sady (2009)** do not hold coincident opinions on the impact of fertilization (foliar) on refractometric dry matter content. In their experiments, the refractometric dry matter content increased in some cases, while decreased in others.

CONCLUSION

In four soil variants model varieties of carrots (Romosa, Kamaran F1, Komarno F1) were evaluated in terms of qualitative parameters (total carotenoids, dry matter, and refractometric dry matter). The study of total carotenoid content in carrot varieties shows that the most significant effect on the synthesis and carotenoid content was detected in the variants fertilized with compost and a mixture of compost and manure. Averaging the results from all four variants, the best source of carotenoids in terms of varieties was measured in the Romosa variety (167.48 $mg.kg^{-1}$). The lower content of total carotenoids was found in Kamaran F1 (153.19 $mg.kg^{-1}$, 9% lower) and Komarno F1 (144.13 $mg.kg^{-1}$, 14% lower) varieties. The variants with compost and a mixture of compost and livestock manure had the highest influence on the content of dry matter. The Kamaran F1 variety was found to have the highest average dry matter content (13.75%). Lower dry matter content was found in Romosa variety (12.88%, by 6.33% lower) and Komarno F1 variety (13%, by 5.46% lower). What regards the refractometric dry matter, the highest effect on the varieties had variants fertilized with compost and a mixture of compost and livestock manure. Averaging the results of all the variants for the specific variety, the highest refractometric dry matter content was detected by the Kamaran F1 variety (11.33 °Brix). A lower dry matter content was found in the Romosa variety (10.64 °Brix, lower by 6.09%) and Komarno F1 (10.27 °Brix, lower by 9.36%).

A CASE STUDY COMPARING DISTILLATION TECHNOLOGIES FOR PLUM PALINKA PRODUCTION

Péter Korzenszky, Gábor Barátossy, László Székely, Gábor Géczi

ABSTRACT

Palinka production has a long tradition in Hungary and the neighboring countries. Previously, the fruit distillate was produced exclusively using the traditional Pot-Still Double Distillation (PSDD) technology. This distillation method means, in practice, a simple fractional distillation repeated twice. However, in other industries, such as the petroleum industry or the pharmaceutical industry, a continuous, so-called repeated distillation procedure is used (RCDS – Rectification Column Distillation Systems). In the production of palinka, the latter procedure has gained more and more ground in recent years, thus displacing the traditional technology. In the territory of today's Hungary, there are more than 16,000 registered private palinka distillers. However, based on public databases, it is not possible to know the proportion of the two different palinka making processes used in palinka production. The two processes differ to a large degree. The amount of hearts obtained using the continuous operation plate rectification column (RCDS) is lower, while its alcohol content is very high: 75 – 90 vol%, depending on the fruit. On the other hand, when using the traditional pot-still double distillation (PSDD) method, the amount of hearts is higher, but its alcohol content is lower (60 – 70%). The continuous procedure, also called single-stage, is faster. This is one of the reasons for its popularity because it makes production more economical. The objective of our research was to find out whether a significant difference could be detected between the two plum palinkas produced using the two different distillation technologies, based on current legal requirements. Our research also included sensory testing to determine whether consumers could distinguish between the products manufactured in different ways. Our analyses were carried out in 2019 in the accredited laboratory of the National Food Chain Safety Office and among the students and staff of the Gödöllő campus of Szent István University.

Keywords: plum palinka, distillation, pot-still double distillation, rectification column

INTRODUCTION

According to the current regulation, only alcoholic beverages prepared from fruit produced in Hungary, by fermentation and distillation and with an alcohol content between 37.5% and 86% (V/V%) can be called palinkas **(László, Hodúr and Csanádi, 2016; Panyik, 2018)**. The name palinka can also be used for beverages produced in four Austrian provinces from apricots. However, distillation is also used in other countries to produce alcoholic products: brandy, spirit schnaps, obstbrand (fruit-based), vodka (corn, potatoes), whiskey (grain), borovička (juniper), cachaca (sugar cane juice), rum (cane sugar), tequila (blue agave), mezcal (agave), poitin (barley malt), baijiu (sorghum, rice). Alcoholic drinks, made by fermentation and distillation from fruits, mainly from plums, are very popular in Europe, primarily in Slovakia (*Slivovica*), the Czech Republic (*Slivovice*), Poland (*Sliwowica*), Serbia (*Prepečenica and Sljivovica*), Romania (*Tuica*) and Hungary (*Szilvapálinka*) **(Portugal, et al., 2016; Śliwińska et al., 2016; Satora and Tuszyński, 2008; Zheng et al., 2014)**.

Due to the technology, the quality of palinka is influenced by three well-distinguishable stages: the fruit itself (its variety, state of ripeness, and date of harvest); the mashing procedure, and, finally, the distillation technology. Storage and consumption habits may also be influencing factors, but experts agree that the three areas listed are dominant. In the course of our research, distillation technology has been analyzed. Distillation is a separation technology process in which the volatile components that enter the vapor phase during the evaporation are separated from the liquid phase. This is followed by the condensation of the generated vapors and re-liquefaction. The composition of the condensate formed after recooling the vapors that formed during the distillation of the mash is different than that of the mash since the mash does not contain only volatile compounds. The different components are found in higher concentrations in the distillate than in the mash, depending on their volatility. Distillation has a dual purpose during the brewing of palinka. On the one hand, the extraction of the alcohol content of the mash, and on the other hand, the separation of undesirable volatile components present in

the mash from the precious hearts, by including them in the heads and the tails **(Nagygyörgy, 2010)**.

The traditional Hungarian method is considered to be the double distillation performed in pots, and this is commonly called pot-still technology. By definition, pot-still technology is brewing in an apparatus that has a pot with a volume of no more than 1,000 liters. The pot-still technology begins with the distillation of the mash that has a relatively low alcohol content (2 to 10%). The first distillate (brute alcohol) has an alcohol content of 15 to 30%, depending on the fruit and the apparatus. The second step is the refining of the brute alcohol, that is, the increase of the alcohol concentration to 60 – 70%. At the same time, the heads and the tails are also separated. PSDD (Figure 1a) in the breweries is usually carried out in two separate pots, mainly due to excise regulation and economic operation reasons. However, technically, the second distillation can be carried out in the same pot, but this is most typical of home brewing.

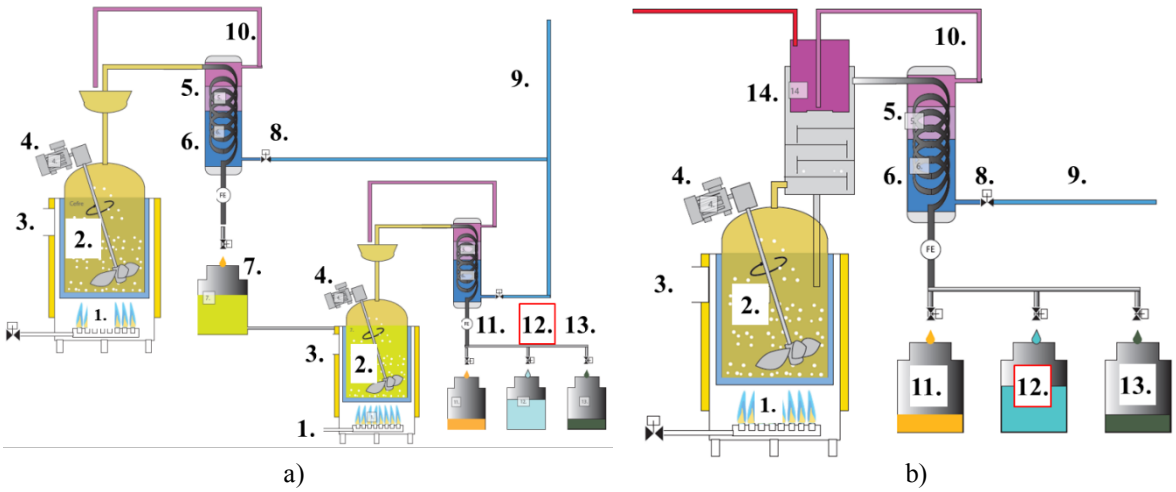
The other technology, which is gaining more and more ground due to Austrian and German influences, is continuous distillation based on column or tower apparatuses (RCDS). In the case of the RCDS technology, multiple distillations can occur in the distillation column. The operating principle is based on having the upward flowing vapors containing volatile substances meet a downward liquid stream while ensuring an adequate exchange of heat and material. The meeting of the vapors and the reflux liquid takes place on the plates in the column. Going up, the alcohol and other volatile component content of the vapor increases and, after condensation of the vapor, a distillate with an ethyl alcohol concentration of 70 to 90% can be obtained. (Figure 1b). In tower systems, depending on the design, 4 to 6 rectifications are carried out, but the separation of the heads and the tails are realized here as well in the final distillate (condensate) **(Nagygyörgy, 2010; Balcerek et al., 2017, Géczi, Korzenszky and Nagygyörgy, 2018)**.

From a palinka brewing point of view, one of the most important points of distillation is the sharp separation of the heads. According to the theory, the amount of the heads is appropriate if the highest possible amount of aroma, characteristic of the fruit, is transferred to the hearts, but unfavorable components, mainly ethyl acetate, are only included in the hearts in such small amounts that they do not cause sensory faults. After the separation of the heads, distillation is continued by the collection of the hearts. The ethyl alcohol content of the vapor decreases continuously and, at the same time, the concentration of the necessary aromas decreases as well, and if distillation is continued, the condensate will have an undesirable, unpleasant sour taste. So the characteristics of the heart are influenced not only by the distillation apparatus but also by the selection of the heads and tails cut points. Palinka suitable for consumption can then be obtained by rest and dilution with softened water **(Nagygyörgy, 2010)**.

To improve the quality of palinka, research into palinka distillation is ongoing, with the number of papers increasing significantly in recent years, although being still less than the amount of scientific publications investigating the quality of beer and wine products.

The determination of the cut points is clearly of great importance, and a numerical method to predict cut-points was developed by **Gössinger et al. (2012)** of Austria for apple distillates. For the more accurate identification of the cut points, research has been focusing on the determination of the volatile components characteristic of the fruit. **Rodriguez-Solana et al. (2018)** performed the analysis of fig distillates popular in Mediterranean countries. 130 volatile compounds were identified in the fig distillates, including, as common constituents, ethyl decanoate, ethyl octanoate, and ethyl dodecanoate, the aldehydes benzaldehyde and furfural, the monoterpene limonene, and the norisoprenoid β-damascenone. Knowledge of the volatile components also allows for objective control of the market, which is a part of the fight against counterfeiting as well.

Claus and Berglund (2005) showed in the case of a tower system technology that the plate number and dephlegmation (reflux) play significant roles. The concentrations of ethanol and related compounds, such as methanol, acetaldehyde, ethyl acetate, 1-propanol, and



a) b)

isoamyl alcohol in the final product were affected by the plate number.

The effect of dephlegmation was also investigated by **Rodríguez-Bencomo et al. (2016).** The results showed that a high reflux ratio at the beginning of the distillation is a good way to reduce the amount of unpleasant compounds in the hearts. **Nagygyörgy (2016)** paid great attention to the research of the effect of dephlegmation. It was determined by him that dephlegmation is primarily determined by the surface of the dephlegmator, the temperature of the vapor tube, and the intensity of heating.
In addition to research into cut points and components that determine advantageous quality, there has been a strong focus on studies investigating the legal background of palinka production and the effects of changes in it **(Zsótér and Molnár, 2015)**. **Deák et al. (2010)** stressed the importance of ethyl carbamate detection in their article. Ethyl carbamate (EC, urethane, $C_2H_5OCONH_2$) is a genotoxic carcinogen and is regularly found in fermented foods, including alcoholic beverages **(Monakhova, Kuballa, Lachenmeier, 2012).** The target value for ethyl carbamate according to the recommendation of the European Food Safety Authority (EFSA) is 1 $mg.L^{-1}$. For a rapid determination of the components, **Śliwińska et al. (2016)** drew attention to the suitability of the electronic nose.

The importance of the cut points and product components is not disputed by anyone, and many professionals see technology development as the solution. A pervaporation membrane technology for the production of apple palinka was developed by **Molnár, Márki and Vatai (2016)**, which is energetically more efficient than the traditional pot-still technology.

García-Llobodanin et al. (2008) examined the concentration and quality of the raw material placed in the still and, regarding pear distillates, found that using natural pear juice does not offer any benefit when compared to using concentrated pear juice from Blanquilla variety pears.

Balcerek et al. (2017) investigated the effect of pot-still and rectification column distillation technologies on the hearts, namely the distribution of the volatile matter content and the concentrations of undesirable compounds (methanol, hydrogen cyanide, ethyl carbamate) in plum palinka. Irrespective of the distillation method used, the heads contained mainly aliphatic aldehydes, acetals, and esters, as well as higher alcohols (1-propanol, 2-methyl-1-propanol, 1-butanol, 2-methyl-1-butanol, and 3-methyl-1-butanol). Increasing the alcohol concentration in the hearts from 70% to 90% resulted in the gradual decrease in the concentration of all detected volatile compounds. Compared to the pot-still technology, single-stage distillation (tower system) resulted in hearts with lower concentrations of acetaldehyde and benzaldehyde. In the case of the pot-still technology, a statistically significant increase in the amount of methanol and ethyl carbamate in the hearts was observed.

Technological, as well as tourism issues, are discussed by **Harcsa (2017a)** and **Harcsa (2017b)**, in his research aimed at the comparison of the energy consumptions of the two different systems (pot-still and tower).

Kovács et al. (2018) stressed that the quality of fruit-based alcohol content varies from year to year; therefore, it is necessary to identify the vintage of distilled alcoholic beverages. They found that three ingredients are associated with the vintage, regardless of the type of fruit: propanol, butanol, and ethyl propionate.

It was mentioned in the introduction that some of the most popular distillates in neighboring countries are made from plums, and based on this it is understandable that plum palinka is a popular research subject. **Jakubíková et al. (2019)** showed differences between the origin and harvest time of raw materials by examining the phenol and anisole compounds of plum palinkas. **Satora et al. (2017)** examined the quality of distillates prepared from four varieties of plums and found that the aroma of the samples is determined by six compounds (ethyl dodecanoate, benzyl acetate, methyl cinnamate, 1-heptanol, α-terpineol and benzothiazol).

Pecić et al. (2012) found that the ageing of Serbian plum palinka in wooden casks not only improves organoleptic characteristics, but also changes the total polyphenol content and contributes to other important health properties, such as the increase in their antioxidant capacity.

As early as 1980, **Ismail, Williams and Tucknott (1980)**, identified 54 constituents based on the gas chromatographic and mass spectrometric analysis of volatile compounds in the distillate of fermented plum leaves, including 11 hydroxy compounds, 1 acid, 30 esters, 4 carbonyl compounds, 3 lactones, and 5 acetals. Thirty of these compounds had not been previously reported in fermented plum products. Benzaldehyde, linalool, methyl cinnamate, and y-decalactone, based on gas chromatographic odor assessment, are believed to contribute significantly to the plum character of this beverage. However, in 1982, **Velíšek et al. (1982)** pointed out that, in the Czechoslovakia of the time, when examining the volatile taste components of plum palinka, higher aliphatic aldehydes (nonanal and some others), 2-undecanone, benzaldehyde, damascenone, benzyl acetate, ethyl phenylacetate, phenyl ethyl acetate, ethyl 3-phenyl propionate, methyl cinnamate, and ethyl cinnamate were the most significant contributors to the typical plum palinka aroma.

Sádecká et al. (2016) used synchronous fluorescence spectroscopy, combined with principal component analysis (PCA) and linear discriminant analysis (LDA), to distinguish plum distillates according to their geographical origins. A total of 14 Czech, 12 Hungarian, and 18 Slovak plum distillate samples were used.

Jurica et al. (2016) investigated the occurrence of phthalates during the production of plum distillates and in the plum distillate final product manufactured by registered producers in five European countries using gas chromatography-mass spectrometry (GC-MS). As the distillation process progressed, a decreasing trend was observed for the mean values of diethyl phthalate (DEP), diisobutyl phthalate (DiBP), and di-n-butyl phthalate (DBP).

Satora and Tuszyński (2008) found that homemade Polish plum palinka usually contained more ethanol (64.7 – 72.5 vol%), methanol (5.59 – 8.74 $g.L^{-1}$ AA) and butanol (32 – 335 mg. L^{-1} AA) and less isobutanol (406 – 491 mg. L^{-1} AA). The results showed that plum palinkas produced in the Łacko area are characterized by similar and original

chemical compositions, which come mainly from spontaneous fermentation, as well as the traditional production technology.

The importance of plum palinka in Hungary is demonstrated by the fact that in 2013 it was included on the list of Hungarikums. Hungarikums are products, foods, or values that represent Hungarian traditions with their properties, uniqueness, specialty, and quality **(Harcsa, 2018)**.

Fodor, Hlédik and Totth (2011) demonstrated that the popularity of palinka is on the rise, but consumers are choosing well-known brand names. The role of the regions can also be observed in Hungary in connection with plum palinka, indicating a certain quality: plum palinka of Békés and Szatmár **(Kassai et al., 2016)**. Food safety is becoming increasingly important among consumers. According to a survey of Slovak researchers, in Slovakia, 84% of respondents buy higher-quality foods **(Nagyová et al., 2019)**.

A large scale questionnaire survey was conducted by **Szegedyné Fricz et al. (2017)** to evaluate consumer behavior. Their conclusion was, among other things, that a significant proportion of consumers do not have even the slightest knowledge regarding the production of palinka.

Scientific hypotheses

Hypothesis No. 1: The instrumentally measurable content values, based on legal obligations, of final products prepared by various distillation technologies from the same batch of raw materials with identical preparation procedures are different.

Hypothesis No. 2: The final products prepared by various distillation technologies from the same batch of raw materials with identical preparation are different based on sensory evaluation.

MATERIAL AND METHODOLOGY

Materials

The raw material used in the study was an 18 Brix% (g sugar/100 g mash) mash made from President (*Prunus domestica President*) and Stanley (*Prunus domestica Stanley*) plums harvested in mid-September 2018. President plum is a slightly elongated, very large (45 – 55 g), hard, freestone, sweet variety with a purple-red skin, yellow flesh, and a pleasant taste. Stanley plum is one of the most widespread varieties in the world, it is large (diameter 34 – 36 mm), its peel is dark blue, strongly waxy, the flesh is yellowish-green, tasty, juicy, freestone. (Figure 2) Due to the unusually warm weather, the ripening period of the two varieties was longer, making it possible to harvest the required amount of both varieties at the same time at their optimal stage of ripeness.

Preparation

The mashing procedure took place in Bózsva, at the premises of Tiszta Gyümölcs Kft. According to the planned program, 500 kg of pitted plums were fermented at 18 °C in a stainless-steel tank that could be cooled and was equipped with a stirrer for 21 days. At the same time when the precooled raw material was placed in the tank, Lallyzim HC pectin breakdown mixture was added to the raw material. The pH was adjusted (pH = 3.2) with a 10% solution of citric acid, and inoculation was performed by the addition of Uvaferm 228 yeast and Uvavital yeast nutrient.

After the fermentation of the mash was over, the raw material was homogenized by stirring, and then it was divided into two parts. Tower system (RCDS) distillation was carried out at the same site in Bózsva, using the German-made Christian Carl equipment of Tiszta Gyümölcs Kft., and the plum palinka thus obtained was marked I. The location of the pot-still technology was the brewery of the Veresegyház Palinka House, where the distillation was carried out using the Czech-made Kovodel Janca s.r.o. double-still (PSDD) equipment and the final product thus obtained was marked II.

Due to the various distillation processes, the products were available with different alcohol concentrations. In the case of the pot-still technology, the alcohol content of the hearts was 66.9 vol%, while in the case of the column technology it was 84.4 vol%.

The final products were prepared by adjusting the alcohol concentration to the planned value of 44 vol% with the same distilled water.

This way, 24.1 liters of product were obtained during pot-still distillation and 23.5 liters using the tower technology. Analytical tests were performed in February 2019, while sensory evaluations took place in October 2019, when the plum palinka was 1 year old.

President Stanley

Figure 2 The plums included in the study (*Prunus domestica*).

Table 1 The parameters measured in the tests and their measurement methods.

Parameter	Measurement method	Measurement technique	Limit of quantification	Regulatory limit value
Actual alcohol	IR-1:2000	Anton Paar, Alcolyzer	1.00%vol.	37.5% – 86%
Acetaldehyde	Regulation (EC) No 2870/2000*	GC	3.7 mg.L^{-1}	no limit value
Allyl alcohol	Regulation (EC) No 2870/2000*	GC	2.0 mg.L^{-1}	no limit value
Methanol	Regulation (EC) No 2870/2000*	GC	2.0 mg.100cm^{-3}	1200 g.hL^{-1} AA
Propanol	Regulation (EC) No 2870/2000*	GC	1.6 mg.L^{-1}	no limit value
2-Butanol	Regulation (EC) No 2870/2000*	GC	0.7 mg.L^{-1}	no limit value
2-Methyl-1-propanol	Regulation (EC) No 2870/2000*	GC	1.3 mg.L^{-1}	no limit value
n-Butanol	Regulation (EC) No 2870/2000*	GC	1.9 mg.L^{-1}	no limit value
2-Methylbutanol	Regulation (EC) No 2870/2000*	GC	0.8 mg.L^{-1}	no limit value
3-Methylbutanol	Regulation (EC) No 2870/2000*	GC	2.0 mg.L^{-1}	no limit value
Volatile matter	Regulation (EC) No 2870/2000*	Calculated value	2.0 mg.100cm^{-3}	min.: 200 g.hL^{-1}AA
Ethyl acetate	Regulation (EC) No 2870/2000*	GC	1.7 mg.L^{-1}	no limit value
Acetal	Regulation (EC) No 2870/2000*	GC	2.9 mg.L^{-1}	no limit value
Total hydrogen cyanide	MSZ 9589-12:2013	titrimetry	1 mg.100cm^{-3}	7 g.hL^{-1}AA
Ethyl carbamate	CEN/TC 275/WG 13:2012	GC-MS	0.41 mg.L^{-1}	no limit value

Note: *Method III.2 of **Regulation (EC) No 2870/2000** for alcoholic beverages (distillate).

Analytical test

Laboratory analysis of samples was performed by a blind test in the testing laboratory of the Directorate of Oenology and Alcoholic Beverages of the National Food Chain Safety Office, accredited under reg. no. NAH-1-1673/2015, under current legal regulations. 15 parameters were tested for both samples with multiple replicates. The tested parameters, measurement methods, descriptions of the measurement techniques, limits of quantification, and regulatory limit values are given in the following table (Table 1). Sampling and sample preparation was carried out by qualified personnel.

Organoleptic tests were carried out according to Hungarian Standard MSZ 9600:2016 Guidelines for sensory analysis of spirit drinks.

Organoleptic test

Tests were carried out among the students and staff of the Gödöllő campus of Szent István University, in groups of 15 – 25 people, on 18 occasions in October 2019, in the Food Technology and Machines Laboratory of the university. All participants were occasional palinka consumers who participated in the study voluntarily. Test conditions (room temperature, palinka temperature) were the same in all cases so that external parameters did not affect the results.

During the organoleptic tests, samples were marked only with labels suitable for distinction („I" and „II"), test subjects did not know which mark meant what. For the sensory examination, samples with a volume of 2 cl were provided. A total of 341 people participated in the sensory examinations, all of them only once.

In each case, during the sensory evaluation, respondents had to answer the question: „Do you feel a difference between the two samples?" Those who did feel a difference, had to answer the question: „Which palinka sample tasted better?" The questionnaire included a minimal number of demographic questions regarding the gender and age of the respondents.

Statistical analysis

Statistical analysis was performed based on the data obtained during the laboratory tests. The difference in the variance of the two-sample series was checked by the *F*-test. Since there was no significant difference between them two-tailed independent sample *t*-test was used to determine if there is a significant difference between any of the examined parameters. We say that the difference is significant if the corresponding *p*-value $p < 0.05$ holds.

Questionnaires of the sensory examinations were summarized using Excel. As a further analysis, we examined whether the choice of palinka of our sample population depends on gender or age. To this end, contingency tables were applied. The dependencies were examined by using Pearson's χ^2-test, furthermore, Goodman, and Kruskal's λ value was calculated to measure the strength of the association.

Our data analysis was performed using the data analysis module (Analysis ToolPak) of Excel and IBM SPSS 25.

RESULTS AND DISCUSSION

A test report was compiled on the measurement results of the different plum palinka samples analyzed in the accredited testing laboratory. Available data were processed and evaluated using the statistical methods described.

The following table lists the 15 parameters tested by the laboratory and the average values of 10 measurement series for both samples (Table 2). For the anonymous identification of the samples during the laboratory tests, marks of I and II were used. Sample I marked the final product of the tower distillation apparatus, while sample II meant the plum palinka sample made with the traditional pot-still technology.

Based on the statistical analysis it can be stated that our hypothesis No.1 must be rejected because no significant differences ($p < 0.05$) could be detected between the two samples in the statutory palinka quality parameters of the final products prepared from the same batch of raw material and the same preparation using various distillation technologies.

Table 2 Statistical results.

Measured parameter	Expected value of sample I	Expected value of sample II	p value of *F*-test	p value of *t*-test
Actual alcohol [%]	44.08 ±0.23	44.00 ±0.34	0.2670	0.5461
Acetaldehyde [mg.L^{-1}]	69.1 ±4.56	64.3 ±5.14	0.7301	0.0506
Allyl alcohol [mg.L^{-1}]	<LOQ*	<LOQ*	–	–
Methanol [mg.100cm^{-3}]	807.1 ±51.43	803 ±53.05	0.9278	0.8696
Propanol [mg.L^{-1}]	920.2 ±108.7	831.8 ±68.88	0.1902	0.0540
2-Butanol [mg.L^{-1}]	6.82 ±2.29	8.02 ±0.39	0.3781	0.1400
2-Methyl-1-propanol [mg.L^{-1}]	179.2 ±13.30	192.3 ±14.13	0.8594	0.0580
n-Butanol [mg.L^{-1}]	4.5 ±0.31	4.5 ±0.27	0.6959	1
2-Methylbutanol [mg.L^{-1}]	149.7 ±9.74	158.7 ±9.46	0.9316	0.0623

Total hydrogen cyanide [mg.100cm^{-3}]	<LOQ*	<LOQ*	–	–
Ethyl carbamate [mg.L^{-1}]	<LOQ*	<LOQ*	–	–

Note: <LOQ* – Limit Of Quantification.

The actual alcohol content values of the plum palinka samples included in the study met the minimum value of 37.5% specified in **Regulation (EC) No 110/2008**, based on the measurements the alcohol content of the distillates were 44.08 ±0.23% and 44.0 ±0.34%, respectively.

The presence of large amounts of acetaldehyde can lead to headaches and nausea. In the samples tested by us, acetaldehyde was detected in amounts of 69.1 ±4.56 and 64.3 ±5.14 mg.L^{-1}, respectively. This is in contrast to the scientific results of **Balcerek et al. (2017)** who obtained significantly different values when comparing the two technologies.There is no limit value for this component in the regulation.

Allyl alcohol was present in the samples tested in concentrations below the limit of quantification of 2 ±0.2 mg.L^{-1}.

Methanol is converted by our bodies to formaldehyde, which is toxic and can cause blindness or even death in large quantities. In the case of the samples tested, it could be detected in amounts of 807.1 ±51.43 mg.100cm^{-3} and 803 ±53.05 mg.100 cm^{-3}, while its legal limit value is 1.200 g.hL^{-1} absolute alcohol in the case of plum distillates.

Fusel alcohols, such as propanol, butanol, and methyl butanol, are formed during fermentation, and they have a solvent odor and taste. Depending on their quantities, they may cause opacification during reconstitution. The esters of these higher alcohols with organic acids are pleasant, desirable aroma components in the distillate. Propranol and butanol are suitable for determining vintage **(Kovács et al., 2018)**, however, no difference between the technologies was found. There are no specific limit values in the regulation for the individual components. However, the limit value for the volatile matter content, which is associated with it, is set at 200 g.hL^{-1} of absolute alcohol. In the case of the plum palinka samples included in the study, the volatile matter content values were 480.4 ±30.08 and 484.4 ±29.74 mg.100cm^{-3}, respectively.

The amounts of the components ethyl acetate and acetal are not legally regulated.

Research has shown that in the case of omitted or poorly performed pitting, more hydrogen cyanide can be present in the palinka than the permissible amount, which is detrimental to health. The legal upper limit is 7 g.hl^{-1} absolute alcohol. In the case of the samples analyzed by us, the amount of hydrogen cyanide was below the limit of quantification of 1 ±0.1mg.100cm^{-3} in all cases.

Carcinogenic ethyl carbamate may form from components added as unsuitable yeast nutrients **(Deák et al., 2010; Monakhova, Kuballa and Lachenmeier, 2012)**. The regulation does not set a limit value for it, but based on the recommendation of EFSA, it is proposed that it is kept below a value of 1 mg.L^{-1}. The presence of this component could not be detected in the samples analyzed. The limit of quantification for ethyl carbamate was 0.41 ±0.041 mg.L^{-1}.

Emphasizing the importance of the testing of 15 components, the presence of propanol specifically indicates the presence of the fruit raw material, while its absence can be an indicator of counterfeiting, for example, by grain alcohol.

Legal regulations are always aimed at producing safe and healthy food. It is necessary to measure the components of the distillate and to set limit values, as exceeding them can either initiate severe irreversible processes in the human body or even cause death. Even though there are no specified limit values for fusel alcohols, however, it has been mentioned that their excessive presence gives the distillate a pungent odor and an unpleasant aftertaste. Our analyses revealed that, in the case of the samples tested by us, each batch complied with the legal requirements, i.e., the foods were safe.

However, based on previous research by **Satora et al. (2017)**, **Ismail et al. (1980)**, **Velíšek et al. (1982)**, measurements that meet the legal requirements do not include components that determine the character of plums.

Results of sensory tests

The opinions of consumers were tested by sensory analyses and this was not difficult since it was also found by **Fodor, Hlédik and Totth (2011)** that the popularity of palinka is increasing. We have 341 questionnaires completed in October 2019 at our disposal on the sensory comparison of plum palinkas produced in 2018.

	I. sample Men	II. sample Men	I. sample Women	II. sample Women
18-25 years	61	33	30	8
25-50 years	55	8	30	22
50+ years	26	34	10	22
Total	142	75	70	52

Figure 3 Results of the palinka test.

64% of respondents were male, 36% were female; in terms of age distribution, 34% were between 25 and 50 years old, 39% were between 18 and 25 years old, typically college students, while 27% were over 50 years old. The results of the questionnaire survey are shown in Figure 3.

As a result of the study it can be stated that in the comparative organoleptic study of the one-year-old products, 99.4% of the respondents (339 people) distinguished between the two palinka samples. There were only two people who found no difference between the samples. 63% of those who found a difference marked plum palinka I tastier, while 37% chose sample II. To examine that the choice depends on gender or age contingency tables (or crosstabs) were used. In terms of gender the p-value for Pearson's χ^2-test was $p = 0.141$, thus it can be stated that no difference was found between the choice pattern of the different genders. On the other hand, in the case of age groups for the p-value of Pearson's χ^2-test $p < 0.001$ holds, therefore the preference of palinka does depend on age, but this dependence is weak since the Goodman and Kruskal's λ value equals to 0.157. Although the pool of respondents cannot be considered representative, it can be stated that the sample produced using the pot-still technology (sample II) was chosen by the age group over 50, while the age group 25 – 50 found the sample prepared using the column technology tastier. According to our results, we can say as well, that young adults don't really have a clear preference of palinka with respect to the technology it was produced. A similar conclusion, that consumers are unaware of production technology processes, was reached by **Szegedyné Fricz et al. (2017)**. In Table 3 we present the corresponding contingency table. In this table, Count means the number of persons in a specific category while Expected Count shows the number of persons in the same category in the case when there would be no association between age and palinka choice. Too high difference between these values indicates that in this certain category age has an effect on palinka choice. Based on the answers given to question 1 during the sensory examinations, it can be stated that our hypothesis No. 2 can be retained, that is, the final products prepared using different distillation technologies from the same batch of raw material and the same preparation differ based on organoleptic evaluation. The answers to the second question do not explain the reason for the discrimination but confirm the difference. Naturally, another question arises as to the product made by which technology is found to be tastier by consumers, but the present case study does not examine this issue and our previous research **(Géczi, Korzenszky and Nagygyörgy, 2018)** has shown that during the relaxation and maturation of palinka, processes take place that influences the quality of palinka and the perception of being the tastier technology highly depends on the "age" of the product.

Taking into account the differences in sensory examinations, in order to compare the technologies, it would be necessary to measure the components characteristic of the product and to compare the degree of dephlegmation analyzed by **Nagygyörgy (2010)** and **Nagygyörgy (2016)**.

Table 3 Contingency table for age groups and palinka.

			palinka I	palinka II	Total
Age	18 – 25	Count	91	41	132
		Expected Count	82.5	49.5	132
	25 – 50	Count	85	30	115
		Expected Count	71.9	43.1	115
	50<	Count	36	56	92
		Expected Count	57.5	34.5	92
Total		Count	212	127	339
		Expected Count	212	127	339

CONCLUSION

Based on the measurement results it can be stated that there is no significant difference in the legally specified and tested 15 content values between the two plum distillates produced from the mash prepared from the same raw material and the same preparation technology but using two various distillation technologies. No differences could be detected between the final products prepared using the pot-still technology (PSDD) and the rectification column technology (RCDS) with accredited instrumental analyses, so our No.1 hypothesis was rejected.

However, in the case of organoleptic analyses, participants in the study made a clear distinction between the samples tested. In each case, they found one of the samples tastier than the other. It can be stated that the final products made using the two different distillation technologies can be clearly distinguished from each other based on organoleptic tests, but the analytical tests could not support this result. To support this, we consider it necessary to perform analytical determination of further components specific to plums. Legally prescribed qualification parameters generally do not include components specific to distillates made from the individual fruits, such as benzaldehyde, methyl cinnamate, and y-decalactone in the case of plums. Regardless, our hypothesis No. 2 was accepted. Consequently, we are developing new measurement and evaluation methods to investigate the cause of the difference.

As a result of our tests, it can be stated that the analytical parameters of the legal requirements are not suitable for the comparison of palinkas produced using various technologies.

THE USE OF CONSUMER NEUROSCIENCE IN AROMA MARKETING OF A SERVICE COMPANY

Jabuk Berčík, Anna Mravcová, Jana Gálová, Martin Mikláš

ABSTRACT

In today's highly competitive era, it is becoming increasingly difficult for businesses to attract and keep customers. Modern marketing strategies focused on examining customer behavior, and possibilities of the business sector in influencing them are becoming increasingly beneficial. Consumer neuroscience has great potential here, as it reveals internal consumer preferences by using innovative techniques. Human senses play an important role in affecting these preferences, and smell has the greatest potential to influence customers subconsciously, and thus support the sale of products, keep customers in the store longer, or build a brand. Aroma marketing is the continuously developing field of consumer neuroscience. The paper aims to examine the use of consumer neuroscience in aroma marketing of a service company. After theoretical analysis, we carried out practical research aimed at examining the impact of aroma marketing in a selected service company – Sport Café in Nitra – to increase the sales of a particular product, and its real impact on the economic indicators of this company through the use of consumer neuroscience tools and questionnaire survey. In aromatization, choosing the right aroma is of the utmost importance, therefore in our research, this selection was done in the Laboratory of Consumer Studies at the Faculty of Economics and Management, SUA in Nitra. The research was carried out through conscious and unconscious testing of selected aromas by a randomly chosen sample of customers. Conscious testing included using a questionnaire method and unconscious testing was done using a face-reading device that provides an objective assessment of emotions based on facial expressions. The choice of aroma was followed by testing in real conditions, by diffusing the aroma in the café. Based on the collected data, we confirmed the positive impact of aromatization on coffee sales. In conclusion, we present some recommendations for service companies, focused mainly on cafés, with emphasis on the importance of aromatization for attracting and keeping customers and improving profitability.

Keywords: consumer neuroscience; aroma marketing; service company; aroma; Sport Café

INTRODUCTION

The current era is characterized by intensifying competition of business environments and entities. It is becoming increasingly difficult to attract as well as keep customers. It is why new strategies and approaches are increasingly spreading in the marketing environment, which focuses on examining consumer behavior and the possibilities of influencing it positively by enterprises. To understand what guides consumers' steps and behavior during shopping in a world of advertisement overload, traditional marketing tools seem to be still less effective, because the majority of people´s thoughts are in the subconscious mind and consumers mostly do not choose products rationally. The trend nowadays is the communication simultaneously oriented on several human senses, which is represented by the modern field of consumer neuroscience, or neuromarketing, which is using neuroscience to reveal subconscious consumer decision-making processes **(Berčík et al., 2018; NMSBA, n. d.; Genco, Pohlmann and Steidl, 2013)**.

Consumer neuroscience refers to the measurement of physiological and neural signals to gain insight into the customers' motivations, preferences, and decisions, which can help improve creative advertising, product development, pricing, and other marketing areas **(HBR, 2020)**. By this, marketers learn why consumers make the decisions they do, and what parts of the brain are motivating them to do so.

Neuromarketing is focusing on understanding the thoughts and behavior of consumers to "transfer insights from neurology to research in consumer behavior by applying neuroscientific methods to marketing relevant problems" **(Miljković and Alčaković, 2010)**. Therefore, it is an interdisciplinary field that combines aspects of neuroscience, psychology, and marketing. It represents a marketing strategy that is connected to the subconscious, emotional aspect of the customer and it then wants to create a strong bond with the customer and the product **(Karmarkar, 2011)**. The goal is to study how the brain is physiologically affected by advertising and marketing

strategies, and how to improve their effectiveness. Therefore, "neuromarketing studies are focusing on obtaining objective information about the inner workings of the brains of consumers" **(Miljković and Alčaković, 2010)**.

According to **Labská, Tajtáková and Foret (2009)**, the general goal of marketing communication is to influence buyer behavior Every business entity wants to present its products and services in a way that strengthens customers' interest in buying them.

We agree with **Kulynych (2002)** that neuromarketing focuses on measuring the proper functioning of marketing in practice, and it is based on the realistic understanding of how the customer's brain works. So, neuromarketing can be understood as a new era of marketing that seeks the direct impact of marketing incentives on customer and consumer responses at the time of purchasing decision-making **(Ferguson, 2009)**. Neuromarketing, as a scientific discipline using advanced methods, brings a new perspective on consumer shopping behavior. This significantly affects the subsequent creation of marketing strategies and integrated marketing communication in all its areas. Looking into the minds of customers, finding out and researching what they react or do not react to, is the subject of many discussions **(Púchovský and Kohoutová, 2015)**. Predicting customer behavior is of great importance to marketers and the business environment as then they can offer the customer what he wants.

The importance of neuromarketing potential is underlined by the finding that about 95% of thoughts occurred in the subconscious mind cannot be measured by traditional research methods **(Marketing-Schools, 2012)**, whereas these thoughts greatly influence emotions, and decision-making thus begins before all the provided information is obtained **(Genco, Pohlmann and Steidl, 2013)**. Neuromarketing using various techniques, such as those used in medicine and psychology, tries to identify consumer preferences more accurately. It is a more detailed examination of the economic behavior of consumers. Besides, it is also used in the development, creation, and placement of products on the market **(Berčík et al, 2016)**. Neuromarketing uses brain imaging, scanning, and other brain activity measurement technologies to measure the response to a specific product, packaging, advertisement, etc. **(Neuroscience marketing, 2019)**. Phan states that it uses these medical technologies to determine consumer reactions to those particular marketing elements **(Phan, 2010)**.

We recognize several technologies here. **Berčík et al. (2016)** divide research tools and neuromarketing techniques into two basic categories. Each approach captures a different type of signal:

Neuroimaging measurements – devices measuring brain responses under the influence of marketing stimuli. The two most important for scanning the brain are *fMRI* (functional magnetic resonance imaging) and *EEG* (electroencephalogram). However, they are expensive, and fMRI is also too large. FMRI uses strong magnetic fields to monitor changes in blood flow across the brain. It examines brain functions through a three-dimensional display of the brain. EEG reads brain-cell activity using sensors placed on the subject's scalp **(HBR, 2020)**. When a stimulus is applied, the neurons create electric currents that create brain waves, and the device displays them as curves. It measures attention, engagement/boredom, excitement, cognition, memory coding, or emotional valence. These tools are used, for example, to test new products, advertisements, product placement on shelves and identify customer needs **(Púchovský and Kohoutová, 2015)**.

Biometric measurements – tools measuring the physiological proxies for brain activity. They tend to be more affordable and easier to use. These include:
Eye tracker can measure attention (via the eyes' fixation points) and arousal (via pupil dilation). It allows us to examine consumer behavior by the point of gaze, how long it lasts, and also the motion of the eye. It measures the intensity and frequency of gaze.
Face reader is about facial-expression coding as it reads muscles in the face. It measures emotional responses through the face and represents an automatized facial expression analysis software that provides an objective assessment of emotions. It is fast, flexible, objective, and easy to use.
Heart rate variability (HRV) is a physiological marker of how we experience and regulate our emotions. It represents the number of seconds that pass between one heartbeat and the next, which is called the interbeat interval **(Aldo, 2014)**.
Galvanic skin response (GSR) analyses changes in the sweat gland activity of the skin when the vegetative nervous system is activated. It measures emotional arousal and can distinguish between real excitement and noise, but it is not able to distinguish between positive excitement and stress **(Púchovský and Kohoutová, 2015; HBR, 2020)**.

Aroma marketing

In this field, sensory marketing has an increasing role. It involves communication with consumers through sight, hearing, smell, touch, and taste to influence perceptions, judgments, and behaviors of consumers through their senses to create a pleasant environment, so that the customer increases the purchase time at a particular place **(Krishna, 2012; Jiménez-Marín, Bellido-Pérez and López-Cortés, 2019; Bilek, Vietoris and Ilko, 2016; Tauferova et al. 2015)**.

We can say that the nose is one of the most sensitive and emotional senses with a great ability to associate certain aromas with specific situations. Neuromarketing related studies affirm that 75% of our emotions experienced during the day are related to aromas, and humans can distinguish around 10,000 different aromas **(Bell, 2006; Minsky, Fahey and Fabrigas, 2018; Jiménez-Marín, 2016; Erenkol, 2015)**. They also strongly influence buying behavior. As several types of research indicate, while humans are only able to remember 50% of the things they have seen after three months, in the case of aromas it is up to 65% after one year **(Mukherjee, 2015)**. Thus, aroma marketing has big potential in marketing and can be utilized in the business environment and services.

Aroma marketing has still not been fully discovered yet, however, it can play an enormous role in supporting shopping processes and human behavior, since smell has an advantage over other senses, because it can stimulate human emotions immediately. Using aromas, marketers can create a connection with customers at a deeper emotional level and provide them an unforgettable experience.

The smell is one of our most primal and deeply rooted senses and it functions as our chemical alert system. With all other senses, the person thinks before he responds, but with aroma, the brain responds before humans think **(Vlahos, 2007; Aroma Marketing, 2020)**. The smell can create direct reactions to marketing stimuli as it is most closely related to emotional reactions. The smell is the only sense directly connected with the limbic system, which controls memory and emotions. Humans react emotionally to some aroma even before they can identify it. This has a subconscious effect on their behavior and consequently on a company. Customers affected by the nice smell in the store stay 44% time longer than they would without the pleasant aroma **(Conick, 2017)** and this significantly increases the impact of aroma marketing on the store's profit.

However, smell perception varies, and it involves many factors, including individual preferences. Therefore, the most important is to find those aromas that will attract as many potential consumers as possible **(Virkkunen, 2015)**. By this, aroma marketing becomes an essential part of marketing communication **(Sikela, 2015)**. According to the studies and above-mentioned knowledge, our smell is the strongest sense about memory, finding that we are 100 times more likely to remember something that we smell in comparison with something that we see, hear, or touch **(Vlahos, 2007)**. All senses evoke memories, but smell evokes more emotional ones **(Nadányiová, 2017)**. The positive results about the use of aroma in a business environment suggest "that customer satisfaction can be increased through thoughtful manipulation of ambient stimuli" **(Bradford and Desrochers, 2010)**.

Aroma marketing is more than just diffusing a pleasant aroma in a space. It is the art of combining the brand – a company identity with aroma, and thus highlighting the brand and ensuring that it is differentiated from the competition. It is not only about the induction of impulsive consumer shopping behavior, but also about the support of the company's image, as well as identification or recognizability of the communicated product, service, and company **(Füziková and Madleňák, 2017)**. The right application of aroma contributes in particular to a positive evaluation of the company by customers, to a better perception of the company's products and services, and to the fact that customers subconsciously tend to return to the companies that use aroma marketing **(ScentAir, 2020)**. Businesses thus often have their aroma – the so-called aroma logo – mixed following the overall image of the brand and its environment. When shopping, the customer does not think about the aroma, but if one comes to the store and smells it, they automatically remember the brand without seeing its logo. Aroma branding aims to create an immediate association with the brand when smelling it so that it expands brand recognition which can also attract new customers, but especially strengthen the brand image, increase customer satisfaction and sales, create a brand association, build a relationship with the brand, induce a positive perception of products, services, and staff, as well as extend the customer's time spent in the store and increase their spending patterns **(Spectrio, 2020; Air/Aroma, 2020; Berčík et al., 2016; Paluchová, Berčík and Neomániová, 2016; Cartwright, 2014)**.

Applying the right aroma also helps to improve the mood not only among customers but also among employees, and tends to make customers more generous **(Jurášková and Horňák, 2012)**. We agree that special emphasis should be placed on selecting the appropriate aroma because selecting one that does not suit the product/service or if its intensity is adjusted incorrectly, may have the opposite effect **(Bradford and Desrochers, 2010)**. Therefore, an important task for market specialists and store owners is to find the right aroma and the right intensity, and it is necessary to examine it before its implementation, to avoid these problems and mistakes **(Berčík et al., 2017)**.

Scientific hypothesis

To examine the use of neuroscience in aroma marketing of a selected service company, it is essential to examine the importance and potential of the use of neuromarketing in aroma marketing of restaurants/cafés. As we mentioned above, the use of aroma can significantly positively influence consumer behavior, increase the productivity of employees and, last but not least, create positive and long-term emotions associated with the brand. When entering any sales space, including a café, the first impression is very important. It decides on whether the customer will feel pleasant, thus the use of aromatization with a suitably selected scent is even more important.

The service company selected for our research was the Sport Café in Nitra, where we tested aroma marketing and its influence on the marketability of coffee as our selected product, and ultimately its effect on the economic indicators of the company using consumer neuroscience tools. For this purpose, we also set an assumption that when using aromatization, the sales of coffee are higher than without it, which we verified with our research.

MATERIAL AND METHODOLOGY

The research, originating from theoretical analysis, was focused on a selected service company and on examining aroma marketing through the use of consumer neuroscience tools as well as a questionnaire survey. The research was carried out in the laboratory and also in real conditions, at the Sport Café located in Nitra in the City Hall building. After testing in a laboratory, and the aroma was chosen for testing in real conditions, through which we verified the defined assumption that aromatization used in a selected café increases coffee sales.

For the research, the sales of coffee types were monitored in the selected company in February (between February 1, 2020, and February 14, 2020): in the morning, in the afternoon, and total for the whole day.

During this period, a target sample of 8 respondents visiting the café was selected. The test was carried out on this sample, aiming at deciding which aromas are suitable for the café, to select the most suitable one for the subsequent aromatization of the café space. The test was performed in the Laboratory of Consumer Studies at the Faculty of Economics and Management SUA in Nitra and the sample of respondents involved 4 men and 4 women.

During the testing in laboratory conditions, in addition to traditional feedback, unconscious feedback was also obtained by monitoring visible changes in mimic muscles and dilation of eye pupils using facial biometrics. We were

interested in the conscious and unconscious preferences of the respondents and their emotional responses. Therefore, laboratory testing was performed in two ways – conscious perceptions testing (through a questionnaire) and unconscious perceptions testing (through face reader):

- Conscious and unconscious testing of blind samples was carried out simultaneously. 7 types of coffee aromas were tested – 1. Coffee Pure, 2. Coffee and Cake, 3. Cappuccino Cocoa, 4. Sugared Almonds, 5. Cappuccino, 6. Cappuccino Amaretto, 7. Coffee House. After smelling the sample for at least 10 seconds, the respondents evaluated their conscious preference, which they expressed in an electronic questionnaire form.
- At the same time, their emotional feedback was monitored through a facial biometric tool – it was the testing of unconscious (implicit) reactions using a face-reading device. Respondents sat behind the table and while testing each aroma, they were looking into the camera that captured and evaluated their unconscious reactions using automated software, based on their facial expressions (see Figure 1).

Subsequently, we carried out the testing in real conditions, when based on the results obtained from laboratory testing, we aromatized the space of the café for 2 weeks, from February 29, 2020, to March 13, 2020. Based on laboratory tests, the Coffee House aroma was used for aromatization. We placed the aroma streamer device in the café, away from the door and the ventilation. Using the Reima mobile app, we connected to the device via Bluetooth and set the aroma release interval and its intensity.

After testing, we processed the results of coffee sales during aromatization and compared them with the research period before aromatization. After evaluating the results, we formulated conclusions and recommendations for practice.

Emotional feedback was monitored using the somatic biometric method Facereader 7 from the Dutch company Noldus, which identifies the emotional feedback (valence, excitement) of the respondents with maximum accuracy based on observable changes in mimic muscles and recognizes basic micro-emotions (happy, sad, angry, disgusted, surprised, neutral).

During the test, it was also necessary to check the air quality in the room, which was monitored by the Air Quality data logger device, which enables the real-time display of values of basic air quality parameters such as CO_2, temperature, humidity, volatile substances VOC, and dust particles.

Statistical analysis

The data obtained from the measurements were synchronized and correlated in Observer XT 10 by Noldus. This program allows to synchronize structured and unstructured data from different devices and at the same time to create their variables during the implementation of experiments. Processing was carried out in the Matlab R2019a and Microsoft Excel 2010 program environments.

Descriptive and inductive statistic methods were used to process the primary data. As part of inductive statistics, we used the Mann-Whitney U test (one-sided) to verify our hypothesis. It is a test of the agreement of two mean values for independent files (parametric equivalent).

RESULTS AND DISCUSSION

Aromas can create lasting memories, eliminate stress, and support the creation of emotions. Thanks to an appropriately chosen aroma in the store, the seller can influence the behavior of customers, who then can evaluate the company more positively, tend to subconsciously return to these spaces, perceive the higher quality of products and spend more time there. Hence, we focused our research on verifying the assumption that the aroma implemented within the store will increase coffee sales. Our research about the use of consumer neuroscience in aroma marketing of a service company was carried out first in the laboratory and subsequently in real conditions.

In the laboratory, we tested the conscious and unconscious reactions of the eight chosen respondents (who are visitors of the café) to the 7 selected aromas associated with coffee. The first part of the testing consisted of a conscious response to the tested aromas while completing a questionnaire. The results here showed that respondents liked Aroma 7 (Coffee House) the most (see Figure 2).

In the second part of the laboratory testing, the unconscious reactions of the respondents to the choice of aromas were examined and recorded using the Facereader device, where we found out that our respondents perceived Aroma 5 (Cappuccino), the most positively. The most negatively perceived aroma here was Aroma 7 (Coffee House), as seen in Figure 3.

During the test, we were checking the air quality in the room using the Air Quality data logger device. We focused primarily on CO_2 concentration, as it can affect human preferences the fastest. Attributes should be up to the CO_2 level of 700ppm (see Figure 4).

Based on the results of laboratory testing, we placed an aromatizing unit directly in the selected café. However, the results from laboratory testing were contradictory. The Coffee House aroma was perceived most positively during conscious testing, but it was also evaluated most negatively by unconscious testing. There can be several reasons for this. One option is that the aroma was too intense, which had an immediate strong effect on the olfactory organ and the facial expression could therefore seem negative. But ultimately, it had a positive effect on the smell. It is not always possible to obtain an explicit result when examining unconscious feedback, as the process may be affected and distorted by various side factors. In real conditions, we, therefore, decided to deploy and test the Coffee House aroma that was most positively evaluated in conscious testing and this was implemented in the Sport Café. For the aromatization, we used the aroma streamer unit placed in the company. Using Bluetooth, the aroma release interval was set on the device, which was daily from 11:00 to 20:00, and the intensity was set at level 7.

We then compared the coffee sales before the aromatization with the sales of coffee during the aromatization. The results are presented in Table 1 and Table 2, which contain the date of recording, the number of coffees sold in the morning and the afternoon, and then the total sum of coffees sold. The types of sold coffees were: 1. Turkish coffee; 2. Espresso, 3. Decaffeinated coffee; 4. Viennese coffee; 5. Latte Macchiato; 6. Cappuccino; 7. Iced coffee.

Note: Source: Own evaluation, 2020.

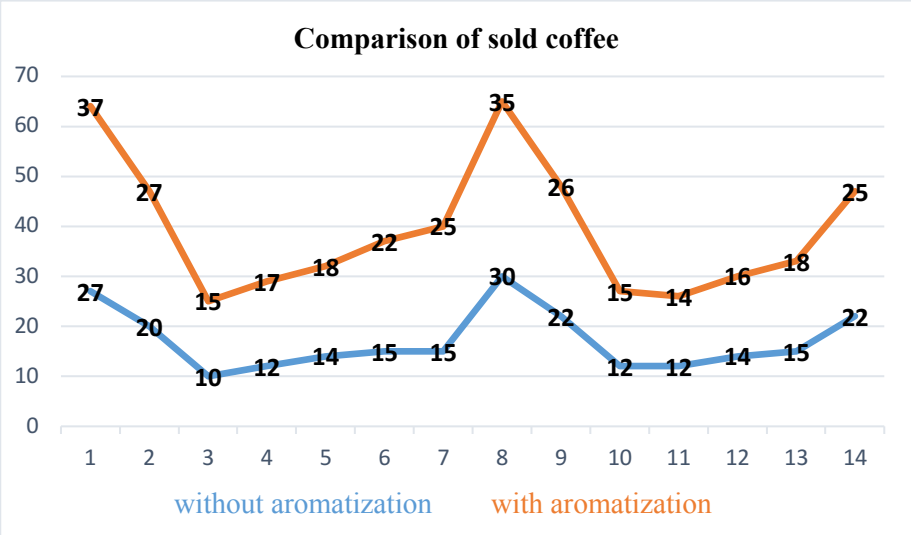

Figure 5 Comparison of sold coffee. Note: Source: Own evaluation, 2020.

In the 2 weeks before aromatization (February 1, 2020 – February 14, 2020), 240 coffees were sold in the café, from these 150 in the morning and 90 in the afternoon. Cappuccino and Espresso were sold the most, while iced coffee was sold the least – the reason might have been the season – as well as Decaffeinated coffee since it is a specific product, which customers do not seek very much in Slovakia (see Table 1).

During the 2 weeks of aromatization of the Sport Café with the Coffee House aroma (from February 29, 2020, to March 13, 2020), we recorded an increase in coffee sales by approximately 30%. Sales increased by 70 coffees, with the total number of coffees sold in this period being 310. Most coffees (188) were sold in the morning and 122 in the afternoon. The cappuccino was sold the most, then Espresso, while sales of Turkish coffee increased too (see Table 2). For a better presentation and comparison of sales, we summarized the results in Figure 5.

During our research, we successfully verified the stated assumption using a Mann-Whitney test – one-tailed (p-value of 0.015 is less than alpha 0.05, we reject A0 and accept A1), so when using aromatization, the sales of coffee were higher than without it.

Examining consumer behavior is of great interest in many research and studies in various fields, focused mostly on the goal to make the products more attractive to the consumers (see, for example, **Karmarkar, 2011; Miljković and Alčaković, 2010; Kozelová et al., 2013; Kozelová et al., 2011)**. Many studies and research are focused on food and drinks where a wide range of attributes are being examined **(Vietoris et al., 2016; Zinina et al., 2019; Zajác et al., 2015)**.

There are also many studies focusing on the effect of aromas on consumer behavior (see, for example, **Conick, 2017; Virkkunen, 2015; Bradford and Desrochers, 2010; Berčík et al., 2017**) and several are aimed at service companies that have similar results confirming the increase of product sales after using aromatization. There was, for example, a study carried out in a restaurant where the lavender aroma was diffused and compared to a no-aroma controlled condition. Results showed that lavender caused customers to stay longer and increased the amount of purchasing since it seemed to relax people. When relaxing, the customers ordered additional items and thus increased the amount spent **(Guéguen and Petr, 2006)**. Another study was done, for example, in the Brooklyn food market NetCost which aromatized delicious smells through their aisles. After coordinating the scents with store sections, such as putting rosemary close to freshly baked bread, they saw at least a 7% sales increase. Since smell extends appetite past normal boundaries, customers were more likely to spend money **(Pulido, 2019)**. Also, according to Swedish researchers, good smells can heighten the will to buy, for example, coffee or sweet rolls. In their research in front of the Stockholm café using Eyetracker (see also, **Wästlund, et al., 2010)**, those participants who were exposed to the smell of chocolate chip cookies were 40% more likely to buy something in the café compared to the participants who were not exposed to the aroma. According to these researchers, café-related scents increased the intention to buy something **(Shams, 2013)**. Participants who were exposed to the aroma were more willing to buy also other café products **(Shams, 2013; Stranden, 2016)**.

In summary, we can conclude that our study has some limitations. Only one café was examined, and the sample of customers tested was small, and there were contradictory results from laboratory testing. However, given the theoretical research that showed the effect of aromas on customers' purchasing behavior, according to the results of this study and other similar researches, we can confirm that it is beneficial for cafés and other service companies to aromatize their spaces to influence their customers and increase their expenditures. We agree with the statement, that profit is the driving factor behind marketing decisions for cafés, restaurants as well as other businesses, and manipulating aromas can be an attractive financial move as the right smell can encourage consumers to buy more than they usually would **(Pulido, 2019)**.

CONCLUSION

Based on our research, we can state that the use of aroma marketing and the implementation of aromatization in a business space has great potential in the context of a positive impact on economic indicators of the company, including services companies. At the same time, the use of various consumer neuroscience tools is important for the deployment and application of aroma marketing in such companies, which can significantly help in selecting a suitable aroma, it's diffusing and setting the intensity of aromatization. Since smell is associated to a large extent with the reactions of the subconsciousness, it may differ from the conscious one, without being perceived. Therefore, it is necessary to supplement it with testing conscious reactions, to carry out several tests, and use different methods and tools for the correct implementation of aroma marketing and aromatization, to select the most suitable aroma and to achieve the greatest possible positive impact on customers.

Based on the results of our research on the use of consumer neuroscience in aroma marketing of a service company and on examining the coffee sales during the application of aroma marketing in the selected café, we conclude by formulating several proposals and recommendations that we believe could help positively increase economic indicators.

We recommend implementing aroma marketing permanently, as the aromatization of the space has contributed to increased coffee sales, confirmed by sales numbers and the statistical test. It is also a space for creating aroma branding, an opportunity to change the customer perception of the café, attract new and retain old customers using a pleasant aroma. Deploying a coffee aroma in a selected company significantly improved the economic indicators when coffee sales increased by approximately 30%. Although the costs of aromatization are not negligible, even after their implementation, the company's sales would be higher than without aromatization, based on the calculated expected financial inputs. Revenues from sold coffee in the examined period without aromatization were calculated as 480 euros per 2 weeks, while in the period of aromatization it was 620 euros per 2 weeks (according to the set prices of the company´s menu). The difference, in this case, is 140 euros more per 2 weeks. The monthly cost of an aroma is approximately 60 euros and the rent of the aromatizing unit is 20 euros, meaning the business would still be more profitable. Certainly, this can also mean that

sales will gradually increase even more in the longer period, and aromatization will attract more new customers, so we assume that economic indicators would change even more positively. Therefore, we recommend the selected company, as well as service companies in general, to aromatize their spaces, but it is necessary to expose the choice of aroma to proper in-depth testing.

We also propose including seasonal products in the menu, such as Pumpkin Latté in autumn, since adapting aromatization to this can also help to improve the economic indicators of the company. This could attract more customers and bring the company something new that differentiates it from at least part of the competition. The cost of preparing 1 Pumpkin Latte would be 1 EUR since it only requires pumpkin puree, spices, and one cup of espresso. The company could sell it for 2.50 EUR, as it would be a new and seasonal product. The price is set based on the competition that sells similar types of special coffees in Nitra.

Coffee sales could also be increased by including cakes into the menu, e.g. a cheesecake which would revive the company's range. It would be advisable to start with one or two cakes first (to offer some options due to food allergies, etc.), to find out if customers are interested in this type of product. The main purpose of selling cakes would be to increase sales of coffee (cross-selling). The costs involved are related to procuring the cake(s) and transport. Cake from Babičkina cukráreň company in Nitra with regular intake would cost 22 euros for 12 pieces, which is 1.80 euros per piece. Sport Café could sell a piece for 2.5 euros, which would make a profit of 0.70 cents per piece. The types of cakes could be selected based on a specific season and the final impression would be enhanced by the seasonally set aromatization.

PREFERENCE MAPPING OF SLOVAK CHEESE

Patrícia Martišová, Jana Štefániková, Matej Hynšt, Vladimír Vietoris, Patrícia Macková

ABSTRACT

The production of steamed cheese has a long tradition in Slovakia. Some of these cheeses have even received the PGI designation, which is a designation granted to products with specific geographical characteristics (Slovenská parenica, Zázrivské vojky, Zázrivský korbáčik, and Oravský korbáčik). In our study, eight samples of various unsmoked steamed cheese from small dairy farms (samples D, F, G, and H) and medium-sized farms (A, B, C, and E) were evaluated. Our work aimed to determine whether there are significant differences in sensory characteristics between samples from small and medium-sized dairy farms and whether there are differences in the preferences between these samples for consumers. Samples were evaluated by sensory analysis, where the assessors evaluated the characteristics of color, odor, texture, flavor, and overall appearance on a nine-point hedonic scale. Differences at a statistically significant level in the attributes of odor, texture, flavor, and overall appearance were confirmed (p <0.05) between samples from small and medium dairy farms, no statistically significant difference was proved in the attribute color (p >0.05). The results were processed using PCA, whereas can be seen from the graphic representation the carriers of all evaluated attributes were samples from medium-sized farms (except for sample D, which belonged to the first group of samples together with samples from medium-sized farms). We constructed a preferential map by combining internal and external mapping, while the internal data were formed by data obtained from assessors using sensory analysis and the external data came from an online questionnaire. Using the preferential mapping technique, we found out that samples from medium-sized dairy farms were classified as the most preferred samples which correspond with the results of sensory analysis.

Keywords: steamed cheese; unsmoked; preference mapping; sensory analysis

INTRODUCTION

Cheese production is one of the traditional ways of food preservation. Preservation of fats and proteins as the most important components of milk in the form of cheese uses two principles of food preservation: lactic acid fermentation and water activity reduction by removing water and adding NaCl **(Fox et al., 2004)**. There are more than 1000 types of cheese in the world, which differ from each other in sensory and chemical characteristics **(Montel et al., 2014)**.

Production of steamed cheese has a long tradition not only in Slovakia but also in eastern Europe and Balkan countries. This type of cheese is according to **Čuboň et al. (2015)** called Pasta filata. Traditional Slovak steamed cheese can be found in many different shapes and sizes, smoked or unsmoked, made from pasteurized or unpasteurized milk, bovine, ovine or mixed origin, etc. Characteristic shapes are strings (Zázrivské vojky), little whips (Zázrivský korbáčik, Oravský korbáčik), and most traditional „S“ shape (Slovenská parenica) **(Tasteatlas, 2020)**. Zázrivské vojky **(Commission Regulation (EU) no 963/2014)**, Zázrivský korbáčik **(Commission Regulation (EU) no 238/2011)**, Oravský korbáčik **(Commission Regulation (EU) no 243/2011)**, and Slovenská parenica **(Commission Regulation (EC) no 656/2008)** are included in the PGI and PDO list of the European Union. According to **Council Regulation (EC), no 510/2006** traditional Slovak parenica cheese is described as steamed cheese that can be unsmoked or smoked, traditionally manufactured and shaped in „S“ shape.

In recent years there have been several food scandals that decreased consumers´ trust in food safety **(Kozelová et al., 2013)**. Consumers´ demands for food with high-quality are still growing **(Rana and Paul, 2017)**. For the last few years, there has been increasing attention towards food quality and food safety and also growing demand for „natural“ products (mostly those with PGI, PDO, and TSG designation) **(Todaro et al., 2017)**.

From the point of view of human nutrition, as well as from the economic point of view, the dairy industry belongs to the main branches of the food industry in the Slovak Republic. In line with the global trend, the consumption of cheese and curds has increased, with consumers preferring natural cheese over processed

cheese. The largest volume of the total value of foreign trade in the dairy industry consists of cheese and cottage cheese. The export of Slovak cheese is mainly focused on the EU-28 market **(Gálik, 2019)**.

Consumption of milk and dairy products without butter in 2018 was 171.1 kg, which was less by 3.5 kg (2.0%) compared to the year 2017. The decrease in consumption was mainly reflected in sour milk products by 0.6 kg (3.4%) and cheese and curds together by 0.2 kg (1.5%). Because milk and dairy products are the main sources of calcium and protein, their low consumption is nutritionally unfavorable. In 2017, according to available data from Central European countries, for example, the Czech Republic (239.3 L) and Poland (218 L) had a high consumption of dairy milk in the value of butter-free milk per capita. In the Slovak Republic, the consumption of milk was 169.5 L per capita. Hungary had a comparable value of consumption as in Slovakia in 2017 with 160.7 L per capita. The total consumption of cheese and curd in 2018 was 13.3 kg per capita in the Slovak Republic, in 2017 it was 13.5 kg **(ŠÚSR, 2019)**.

Preference mapping is a methodology that helps us to identify the sensory attributes which are the main drivers of liking and the most preferred products for different consumer groups. This technique uses multivariate tools to create bidimensional plots (maps) that link product characteristics and consumer preferences **(Berget et al., 2020)**. Preference mapping has become a standard tool not only in sensory studies of food but also in other product categories **(Mattila, 2001; Zacharov and Koivuniemi, 2001)**. For performing preference mapping liking/preference data obtained from consumers and a descriptive sensory profile for the same products is needed. Firstly, PCA (Principal Component Analysis) is used on the independent data, then the dimension reduction techniques are applied depending on the data. There are conceptually two different ways of performing preference mapping – internal and external. In internal preference mapping, the sensory data is modeled from the consumer data and in external preference mapping the order is switched, so consumer preferences are predicted from sensory data **(Berget et al., 2020)**. Both internal and external approaches have their pros and cons **(Næs, Varela, and Berget, 2018)**.

Our work aimed to find out the preferences of consumers of unsmoked steamed cheese from small and medium-sized producers and confirmation that there are differences in sensory characteristics between cheese from medium-sized and small farms.

Scientific hypothesis

Hypothesis 1: There exist significant differences in sensory attributes between unsmoked steamed cheese from small and medium-sized producers.

Hypothesis 2: There exist differences in preferences between unsmoked steamed cheese from small and medium-sized producers.

MATERIAL AND METHODOLOGY

Samples

8 samples of unsmoked steamed cheese (nite and parenica) were obtained directly from medium-sized producers and small farms on the day of production. Samples A, B, C, and E (4 samples) were produced by medium-sized producers, and samples D, F, G, and H (4 samples) were manufactured in small farms. All of the samples of unsmoked steamed cheese can be seen in Figure 1.

Sensory analysis

The sensory evaluation was performed in a sensory laboratory designed according to **ISO 8589:2007** located in the Slovak University of Agriculture in Nitra. Samples were coded with 3-digit number codes and served on white ceramic plates at temperature 20 ±2 °C. Samples for evaluation were prepared by cutting the cheese into smaller portions. Samples were evaluated the day after production. 10 assessors who were all students and employees of the Slovak University of Agriculture in Nitra took part in this evaluation. All of them had previous experiences with a sensory evaluation of dairy products.

A nine-point hedonic scale was used for sensory evaluation, where 1 was very bad and 9 was very good. Evaluated attributes were color, odor, texture, flavor, and overall appearance. Wiliams Latin square design was used for sample randomization **(Williams, 1949; Wang, Wang, and Gong, 2009)**. Mineral water was used as a palate cleanser to neutralize the taste between samples.

Preference mapping

Internal mapping data were obtained from the sensory analysis of samples. Data needed for external mapping were collected from an online questionnaire with 120 responses. Respondents were asked to score the samples according to their personal preferences on a nine-point scale.

Statistical analysis

For analysis of sensory data was used Shapiro-Wilk normality test and parametric t-test (RStudio software, version 1.3.1093, R Foundation for Statistical Computing, Vienna, Austria). Data analysis for PCA and Preference mapping was carried out with XLSTAT statistical software (version 2020.5.1 by Addinsoft). Internal data from the sensory evaluation were processed with PCA (Principal Component Analysis) and external data from the online questionnaire were used for AHC (Agglomerative Hierarchical Clustering).

RESULTS AND DISCUSSION

Slovenská parenica, Oravský korbáčik, Zázrivský korbáčik, and Zázrivské vojky granted the PGI designation (Protected Geographical Indication) in 2008 – 2014. Regarding the PDO, PGI, and TSG labels there have been reported numerous problems. Food adulteration has many forms e.g. substitution, mislabelling, masking of origin, decreasing quality of food products, intentional misinterpretation, artificial enhancement, etc. **(Fikselová et al., 2020)**. According to **Singh and Gandhi (2015)**, milk and milk products are typically adulterated with the use of preservatives and adulterants (benzoic acid, water addition, hydrogen peroxide, salicylic acid, etc.).

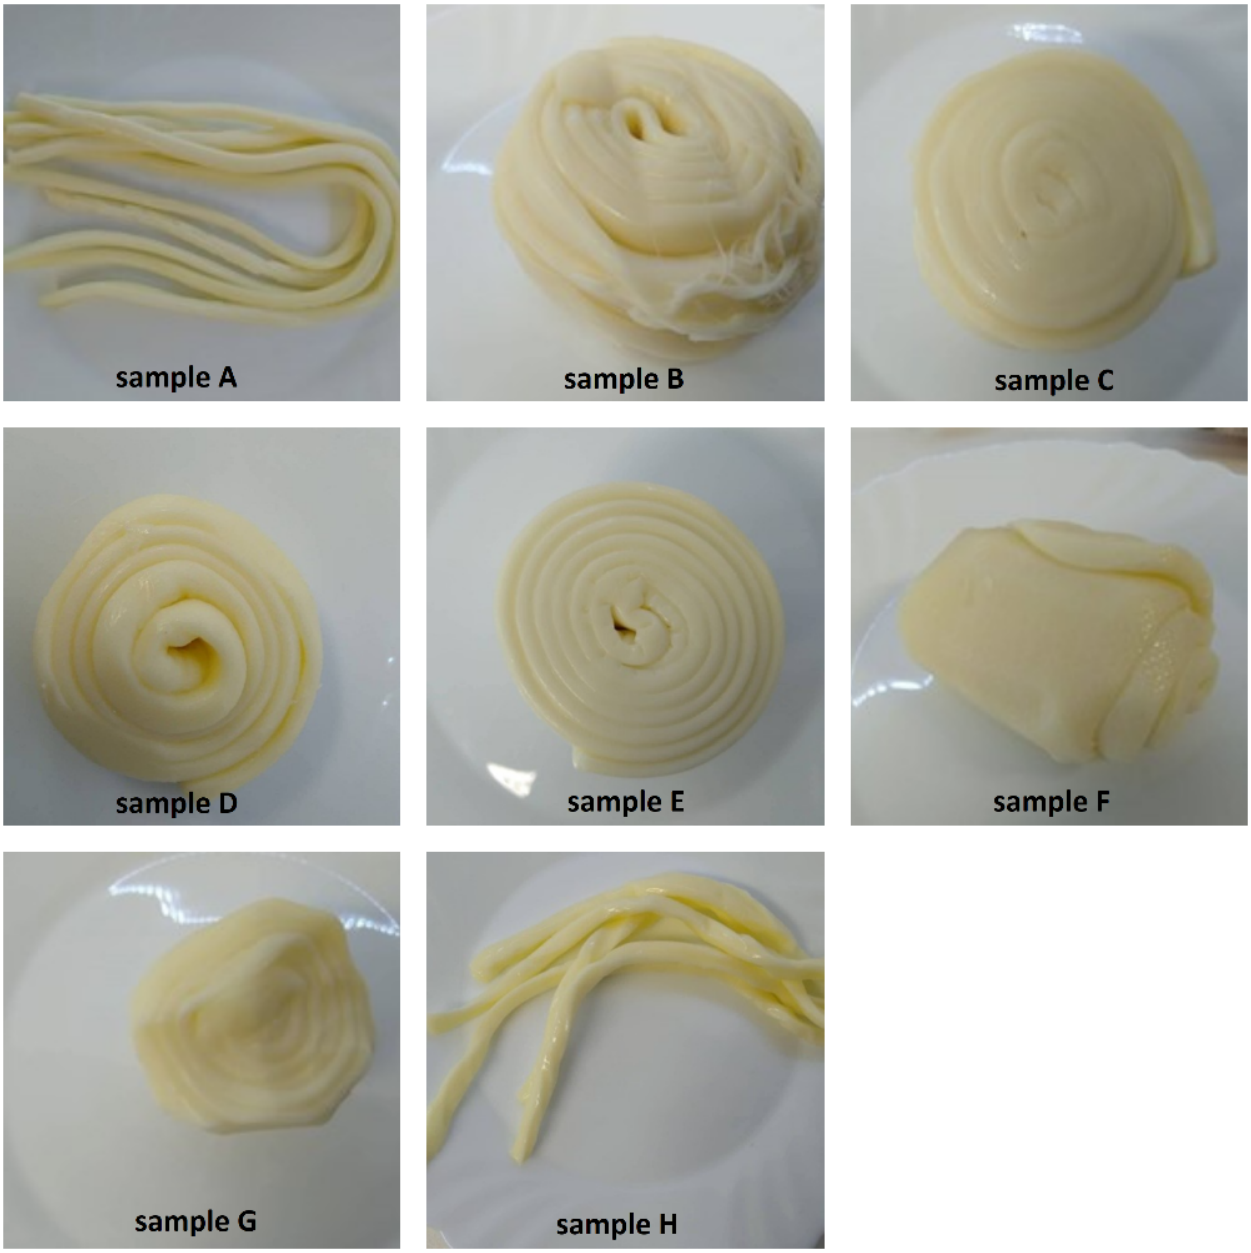

Figure 1 Samples (A – H) of unsmoked steamed cheeses.

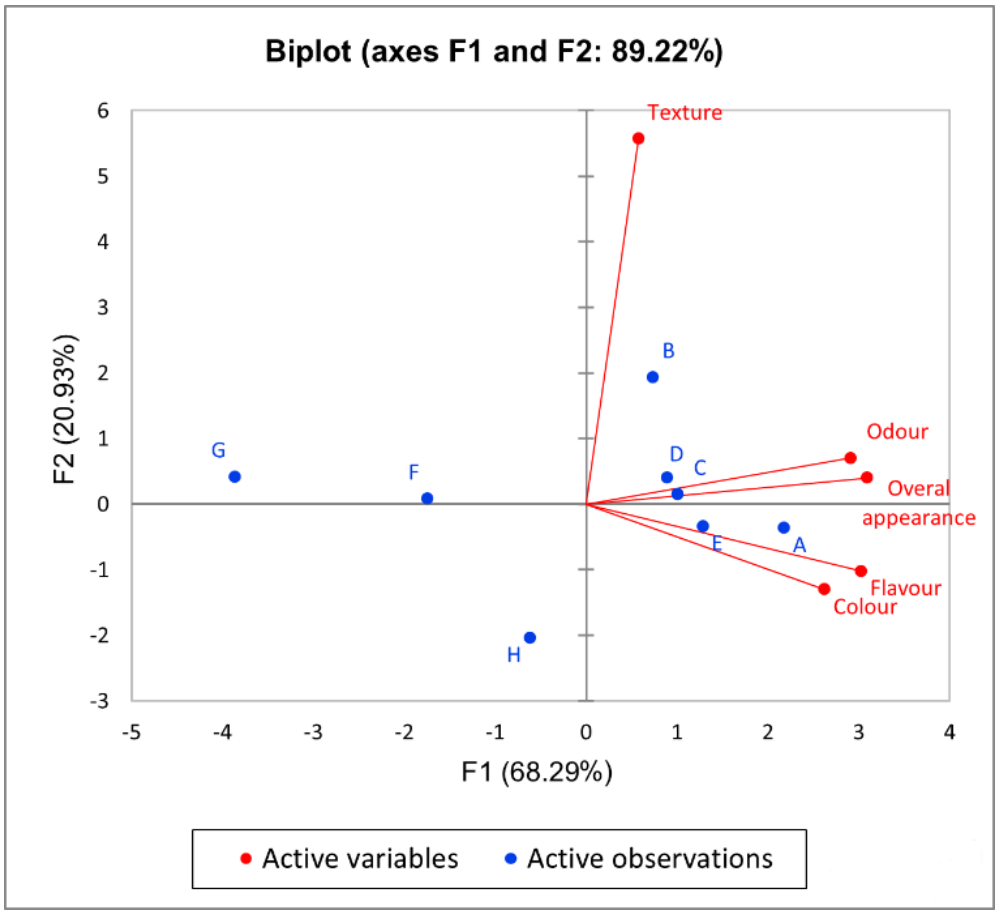

Figure 2 PCA map of samples.

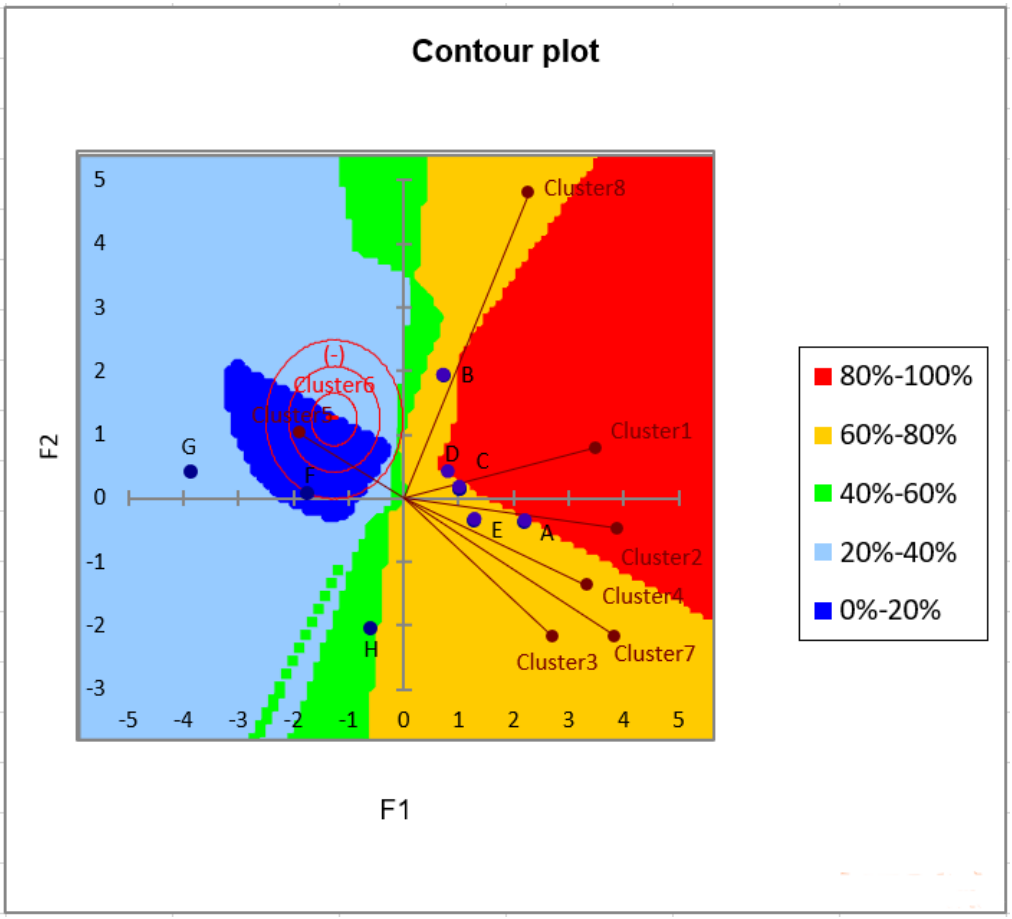

Figure 3 Visualization of the consumers preferences with preference map.

Characteristic steamed cheese production and starter cultures are mentioned in the work of **Onipchenko et al. (2012)**, **Štefániková et al. (2019),** and **Zimanová et al. (2016)**.

The summary of sensory analysis results is presented in Table 1. There was no significant difference between samples from medium-sized and small farms in the parameter color (p >0.05). Statistically significant differences were detected in the attributes odor, texture, flavor, and overall appearance (p <0.05), where samples with higher consumer acceptance were evaluated samples from medium-sized farms in all parameters (Table 1). Authors **Semjon et al. (2019)** detected differences between experimental parenica cheese samples in every evaluated sensory parameter in the early stage of storage. They also observed statistically significant differences (p <0.05) between samples in sensory parameters after storage. Similar sensory attributes and a nine-point scale were used by authors **Tauferova et al. (2014)** in their study of the sensory texture of ketchup.

PCA map of evaluated unsmoked steamed cheese samples can be seen in Figure 2. Samples were divided into two groups, the first group consisted of samples from medium-sized farms (A, B, C, E) and one sample from the small farm (D), the second group consisted of three samples of cheese from small farms (F, G, H). All of the evaluated parameters were characteristic for the first group of samples. Sample B had the highest rating in texture parameters. Samples A, C, D, and E obtained high values in the evaluation of odor, overall appearance, flavor, and color. On the other hand, there were samples from the second group (F, G, H) where sample H had the worst texture, it was very solid and firm. Samples in the second group also lacked odor, flavor, color, and overall appearance attributes.

The preference map of evaluated unsmoked cheese can be seen in Figure 3. In the highest consumer preference zone (80 – 100%) were partly located samples A, C, and D, these samples were also located in the second preference zone of 60 – 80%. These samples were preferred the most by the respondents. Samples B and E were located in the zone of preference 80 – 60% and sample H can be seen in the green field with preference 40 – 60%. As less preferred sample consumers chose sample G (20 – 40%) and the least preferred sample was sample F (0 – 20%). The preference map corresponded with the results of sensory analysis and samples obtained from medium-sized farms had higher preferences from consumers than samples coming from small farms. Preference mapping was previously used in the analysis of a wide variety of foodstuffs e.g. ham **(Benešová et al., 2019)**, parenica steamed cheese **(Semjon et al., 2019)**, raw garlic **(Drdolová, Martišová and Benešová, 2019)**, fresh fruit **(Villamor et al., 2013; Jaeger et al., 1998; Lado et al., 2010)**, vegetable **(Sinesio et al., 2010)**, etc.

In a similar study authors **Drdolová, Martišová and Benešová (2019)** evaluated 10 varieties of winter garlic using PCA and preference mapping techniques. According to their findings, assessors tend to overestimate samples with attractive appearance and to focus on textural parameters of samples.

According to **Zajác et al. (2019)** quality of a traditional product can vary from farm to farm. It is mainly caused by differences in cheese-making technology e.g. temperature of milk pasteurization, type, and a dose of rennet, amount of salt, smoking, drying process, etc. In their work, **Zajác et al. (2019)** studied differences in textural and sensory characteristics of typical Slovak cheese – oštiepok. They confirmed significant differences (p <0.05) between the samples from different regions in both textural and sensory attributes.

The different temperature used during cheese maturation affects the content of the microorganisms **(Kunová et al., 2015)**. Microbial count increases when using insufficient pasteurization and there is a possibility of cross-contamination **(Zajác et al., 2019)**.

Authors **Ducková et al. (2019)** in their work studied the effect of somatic cell count (SCC) in milk intended for parenica cheese making. They compared the number of somatic cells in milk from small dairy farms with milk from industrial companies and they did not find the statistically significant difference (p >0.05). However lower SCC was observed in samples from industrial dairies. According to **Hachana, Znaidi and M´Hamdi (2018)** higher values of SCC can have a negative effect on dairy products shelf life and sensory characteristics.

CONCLUSION

In our study, we proved the existence of differences in sensory attributes between samples manufactured in small dairy farms and samples from medium-sized industry farms. The differences at the statistically significant level (p <0.05) were detected in the parameters odor, texture, flavor, and overall appearance. From the map of principal component analysis can be seen that samples from industry farms obtained high values in the evaluation of all sensory attributes and samples from small dairy farms (except sample D) lacked in these parameters. The results obtained from preference mapping also coincided with the above mention analyses and therefore the most preferred samples came from medium-sized industry farms.
